Reference manual

SPC574Sx 32-bit Power Architecture® microcontroller for automotive ASILD applications

Overview

This document defines the functionality of the SPC574Sx microcontroller for use by software and hardware developers. The SPC574Sx is built on Power Architecture® technology and integrates technologies that are important for today's and tomorrow's automotive applications.

SPC574Sx targets Chassis & Safety applications such as EPS (Electric Power Steering), ESC (Electronic Stability Control), Dual 3-phase brushless DC FOC (Field Oriented Control) motor controls, Hybrid drive, DC-DC converters/inverters and high-end airbag applications which require a high safety integrity level.

The information in this book is subject to change without notice, as described in the disclaimers on the title page. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the ST Web site at http://www.st.com.

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC574Sx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

Contents

1 Preface 45

1.1 Register conventions 45

1.2 Acronyms and abbreviations 45

2 Introduction 46

2.1 SPC574Sx microcontroller 46

2.1.1 Target applications 46

2.1.2 Overall architecture 46

2.1.3 Core features 46

2.1.4 Memory hierarchy 47

2.2 Features 48

2.3 Feature summary 50

2.4 Packages 51

2.5 Block diagram 51

3 System architecture 53

3.1 Platform Architecture 53

3.1.1 XBAR Masters 53

3.1.2 Functionality 55

3.1.3 Performances 56

3.2 Embedded memories 58

3.2.1 SRAM 58

3.2.2 Flash memory 59

3.2.3 End-to-end Error Correction Code (e2eECC) 61

3.2.4 Security features 63

3.3 Motor control Architecture 64

4 Signal description 73

4.1 Pin descriptions 73

4.1.1 Pin startup and reset states 73

4.1.2 Power supply and reference voltage pins 73

4.1.3 System pins 75

4.1.4 Debug and trace pins 76

4.1.5 Pin multiplexing 76

4.2 Package pads/pins 180

5 Memory map 185

5.1 Architecture 185

5.2 Memory map 185

6 Functional safety 195

6.1 Introduction 195

6.2 Assumptions and usage constraints 195

6.3 Module categorization 196

6.4 Safety architecture overview 197

6.4.1 Lockstep 198

6.4.2 End to end (E2E) protection on the data path and memory ECC 200

6.4.3 Additional address coverage 201

6.4.4 I/O safety 218

6.4.5 Clock 218

6.4.6 Power 218

6.4.7 Failure handling 218

6.4.8 Failure indication 237

6.4.9 Latent fault detection 237

6.4.10 Common Cause Failures (CCFs) 238

6.4.11 Resets 238

6.4.12 LBIST / MBIST architecture 239

6.5 Register classifications 241

7 Device configuration 242

7.1 Introduction 242

7.2 Core modules 242

7.2.1 Core Reset Settings 242

7.2.2 Special Purpose Register Summary 244

7.3 System modules 247

7.3.1 SIUL2 configuration 247

7.3.2 Crossbar switch 247

7.3.3 System Memory Protection Unit (SMPU) configuration 249

7.3.4 Peripheral bridge configuration 251

7.3.5 Interrupt controller (INTC) configuration 252

7.3.6 DMA controller configuration 260
7.3.7 DMA channel multiplexer (DMACHMUX) configuration 261
7.3.8 Wakeup unit (WKPU) configuration 268
7.3.9 Crossbar integrity checker (XBIC) 269
7.4 Clocking 269
7.5 Memories and memory interfaces 269
7.5.1 Flash memory controller (PFLASH) configuration 269
7.5.2 Decorated Storage Memory Controller (DSMC) 270
7.6 Analog modules 271
7.6.1 Temperature sensor configuration 271
7.6.2 SARADC 271
7.7 Motor control modules 319
7.7.1 ECTU 319
7.7.2 eTimer 321
7.7.3 FlexPWM 321
7.8 Timers 333
7.8.1 System Timer Module (STM) configuration 333
7.8.2 Software Watchdog Timer (SWT) configuration 334
7.8.3 Periodic Interupt Timer (PIT) configuration 334
7.9 Communication interfaces 335
7.9.1 CAN subsystem configuration 336
7.9.2 DSPI configuration 336
7.9.3 FlexRay Configuration 338
7.9.4 SENT Receiver (SRX) configuration 339
7.9.5 LinFlexD 341
7.10 Reset and Boot modules 343
7.10.1 BAF configuration 343
7.10.2 System Status and Configuration Module (SSCM) configuration 344
7.11 Safety modules 345
7.11.1 CRC – Number of contexts 345
7.11.2 MEMU configuration 345
7.11.3 FCCU configuration 353
7.11.4 Register protection (REG_PROT) configuration 354
7.11.5 Password and Device Security Module (PASS) configuration 363
7.11.6 STCU2 configuration 367
7.12 Debug and trace 385

7.12.1 NPC configuration 385

8 Reset and boot 387

8.1 Introduction 387

8.1.1 Architecture 387

8.1.2 Functionality 387

8.2 Hardware reset stage 388

8.2.1 Destructive reset events 388

8.2.2 Functional reset sources 389

8.2.3 Functional reset escalation 390

8.2.4 Destructive reset escalation 391

8.3 Reset sequence 391

8.4 PORST pin functionality 394

8.5 ESR0 pin functionality 396

8.6 PORST and ESR0 pin status during power on, destructive and functional reset 397

8.7 System boot 397

8.8 HW boot record search (SSCM search) 398

8.9 SW boot record search (BAF search) 400

8.10 Performances 401

9 Device Configuration Format (DCF) Records 402

9.1 Introduction 402

9.2 DCF clients 402

9.3 DCF records 403

9.3.1 UTEST DCF records 406

9.4 DCF client table 406

10 Power management 418

10.1 Overview 418

10.1.1 Power management framework 418

10.1.2 Power management supply description 419

10.2 Architecture 420

10.2.1 Start-up sequence 423

10.2.2 Voltage regulator mode 423

10.2.3 Ballast 423

10.2.4 Reduced power modes 424
10.2.5 Voltage monitors 425
10.2.6 Device operating status versus power conditions 430
10.2.7 BIST details 432

11 Security 436
11.1 Basic security 436
11.2 Advanced security 436
11.3 Detailed security information 436

12 Core e200z420n3 Description 437
12.1 Overview of the e200z420n3 Core 437
12.2 Register Model 437
12.3 Dual-issue operation 440
12.4 Reservation instructions and cache interactions 441
12.5 Signal Processing Extension/ Embedded Floating-point Status and Control Register (SPEFSCR) . . . 441
12.6 Cache 444
12.6.1 Cache overview 444
12.6.2 L1 Cache Control and Status Register 0 (L1CSR0) 444
12.6.3 L1 Cache Control and Status Register 1 (L1CSR1) 447
12.6.4 L1 Cache Configuration Register 0 (L1CFG0) 449
12.6.5 L1 Cache Configuration Register 1 (L1CFG1) 451
12.6.6 Data Cache Software Coherency 451
12.6.7 Data Cache Hardware Coherency 452
12.6.8 Cache Invalidate by Set and Way 452
12.6.9 Cache EDC/ECC Parity Protection 454
12.6.10 Cache Error Injection 455
12.7 Exceptions 456
12.7.1 Exception Syndrome Register (ESR) 457
12.7.2 Machine State Register (MSR) 458
12.7.3 Machine Check Syndrome Register (MCSR) 459
12.7.4 Interrupt Vector Prefix Registers (IVPR) 463
12.7.5 Interrupt Definitions 463
12.8 Memory Protection Unit (MPU) 473
12.8.1 MPU Overview 473

12.8.2 Access Protection Operation 473
12.8.3 Software Interface and MPU Instructions 474
12.8.4 MPU Read Entry Instruction (mpure) 474
12.8.5 MPU Write Entry Instruction (mpuwe) 474
12.8.6 MPU Synchronize Instruction (mpusync) 474
12.8.7 MMU/MPU Configuration Register (MMUCFG) 475
12.8.8 MPU0 Configuration Register (MPU0CFG) 475
12.8.9 MPU0 Control and Status Register 0 (MPU0CSR0) 476
12.8.10 MPU Assist Registers (MAS) 479
12.8.11 MAS Registers Summary 484
12.9 Local memories 485
12.9.1 Local Instruction and Data Memory Overview 485
12.9.2 Local Memory Control and Configuration 485
12.10 End-to-End ECC Support 500
12.10.1 End-to-End ECC Control and Configuration 500

13 Crossbar switch (XBAR) 505
13.1 Introduction 505
13.1.1 Features 505
13.1.2 Memory map and register definition 505
13.2 Functional description 509
13.2.1 General operation 509
13.2.2 Register coherency 509
13.2.3 Arbitration 510
13.3 Initialization/application information 511

14 System Integration Unit Lite2 (SIUL2) 512
14.1 Introduction 512
14.1.1 Overview 512
14.1.2 Features 514
14.1.3 Register protection 514
14.2 Memory map and register description 514
14.2.1 Memory map 514
14.2.2 Register descriptions 517
14.3 Functional description 532
14.3.1 General 532

14.3.2 Pad control . . . 532
14.3.3 General purpose input or output pads (GPIO) . . . 533
14.3.4 External interrupts/DMA requests (EIRQ pins) . . . 534

15 Crossbar Integrity Checker (XBIC) . . . 537
15.1 Overview . . . 537
15.2 Features . . . 537
15.3 Block diagram . . . 538
15.4 External signal description . . . 539
15.5 Memory map and register definition . . . 539
15.5.1 Memory map . . . 539
15.5.2 Register descriptions . . . 540
15.6 Functional description . . . 544

16 Peripheral bridge . . . 547
16.1 Introduction . . . 547
16.1.1 Features . . . 547
16.1.2 General operation . . . 547
16.2 Memory map/register definition . . . 547
16.2.1 Master Privilege Registers (PBRIDGE_MPRA) . . . 550
16.2.2 Peripheral Access Control Registers (PBRIDGE_PACR*x*) . . . 551
16.2.3 Off-Platform Peripheral Access Control Registers (PBRIDGE_OPACR*x*) . . . 553
16.3 Functional description . . . 556
16.3.1 Access support . . . 556

17 System Memory Protection Unit (SMPU) . . . 557
17.1 Overview . . . 557
17.2 Block diagram . . . 557
17.3 Features . . . 558
17.4 Memory map and register definition . . . 559
17.4.1 Memory map . . . 559
17.4.2 Register descriptions . . . 560
17.5 Functional description . . . 567
17.5.1 Access evaluation macro . . . 567
17.5.2 Putting it all together and error terminations . . . 569

17.6 Initialization information 569
17.7 Application information 569

18 Intelligent AHB Gasket (IAHBG) 572
18.1 Introduction 572
18.2 Timing modes 572
18.2.1 1:1 572
18.2.2 2:1 572
18.2.3 1:2 573

19 Interrupt Controller (INTC) 574
19.1 Introduction 574
19.2 Block diagram 574
19.3 Features 576
19.4 Modes of operation 576
19.4.1 Software vector mode 576
19.4.2 Hardware vector mode 577
19.5 Memory map and register definition 577
19.5.1 Memory map 577
19.5.2 Register descriptions 578
19.6 Functional description 584
19.6.1 Interrupt request sources 584
19.6.2 Priority management 585
19.6.3 Handshaking with processor 586
19.7 Initialization/application information 588
19.7.1 Initialization flow 588
19.7.2 Interrupt exception handler 589
19.7.3 ISR, RTOS, and task hierarchy 591
19.7.4 Order of execution 592
19.7.5 Priority ceiling protocol 593
19.7.6 Selecting priorities according to request rates and deadlines 596
19.7.7 Software-settable interrupt requests 596
19.7.8 Lowering priority within an ISR 597
19.7.9 Negating an interrupt request outside of its ISR 597
19.7.10 Examining LIFO contents 598
19.8 Interrupt sources 598

20 Enhanced Direct Memory Access (eDMA) 599

20.1 Introduction 599

20.1.1 Features 599

20.2 Modes of operation 600

20.2.1 Normal mode 600

20.2.2 Debug mode 601

20.2.3 Wait mode 601

20.3 Memory map/register definition 601

20.3.1 Control Register (DMA_CR) 603

20.3.2 Error Status Register (DMA_ES) 605

20.3.3 Enable Request Register Low (DMA_ERQL) 607

20.3.4 Enable Error Interrupt Register Low (DMA_EEIL) 609

20.3.5 Set Enable Request Register (DMA_SERQ) 613

20.3.6 Clear Enable Request Register (DMA_CERQ) 613

20.3.7 Set Enable Error Interrupt Register (DMA_SEEI) 614

20.3.8 Clear Enable Error Interrupt Register (DMA_CEEI) 615

20.3.9 Clear Interrupt Request Register (DMA_CINT) 615

20.3.10 Clear Error Register (DMA_CERR) 616

20.3.11 Set START Bit Register (DMA_SSRT) 617

20.3.12 Clear DONE Status Bit Register (DMA_CDNE) 617

20.3.13 Interrupt Request Register Low (DMA_INTL) 618

20.3.14 Error Register Low (DMA_ERRL) 621

20.3.15 Hardware Request Status Register Low (DMA_HRSL) 624

20.3.16 Channel *n* Priority Register (DMA_DCHPRI*n*) 626

20.3.17 Channel *n* Master ID Register (DMA_DCHMID*n*) 627

20.3.18 TCD Source Address (DMA_TCD*n*_SADDR) 628

20.3.19 TCD Transfer Attributes (DMA_TCD*n*_ATTR) 629

20.3.20 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF) 629

20.3.21 TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCD*n*_NBYTES_MLNO) 630

20.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO) 631

20.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES) 632

20.3.24 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST) 633

20.3.25 TCD Destination Address (DMA_TCD*n*_DADDR) 634

20.3.26 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES) 634

20.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO) 635
20.3.28 TCD Signed Destination Address Offset (DMA_TCD*n*_DOFF) 636
20.3.29 TCD Last Destination Address Adjustment/ Scatter Gather Address (DMA_TCD*n*_DLASTSGA) 637
20.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES) 637
20.3.31 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO) 638
20.3.32 TCD Control and Status (DMA_TCD*n*_CSR) 639
20.4 Functional description 641
20.4.1 eDMA microarchitecture 642
20.4.2 eDMA basic data flow 643
20.4.3 Error reporting and handling 646
20.4.4 Channel preemption 648
20.4.5 eDMA performance 648
20.5 Initialization/application information 651
20.5.1 eDMA initialization 651
20.5.2 DMA programming errors 653
20.5.3 DMA Arbitration mode considerations 654
20.5.4 DMA transfer 655
20.5.5 eDMA TCD*n* status monitoring 658
20.5.6 Channel linking 660
20.5.7 Dynamic programming 661

21 DMA channel multiplexer (DMACHMUX) 664
21.1 Introduction 664
21.1.1 Overview 664
21.1.2 Features 665
21.1.3 Modes of operation 665
21.2 External signal description 665
21.2.1 Overview 665
21.3 Memory map and register definition 665
21.3.1 Register descriptions 666
21.4 Functional description 667
21.4.1 DMA channels with periodic triggering capability 667
21.4.2 DMA channels with no triggering capability 669
21.4.3 “Always Enabled” DMA sources 669

21.5 Initialization/Application information 670
21.5.1 Reset 670
21.5.2 Enabling and configuring sources 670

22 Wakeup unit (WKPU) 675
22.1 Introduction 675
22.1.1 Overview 675
22.1.2 Features 675
22.2 Memory Map and Register Description 675
22.2.1 Memory Map 676
22.2.2 Register Descriptions 676
22.3 Functional Description 680
22.3.1 General 680
22.3.2 Non-Maskable Interrupts 680

23 Temperature sensor (TSENS) 682
23.1 Introduction 682
23.2 Features 682
23.3 Signals 682
23.4 TSENS outputs 682
23.5 Obtaining device temperature using TSENS 683
23.5.1 TSENS calibration constants 683
23.5.2 Equations for converting TSENS voltage to device temperature 683
23.6 Equations for converting CTAT and PTAT voltages into constant reference code 684

24 Clocking 685
24.1 Introduction 685
24.2 Clock generation 685
24.2.1 MC_CGM registers 686
24.3 System clock frequency limitations 687
24.3.1 JTAG frequencies 689
24.4 Default clock configuration 689
24.5 Clock sources 689
24.5.1 PLL 689
24.5.2 External oscillator (XOSC) 691

24.5.3 16 MHz internal RC oscillator (IRCOSC) . . . 693
24.6 Peripheral clocks . . . 693
24.6.1 MCAN clocking . . . 694
24.7 Clock monitoring . . . 695
24.7.1 CMU configuration . . . 695
24.7.2 PLL0 monitor . . . 697
24.7.3 External oscillator (XOSC) monitor . . . 697
24.7.4 Internal RC oscillator (IRCOSC) monitor . . . 698
24.7.5 System clock monitors . . . 698
24.8 Loss of system clock behavior . . . 698
24.8.1 Loss of PLL/XOSC clock . . . 698
24.8.2 Loss of IRCOSC clock . . . 698

25 Dual PLL Digital Interface (PLLDIG) . . . 699
25.1 Introduction . . . 699
25.2 Block Diagram . . . 699
25.3 Features . . . 699
25.4 Modes of operation . . . 699
25.4.1 Normal mode with reference, PLL0 or both PLLs enabled . . . 700
25.5 Memory map and register definition . . . 700
25.5.1 Memory map . . . 700
25.5.2 Register descriptions . . . 701
25.5.3 Register classification for safety requirements . . . 709
25.6 Functional description . . . 710
25.6.1 Input clock frequency . . . 710
25.6.2 Clock configuration . . . 710
25.6.3 Loss of lock . . . 711
25.6.4 Frequency modulation . . . 712
25.7 Initialization information . . . 713

26 Clock Monitor Unit (CMU) . . . 716
26.1 Introduction . . . 716
26.1.1 Main features . . . 716
26.2 Block diagram . . . 716
26.3 Signals . . . 716
26.4 Memory map and register definition . . . 717

26.4.1 Register descriptions . . . 718
26.5 Functional description . . . 723
26.5.1 Frequency meter . . . 723
26.5.2 CLKMN0_RMT supervisor . . . 723
26.5.3 CLKMN1 supervisor . . . 723

27 Clock Generation Module (MC_CGM) . . . 724
27.1 Introduction . . . 724
27.1.1 Overview . . . 724
27.1.2 Features . . . 725
27.2 External signal description . . . 726
27.3 Memory map and register definition . . . 726
27.3.1 Register descriptions . . . 727
27.4 Functional Description . . . 756
27.4.1 System Clock Generation . . . 756
27.4.2 Auxiliary Clock Generation . . . 762
27.4.3 Dividers Functional Description . . . 766

28 OSC Digital Interface (XOSC) . . . 767
28.1 Introduction . . . 767
28.2 Functional description . . . 767
28.2.1 Oscillator power-down control and status . . . 767
28.2.2 Oscillator startup delay . . . 767
28.2.3 Oscillator clock available interrupt . . . 768
28.2.4 Oscillator bypass mode . . . 768
28.3 Memory map and register definition . . . 768
28.3.1 Register descriptions . . . 769

29 IRCOSC digital interface . . . 770
29.1 Introduction . . . 770
29.2 Functional description . . . 770
29.3 Memory map and register definition . . . 770
29.3.1 Register descriptions . . . 771

30 Platform RAM controller (PRAM) . . . 774
30.1 Introduction . . . 774

30.2 SRAM controller memory map and register definitions 775
30.2.1 Platform RAM configuration register 1 (PRCR1) 775
30.3 Functional description 776
30.3.1 Read/Write introduction 776
30.3.2 Writes 777
30.4 Initialization/application information 777
30.5 Safety considerations 778
30.5.1 Hsiao ECC algorithm 778
30.5.2 Transaction monitor 781

31 Flash memory controller (PFLASH Controller) 783
31.1 Introduction 783
31.2 Features 783
31.3 Block diagram 783
31.4 Memory map and register definitions 784
31.4.1 Overview 784
31.5 Functional description 796
31.5.1 Basic interface protocol 796
31.5.2 Access protections 797
31.5.3 Read cycles - buffer miss 797
31.5.4 Read cycles – buffer hit 797
31.5.5 Error termination 797
31.5.6 Flash error response operation 798
31.5.7 Censorship 798
31.5.8 Line read buffers and prefetch operation 798
31.5.9 Instruction/Data prefetch triggering 799
31.5.10 Per-Master prefetch triggering 799
31.5.11 Buffer allocation 799
31.5.12 Safety considerations 800
31.5.13 Array integrity considerations 802

32 Embedded Flash Memory 803
32.1 Introduction 803
32.1.1 Overview 803
32.1.2 Features 805
32.1.3 Modes of operation 805

32.2 Flash memory map and description 806
32.2.1 Flash array memory map 807
32.3 Register memory maps and descriptions 809
32.3.1 Register memory maps 810
32.3.2 User register descriptions 811
32.4 Functional description 843
32.4.1 Reset 843
32.4.2 Power-down mode (Disable mode) 843
32.4.3 Low-power mode (Sleep mode) 844
32.4.4 Read mode 845
32.4.5 Modify mode 847
32.4.6 Protection strategy 858

33 Decorated Storage Memory Controller (DSMC) 860
33.1 Introduction 860
33.2 Decorated Stores: st[b,h,w]d{cb}x rS,rB,rA 862
33.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container . . . 862
33.2.2 Compare-and-Store (CAST) 864
33.2.3 Logical AND (AND) 864
33.2.4 Logical OR (OR) 865
33.2.5 Logical Exclusive-OR (XOR) 865
33.3 Decorated Loads: l[b,h,w]d{cb}x rT,rB,rA 865
33.3.1 Simple Load (SLD) 866
33.3.2 Registers-and-Memory Exchange (SWAP) 866
33.3.3 Load-and-Set-1(Bit) (LAS1) 867
33.4 DSMC Instantiations 867

34 Successive Approximation Register Analog-to-Digital Converter (SARADC) 868
34.1 Introduction 868
34.2 Overview 868
34.3 Feature description 870
34.3.1 Main features 870
34.4 Functional description 870
34.4.1 Normal channel conversion 871
34.4.2 Injected channel conversion 872

34.4.3 Abort conversion . . . 873
34.4.4 Analog conversion timings . . . 873
34.4.5 CrossTriggering Unit (CTU) interface . . . 875
34.4.6 Test channel connection with internal analog channel . . . 877
34.4.7 Programmable analog watchdog . . . 877
34.4.8 DMA functionality . . . 879
34.4.9 Interrupts . . . 879
34.4.10 Power down mode . . . 880
34.4.11 Stop Mode . . . 880
34.5 Memory map and registers . . . 880
34.5.1 Register descriptions . . . 883
34.6 Start of conversion pulse delay . . . 913
34.7 Initialization Information . . . 915

35 Enhanced Cross Trigger Unit (ECTU) . . . 917
35.1 Introduction . . . 917
35.2 Main features . . . 917
35.3 Block diagram . . . 917
35.4 Functional description . . . 918
35.4.1 Trigger generator subunit (TGS) . . . 918
35.4.2 Digital filter . . . 920
35.4.3 Scheduler subunit (SU) . . . 921
35.4.4 CTU FIFO . . . 922
35.5 CTU interrupt and DMA requests . . . 923
35.5.1 DMA support . . . 923
35.5.2 CTU faults and errors . . . 924
35.6 ADC commands list . . . 926
35.6.1 ADC commands list format . . . 926
35.6.2 ADC results . . . 930
35.6.3 ADC-CTU interface timing . . . 930
35.7 Low power mode . . . 931
35.8 Safety features . . . 932
35.8.1 Conversion time check . . . 932
35.8.2 CTU reset . . . 932
35.8.3 Motor function iMonitor . . . 933
35.9 CTU error flags examples . . . 935

35.9.1 Invalid command error . . . 935
35.9.2 Maximum concurrent conversion error . . . 935
35.10 Register description . . . 936
35.10.1 Synchronization . . . 936
35.10.2 Double buffered registers . . . 936
35.10.3 TGS counter precision . . . 938
35.10.4 Memory map . . . 940
35.10.5 Trigger generator subunit input selection register (TGSISR) . . . 943
35.10.6 Trigger generator subunit control register (TGSCR) . . . 947
35.10.7 Trigger compare register n (TCRn) . . . 948
35.10.8 TGS counter compare register (TGSCCR) . . . 948
35.10.9 TGS counter reload register (TGSCRR) . . . 949
35.10.10 Commands list control register 1 (CLCR1) . . . 949
35.10.11 Commands list control register 2 (CLCR2) . . . 950
35.10.12 Commands list control register 3 (CLCR3) . . . 950
35.10.13 Commands list control register 4 (CLCR4) . . . 951
35.10.14 Trigger handler control register 1 (THCR1) . . . 952
35.10.15 Trigger handler control register 2 (THCR2) . . . 954
35.10.16 Trigger handler control register 3 (THCR3) . . . 956
35.10.17 Trigger handler control register 4 (THCR4) . . . 958
35.10.18 Commands list register n (CLRn) . . . 960
35.10.19 Control register (CR) . . . 961
35.10.20 Control register 1 FIFO (FCR1) . . . 962
35.10.21 Control register 2 FIFO (FCR2) . . . 964
35.10.22 THRESHOLD register 1 (TH1) . . . 967
35.10.23 THRESHOLD register 2 (TH2) . . . 967
35.10.24 THRESHOLD register 3 (TH3) . . . 968
35.10.25 THRESHOLD register 4 (TH4) . . . 969
35.10.26 Status register 1 (ST1) . . . 970
35.10.27 Status register 2 (ST2) . . . 972
35.10.28 FIFO right aligned register n (FRn) . . . 974
35.10.29 FIFO left aligned register n (FLn) . . . 975
35.10.30 Cross triggering unit error flag register (CTUEFR) . . . 976
35.10.31 Cross triggering unit interrupt flag register (CTUIFR) . . . 978
35.10.32 Cross triggering unit interrupt/DMA register (CTUIR) . . . 979
35.10.33 Control on-time register (COTR) . . . 982
35.10.34 Cross triggering unit control register (CTUCR) . . . 982

35.10.35 Cross triggering unit digital filter (CTU_FILTER) 984
35.10.36 Cross triggering unit configuration status register 1 (CTU_CFGSR1) . 985
35.10.37 Cross triggering unit configuration status register 2 (CTU_CFGSR2) . 986
35.10.38 Cross triggering unit expected value n (CTU_EXPECTEDn) 989
35.10.39 Cross triggering unit counter range (CTU_CNT_RANGEn) 990
35.10.40 CTU expected CRC register (CTU_EXP_CRC_VAL) 990
35.10.41 CTU computed CRC register (CTU_COMP_CRC_VAL) 991
35.10.42 CTU Mask CRC computation register (CTU_MASK_CRC_VAL) 991

36 Motor Control Pulse Width Modulator Module (FlexPWM) 993

36.1 Introduction 993
36.1.1 Overview 993
36.1.2 Features 994
36.1.3 Modes of Operation 994
36.1.4 Block Diagrams 996
36.2 External Signal Descriptions 997
36.2.1 PWMA[n] and PWMB[n] - External PWM Pair 997
36.2.2 PWMX[n] - Auxiliary PWM signal 997
36.2.3 FAULT[n] - Fault inputs 998
36.2.4 EXT_SYNC - External Synchronization Signal 998
36.2.5 EXT_FORCE - External Output Force Signal 998
36.2.6 EXTA[n] and EXTB[n] - Alternate PWM Control Signals 998
36.2.7 OUT_TRIG0[n] and OUT_TRIG1[n] - Output Triggers 998
36.2.8 EXT_CLK - External Clock Signal 998
36.2.9 EXT_SWITCH - External Switch Signal 998
36.3 Memory Map and Registers 998
36.3.1 Module Memory Map 999
36.3.2 Counter register n (CNTn) 1000
36.3.3 Initial Count register n (INITn) 1001
36.3.4 Control 2 register n (CTRL2n) 1002
36.3.5 Control 1 register n (CTRL1n) 1004
36.3.6 Value 0 register n (VAL0n) 1007
36.3.7 Value 1 register n (VAL1n) 1008
36.3.8 Value 2 register n (VAL2n) 1008
36.3.9 Value 3 register n (VAL3n) 1009
36.3.10 Value 4 register n (VAL4n) 1009
36.3.11 Value 5 register n (VAL5n) 1010

36.3.12 Output Control register n (OCTRLn) 1010
36.3.13 Status register n (STSn) 1012
36.3.14 Interrupt Enable register n (INTENn) 1013
36.3.15 DMA Enable register n (DMAENn) 1014
36.3.16 Output Trigger Control register n (TCTRLn) 1016
36.3.17 Fault Disable Mapping register n (DISMAPn) 1016
36.3.18 Deadtime Count 0 register n (DTCNT0n) 1017
36.3.19 Deadtime Count 1 register n (DTCNT1n) 1017
36.3.20 Capture Control A register n (CAPTCTRLAn) 1018
36.3.21 Capture Compare A register n (CAPTCMPAn) 1020
36.3.22 Capture Control B register n (CAPTCTRLBn) 1020
36.3.23 Capture Compare B register n (CAPTCMPBn) 1022
36.3.24 Capture Control X register n (CAPTCTRLXn) 1022
36.3.25 Capture Compare X register n (CAPTCMPXn) 1024
36.3.26 Capture Value 0 register n (CVAL0n) 1025
36.3.27 Capture Value 0 Cycle register n (CVAL0CYCn) 1025
36.3.28 Capture Value 1 register n (CVAL1n) 1026
36.3.29 Capture Value 1 Cycle register n (CVAL1CYCn) 1026
36.3.30 Capture Value 2 register n (CVAL2n) 1027
36.3.31 Capture Value 2 Cycle register n (CVAL2CYCn) 1027
36.3.32 Capture Value 3 register n (CVAL3n) 1028
36.3.33 Capture Value 3 Cycle register n (CVAL3CYCn) 1028
36.3.34 Capture Value 4 register n (CVAL4n) 1029
36.3.35 Capture Value 4 Cycle register n (CVAL4CYCn) 1029
36.3.36 Capture Value 5 register n (CVAL5n) 1030
36.3.37 Capture Value 5 Cycle register n (CVAL5CYCn) 1030
36.3.38 Configuration Registers 1030
36.3.39 Fault Channel Registers 1036
36.4 Functional Description 1039
36.4.1 Block Diagram 1039
36.4.2 PWM Capabilities 1039
36.4.3 Functional Details 1049
36.4.4 PWM Generator Loading 1066
36.5 Resets 1069
36.6 Clocks 1069
36.7 Interrupts 1069

36.8 DMA 1071

37 PWM Synchronizer 1073

37.1 Introduction 1073
37.2 Main Features 1074
37.3 Memory map and register description 1074
37.3.1 Memory map 1074
37.3.2 Register descriptions 1075
37.4 Programming Sequence 1084
37.5 Functional description 1084

38 Enhanced Motor Control Timer (eTimer) 1088

38.1 Introduction 1088
38.1.1 Overview 1088
38.1.2 Features 1089
38.1.3 Module block diagram 1090
38.1.4 Channel block diagram 1091
38.2 External signal descriptions 1091
38.2.1 TIO[*n*:0] - Timer Input/Outputs 1091
38.2.2 TAI[*n*:0] - Timer Auxiliary Inputs 1091
38.3 Functional Description 1092
38.3.1 General 1092
38.3.2 Counting Modes 1092
38.3.3 Other Features 1100
38.4 Memory Map and Registers 1101
38.4.1 Overview 1101
38.4.2 Module Memory Map 1101
38.4.3 Register Descriptions 1102
38.4.4 Timer Channel Registers 1102
38.4.5 Watchdog Timer Registers 1117
38.4.6 Configuration Registers 1118
38.5 Resets 1122
38.6 Clocks 1123
38.7 Interrupts 1123
38.8 DMA 1123

39 System Timer Module (STM) 1125
39.1 Introduction 1125
39.1.1 Overview 1125
39.1.2 Features 1125
39.1.3 Modes of operation 1125
39.2 External signal description 1125
39.3 Memory map and register definition 1125
39.3.1 Memory map 1125
39.3.2 Register descriptions 1126
39.4 Functional description 1129

40 Software Watchdog Timer (SWT) 1130
40.1 Introduction 1130
40.1.1 Overview 1130
40.1.2 Features 1130
40.1.3 Modes of operation 1130
40.2 External signal description 1130
40.3 Memory map and register definition 1130
40.3.1 Register descriptions 1131
40.4 Functional description 1136
40.4.1 Introduction 1136
40.4.2 Configuration locking 1137
40.4.3 Unlock sequence 1137
40.4.4 Servicing operations 1137
40.4.5 Time-out 1138
40.4.6 Initialization 1138

41 Periodic Interrupt Timer (PIT) 1139
41.1 Introduction 1139
41.1.1 Block diagram 1139
41.1.2 Features 1140
41.2 Signal description 1140
41.2.1 Memory map/register description 1140
41.3 Functional description 1143
41.3.1 General 1144
41.3.2 Interrupts 1145

41.3.3 Chained timers 1145
41.4 Initialization and application information 1145

42 CAN Subsystem 1147
42.1 Introduction 1147
42.2 Features 1148
42.3 Modular CAN (M_CAN) cores 1149
42.3.1 Features 1150
42.3.2 Block diagram 1151
42.3.3 Dual clock sources 1152
42.3.4 Dual interrupt lines 1152
42.3.5 Memory map and register descriptions 1152
42.3.6 Message RAM 1200
42.3.7 M_CAN functional description 1210
42.3.8 Timestamp generation 1220
42.3.9 Timeout counter 1220
42.3.10 Rx handling 1221
42.3.11 Dedicated Rx Buffers 1227
42.3.12 Debug on CAN Support 1228
42.3.13 Tx handling 1230
42.3.14 FIFO acknowledge handling 1234
42.3.15 Clock Calibration on CAN Unit (CCCU) 1234
42.4 CAN RAM arbiter 1246
42.4.1 Features 1247
42.4.2 Functional overview using examples 1247
42.5 SRAM interface and memory organization 1247
42.5.1 ECC controller 1247
42.6 CAN nodes 0 and 2 I/Os sharing 1248
42.7 External signal description 1249
42.8 Shared memory map 1249

43 Deserial Serial Peripheral Interface (DSPI) 1252
43.1 Introduction 1252
43.1.1 Block diagram 1252
43.1.2 Features 1253
43.1.3 SPI configuration 1254

43.1.4 Modes of operation 1255
43.2 DSPI signal description 1256
43.2.1 PCS0/SS — Peripheral Chip Select 0 / Slave Select 1256
43.2.2 PCS[1:3] — Peripheral Chip Selects 1 – 3 1257
43.2.3 PCS4/MTRIG — Peripheral Chip Select 4 / Master Trigger 1257
43.2.4 PCS5/PCSS — Peripheral Chip Select 5 / Peripheral Chip Select Strobe 1257
43.2.5 PCS[6:7] — Peripheral Chip Selects 6 – 7 1257
43.2.6 SIN — Serial Input 1257
43.2.7 SOUT — Serial Output 1257
43.2.8 SCK — Serial Clock 1257
43.2.9 Memory map/register definition 1257
43.3 Register classification for safety 1283
43.4 Functional description 1283
43.4.1 Start and Stop of DSPI transfers 1284
43.4.2 Serial Peripheral Interface (SPI) configuration 1285
43.4.3 DSPI baud rate and clock delay generation 1288
43.4.4 Transfer formats 1291
43.4.5 Continuous Serial Communications Clock 1300
43.4.6 Slave mode operation constraints 1301
43.4.7 Parity generation and check 1302
43.4.8 Interrupts/DMA requests 1302
43.4.9 Power saving features 1305
43.5 Initialization/application information 1306
43.5.1 Managing DSPI queues 1306
43.5.2 Switching master and slave mode 1306
43.5.3 Initializing DSPI in Master/Slave Modes 1307
43.5.4 Baud rate settings 1307
43.5.5 Delay settings 1308
43.5.6 Calculation of FIFO pointer addresses 1309

44 LINFlexD 1312
44.1 Introduction 1312
44.2 Main features 1314
44.2.1 LIN mode features 1314
44.2.2 UART mode features 1315
44.2.3 Standard features 1315

44.3 Functional description 1315
44.3.1 LIN protocol 1315
44.3.2 LINFlexD features 1317
44.3.3 Timer 1333
44.3.4 UART mode 1334
44.3.5 DMA interface 1339
44.4 Memory map and register description 1357
44.4.1 Memory map 1357
44.4.2 Register description 1359
44.5 Programming considerations 1392
44.5.1 Master node 1392
44.5.2 Slave node 1394
44.5.3 Extended frames 1398
44.5.4 Timeout 1398
44.5.5 UART mode 1399
44.5.6 Interrupts 1399

45 SENT Receiver (SRX) 1401
45.1 Introduction 1401
45.1.1 Features 1402
45.1.2 Modes of operation 1403
45.1.3 Block diagram 1405
45.1.4 Design overview 1405
45.2 External signal description 1407
45.2.1 SENT_RX [(CH-1):0] 1407
45.3 Memory map and register definition 1407
45.3.1 Memory map 1407
45.3.2 Register descriptions 1409
45.3.3 Register Classification for Safety 1440
45.4 Functional description 1440
45.4.1 Initialization sequence 1440
45.4.2 DMA read logic 1441
45.4.3 Message reading via interrupts 1447
45.4.4 Overflow behavior 1448
45.4.5 Adjustment for variation in sensor (Tx) clock 1448
45.4.6 Input programmable filter 1449

45.4.7 Receiver diagnostics 1450
45.4.8 Time stamp logic 1454
45.4.9 Bus Idle Diagnostic 1455
45.5 Clocks and resets 1455
45.5.1 Clocking strategy 1455
45.5.2 System bus clock requirements 1456
45.5.3 High frequency receiver clock (protocol clock) requirements 1456

46 FlexRay Communication Controller (FlexRay) 1458
46.1 Introduction 1458
46.1.1 Reference 1458
46.1.2 Color coding 1458
46.1.3 Overview 1458
46.1.4 Features 1460
46.1.5 Modes of operation 1461
46.2 External Signal Description 1463
46.2.1 Detailed signal description 1464
46.3 Controller Host Interface clocking 1465
46.4 Protocol engine clocking 1465
46.4.1 Oscillator clocking 1465
46.4.2 PLL clocking 1465
46.5 Memory map and register description 1465
46.5.1 Memory map 1466
46.5.2 Register descriptions 1471
46.6 Functional description 1562
46.6.1 Message buffer concept 1562
46.6.2 Physical message buffer 1562
46.6.3 Message Buffer Types 1563
46.6.4 FlexRay memory area layout 1570
46.6.5 Physical message buffer description 1573
46.6.6 Individual message buffer functional description 1583
46.6.7 Individual message buffer search 1601
46.6.8 Individual message buffer reconfiguration 1604
46.6.9 Receive FIFOs 1604
46.6.10 Channel device modes 1610
46.6.11 External clock synchronization 1612

46.6.12 Sync frame ID and sync frame deviation tables 1613
46.6.13 MTS generation 1616
46.6.14 Key slot transmission 1617
46.6.15 Sync frame filtering 1617
46.6.16 Strobe signal support 1618
46.6.17 Timer support 1619
46.6.18 Slot status monitoring 1620
46.6.19 System bus access 1624
46.6.20 Interrupt support 1625
46.6.21 Lower bit rate support 1629
46.6.22 PE data memory (PE DRAM) 1630
46.6.23 CHI lookup-table memory (CHI LRAM) 1631
46.6.24 Memory content error detection 1632
46.6.25 Memory error injection 1636
46.6.26 StopWatch function 1638
46.7 Application information 1639
46.7.1 Module configuration 1639
46.7.2 Initialization sequence 1640
46.7.3 Memory error injection out of POC:default config 1642
46.7.4 Shutdown sequence 1642
46.7.5 Number of usable message buffers 1642
46.7.6 Protocol Control Command Execution 1644
46.7.7 Message buffer search on simple message buffer configuration 1645

47 Reset Generation Module (MC_RGM) 1648
47.1 Introduction 1648
47.1.1 Overview 1648
47.1.2 Features 1649
47.1.3 Reset sources 1650
47.2 External signal description 1651
47.3 Memory map and register definition 1651
47.3.1 Memory map 1651
47.3.2 Register descriptions 1653
47.4 Functional description 1691
47.4.1 Reset state machine 1691
47.4.2 ‘Destructive’ resets 1694
47.4.3 ‘Functional’ resets 1694

47.4.4 Alternate event generation 1695
47.4.5 ‘Functional’ reset escalation 1695
47.4.6 ‘Destructive’ reset escalation 1696
47.4.7 Individual peripheral resets 1696

48 Boot Assist Flash (BAF) 1697
48.1 Introduction 1697
48.2 Memory map 1697
48.2.1 BAF image header 1697
48.3 Functional description 1698
48.3.1 Boot modes 1698
48.3.2 Device initialization 1698
48.3.3 Flow of control 1699
48.3.4 Initialization of BAF DCF clients 1700
48.3.5 Optionally perform a serial boot 1705
48.3.6 Serial boot configuration 1710
48.4 Resources accessed by BAF code execution 1713

49 System Status and Configuration Module (SSCM) 1714
49.1 Introduction 1714
49.1.1 Overview 1714
49.1.2 Features 1714
49.1.3 Modes of operation 1714
49.2 Memory map and register definition 1714
49.2.1 Register descriptions 1715
49.3 Functional description 1719
49.3.1 DCF mechanism 1719
49.3.2 Boot mode functionality 1721
49.3.3 BAF configuration 1721
49.3.4 User code boot sector search 1722
49.3.5 Life Cycle 1723
49.4 Initialization and application information 1724
49.4.1 Reset 1724
49.5 Additional safety measures 1724
49.5.1 Spurious reset protection 1724

50 Power management controller digital interface (PMC_Dig) 1725

50.1 Introduction 1725

50.2 Main features 1727

50.2.1 Standard features 1727

50.3 IPS bus interface 1727

50.4 Memory Map and Registers 1727

50.5 Register description 1730

50.5.1 Event Pending Register (EPR_LV0) 1730

50.5.2 Reset Event Enable Register (REE_LV0) 1731

50.5.3 Reset Event Select Register (RES_LV0) 1732

50.5.4 Interrupt Enable (IE_LV0) 1732

50.5.5 FCCU Event Enable Register (FEE_LV0) 1733

50.5.6 Event Pending Register (EPR_LV1) 1734

50.5.7 Reset Event Enable Register (REE_LV1) 1734

50.5.8 Reset Event Select Register (RES_LV1) 1735

50.5.9 Interrupt Enable (IE_LV1) 1736

50.5.10 FCCU Event Enable Register (FEE_LV1) 1737

50.5.11 Event Pending Register (EPR_HV0) 1738

50.5.12 Reset Event Enable Register (REE_HV0) 1739

50.5.13 Reset Event Select Register (RES_HV0) 1741

50.5.14 Interrupt Enable (IE_HV0) 1742

50.5.15 FCCU Event Enable Register (FEE_HV0) 1743

50.5.16 Event Pending Register (EPR_HV1) 1745

50.5.17 Reset Event Enable Register (REE_HV1) 1746

50.5.18 Reset Event Select Register (RES_HV1) 1748

50.5.19 Interrupt Enable Register (IE_HV1) 1749

50.5.20 FCCU Event Enable Register (FEE_HV1) 1751

50.5.21 Supply Gauge Status Register (*GR_S*) 1752

50.5.22 Pending Gauge Status Register (GR_P) 1755

50.5.23 Interrupt Enable Pending Register (IE_G) 1756

50.5.24 Voltage Selection of IO (VSIO) 1758

50.5.25 IPS Regulator Control PMOS NMOS register (IREGU_CTL_PN) . . . 1759

50.5.26 Event Pending Register (EPR_TD) 1760

50.5.27 Reset Event Enable Register (REE_TD) 1762

50.5.28 Reset Event Select Register (RES_TD) 1763

50.5.29 Temperature Sensor Configuration register (CTL_TD) 1765

50.5.30 Temperature Sensor FCCU Event Enable Register (FEE_TD) 1766
50.5.31 IPS Regulator Monitor Register (IREGU_MON) 1767
50.5.32 ESR0 ConFiGuration Register (ESR0_CFG) 1768
50.5.33 User BIST Flags_IO10 Register (BIST_FLAGS_IO10) 1768
50.5.34 User BIST Flags Register (BIST_FLAGS) 1769
50.5.35 User BIST Control Register (BIST_CTRL) 1770
50.5.36 User BIST Time1 and Time0 Register (BIST_TIME10) 1771
50.5.37 User BIST Time3 and Time2 Register (BIST_TIME32) 1772
50.5.38 User BIST Time6 and Time5 Register (BIST_TIME65) 1772
50.5.39 User BIST VD Under Test Monitor Register (BIST_DEBUG) 1773
50.6 Temperature Sensor Interface Logic 1774
50.7 FCCU Interface 1774
50.8 Power On Reset (MC_RGM Phase Gates) 1775
50.9 Flash interface (DCF client usage) 1775

51 Power Control Unit (MC_PCU) 1777
51.1 Introduction 1777
51.1.1 Overview 1777
51.1.2 Features 1778
51.2 External signal description 1778
51.3 Memory map and register definition 1778
51.3.1 Memory map 1778
51.3.2 Register descriptions 1778

52 Mode Entry Module (MC_ME) 1780
52.1 Introduction 1780
52.1.1 Overview 1780
52.1.2 Features 1782
52.1.3 Modes of operation 1782
52.2 External signal description 1783
52.3 Memory map and register definition 1783
52.3.1 Memory map 1784
52.3.2 Register description 1787
52.4 Functional description 1825
52.4.1 Mode Transition Request 1825
52.4.2 Modes details 1826

52.4.3 Mode Transition Process 1830
52.4.4 Protection of mode configuration registers 1838
52.4.5 Mode Transition Interrupts 1838
52.4.6 Peripheral Clock Gating 1840
52.4.7 Application example 1840

53 e200z420n3 Core Debug Support 1842

53.1 Overview 1842
53.1.1 Software Debug Facilities 1842
53.1.2 Additional Debug Facilities 1843
53.1.3 Hardware Debug Facilities 1843
53.1.4 Sharing Debug Resources by Software/Hardware 1844
53.2 Software Debug Events and Exceptions 1845
53.2.1 Instruction Address Compare Event 1846
53.2.2 Data Address Compare Event 1847
53.2.3 Linked Instruction Address Compare and Data Address Compare Events 1854
53.2.4 Trap Debug Event 1855
53.2.5 Branch Taken Debug Event 1855
53.2.6 Instruction Complete Debug Event 1855
53.2.7 Interrupt Taken Debug Event 1856
53.2.8 Critical Interrupt Taken Debug Event 1856
53.2.9 Return Debug Event 1856
53.2.10 Critical Return Debug Event 1856
53.2.11 External Debug Event 1857
53.2.12 Unconditional Debug Event 1857
53.2.13 Performance Monitor Interrupt Debug Event 1857
53.3 Debug Registers 1857
53.3.1 Debug Address and Value Registers 1858
53.3.2 Debug Control and Status Registers 1859
53.3.3 External Debug Resource Allocation Control Register (EDBRAC0) . 1885
53.3.4 Debug Event Select Register (DEVENT) 1892
53.3.5 Debug Data Acquisition Message Register (DDAM) 1893
53.4 Using Debug Resources for Stack Limit Checking 1894
53.5 External Debug Support 1896
53.5.1 External Debug Registers 1897
53.5.2 OnCE Introduction 1903

53.5.3 JTAG/OnCE Pins . . . 1906
53.5.4 OnCE Internal Interface Signals . . . 1906
53.5.5 OnCE Interface Signals . . . 1907
53.5.6 OnCE Controller and Serial Interface . . . 1909
53.5.7 Access to Debug Resources . . . 1916
53.5.8 Methods of Entering Debug Mode . . . 1918
53.5.9 CPU Status and Control Scan Chain Register (CPUSCR) . . . 1919
53.5.10 Reserved Registers (Reserved) . . . 1926
53.6 Watchpoint Support . . . 1926
53.7 MPU Operation During Debug . . . 1929
53.8 Cache Array Access During Debug . . . 1929
53.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode . . . 1929

54 Debug and Calibration Interface (DCI) . . . 1932
54.1 Introduction . . . 1932
54.1.1 Features . . . 1932
54.1.2 Overview . . . 1932
54.1.3 Operating modes . . . 1934
54.2 External signal description . . . 1941
54.3 Register description . . . 1941
54.3.1 DCI control register (DCI_CR) . . . 1941
54.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR) . . . 1942

55 Debug and Trace . . . 1943
55.1 Introduction . . . 1943
55.1.1 Features . . . 1943
55.1.2 Architecture . . . 1944
55.2 Register description . . . 1946
55.2.1 Nexus Crossbar Multimaster Trace Clients (NXMC) . . . 1946
55.2.2 Sequence Processing Unit (SPU) . . . 1946
55.3 Lock step behavior . . . 1962
55.3.1 Debugging phases . . . 1965
55.3.2 Internal register reading . . . 1966
55.3.3 Step-by-step execution . . . 1966
55.3.4 Exiting a debug session . . . 1967
55.3.5 External tool operation . . . 1967

55.4 Lock step tracing 1967
55.5 External signal description 1967
55.5.1 Interfaces 1967
55.5.2 Nexus trace enabling during reset 1968
55.6 Functionality 1976
55.6.1 JTAG Master (JTAGM) 1976
55.6.2 Nexus Crossbar Multimaster Trace Client (NXMC) 1976
55.6.3 JTAG Data Communication module (JDC) 1976
55.6.4 Nexus Port Controller (NPC) 1976
55.6.5 Sequence Processing Unit (SPU) 1977

56 JTAG Controller (JTAGC) 1978
56.1 Introduction 1978
56.1.1 Block Diagram 1978
56.1.2 Features 1979
56.1.3 Modes of operation 1979
56.2 External signal description 1980
56.2.1 TCK—Test clock input 1980
56.2.2 TDI—Test data input 1980
56.2.3 TDO—Test data output 1980
56.2.4 TMS—Test mode select 1980
56.2.5 JCOMP—JTAG compliancy 1981
56.3 Register description 1981
56.3.1 Instruction register 1981
56.3.2 Bypass register 1981
56.3.3 Device identification register 1981
56.3.4 TEST_CTRL Register 1982
56.3.5 JTAG_PASSWORD register 1983
56.3.6 DATA1 register 1983
56.3.7 DATA2 register 1984
56.3.8 Boundary scan register 1984
56.4 Functional description 1985
56.4.1 JTAGC reset configuration 1985
56.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port 1985
56.4.3 TAP controller state machine 1985
56.4.4 JTAGC block instructions 1987

56.4.5 Boundary scan 1991
56.5 Initialization/Application information 1991

57 JTAG Data Communication (JDC) 1992
57.1 Introduction 1992
57.2 Overview 1992
57.3 Register definition 1993
57.3.1 Register descriptions 1993
57.3.2 Non-Memory mapped register definition 1995
57.4 Functional description 1996
57.4.1 IPS register access 1997
57.4.2 JTAG register access 1997

58 JTAG Master (JTAGM) 1998
58.1 Introduction 1998
58.1.1 Overview 1998
58.1.2 Feature description 1999
58.2 Functional description 1999
58.2.1 Module architecture 1999
58.2.2 JTAGM Ready signal 2000
58.2.3 EVTO and EVTI signals 2000
58.2.4 JTAGM configuration and status monitoring 2001
58.2.5 JTAGM to DCI serial interface 2001
58.2.6 Software interface 2001
58.3 Modes of operation 2001
58.4 Memory map and register definition 2001
58.4.1 Register descriptions 2002

59 Nexus Port Controller (NPC) 2008
59.1 Introduction 2008
59.1.1 Overview 2008
59.1.2 Features 2009
59.1.3 Modes of Operation 2009
59.2 External signal description 2010
59.2.1 Overview 2010
59.2.2 Detailed Signal Descriptions 2010

59.3 Register definition 2011
59.3.1 Register descriptions 2012
59.4 Functional description 2015
59.4.1 NPC reset configuration 2015
59.4.2 Auxiliary Output Port 2016
59.4.3 IEEE 1149.1-2001 (JTAG) TAP 2019
59.4.4 Nexus JTAG Port Sharing 2023
59.4.5 MCKO Control 2023
59.4.6 EVTO Sharing 2023
59.4.7 Nexus Reset Control 2023
59.5 Initialization/Application Information 2024
59.5.1 Accessing NPC tool-mapped registers 2024

60 Sequence Processing Unit (SPU) 2025
60.1 Introduction 2025
60.1.1 SPU block diagram 2025
60.1.2 Overview 2026
60.1.3 Features 2028
60.2 SPU actions 2029
60.3 Operation mode 2030
60.3.1 SPU enable/disable 2030
60.4 SPU module interface 2030
60.5 Register definition 2030
60.5.1 Registers description 2035
60.6 Functional description 2072
60.6.1 Input Mux unit 2072
60.6.2 Processor exception vector encoding 2074
60.6.3 State logic unit (SLU) 2075
60.6.4 Sequence formation 2076
60.6.5 Performance counters/timers unit 2079
60.6.6 Action unit 2081
60.6.7 Optional trace group 2081

61 e200z420n3 Nexus 3 Module 2082
61.1 Introduction 2082
61.1.1 General Description 2082

61.1.2 Terms and Definitions 2082
61.1.3 Feature List 2083
61.1.4 Functional Block Diagram 2085
61.2 Enabling Nexus 3 Operation 2085
61.2.1 Interaction with Low Power Modes 2086
61.3 TCODEs supported 2086
61.4 Nexus 3 Programmer's Model 2092
61.4.1 Client Select Control Register (CSC) 2094
61.4.2 Port Configuration Register - reference only (PCR) 2094
61.4.3 Nexus Development Control Register 1 (DC1) 2095
61.4.4 Nexus Development Control Registers 2-3 (DC2-3) 2097
61.4.5 Nexus Development Control Register 4 (DC4) 2098
61.4.6 Development Status Register (DS) 2100
61.4.7 Watchpoint Trigger Registers (WT, PTSTC, PTETC, DTSTC, DTETC) 2100
61.4.8 Nexus Watchpoint Mask Register (WMSK) 2110
61.4.9 Nexus Overrun Control Register (OVCR) 2112
61.4.10 Data Trace Control Register (DTC) 2113
61.4.11 Data Trace Start Address Register n (DTSAn) 2115
61.4.12 Data Trace End Address Register n (DTEAn) 2116
61.4.13 Read/Write Access Control/Status (RWCS) 2117
61.4.14 Read/Write Access Data (RWD) 2118
61.4.15 Read/Write Access Address (RWA) 2120
61.5 Nexus 3 Register Access via JTAG/OnCE 2120
61.6 Nexus 3 Register Access via Software 2121
61.7 Nexus Message Fields 2121
61.7.1 TCODE Field 2122
61.7.2 Source ID Field (SRC) 2122
61.7.3 Relative Address Field (U-ADDR) 2122
61.7.4 Full Address Field (F-ADDR) 2123
61.8 Nexus Message Queues 2123
61.8.1 Message Queue Overrun 2124
61.8.2 CPU Stall 2124
61.8.3 Message Suppression 2124
61.8.4 Nexus Message Priority 2124
61.8.5 Data Acquisition Message Priority Loss Response 2125

61.8.6 Ownership Trace Message Priority Loss Response 2126
61.8.7 Program Trace Message Priority Loss Response 2126
61.8.8 Program Trace Sync Message Priority Loss Response 2126
61.8.9 Data Trace Message Priority Loss Response 2126
61.9 Debug Status Messages 2126
61.10 Error Messages 2127
61.11 Ownership Trace 2127
61.11.1 Overview 2127
61.11.2 Ownership Trace Messaging (OTM) 2127
61.12 Program Trace 2128
61.12.1 Branch Trace Messaging Types 2129
61.12.2 BTM Message Formats 2130
61.12.3 Program Trace Message Fields 2131
61.12.4 Resource Full Messages 2132
61.12.5 Program Correlation Messages 2133
61.12.6 Program Trace Overflow Error Messages 2134
61.12.7 Program Trace Synchronization Messages 2134
61.12.8 Program Trace Direct/Indirect Branch with Sync Messages 2136

1 Preface

1.1 Register conventions

Figure 1 and *Table 1* provide the register conventions used throughout this manual.

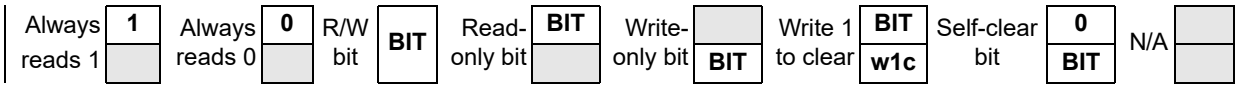

Figure 1. Key to register fields

Table 1. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset values	
0	Resets to zero
1	Resets to one
—	Undefined at reset

1.2 Acronyms and abbreviations

Appendix A: Acronyms and abbreviations lists acronyms and abbreviations used in this document.

2 Introduction

2.1 SPC574Sx microcontroller

The SPC574Sx microcontroller is a member of the SPC57S family. SPC574Sx provides significant improvement over the first member of the SPC57S family in terms of performance and memory while maintaining compatibility with SPC570S50

The SPC574Sx device implements two e200z4d processor cores:

- Core_0—Main core
- Core_0s—Checker (safety) core

2.1.1 Target applications

This device is primarily targeted at the following automotive safety critical applications:

- EPS (Electric Power Steering)
- ESC (Electronic Stability Control)
- Dual 3phase BLDC FOC motor control
- Hybrid drive and DC-DC con-/inverters
- High-end airbag applications

These applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-D compliance.

For this reason, safety measures have been added which are further described in *Chapter 6: Functional safety*.

2.1.2 Overall architecture

The architecture comprises a computational shell. The computational shell consists of two CPUs (in lock-step for safety) and fast system memory. All components of the computational shell are connected through a crossbar switch (XBAR).

Beyond the computational shell the device architecture results from a comprehensive implementation of a new generation ASILD safety concept following the SEooC approach (Safety Element out of Context).

2.1.3 Core features

The computational shell consists of an e200z420n3 CPU operating up to 140 MHz with a second isafety checker CPU running in delayed lockstep mode. The overall core, interconnect and memory subsystem is running at same frequency for optimum performance per MHz. The e200z420n3 is compatible with the Power Architecture® VLE instruction set, that supports code size reduction and embeds a floating-point unit, 8 KB instruction cache, 4 KB data cache, 32 KB data core local memory (zero latency access), a core memory protection memory unit, end-to-end error correction as well as Nexus Class3+ real time debug module. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.1.4 Memory hierarchy

The SPC574Sx computational shell has two levels of memory hierarchy. At the top level is system RAM (SRAM) and flash memory. Two AIPS peripheral bridges provide access to 2 independent clusters of I/O peripherals supporting safety redundancy for I/O.

2.2 Features

On-chip modules within the SPC574Sx include the following features:

- Operating parameters
  - Fully static operation, up to 140 MHz
  - Up to -40 °C to 150 °C junction temperature operating range
- Power management features
  - HALT mode — core clocks are stopped but the PLL is configurable
  - STOP mode — all clocks are stopped including the PLLs
  - Software-controlled clock gating of peripherals
- High performance, low cost e200z420 core processor
  - 32-bit CPU core complex (e200z420n3)
  - Compliant with the Power Architecture® embedded category
  - Includes an instruction set enhancement allowing variable length encoding (VLE) for code size footprint reduction. Optional encoding of mixed 16-bit and 32-bit instructions makes it possible to achieve significant code size footprint reduction.
- Advanced and flexible supply scheme
  - Internal or External regulator mode for 1.2 V supply
  - 3.3 V +/- 5% or 5 V +/- 5%
  - Up to 2 power rails for GPIOs and 2 power rails for analog/input pins enabling supply redundancy concept.
  - The 4 power rails can be supplied in independent way (depending on selected package and device configuration)
- Designed with EMI reduction techniques
  - Internal phase-locked loop
  - Frequency modulation of system clock frequency
  - On-chip regulator
  - Controlled I/O slew rate
- Advanced microcontroller bus architecture (AMBA) crossbar switch (XBAR) providing concurrent access to peripherals, Flash memory and SRAM
  - 4 master ports: FlexRay, DMA, CPU instruction bus and CPU data bus
  - 5 slave ports: Flash Controller, TCM Back-door (Port to local Data RAM), RAM controller, PBRIDGE0 and PBRIDGE1
- 32-bit internal address bus, 32-bit internal data bus
- ECC (Error Correction Code) Flash memory with Flash controller
  - Up to 1.5 MB Code Flash—single module with prefetch buffer and 256-bit data access port
  - 64 KB Data Flash—single module with prefetch buffer and 256-bit data access port
- Up to 96 KB ECC SRAM with RAM controller (in addition to 32 KB core local data RAM)
- 16 KB dedicated OTP Flash for embedded boot code
  - Boot Assisted Flash (BAF)
  - Supports internal Flash programming via a serial link (UART and MCAN)

- System timers:
  - 1 x STM (AUTOSAR®) (4 compare channels)
    1 x PIT (8 channels)
    4 x eTimers (6 channels each)
  - System watchdog timer (SWT)
    32-bit timer
    Programmable selection of system or oscillator clock for timer operation
    Programmable selection of reset or interrupt on an initial time-out
    Enabled out of reset
- Safety and integrity features:
  - Clock Monitor Unit (CMU) for safe oscillator/PLL control using internal RC oscillator reference
  - Watchdog with time window for reload
  - Memory Protection Unit (MPU): 8 regions with 32-bit granularity
  - Register protected accesses to critical peripherals
- Interrupt controller (INTC) with dedicated interrupt source channels, including software interrupts and 32 priority levels
- 12-bit analog-to-digital converter (ADC) with a conversion time of 1.5 µs at maximum operating frequency
  - 16 high-precision channels for each group of 4 ADCs
- 4 general purpose eTimer units, with 6 channels each
- 4 FlexPWM units (2 units with 4 channels each and 2 units with 2 channels each)
- Up to 2 Local Interconnect Network (LIN) controller modules capable of autonomous message handling (master), autonomous header handling (slave mode), and UART support. Compliant with LIN protocol rev. 2.1
- 4 DSPI (Deserial Serial Peripheral Interface) modules for full-duplex, synchronous, communications with external devices
- 3 MCAN (with CAN-FD support)
- Frequency-modulated phase-locked loop (FMPLL)
- Configurable general purpose pins supporting input and output operations:80 GPIO + 32 GPI/ADC input only (eTQFP144), 62 GPIO + 18 GPI/ADC input only (eTQFP100 - default bonding option)" and 64 GPIO + 16 GPI/ADC input only (eTQFP100 - bonding option upon demand)"
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 Class 3
- Device/board boundary scan testing supported with per Joint Test Action Group (JTAG) of IEEE (IEEE 1149.1)
- SPC574Sx family members are offered in the following package types:
  - 144-pin eTQFP, 0.5 mm pitch, 20 mm × 20 mm outline
  - 100-pin eTQFP, 0.5 mm pitch, 14 mm × 14 mm outline

Note: One of four sources can be used as the system clock for this device:

- *External crystal oscillator 4–40 MHz (XOSC)*
- *Internal RC oscillator 16 MHz (IRCOSC)*
- *Primary PLL*
- *Secondary PLL*

2.3 Feature summary

Table 2 lists a summary of major features for the SPC574Sx device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on-chip module is given later in this document.

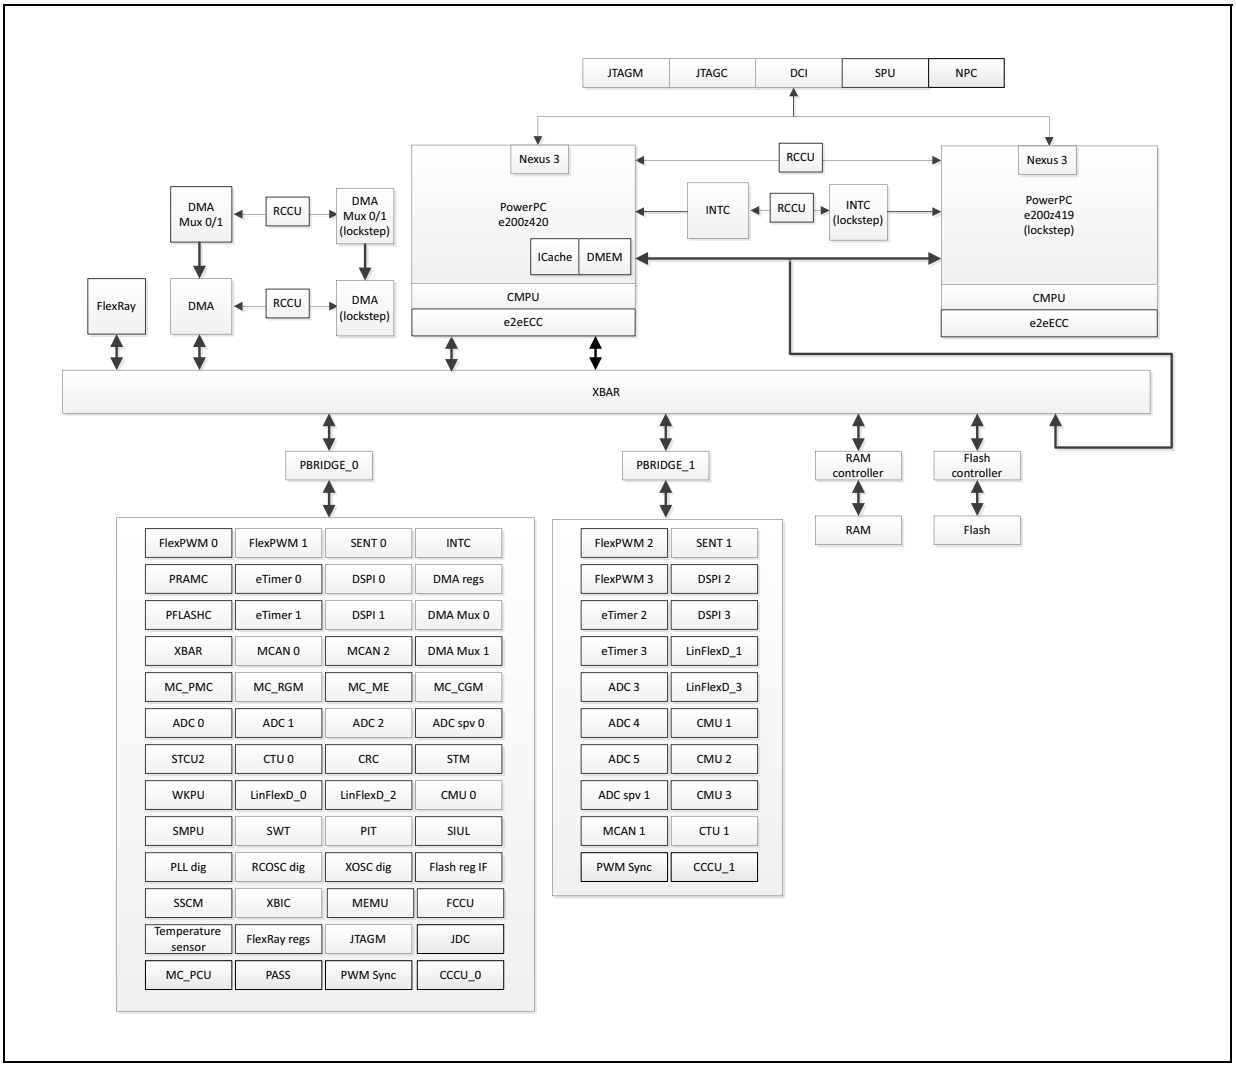
Table 2. SPC574Sx device feature summary (superset configuration)

Feature		Description
Processor	Main Core	e200z420n
	Checker core	e200z419
	Local data RAM	32 KB Data
	VLE	Yes
	Main processor frequency	140 MHz
	Instruction cache	8 KB
	Data cache	4 KB
Interrupt controller (including interrupt controller checker)		1
Software watchdog timer		1
System timers		1 AUTOSAR® STM 1 PIT with eight 16-bit channels
DMA (including DMA checker)		1
DMA channels		32
SMPU		Yes (8 regions)
System SRAM (in addition to core local data RAM)		96 KB
Code Flash memory		1.5 MB
Data Flash memory (EEPROM)		64 KB
UTEST Flash memory		16 KB
Boot assist Flash (BAF)		16 KB
CRC		1
LINFlexD		2
DSPI		4
MCAN		3
FlexRay		1 (128 MB)
SENT		2 x 3 channels
FlexPWM		2 x 4 channels (for motor control) + 2 x 2 channels (for SWG emulation via PWM)
eTimer		4 x 6 channels
ADC (SAR)		8
CTU (Cross Triggering Unit)		2

Table 2. SPC574Sx device feature summary (superset configuration) (continued)

Feature	Description
Temperature sensor	2
Self-test control unit (memory and logic BIST)	1
FCCU	1
MEMU	1
RCOSC	1
XOSC	1
PIT	1 x 8 channels
STM	1
PLL	Dual PLL with FM
Nexus	3(1)
Sequence Processing Unit (SPU)	1
External power supplies	– Single supply mode: 3.3 V or 5 V – Dual supply mode(QFP144): 3.3 V or 5 V for IOs 1.2 V for core supply
Junction temperature	-40 °C to 150 °C
Packages	eTQFP100
	eTQFP144

1. Including trace for the crossbar masters (data & instruction trace on core and data trace on eDMA). 4 MDO pin Nexus trace port for QFP100, 12 MDO pin Nexus trace port for QFP144.



2.4 Packages

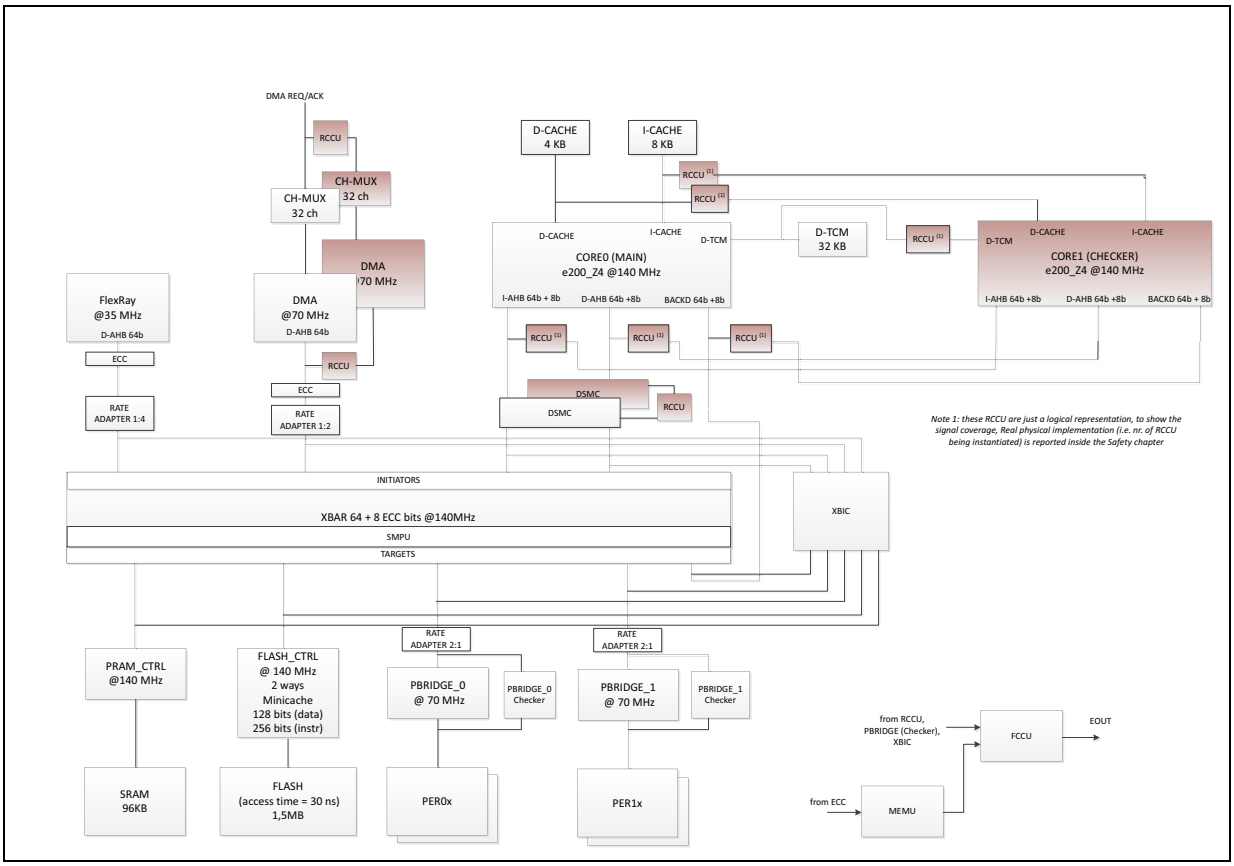
The SPC574Sx is available in three packages: eTQFP100, eTQFP144.

2.5 Block diagram

Figure 2 shows the top-level block diagram.

Figure 2. Block Diagram

3 System architecture



3.1 Platform Architecture

The platform architecture is organized as shown in *Figure 3*.

The brown blocks belong to the safety architecture .

Full platform including system RAM operates at speed (140 MHz) except the DMA, PBRIDGE and Flexray with fixed prescaled 1:4 ratio of the CPU frequency.

Figure 3. Platform block diagram

The platform is organized as a multi-master system, which shares a set of slave resources, accessible through a XBAR interconnection system.

3.1.1 XBAR Masters

Following IP acts as XBAR system master:

- CPU
- DMA
- FlexRay

Table 3 shows the XBAR master port assignment and the corresponding AHB master ID

Table 3. XBAR physical master port assignment

Master port number	Master	AHB Master ID
0	e200z420 CPU IBUS	0 or 8 (1)
1	e200z420 CPU DBUS	0 or 8
2	DMA	3
3	FlexRay	5

1. HMASTER = 0 when the CPU access in Normal Mode;
HMASTER = 8 when used the CPU access in Debug Mode

3.1.1.1 XBAR Slaves

Following IP are connected as XBAR system slaves:

- PBRIDGE_0
- PBRIDGE_1
- Flash Controller
- RAM Controller
- TCM Back-door

Table 4 shows the XBAR slave port assignment.

Table 4. XBAR slave port assignment

Slave port number	IP
0	Flash Controller Port0
1	CPU TCM backdoor
2	RAM Controller
3	PBRIDGE_0
4	PBRIDGE_1
5..7	Reserved

3.1.1.2 Safety architecture

Several IP and architecture solutions exist within the platform, aimed to target ASIL-D ISO26262 compliance. Following IPs are instantiated, as part of the general safety architecture :

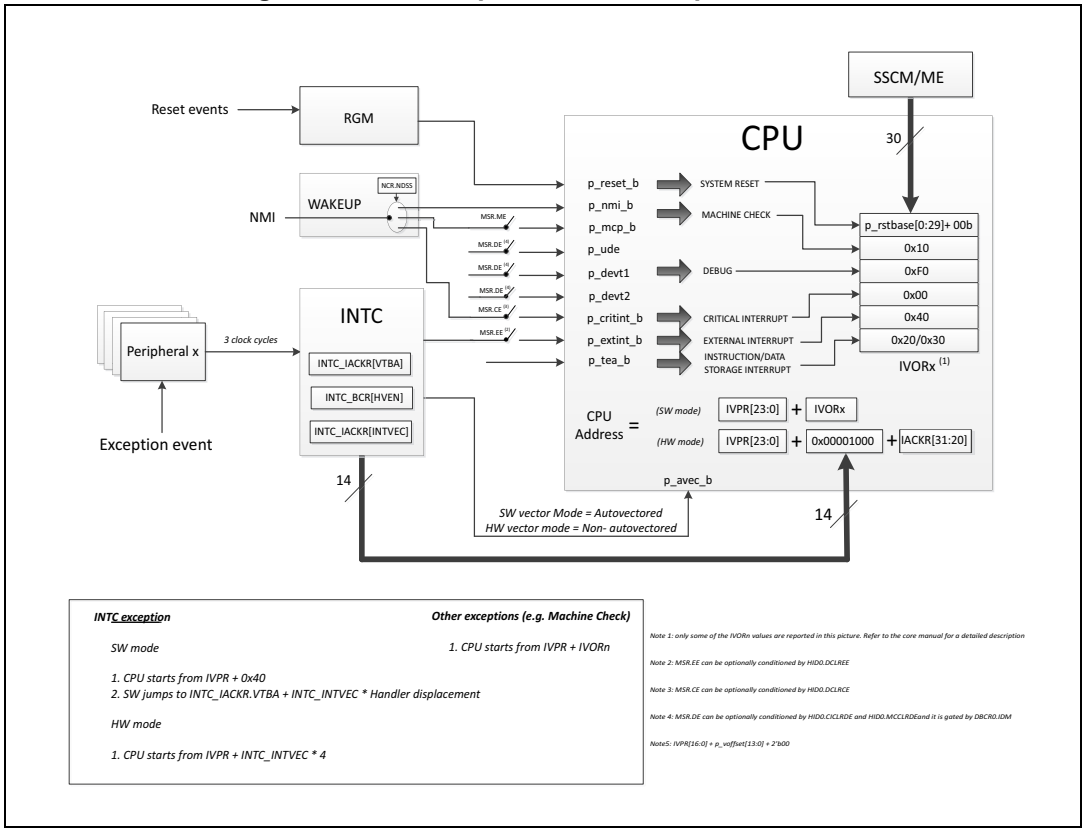
- SMPU
- RCCU
- XBIC

3.1.1.3 Additional platform IPs

Following IPs are also part of the platform:

- Interrupt controller
- System watchdog
- DSMC

3.1.2 Functionality



3.1.2.1 CPU exception system

Figure 4 shows how the CPU exception system mechanism and how the interrupts triggered by the interrupt controller are propagated to the CPU and handled in SW.

The CPU can serve different exceptions, triggered by CPU-internal events (for example an invalid instruction opcode) or CPU-external events (CPU input signals). For each event type, a SW exception handler can be assigned. The space allocated for each exception is 16-bytes memory space. The memory address assignment of each slot is hard-wired, starting form a base address, which is defined by the content of the CPU IVPR register. Modifying this registers, all the exception handlers can be remapped to a different memory location. The HW-wired offsets for each exception handlers can be read form the read-only IVORn. The reset exception is actually handled in a different way: the CPU restarts from the address provided by the SSCM (at the reset) or the ME (upon a run-time mode change) to the CPU. All the interrupts coming from the INTC are assigned to the “External Interrupt” CPU exception (IVOR4). When the INTC triggers the CPU External Interrupt exception signal, the CPU restarts from the address specified by the IVPR register, displaced by the HW-wired content of the IVOR4 register.

The INTC interrupt can be recognized by reading the INTC_IACKR register, which contains the interrupt handler base address and the number of the interrupt channel, which caused the interrupt triggering.

Figure 4. CPU Exceptions vs. Interrupt Controller

3.1.3 Performances

Table 5 includes the wait states number for each transaction of the different initiator versus the related target:

Table 5. Platform performances

Initiator	Target	Access	WS (master IF) with Slave Parked	WS (master IF) w/o Slave parked	Notes
DMA	SRAM	READ 8/16/32/64	1	2	1 WS is the slave is not parked on the Master
		WRITE 64	1	2	1 WS is the slave is not parked on the Master
		WRITE 8/16/32	2	3	1 WS is the slave is not parked on the Master 1 WS for ECC re-computation @ 64 bits -> RMW
	DTCM	READ 8/16/32/64	2	3	1 WS taken by rate adaptor when passing htrans to Core + 1 WS Core Slave introduce to provide hready to Rate adaptor
		WRITE 64/32	2	3	—
		WRITE 8/16	3	4	1 WS for ecc re-computation
Z4 D-AHB	SRAM	READ 8/16/32/64	0	1	—
		WRITE 64	0	1	—
		WRITE 8/16/32	1	2	1 WS for ECC re-computation @ 64 bits -> RMW
		WRAP4 READ 8/16/32/64	0,0,0,0	1,0,0,0	—
		WRAP4 WRITE 64	0,0,0,0	1,0,0,0	—
Z4	DTCM	READ 8/16/32/64	0	—	direct (no arbitration).
		WRITE 64/32	0	—	direct (no arbitration)
		WRITE 8/16	2	—	direct (no arbitration) 1 WS for read 1 WS for ECC re-computation @ 64 bits and write

Table 5. Platform performances (continued)

Initiator	Target	Access	WS (master IF) with Slave Parked	WS (master IF) w/o Slave parked	Notes
Z4 D-AHB	DTCM	READ 8/16/32/64	0	—	remapping + direct
		WRITE 64/32	0	—	remapping + direct
		WRITE 8/16	2	—	remapping + direct 1 WS for read 1 WS for ECC re-computation @ 64 bits and write
	FLASH	READ 32/64	5	6	minicache miss (pflash_ctl.pfcr1.RWSC = 4) access time = 30 ns
		READ 32/64	0	1	minicache hit (minicache= 256 bits) access time = 30 ns
		WRAP4 READ 64	5,0,0,0	6,0,0,0	minicache miss (pflash_ctl.pfcr1.RWSC = 4) access time = 30 ns (With First Miss, other 3 subsequent accesses will be hit)
		WRAP4 READ 32	5,0,0,0	6,0,0,0	minicache miss (pflash_ctl.pfcr1.RWSC = 4) access time = 30 ns (With First Miss, other 3 subsequent accesses will be hit)
		WRAP4 READ 32/64	0,0,0,0	1,0,0,0	minicache hit (minicache= 256 bits) access time = 30 ns
Z4 I-AHB	FLASH	READ 32/64	5	—	minicache miss (pflash_ctl.pfcr1.RWSC = 4) access time = 30 ns
		READ 32/64	0	—	minicache hit (minicache = 256 bits) access time = 30 ns
		WRAP4 READ 32/64	5,0,0,0	—	minicache miss (pflash_ctl.pfcr1.RWSC = 4) access time = 30 ns (With First Miss, other 3 subsequent accesses will be hit)
		WRAP4 READ 32/64	0,0,0,0	—	"minicache hit (minicache= 256 bits) access time = 30 ns"

Table 5. Platform performances (continued)

Initiator	Target	Access	WS (master IF) with Slave Parked	WS (master IF) w/o Slave parked	Notes
Z4 D-AHB	PBRIDGE	READ 8/16/32	7	8	—
		WRITE 8/16/32	7	8	—

3.2 Embedded memories

The embedded memory architecture for SPC574Sx devices is a significant departure from previous-generation devices. Features include:

- Onboard SRAM, including system SRAM, local data memory for processor core
- Onboard system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Embedded memories in the peripherals[(a)]:
  - CAN
  - eDMA
  - Flexray

3.2.1 SRAM

3.2.1.1 System memory

SPC574Sx devices include 96 KB of general-purpose on-chip ECC SRAM.

- See *Chapter 30: Platform RAM controller (PRAM)* for details on configuring the PRAM controller.
- See *Table 15: Memory map (XBAR slave ports)* in *Chapter 5: Memory map* for the SPC574Sx SRAM address range.

3.2.1.2 Processor core local memory (D-MEM)

SPC574Sx devices include local data SRAM (D-MEM) for processor core to provide enhanced performance.

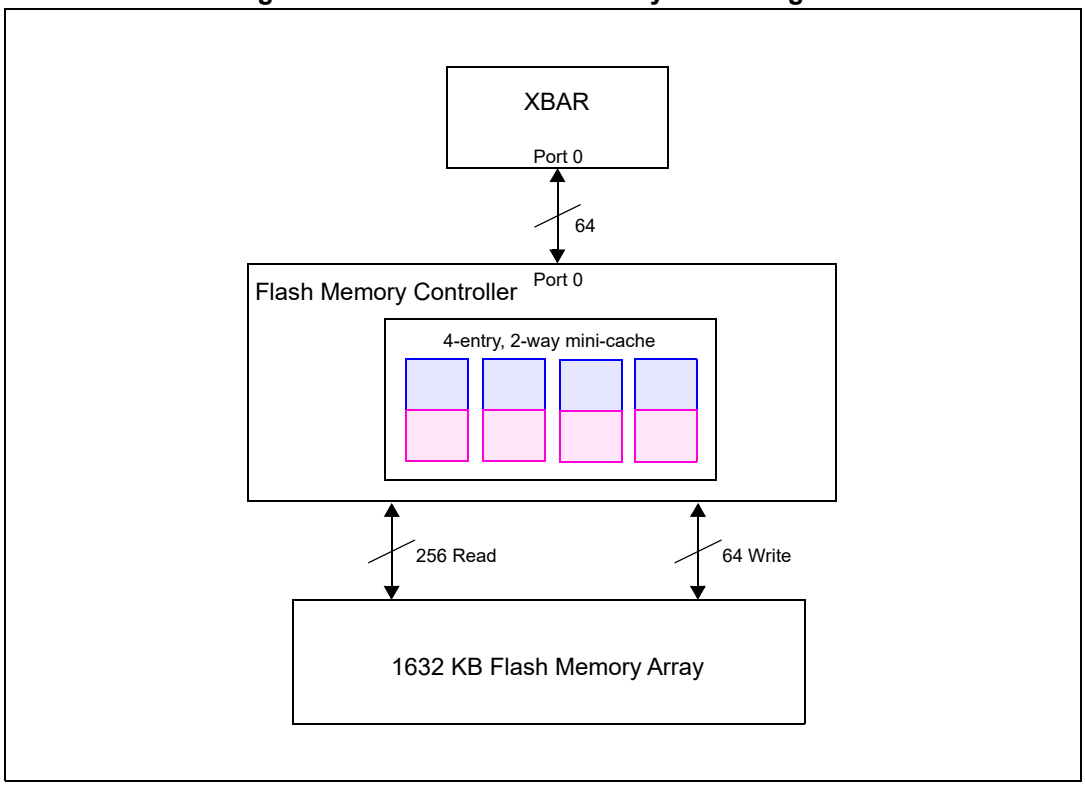
Processor core has 32 KB of D-MEM.

Each area of D-MEM is accessible by bus mastering peripheral devices.

3.2.1.3 Processor core data cache memory

Data cache memory size is 4 KB.

3.2.1.4 Processor core instruction memory



Instruction cache memory size is 8 KB.

a. Refer to the respective module chapter for details.

3.2.2 Flash memory

Flash memory on SPC574Sx devices consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. *Figure 5* shows the memory architecture.

Figure 5. SPC574Sx flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

3.2.2.1 Flash memory controller

The SPC574Sx flash memory controller acts as an interface between the system bus and the flash memory array.

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, and read wait state management of the flash memory.

See *Chapter 31: Flash memory controller (PFLASH Controller)*, for details.

3.2.2.2 Flash memory array

The first partition in the array includes 1536 KB of Code Flash and a 32 KB one-time programmable (OTP) region comprising UTEST (16 KB) and BAF (16 KB), included to support systems that require non-volatile memory for security features or system initialization information. The second 64-KB partition is EE-Emulated Data Flash.

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64 bits). Flash memory is erased on a block by block basis.

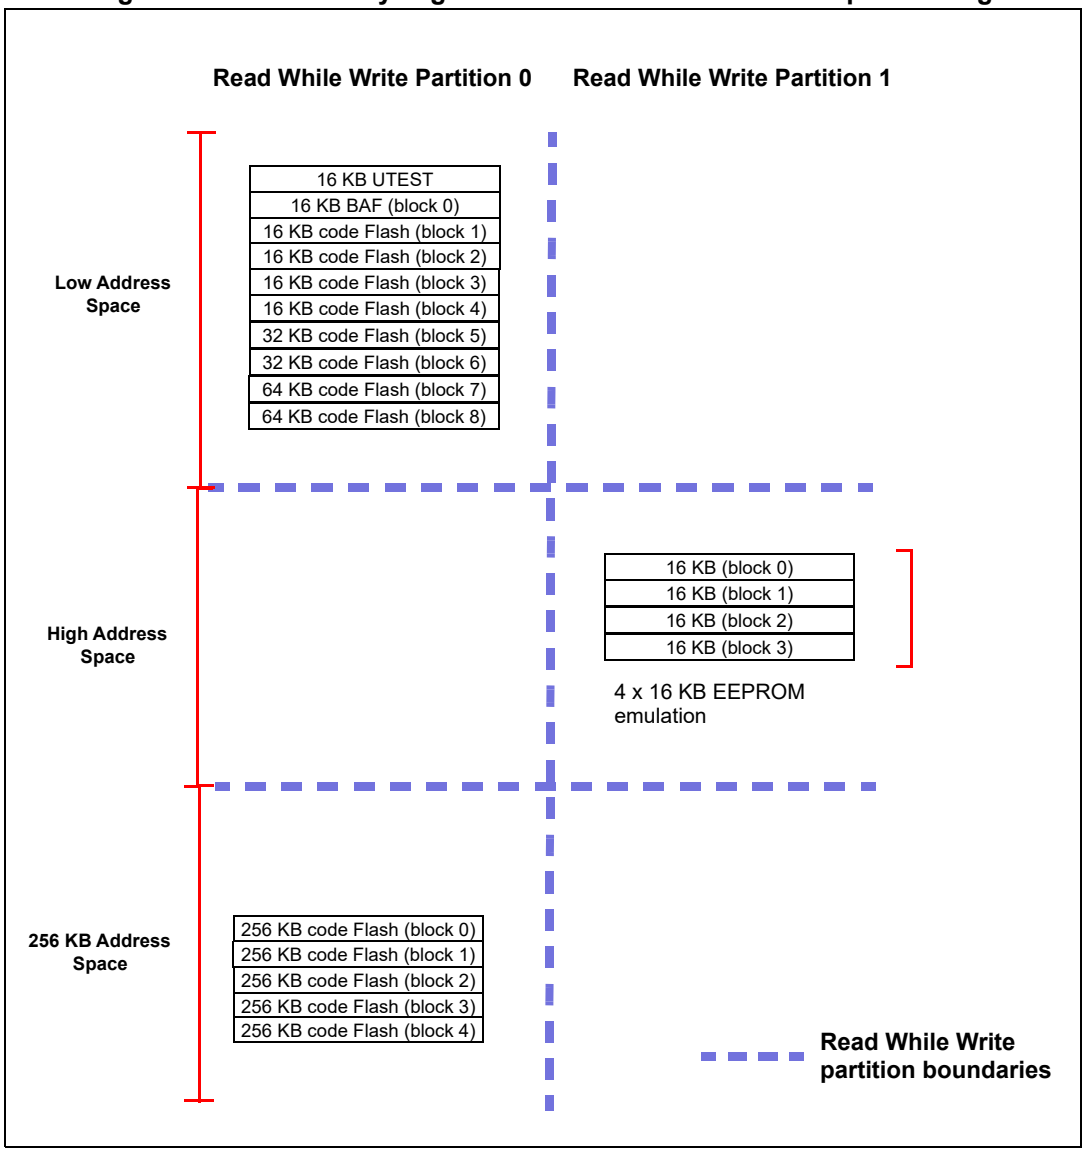
3.2.2.2.1 Features

- Flash segmentation
  - 4x 16 KB, 2x 32 KB, 2x 64 KB, and 5x 256 KB blocks for code
  - 4x 16 KB EEPROM emulation blocks for data
  - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST and BAF block
- ECC with double bit detection, single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.2.2.2.2 Flash organization

The embedded flash memory consists of address spaces in groupings:

- 16 KB block in low address space, 32 KB block in low address space and 64 KB block in low address space
- 16 KB block in high address space
- 256 KB block in 256 KB address space



Address space group (low- or high-address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The flash module is further divided into three partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously read from other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

Figure 6 shows the flash block segmentation and read-while-write partitioning for SPC574Sx devices.

Figure 6. Flash memory segmentation and read-while-write partitioning

Note: See Table 16: Flash memory map in Chapter 5 for the SPC574Sx flash memory map.

3.2.2.2.3 UTEST memory space

Devices in the SPC574Sx family contain a 16 KB area of OTP flash memory for storing test information and device configuration data. See *Table 19: UTEST memory map in Chapter 5* for the SPC574Sx UTEST flash memory map.

3.2.3 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional “ECC at memory” functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in *Table 6*.

Table 6. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell or 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location

Table 6. ECC comparison of data write-then-read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.2.4 Security features

The SPC574Sx architecture uses a combination of device life cycle monitoring and password protection to limit the conditions under which debugging interfaces can access certain areas of flash memory.

3.3 Motor control Architecture

The device offers the capability to control 2 synchronized three-phases motor. *Figure 7* shows the motor control architecture, which is composed by the following elements:

- SARADC
  - 8 ADC, divided into two groups, each one comprising 3 ADC + 1 supervisor ADC
  - 6+5+5 functional channels (fast mode) per ADC group [b]
  - 16 supervision channels (fast mode) per ADC group
  - User test channels (slow mode) for self-test capabilities (VREFH, VREFH/3, 2*VREFH/3, TSENS, VREFL, VSS_ADC, LV HP, LV VSS).
  - 3.3 V or 5 V ADC supply (dedicated IO ring) per ADC group
  - Resolution: 12 bit
  - Conversion time (fast) = 1.5 µs at12 MHz
  - Conversion time (slow) > 2 µs at 12 MHz
  - Leakage current to ADC input = 300 nA (shared channels)
  - For each ADC: 4 configurable analog watchdogs for each ADC
- CTU (cross triggering unit)
  - 2 CTU, one per each ADC group
  - Up to 4 ADC can be controlled by each single CTU
  - 8 sequential triggers based on trigger CMP registers (double buffered)
  - Command list (24 descriptors double buffered) linked to the sequential trigger
  - Max 32 ADC channels per unit
  - Single/dual conversion
  - Max 8 FIFOs for data buffering
  - Max 8 + 1 DMA channels for data transfer and control
- PWM
  - One dedicated FlexPWM unit per each ADC group
  - Up to 3+3 independent or complementary outputs for each FlexPWM unit
  - 1 channel dedicated for CTU control per each PWM unit
  - 16 bits counter registers
  - 120 MHz clock (1-128 pre-scaler)
  - Duty cycle 0-100%
  - Independent control of both edges
  - Independent dead time
  - Center/phase shifted/edge aligned PWM
  - Safe mode/fault protection (fault inputs)
  - External synchronization (timer, external trigger) [c]

b. 6+6+6 channels available as bonding option on QFP100 only

c. EXT SYNC signals can be synchronized or mutually delayed

Figure 7. Motor control architecture

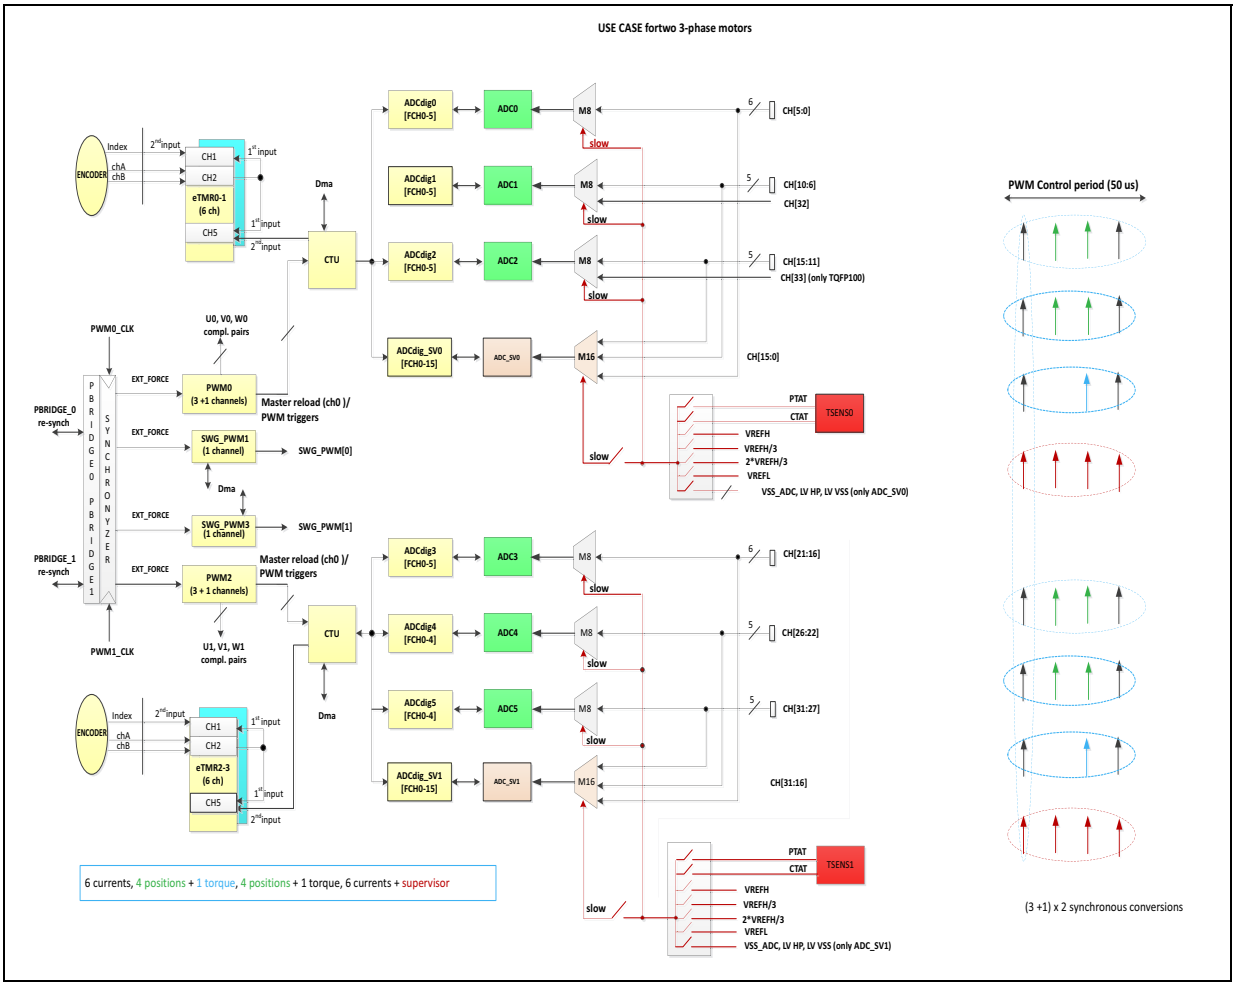


Figure 7 shows the motor control architecture.

The motor control phases are generated by two PWM. The PWM are synchronized (in phase or delayed in phase) by an external synchronizer.

The two ADC clusters, composed of 3 ADC plus 1 supervisor each, are controlled by two CTU units. Up to 4 conversions can be executed in parallel for each ADC cluster. The CTU can schedule a number of sequential conversions for each ADC and retrieve the converted data into separate FIFOs.

The PWM generates an external trigger, which is used to synchronize the CTU master-reload signal with the PWM output waveforms. This way, the ADC conversions are also synchronized with the motor phases. The CTU can periodically trigger a DMA to transfer the converted data (which are stored within the CTU FIFOs) into memory and store in the CTU the next commands for the next set of conversions. Refer to *Table 7* for ADC channels mapping description.

Figure 8 shows an example of a motor control waveforms and conversions.

Figure 8. Example of motor control scheduler

The ADC power supply and references are separated on different pins).

The torque sensors of each motor is controlled by two DSPI.

The DSPI are mapped on different PBRIDGE (*Table 17: Peripheral bridge 1 memory map* and *Table 18: Peripheral bridge 0 memory map*) and the I/O pins can be allocated to specific AF so that they do not interfere (see *Table 13: Peripheral multiplexing table description* for a list of the AF available for each pin).

Safety features of the ECTU (pending patent approval) are:

1. Trigger selection (ADC unit, timer unit) and timing miss
2. ADC channel miss
3. ADC FIFO channel miss
4. ADC ack and timing miss
5. CTU error

which are occurring in application mode based on the programmed configuration of the scheduler. The reaction is a FCCU trigger.

4 Signal description

4.1 Pin descriptions

The following sections provide signal descriptions and related information about the functionality and configuration of the SPC574Sx devices.

4.1.1 Pin startup and reset states

Table 8 provides startup state and reset state information for device pins.

Table 8. Pin startup and reset states

Pin	Startup state(1)	State during reset	State after reset
I/O pins(2)	High-impedance	High-impedance	High-impedance
Analog Inputs(3)	High-impedance	High-impedance	High-impedance
F0 (ERROR0)	High-impedance	Input, weak pullup	Input, weak pullup
F1 (ERROR1)	High-impedance	Input, weak pullup	Input, weak pullup
PORST	Input, pulldown	Input, weak pulldown	Input, weak pulldown
PWMODE	Weak pulldown	Weak pulldown	Weak pulldown
TESTMODE(4)	Weak pulldown	Input, weak pulldown	Input, weak pulldown
TDI	weak pullup	Input, weak pullup	Input, weak pullup
TDO	High-impedance	High-impedance	High-impedance
TMS	weak pullup	Input, weak pullup	Input, weak pullup
TCK	High-impedance	Input, weak pulldown	Input, weak pulldown
XTAL/EXTAL(5)	High-impedance	High-impedance	High-impedance

1. Startup state is exited when the core and high-voltage supplies reach minimum levels as defined in the Power Management chapter.
2. Pins on the device that are not supply or reference are not explicitly defined in this table.
3. Pure analog inputs, on digital output function.
4. Device does not implement system configuration pin. TESTMODE is the only pin affecting device configuration. It is latched on PORST rising edge and internally pull-down.
5. Function of XTAL/EXTAL pins defined by the enable bit in the flash user test row. If enabled, the pins are analog inputs to the oscillator. If disabled, the XTAL/EXTAL pins remain in high-impedance after reset.

4.1.2 Power supply and reference voltage pins

Power supply and reference pins for the device are listed in this section.

Table 9 contains information on power supply and reference pin functions for the devices.

Table 9. Power supply and reference pins

Supply			Pin No.	
Pad	**Type**	**Description**	**eTQFP100**	**eTQFP144**
VDD_LV	Power	Low voltage power supply for device (PLL is also powered by this pin.)	19, 52, 68	22, 23, 39, 47, 63, 79, 99, 126, 138
VDD_HV_IO0	Power	High voltage power supply for I/O 0 and internal power management	20, 51, 85, 95(1)	90, 103, 115, 142
VDD_HV_IO1	Power	High voltage power supply for I/O 1	—(2)	46, 59, 80
VDD_HV_OSC	Power	High voltage power supply unit and oscillator	55	43
VDD_HV_ADC_ TSENS_0	Power	High voltage supply for ADC and TSENS 0	39	18
VDD_HV_ADC_ TSENS_1	Power	High voltage supply for ADC and TSENS 1	—	38
VREFH_ADC_0	Reference	Voltage reference of ADC 0	37	16
VREFH_ADC_1	Reference	Voltage reference of ADC 1	—	36
VREFL_ADC_0	Reference	Ground reference of ADCs	38	17
VREFL_ADC_1	Reference	Ground reference of ADCs	—	37
VSS_HV	Ground	High voltage ground	Exposed pad	Exposed pad
VSS_LV	Ground	Low voltage ground		
VSS_HV_OSC_PMC	Ground	Ground supply for the internal power management unit and the oscillator		
VSS_HV_ADC_TSENS_0	Ground	Ground supply for ADC and TSENS	38	17
VSS_HV_ADC_TSENS_1	Ground	Ground supply for ADC and TSENS	—	37

1. Pin 95 is also used as high voltage supply of flash
2. IO rail split is not supported on eTQFP100, where only PWMODE = 1 is allowed

4.1.3 System pins

Table 10 contains information on system pin functions for the devices.

Table 10. System pins

Pad	Description	Direction	Pin No.	
			eTQFP100	eTQFP144
PORST	Power on reset with Schmitt trigger characteristics and noise filter. PORST is active low.	Bidirectional	66	61
PWMODE	Power Mode Connected to VSS_HV_IO on the board - select external reg for digital voltage (1.2V) Connected to VDD_HV_IO0 on board - select internal reg for digital voltage (1.2V) It has an internal pull up.	Input only	—	40
TESTMODE	Pin for testing purpose only. An internal pull-down is implemented on the TESTMODE pin to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to $V_{SS_HV_IO}$ on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. The device will not exit reset with the TESTMODE pin asserted during power-up.	Input only	64	58
XTAL	Analog output of the oscillator amplifier circuit—to be grounded if the oscillator is used in bypass mode.	Output	54	42
EXTAL	– Analog input of the oscillator amplifier circuit when the oscillator is not in bypass mode – Analog input for the clock generator when the oscillator is in bypass mode	Input	53	41

4.1.4 Debug and trace pins

Table 11 contains information on debug and trace pin functions for the devices.

Table 11. Debug and trace pins

Signal	Description	Direction	Pin No.	
			eTQFP100	eTQFP144
TDI	Test Data Input	Input	59	51
TDO	Test Data Output	Output	61	54
TCK	Test Clock	Input	63	57
TMS	Test Mode Select	Input	60	53

4.1.5 Pin multiplexing

The SIUL module is used to multiplex the device input/output pins and the internal module input/output ports.

Note: Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination.

For additional information, refer to Chapter 14: System Integration Unit Lite2 (SIUL2).

Table 12. Pin multiplexing table description

5 Memory map

5.1 Architecture

Two system memories are included in this device:

- System RAM
- Flash memory

Both memories are interfaced to the system platform through their respective RAM and Flash controllers, which in turn are connected to the XBAR slave ports.

5.2 Memory map

Table 15. Memory map (XBAR slave ports)

Start address	End address	Description
0x0000_0000	0x003F_FFFF	Reserved
0x0040_0000	0x0113_FFFF	Flash memory controller
0x0114_0000	0x3FFF_FFFF	Reserved
0x4000_0000	0x4001_7FFF	System RAM (128 MB)
0x4001_8000	0x4FFF_FFFF	Reserved
0x5000_0000	0x5000_7FFF	Processor local DMEM (32KB)
0x5000_8000	0x5000_FFFF	DMEM mirrored(1) (2)
0x5001_0000	0xF7FF_FFFF	Reserved
0xF800_0000	0xFBFF_FFFF	Peripherals bridge 1 (see *Table 17: Peripheral bridge 1 memory map*)
0xFC00_0000	0xFFFF_FFFF	Peripherals bridge 0 (see *Table 18: Peripheral bridge 0 memory map*)

1. The DMEM window is HW-wired to be 64KB, but in reality only 32KB addresses are used, creating a mirrored version of the DMEM space.
2. In order to avoid ECC errors, it is mandatory to keep a consistent access between write and read within the same DMEM space portion. In other words, if data is written into the upper DMEM window and the same “physical” address is read back from the lower (mirrored) DMEM window, an ECC error will happen because of the different “logical” address being used. The same applies for a write executed into the lower (mirrored) DMEM window, followed by the data reading at the same “physical” address within the upper DMEM window. Whenever there is an access to the DMEM mirrored space, the address feedback alarm gets set. It will be reported to FCCU as ncf [70].

Table 16. Flash memory map

0x0110_0000	0x0113_FFFF	Flash 256 KB Code Block 4	1
0x0114_0000	0x3FFF_FFFF	Reserved	

1. The Test Flash Block is not accessible directly through the Flash controller. It can be accessed only by the SSCM moduleduring the reset. The table reports the test Flash Block address, as it were visible from the Flash controller. In reality, theSSCM module accesses the Test Flash block using the real Flash block address space, which goes from 0x0080_8000 till 0x0080_BFFF.

6 Functional safety

6.1 Introduction

Functional Safety implies requirements on several levels. This chapter comprises a collection of the hardware safety requirements for the SPC574Sx microcontroller unit (MCU).

6.2 Assumptions and usage constraints

The SPC574Sx offer a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL D of ISO 26262. The MCU is used within a system and, to allow analysis of the MCU's ability to satisfy safety requirements, certain assumptions on this system have to be imposed in line with the 'SEooC: Safety Element out of Context' concept. These assumptions are documented in the *SPC574Sx Safety Manual* (AN4247) as constraints on the allowed usage of the MCU in order to satisfy the requested safety level. Note that these requirements do not specify constraints on the MCU itself. Rather, they specify which features of the environment can be relied upon.

The MCU is used in automotive applications with integrity level up to ASILD, requiring a fail-silent fail-indicate MCU.

Safety analysis assumes a fault tolerant time interval (FTTI) of 10ms. ISO 26262 defines the FTTI as the time-span in which a fault or faults can be present in a system before a hazardous event occurs. It is the maximum acceptable time to move the system to a safe state in case of fault.

Shorter , and longer, time intervals are possible, depending on the actual combination of failure detection and signaling mechanisms as documented in the *SPC574Sx Safety Manual* (AN4247).

A driving cycle, that is the time of operation of the MCU without a power-on reset, is assumed to be 12 hours. Driving cycle specifies the multiple-point fault detection interval which is defined by the ISO 26262 as time span to detect multiple-point fault before it can contribute to a multiple-point failure.

The primary safety goal is that the MCU does not leave its safe states for intervals equal or longer than the fault tolerant time interval unless configured by the user to do so.

The secondary safety goal is that the MCU, or the software running on it, is able to detect the permanent unavailability of any safety mechanism required to achieve the primary safety goal. The unavailability of any such mechanisms to be detected at the latest in the successive driving cycle.

Safety goals are achieved by transitioning/maintaining the MCU in the following safe states:

- Unpowered
- In reset
- Operating correctly with respect to random hardware faults
- Explicitly indicating an internal error

Permanent cycling through otherwise safe states or permanent cycling between a safe state and an unsafe one, even if the latter is left before end of Fault Tolerant Time Interval (also

knowned as FTTI), is also considered a violation of the safety goal. This specifically concerns a continuous Reset-Start-of-Operation-Reset or Reset-Selftest-Reset sequence.

Safety analysis assumes that the system reacts safely to the MCU being in or entering all safe states.

If High-Z on an output pin is not safe, pull-ups or pull-downs need to be added at system level to safety-critical outputs depending on application requirements.

The overall system includes measures to monitor the error output pin(s) of the MCU and move the system into a safe state when an error is indicated.

If the MCU signals a failure via its error output pin(s), other output pins cannot be relied on.

Safety analysis assumes that external power of the appropriate voltage is supplied.

In addition different supplies, both internal and external, are supervised for high and low deviations by internal low-voltage and high-voltage detectors..

Note: Power supervision is implemented using LVD/HVD provided by the MCU as other safety mechanisms (for example external watchdog) exist to cover cases when the appropriate reaction of the MCU to the detection of the power failure cannot be guaranteed.

The MCU is kept in reset if external voltage is outside spec. User should protect the device against voltage over the maximum survivable voltage of the technology.

Safety analysis assumes that external watchdog detects any failures that completely disable the MCU and its safety mechanisms.

The external watchdog is assumed to be triggered periodically either by the software providing the safety function on the MCU or by a toggling protocol on the error_out pin.

Communication over high bandwidth communication protocols (for example CAN) is assumed to be protected by a fault-tolerant communication protocol (implemented by the operating system or the application).

6.3 Module categorization

The definition of the SPC574Sx safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in *Table 20*.

Table 20. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, flash, and the bus interconnect). Examples of ViMo are the core, the eDMA, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.

Table 20. PMHF module categories (continued)

Module category	Category abbreviation	Description
Non-safety modules	NoSaMo	Modules that are not part of the safety function. For such modules, no hardware safety mechanisms have been provided on the chip. Examples include the Test and Debug logic, WKPU_NMI. Only their non-interference with modules from the other categories is ensured by hardware. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation.
Other support modules	SuMo	These are modules which, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

Module classifications for SPC574Sx are shown in *Table 21*.

Table 21. Module classification

Category abbreviation	Description
ViMo	Master Safety Core, eDMA, INTC, XBAR, SRAM controller, System RAM array, flash memory controller, flash memory array, MC_RGM, Dual PLL Digital, XOSC, MC_CGM, MC_ME, voltage regulator, MC_PMC, STCU2, SSCM, PIT, Decorated Storage Memory Controller (DSMC), MC_PCU, PMC_dig, DMACHMUX, Safety Core Cache controller and memories, Safety Core TCMs
PeMo	System Timer (STM), eCTU, Flexray, SENT, FlexPWM, eTimer, PIT, DMA RAM, SAR ADC, LinFlexD, DSPI, SIUL2 and PBRIDGEn
NoSaMo	Nexus, JTAG, WKUP and SPU
SuMo	RCCU, Checker Safety Core, CRC Units, Temperature Sensors, IRCOSC, CMUs, HVDs, LVDs, Bandgap reference, LBIST controllers, REG_PROT, SWT, FCCU, MEMU, and SMPU

6.4 Safety architecture overview

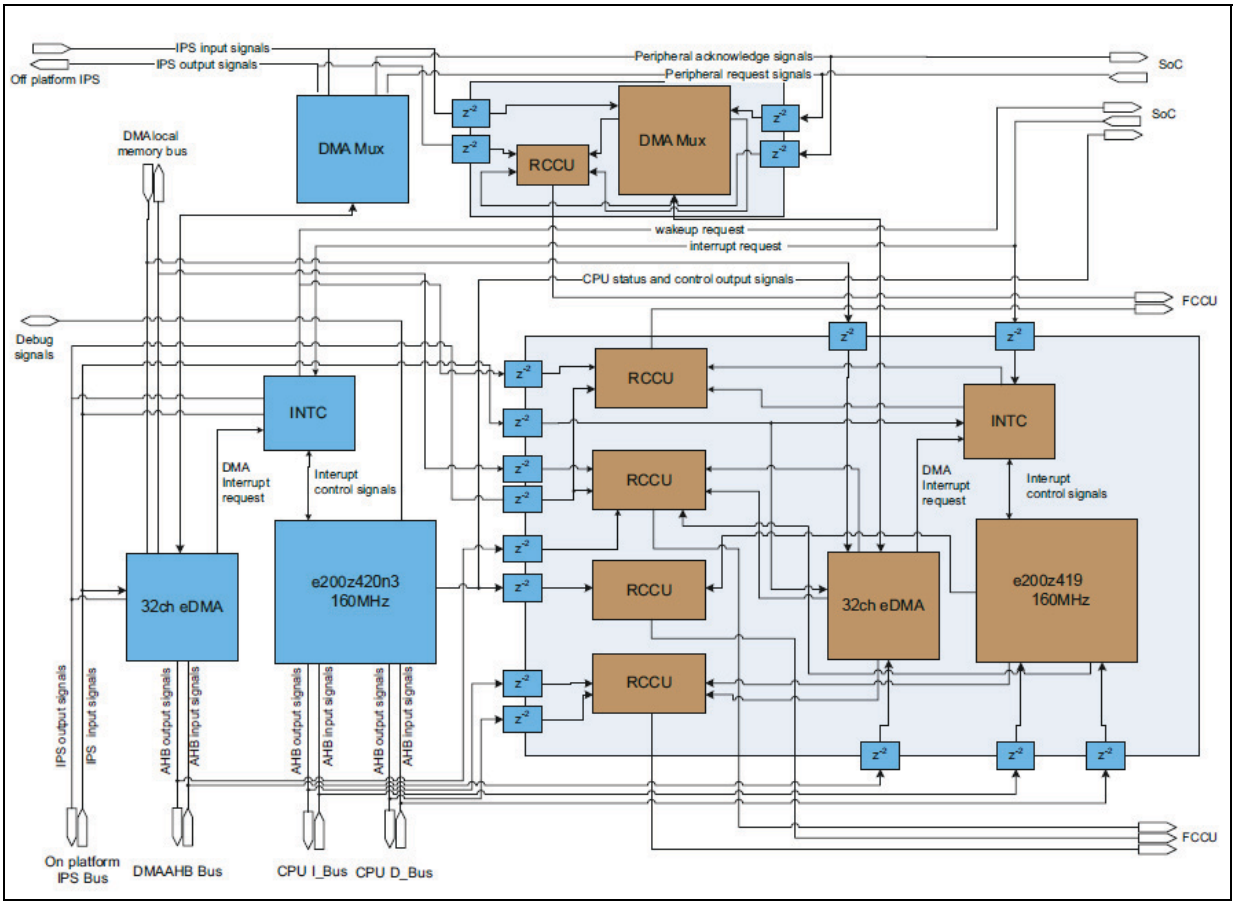
This chapter gives an overview of the safety implementation for the SPC574Sx, and discusses the operation of the main safety mechanisms.

In general, safety integrity is achieved in the following ways:

- For the safety related bus masters, namely core and DMA, safety is ensured by delayed lockstep approach. The same approach is adopted for the INTC.
- The integrity of stored data is ensured by ECC with address encoding (RAM only) and selected additional measures for individual modules.
- The safety of the data path to storage is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for individual modules. For

peripherals, safety of the data path is ensured by E2E EDC. The E2E EDC protection terminates at peripheral bridge.

- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and implementation of a fault tolerant communication protocol). Hardware supports this application-level redundancy by providing redundant modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources.
- Clock and power generation and distribution are supervised by dedicated monitors.
- The Fault Collection and Control Unit is responsible for collecting and reacting to failure notifications. The Memory Error Management Unit (MEMU) is responsible for the collection and reporting (to the FCCU) of error events in system memories including both volatile and volatile ones. Memory related error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Logic and Memory BIST (L/MBIST) are provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms and in memory arrays. Dedicated mechanisms are provided to check the availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection).
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring).



6.4.1 Lockstep

SPC574Sx replicates its safety-relevant processing elements and compares their operation in lockstep.

The following elements are replicated:

- Core
- DMA (including DMA Mux)
- Interrupt controller (INTC)

Figure 9. Replication architecture

Equivalent operation of both channels are supervised by checker units (RCCU) on all functional signals, leaving the channels for the rest of the MCU. A functional signal is a signal participating in the functional operation of a channel. Test signals are not functional signals.

The FCCU is notified of any deviations between the supervised signals.

There is a two-clock delay between the two channels to reduce susceptibility to clock and power glitches.

The checker core and the replicated DMA do not have a direct connection to the Crossbar Switch (XBAR). All their outputs directed to the XBAR end in RCCUs and all their inputs associated with the XBAR are split off to the master IP's inputs from the XBAR.

If additional connections exist via which information can leave the checker channel, these are also compared to the respective signals from the main channel. Examples are DMA acknowledgements to peripherals.

Similarly, if additional connections exist via which information can enter the checker channel, these are split off from the master IP's input. Examples are IRQ signals from peripheral to INTC and peripheral DMA requests.

Signals internal to the channel are not compared (as they are already covered by redundancy). Particularly no RCCU is needed on signals from or to core, to or from INTC and DMA, from or to DMA and to or from INTC.

No dynamic switching of lockstep mode is possible. Lockstep mode can only be toggled by reprogramming information in the Flash and executed on the subsequent boot. When Lockstep mode is switched off, the checker IPs are disabled (see Miscellaneous DCF in *Chapter 9: Device Configuration Format (DCF) Records*).

A register visible to the core indicates whether or not the system is in lockstep mode. Before starting safety-relevant operations, Software checks that the lockstep mode is enabled and also configures the FCCU to react to lockstep disablement.

6.4.2 End to end (E2E) protection on the data path and memory ECC

Error correction and detection mechanism is used to protect the access to the system memories. The general scheme is:

- An ECC error is reported to (stored into) the MEMU, which in turn, will trigger the FCCU
- An EDC or signal integrity check error is reported to the FCCU

All codes have Hamming distance of at least 4 (ECC) or 3 (EDC) except for the Cache where also EDC needs to have a Hamming distance of 4.
All storage arrays in the MCU use column MUXing to sufficiently reduce the probability of triple bit errors.
Error correction to be performed on data and check-bits and both data and check-bits to be returned to the requesting master.
Error correction operations do not cause additional wait states.

Addressing errors to be covered by the inclusion of the address into the End-to-End EDC/ECC. CAN RAM (Message Buffers) to be protected by ECC.

Figure 10 shows the overall ECC architecture. The picture shows when the ECC checkbits are connected between the various modules. Each ECC engine has a number ID, which is looked up into *Table 22* for additional details of each ECC engines. *Table 22* clarifies whether the ECC checkbits contain the address component and where an ECC error is reported to. Refer to *Figure 24* for the list of FCCU input triggers related to the ECC/EDC.

Figure 10. e2eECC general architecture

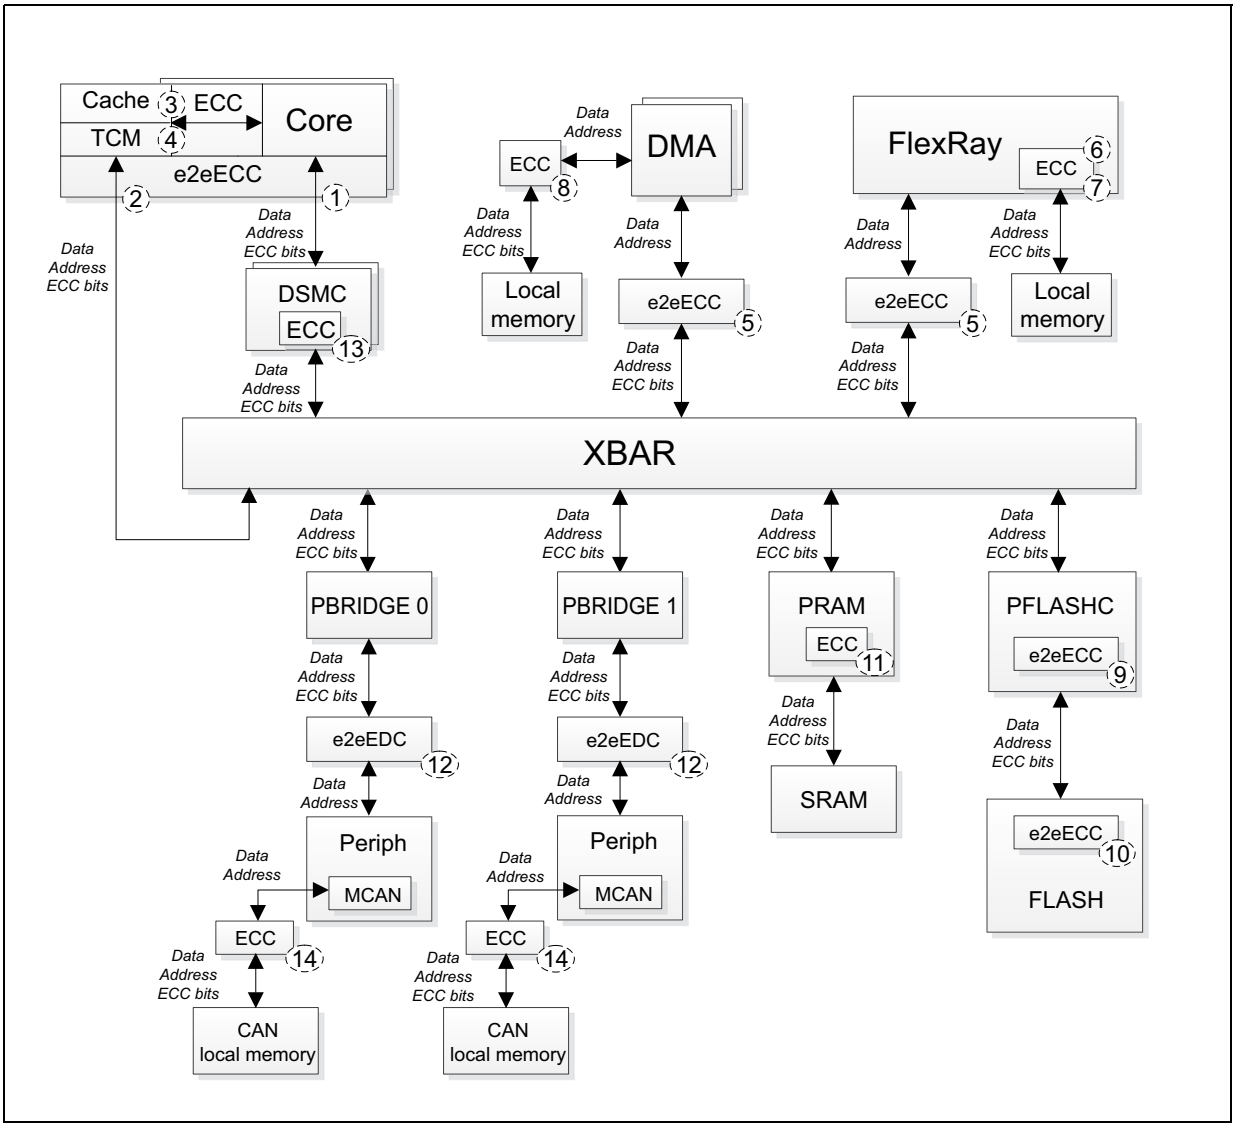


Table 22 shows the characteristics of the ECC engines distributed around the system. The “ID” column reflects the numbering used in *Figure 10*.

For all ECC which includes address into the ECC codebit calculation, the All-X words will not be handled specially. They can be a valid, a correctable or an non-correctable word depending on address.

6.4.3 Additional address coverage

The values stored in the address and control signal input latches of a RAM array are fed back to the control module of that array together with whatever result an access had.

RAM controller, of RAM with address coverage requirements, compare the values fed back from the latches with the values which were written to the latches when it evaluates/forwards the results from the access to the RAM array.

If a deviation is detected during the comparison it is signaled to the FCCU.

Only non-replicated, safety-relevant RAM controller require additional address coverage.

The wordline and the column selected to retrieve the data from the Flash array are re-encoded to the address which corresponds to that wordline/column combination.

This re-encoding is also capable of detecting if more than one wordline/column or none is selected.

The re-encoded address is returned to the Flash controller together with the read data or the write acknowledgement.

Table 22. ECC Engine Summary

ID	Interface	Correct	Detect	Address covered by ECC	Reaction upon ECC error within the address	Data and ECC bit size	Report to
1	CPU I/D-Bus	1-bit	2-bits	Yes	No correction is done. A machine check exception is triggered. Reported as uncorrectable Error to FCCU via MEMU.	64+8	MEMU/FCCU
2	TCM I/D External Port	1-bit	2-bits	Yes	No correction is done. A machine check exception is triggered. Reported as uncorrectable Error to FCCU via MEMU.	64+8	MEMU/FCCU
4	CPU to I/D-TCM	1-bit	2-bits	Yes	No correction is done.	32+8	MEMU/FCCU
3	CPU to I/D-Cache	—	2-bits	Yes	Cache is invalidated. The Error is reported as correctable error to FCCU via MEMU.	64+8	MEMU/FCCU
5	DMA and FlexRay AHB I/F	1-bit	2-bits	Yes	Reported as uncorrectable multi-bit error	64+8	MEMU/FCCU
6	FlexRay PE RAM I/F	1-bit	2-bits	No	—	16+10	MEMU/FCCU
7	FlexRay CHI RAM I/F	—	1/ 2-bits	No	—	96+30	MEMU/FCCU
8	DMA local RAM I/F	1-bit	2-bits	Yes	Indicated by a dedicated output signal (dma_tcd_addr_ecc_err) at platform top	64+8	MEMU/FCCU

Table 22. ECC Engine Summary (continued)

ID	Interface	Correct	Detect	Address covered by ECC	Reaction upon ECC error within the address	Data and ECC bit size	Report to
9	Flash controller	1-bit	2-bits	Yes	Reported as noncorrectable multi-bit error	64+8	MEMU/FCCU
10	Flash	1-bit	2-bits	No	Reported as noncorrectable multi-bit error	64+8	MEMU/ FCCU (through Flash controller)
11	RAM controller	1-bit	2-bits	Yes	Reported as noncorrectable multi-bit error	64+8	MEMU/FCCU
12	AIPS0/1	—	2-bits	Yes	Reported as fault to FCCU.	64+8	FCCU
13	DMSC	1-bit	2-bits	Yes	Reported as noncorrectable multi-bit error	64+8	MEMU/FCCU
14	CAN local RAM	1-bit	2-bits	No	—	32+7	MEMU/FCCU

6.4.3.1 ECC engine embedded into the CPU vs. Machine check exception

The CPU embeds an ECC engine, which detects/corrects the failed bits occurring during the access to either the system (AHB interface) or local (TCM and Cache) memories. The ECC errors are considered HW errrors and are classified as “machine check”. Machine check causes are divided into different types:

- Error Report Machine Check conditions
- Non-Maskable Interrupt (NMI) machine check exceptions
- Asynchronous machine check exceptions

In addition to the ECC errors, the following additional sources can generate a machine check exception:

1. p_mcp_b signal transition from negated to asserted
2. ISI or Bus Error on first instruction fetch for an exception handler
3. External bus error
4. Stack limit check failure

Upon a machine check exception, the p_mcp_out signal is asserted. This signal is connected to the FCCU. In order to understand what is the cause of a machine check, the application reads the CPU MSCR register. In fact, when the processor takes a machine

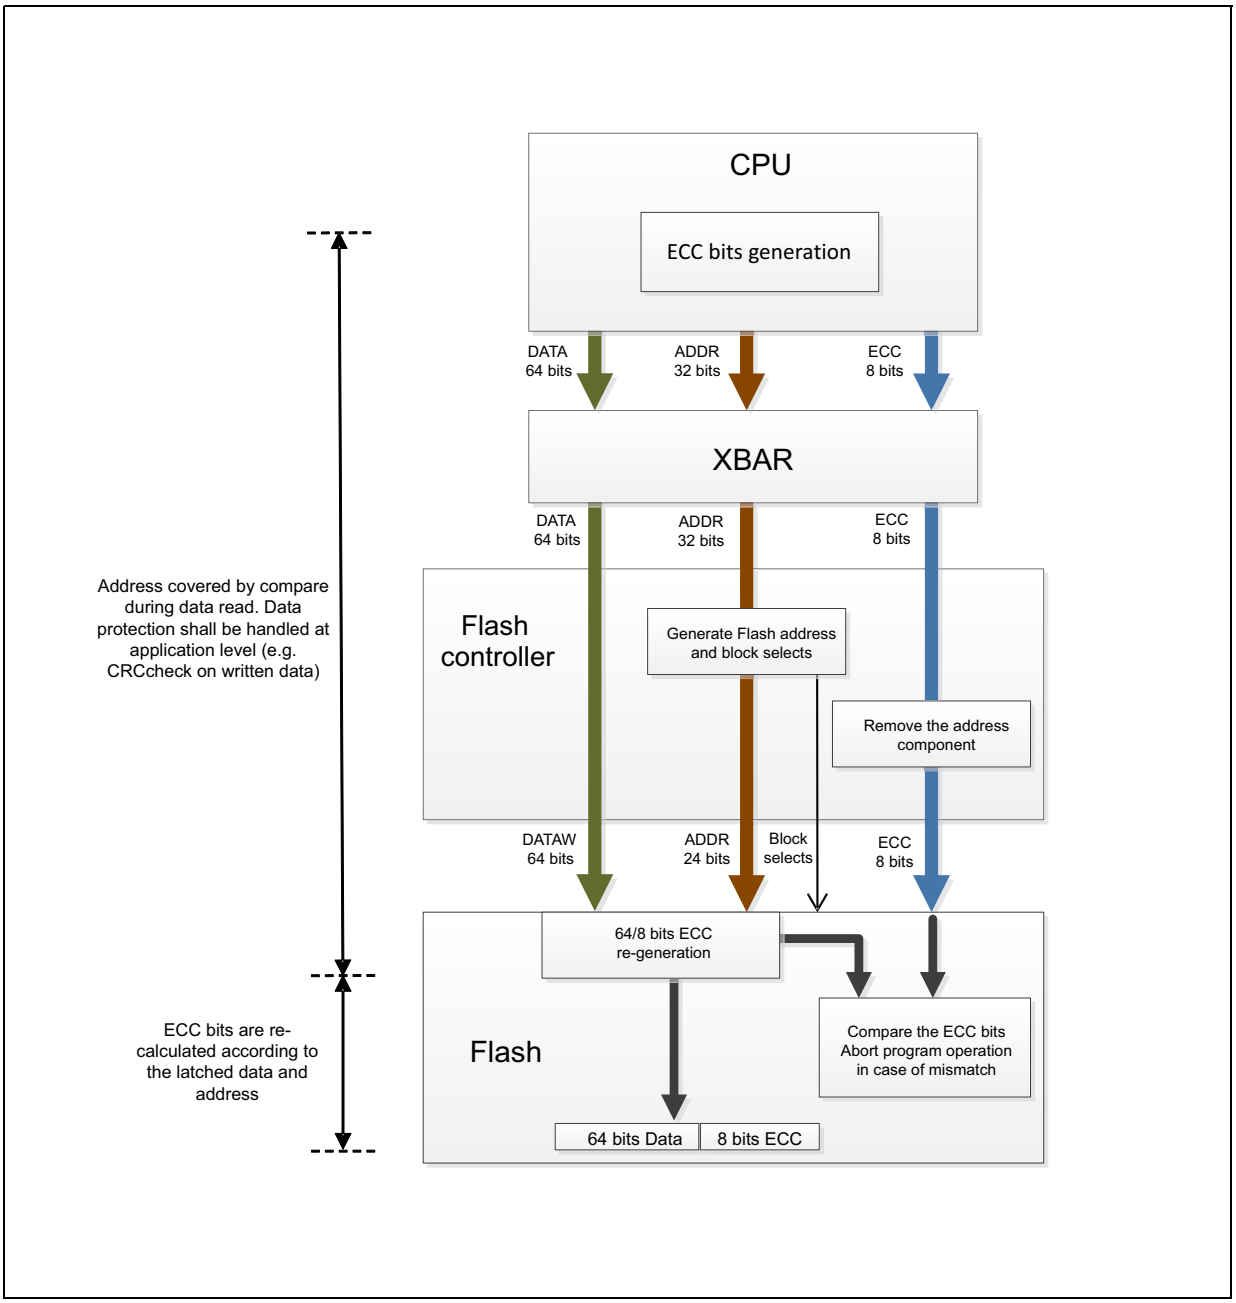
check interrupt, it updates the Machine Check Syndrome register (MCSR) to differentiate between machine check conditions. Following status bits are available:

- Machine check input pin
- Instruction Cache data array parity error (if I-Cache is available)
- Data Cache data array parity error (if D-Cache is available)
- ISI or Bus Error on first instruction fetch for an exception handler
- Instruction Cache Tag parity error
- Data Cache Tag parity error (if D-Cache is available)
- Instruction Cache Lock error (if I-Cache is available)
- Data Cache Lock error (if D-Cache is available)
- NMI input pin
- MCAR Address Valid
- MCAR holds Effective Address
- User (MCAR value captured in user mode)
- Instruction Fetch Error Report
- Load type instruction Error Report
- Store type instruction Error Report
- Guarded instruction Error Report
- Stack Access Limit Check Error
- Instruction Mem (IMEM) Parity Error (if I-MEM is available)
- Data Mem (DMEM) Parity Error (if D-MEM is available)
- Data Mem (DMEM) Write Parity Error (if D-MEM is available)
- Read bus error on Instruction recovery linefill
- Read bus error on data load or linefill
- Write bus error on store to bus or DMEM imprecise write error
- Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case

In addition to the machine check exception, the CPU reports the following signals about the ECC errors:

- single error
- double error
- address error
- address of failed memory location

These information are separated for errors happening in the TCM, Cache, or external AHB interface. The MEMU is triggered accordingly to the type of error and where did it happen.



6.4.3.2 CPU to Flash write path protection

Figure 11 shows the CPU to the Flash memory write path. The ECC bits are generated by the CPU, based on AHB data and address, and checked within the Flash. The Flash memory controller translates the address into the Flash block sector and block enable. The Flash controller removes the AHB address component from the ECC bits and transmits the new ECC bits to the Flash memory. The Flash memory checks the received ECC bits vs. the latched data and aborts the writing operation in case a mismatch is detected. The ECC bits being effectively programmed into the Flash are generated within the Flash memory, based

on the latched data and covers them with the ECC bit generated within the Flash memory itself.
Because all-1 (data+checkbits) is a valid combination (e.g. erased sector), it sets up (as a result of a design failure mode analysis) some safety HW/SW mechanism to detect whether we are reading all-1 because of some failures or because the block is really erased.

Data read and CRC are the measures intended to verify the integrity of the programmed data.

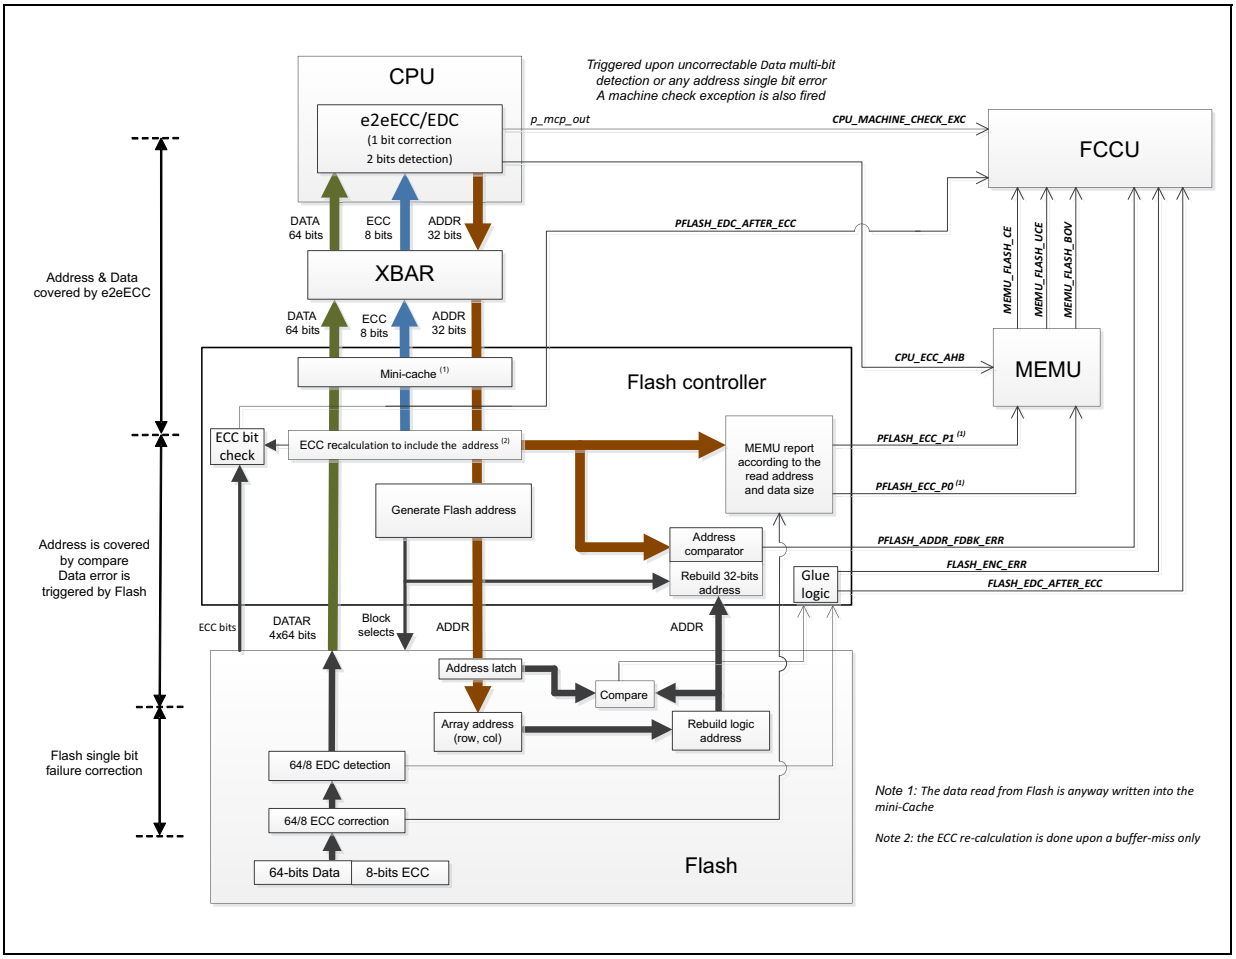
Figure 11. CPU to Flash write path protection

6.4.3.3 CPU to Flash read path protection

Figure 12 shows the CPU to the Flash memory read path. The data is supposed to have been stored into the Flash memory together with the ECC bits necessary to cover the data. The Flash memory is able to correct 1 bit failure and detect 2 bit failures.
Upon data reading, the Flash memory executes an ECC correction, followed by an EDC check after ECC.
The occurrence of an EDC error after ECC error is reported to the FCCU via glue logic within the Flash controller, which takes care to report non- EEProm failures only whereas the occurrence of an ECC error is reported to the Flash memory controller, which in turn will report to the MEMU, which in turn will trigger the FCCU.

In addition, the Flash executes a compare between the latched address and the address used internally to address the memory array. The wordline and the column selected to retrieve the data from the Flash array are re-encoded to the address which corresponds to that wordline/column combination.

This re-encoding is also capable to detect if more than one wordline/column or none is selected. A mismatch between them is reported to the Flash controller, which in turn will trigger the FCCU.



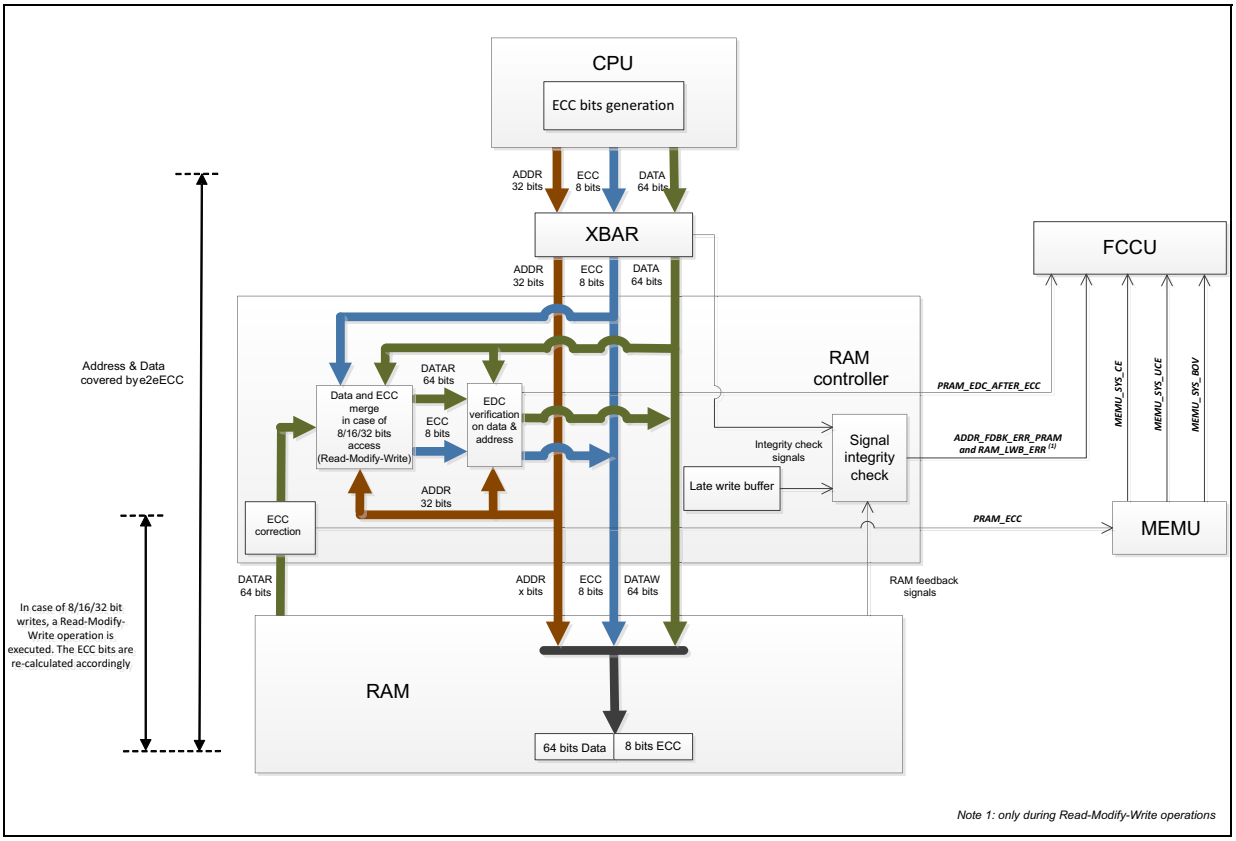
The Flash memory also sends to the Flash memory controller the address where the data has been read from. The Flash memory controller compares this address with the one sent to the Flash memory. An error is reported to the FCCU. This comparison covers the address path between the Flash memory controller and the Flash memory for both the read and write operations.

The Flash memory controller re-calculate the ECC bits taking the address received from the XBAR, in order to match the different address between the one sent to Flash and the one received from the XBAR. After that, the data and ECC checkbits are stored into the mini-cache.

The Flash controller also executes an integrity check on the newly calculated ECC bits and triggers an alarm to the FCCU in case of failure.

The data is finally transferred to the CPU, which will evaluate the check bits. In case of any address bit failure or data multi-bit non-correctable error, a machine check exception is fired and the FCCU is triggered by the p_mcp_out signal. The reason for the machine check can be read from the CPU MCSR register. In parallel, the information about the error is reported to the MEMU, which in turn triggers the FCCU.

Figure 12. CPU to Flash read path protection

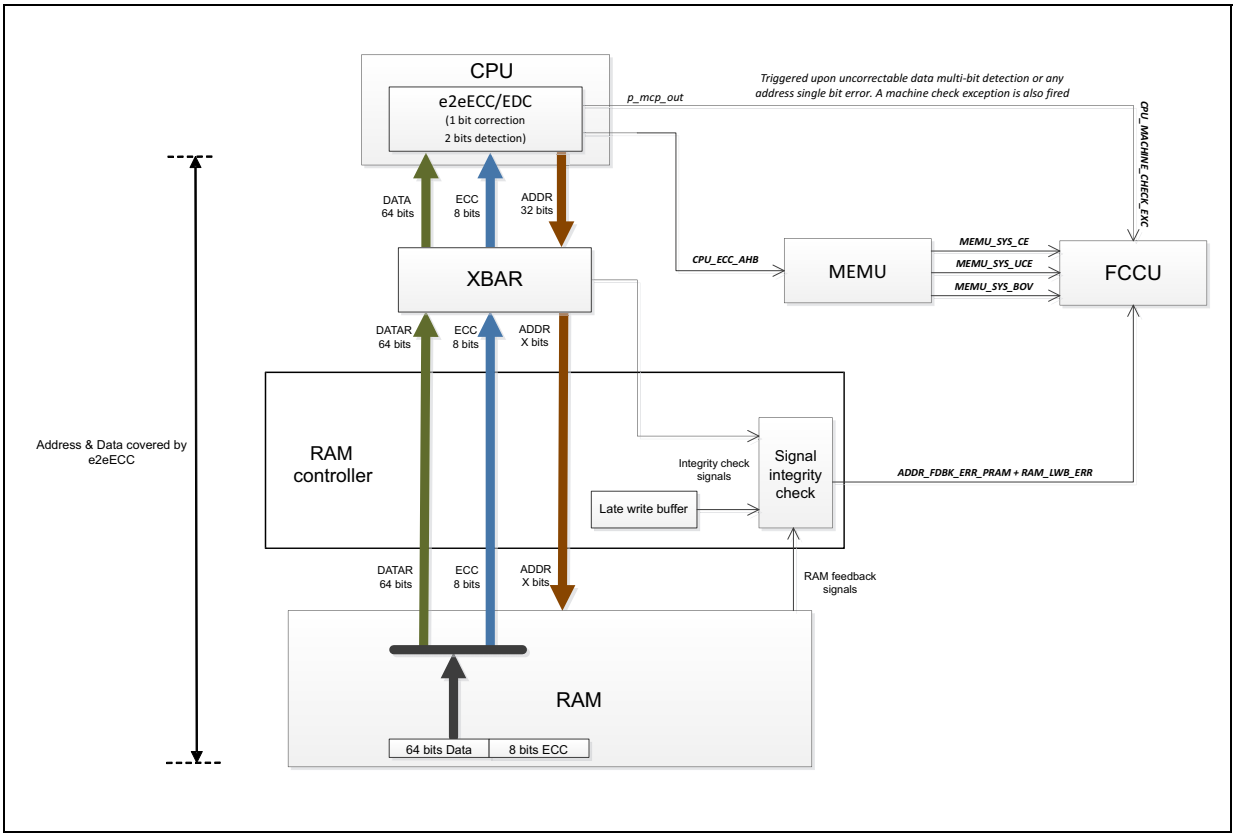


6.4.3.4 CPU to RAM write path protection

Figure 13 shows the CPU to the RAM system memory write path. The ECC bits are generated by the CPU and cover both the AHB address and data (8 ECC bits are used). The RAM controller checks the size of the data being written. In case the size is 64-bit, then the data and the ECC bits are directly stored into the RAM, without any EDC check. Vice verse, in case a RAM write operation is requested for some data, whose size is less than maximum data width, the RAM controller executes a Read-Modify-Write operation.

The signal integrity check module is embedded inside the RAM controller and guarantees the integrity of the signals at the input and output of the RAM controller. If a deviation is detected during the comparison it is signaled to the FCCU.

Figure 13. CPU to RAM write path protection



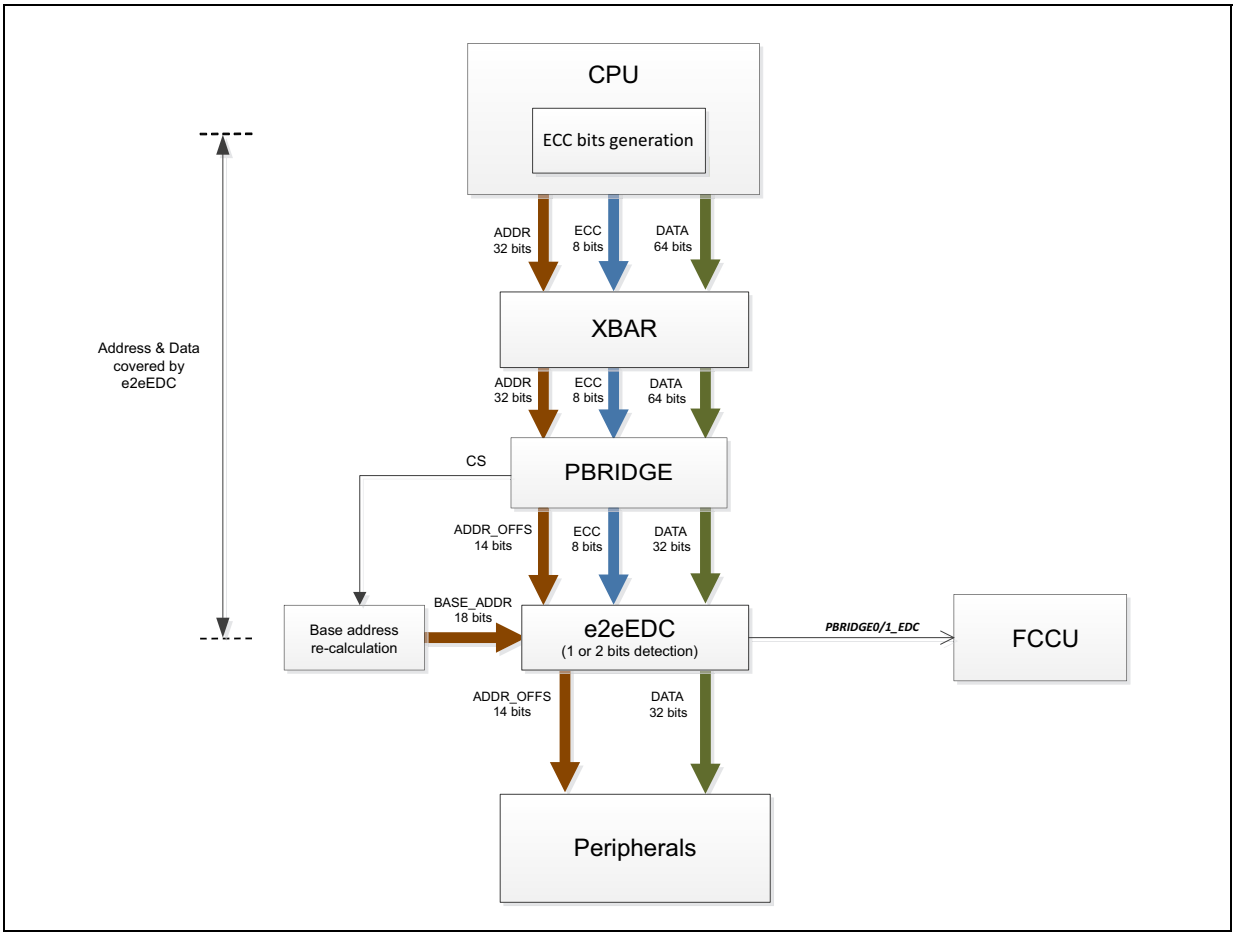
6.4.3.5 CPU to RAM read path protection

Figure 14 shows the CPU to the RAM system memory read path. The data and ECC bits are stored into the RAM and read back from the RAM controller. The signal integrity check module is embedded inside the RAM controller and guarantees the integrity of the signal at the input and output of the RAM controller. The data is finally transferred to the CPU, which will detect any single or double bit fails and report them to the FCCU.

The signal integrity check module is embedded inside the RAM controller and guarantees the integrity of the signals at the input and output of the RAM controller. If a deviation is detected during the comparison it is signaled to the FCCU.

In case of any address bit failure or data multi-bit uncorrectable error detected by the CPU, a machine check exception is fired and the FCCU is triggered by the p_mcp_out signal. The reason for the machine check can be read from the CPU MCSR register. The reason for the machine check can be read from the CPU MCSR register. In parallel, the information about the error is reported to the MEMU, which in turns triggers the FCCU.

Figure 14. CPU to RAM read path protection

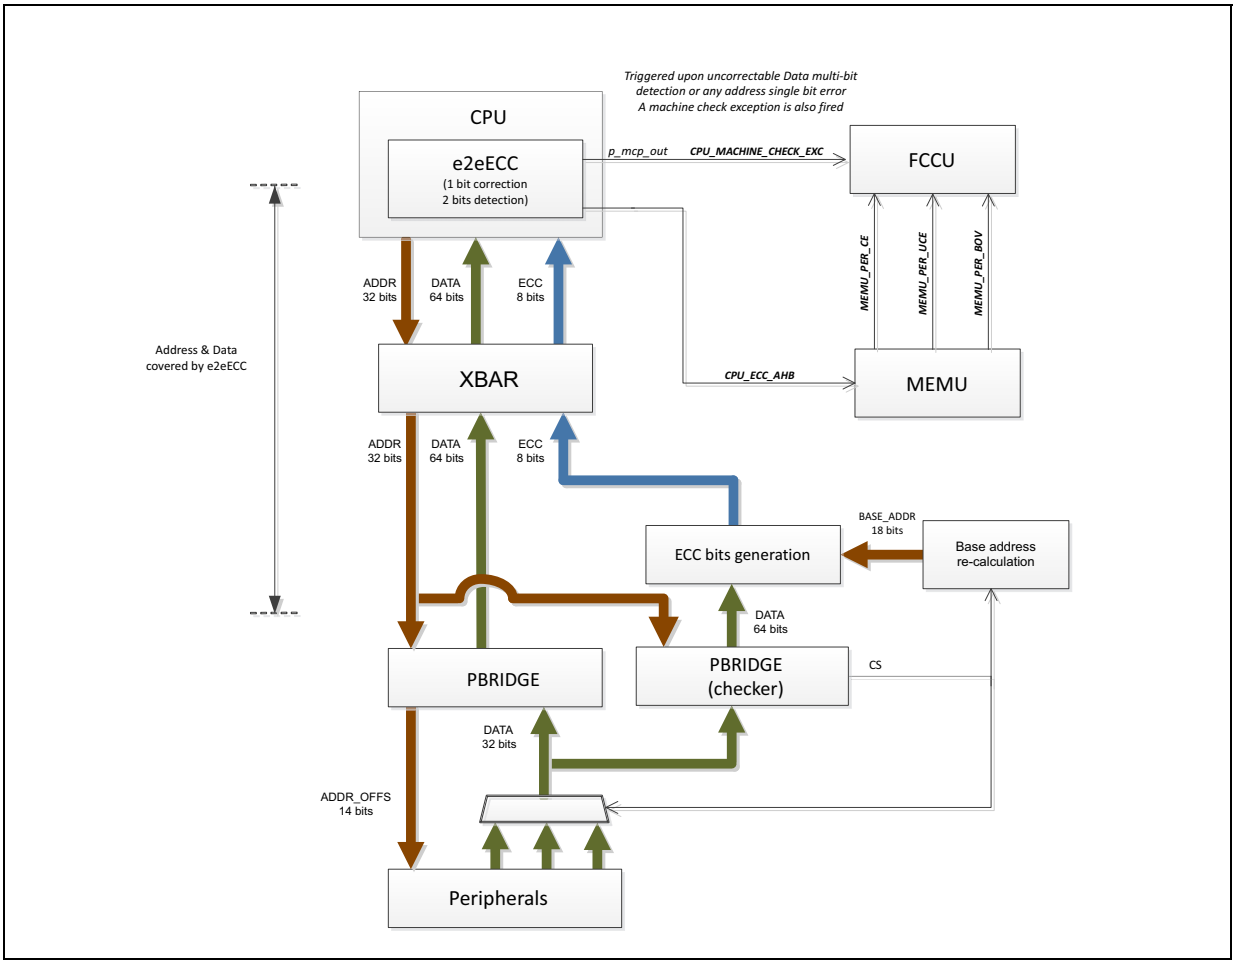


6.4.3.6 CPU to peripheral write path protection

Figure 15 shows the CPU to the peripheral write path. The ECC bits are generated by the CPU and cover both the address and data (8 ECC bits are used). The e2eEDC block after the AIPS bridge checks the received data and address for any bit failures and eventually trigger a signal to the FCCU. No data correction is performed.

The safety mechanism covers also the correctness of the re-mapping of the AHB read/write data busses onto the IPS read/write data busses.

Figure 15. CPU to peripheral write path protection



6.4.3.7 CPU to peripheral read path protection

Figure 16 shows the CPU to the peripheral read path. The ECC bits are generated by the e2eECC module connected under the AIPS port and cover both the address and data (8 ECC bits are used), the latter being output from the multiplexed peripheral data read busses. The AIPS is duplicated in order to check the correctness of the signals. In case of any address bit failure or data multi-bit non-correctable error, a machine check exception is fired and the FCCU is triggered by the p_mcp_out signal. The reason for the machine check can be read from the CPU MCSR register. In parallel, the information about the error is reported to the MEMU, which in turn triggers the FCCU.

The safety mechanism covers also the correctness of the re-mapping of the AHB read/write data busses onto the IPS read/write data busses.

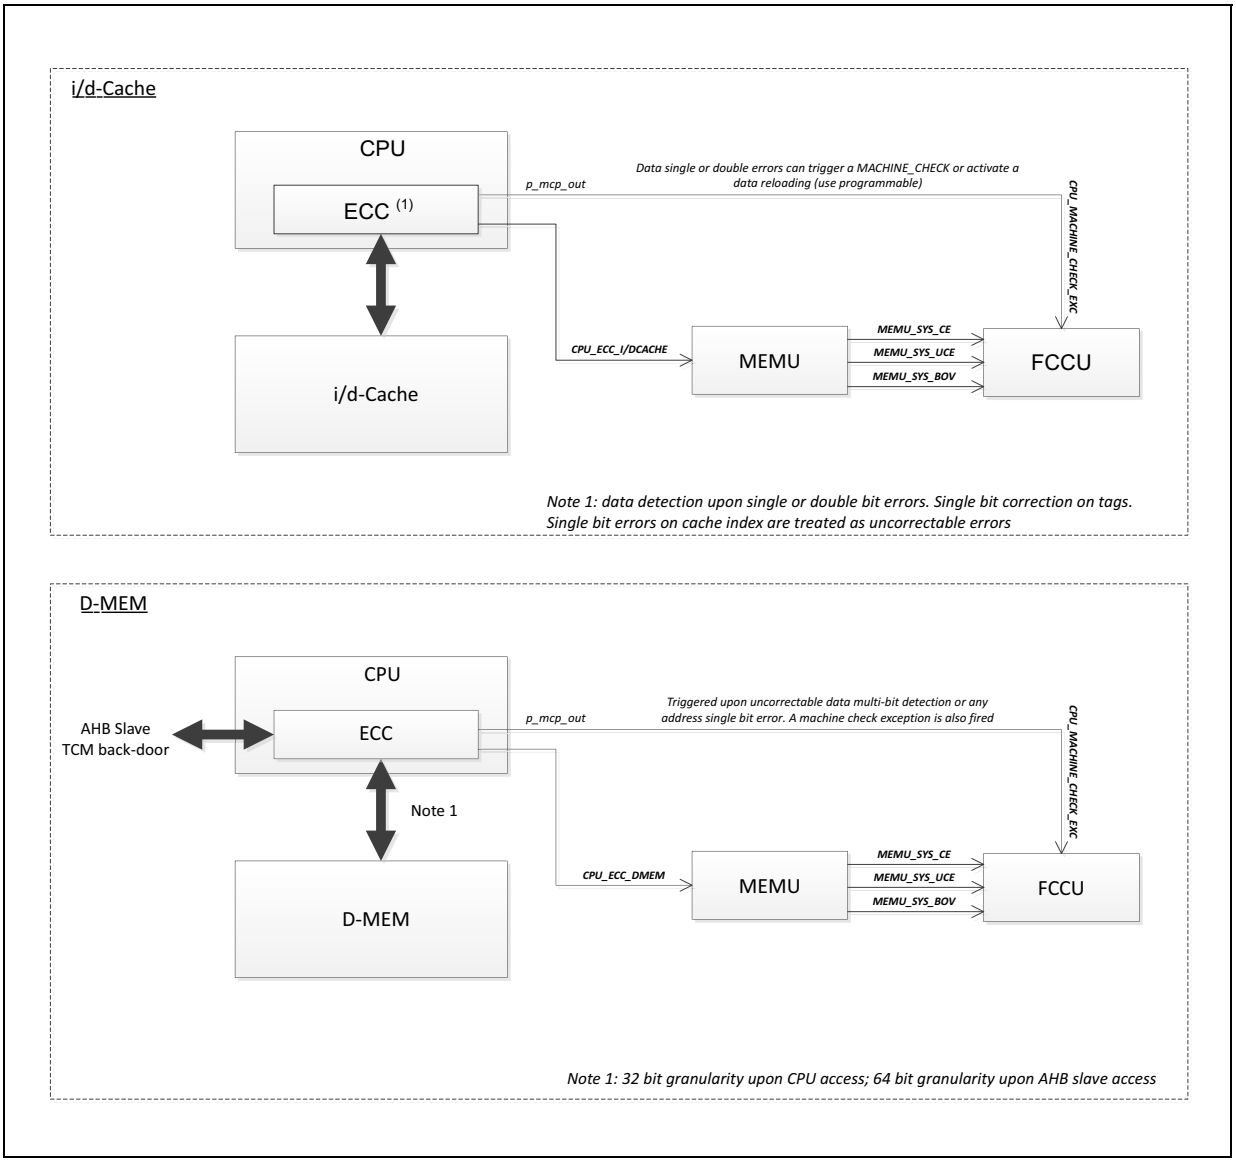


Figure 16. CPU to peripheral read path protection

6.4.3.8 ECC protection for TCM and Cache memories

Figure 17 shows the ECC protection when the CPU accesses the TCM or the Cache. Upon writing, the ECC engine generates the check bits. Upon reading, the check bits are verified and, for the TCM, the data eventually corrected, while for the cache memory no correction is done (except for the cache tags data). In case of any TCM address bit failure, cache index failure, cache tags non-correctable errors, or data multi-bit non-correctable error, a machine check exception can be fired and the FCCU is triggered by the p_mcp_out signal. The reason for the machine check can be read from the CPU MCSR register. In parallel, the information about the error is reported to the MEMU, which in turns triggers the FCCU. The cache configuration registers can be optionally programmed in order to reload the data value upon an ECC error.

Figure 17. ECC protection for TCM and Cache memories

When a write operation to the TCM is done through the XBAR TCM slave port, the ECC checkbits, as generated by the accessing master, are stored into the TCM, following a CPU internal transformation, because the DMEM ECC granularity is 32-bits.
When a read operation from the TCM is done through the XBAR TCM slave port, the originally written ECC bits are internally transformed back to the AHB system ECC granularity (64-bits).

In order to have a match between the checkbits written by non-CPU masters, it is mandatory that the DMEM is seen at the same base address, for both the CPU and

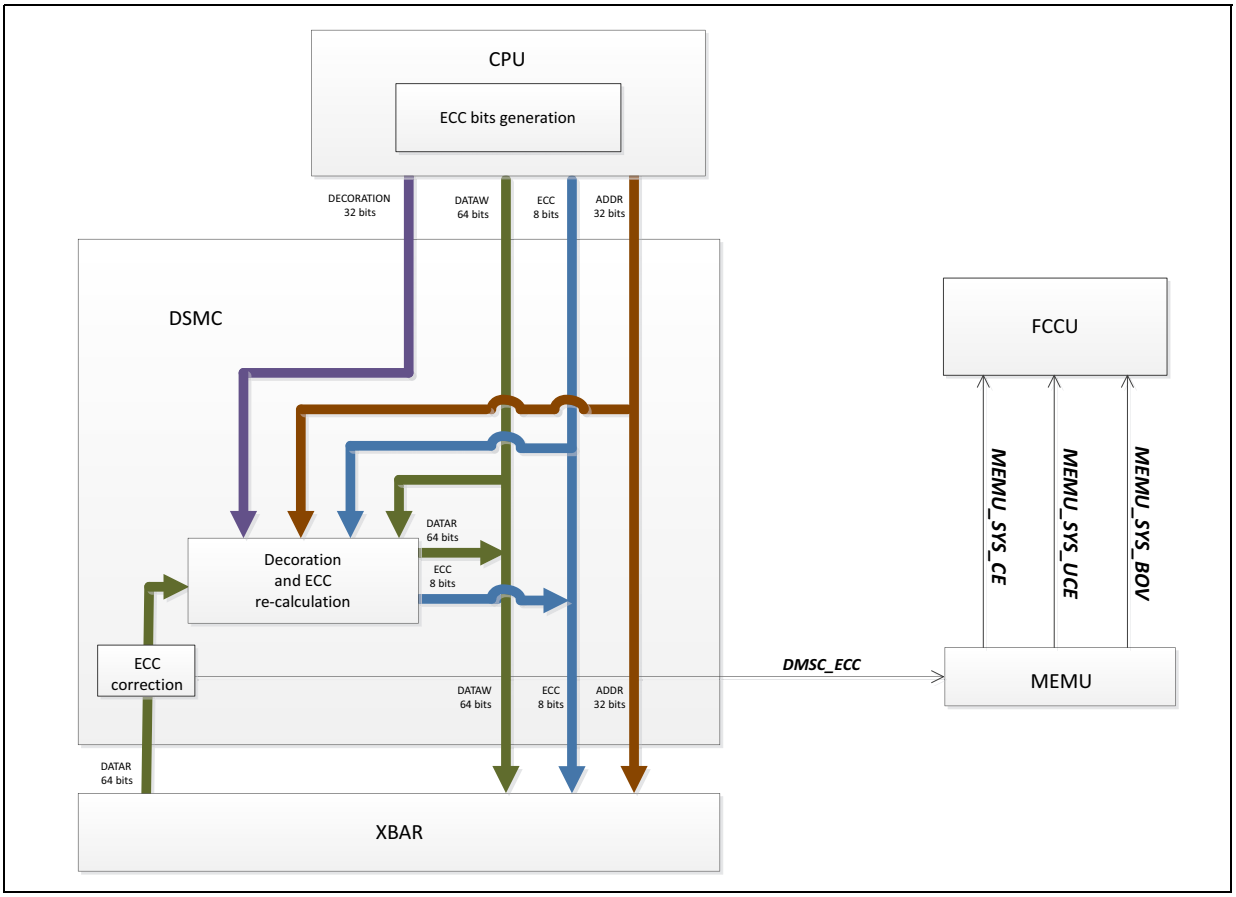
non-CPU accesses.

6.4.3.9 ECC protection for Decorated Memory Storage

The z4h processor embeds a feature used to run atomic read-modify-write instructions. A set of extended instructions are available for this. A functional module, called DSMC

(Decorated Storage Memory Controller), is placed between the CPU and the XBAR. The DSMC decodes the extended instruction and drives the necessary read-modify-write operations. The DSMC module contains the ECC logic applied on the data read during the read-modify-write operation. *Figure 18* and *Figure 19* show the organization of the ECC for the DMSC operations. In reality, only one single operation within the DSMC has no write-back result, while all the other operations are effectively Read-Modify-Write operations. The DSMC reports single/multi-bits errors to the MEMU for the data read from the slave memory address, and to the FCCU for the detection of ECC errors on the master write data and address. In order to cover the faults of the DSMC and the ECC re-generation logic, the DSMC is duplicated and the signals are checked with a dedicated RCCU.

Figure 18. ECC scheme for DSMC operation including a Write-Back operation



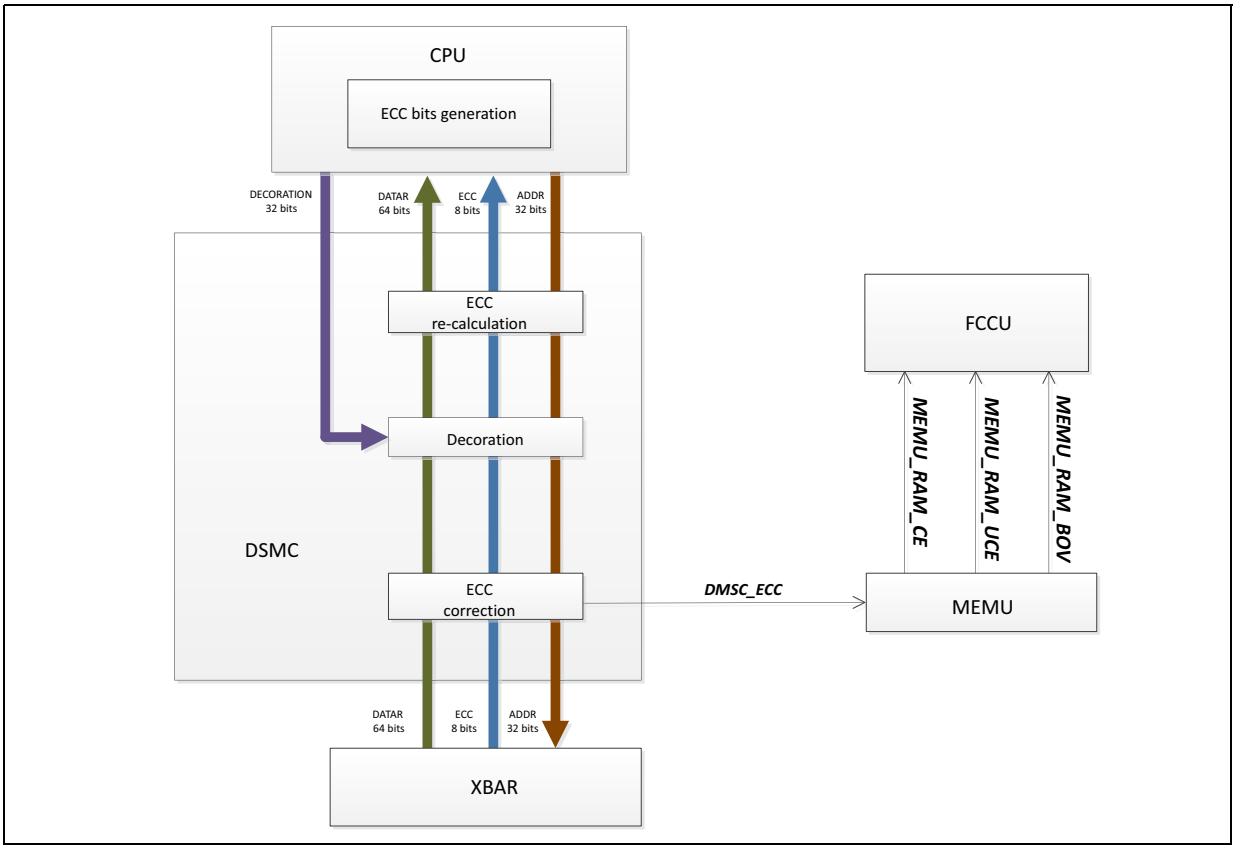


Figure 19. ECC scheme for DSMC operation with no Write-Back operation

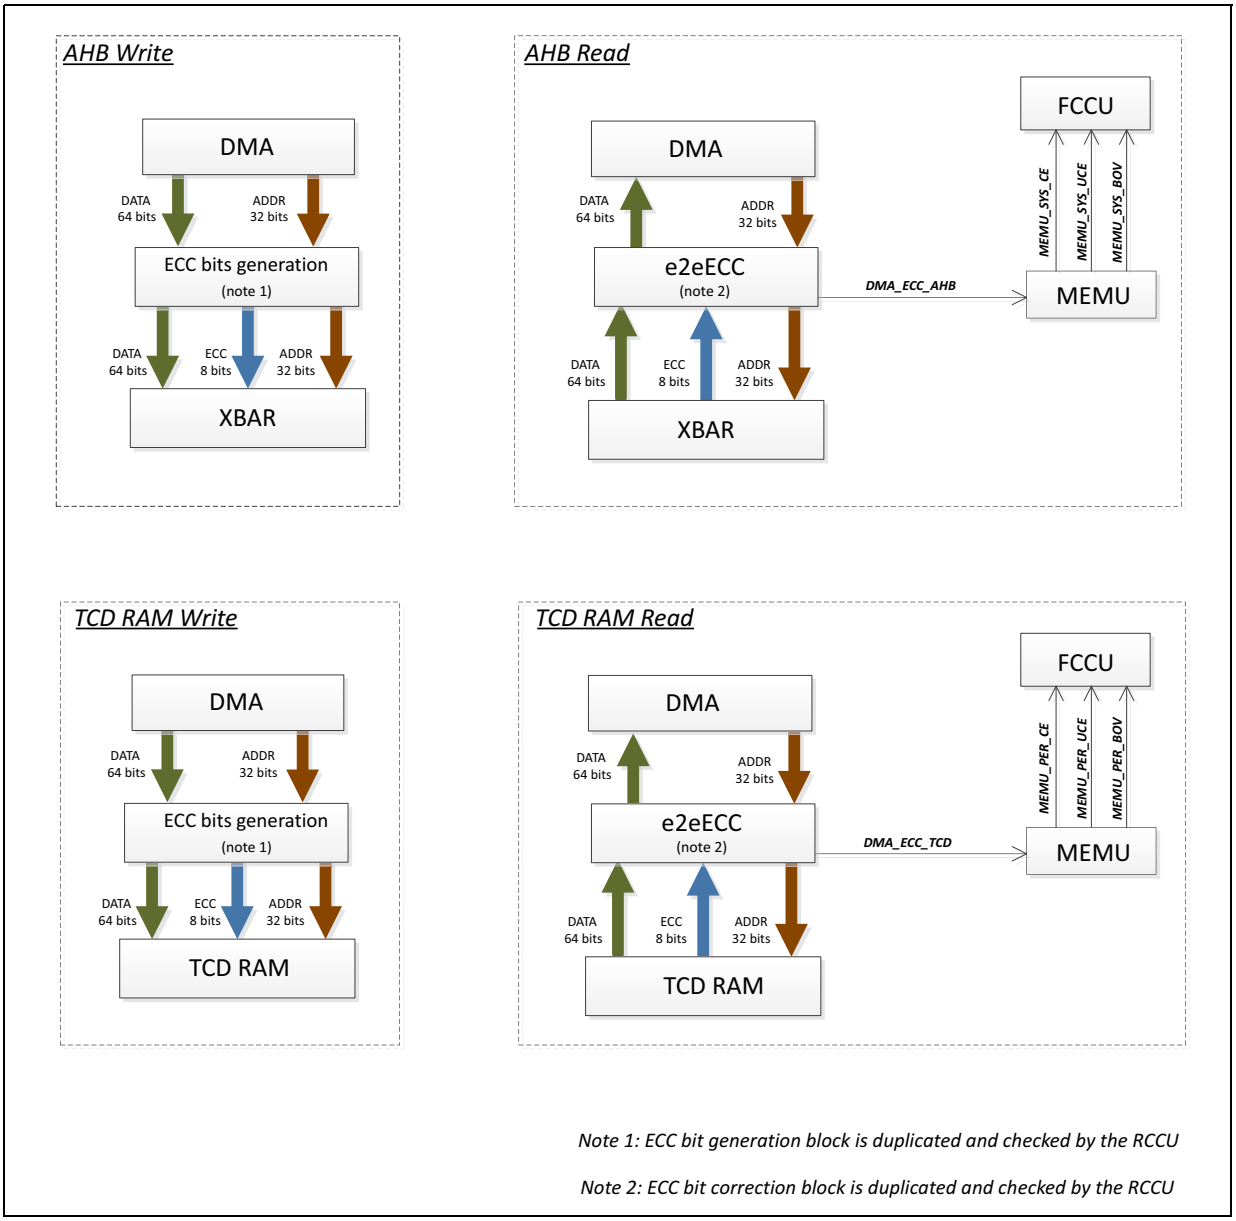
6.4.3.10 ECC protection for DMA



The ECC protection for the DMA is shown in *Figure 20*. The scheme is similar for an AHB transaction towards the XBAR or a local TCD memory transaction.

The e2eECC engines are placed between the DMA IP and the XBAR or TCD RAM.

Upon DMA write operations, the ECC bits are generated. ECC generation faults are covered by replication of the ECC engine.

Upon DMA read operations, the ECC bits are checked and the data eventually corrected, with a reporting to the MEMU. The ECC correction module is also replicated.

Figure 20. ECC protection scheme for DMA

Note 1: ECC bit generation block is duplicated and checked by the RCCU

Note 2: ECC bit correction block is duplicated and checked by the RCCU

6.4.3.11 ECC protection for FlexRay

The ECC protection for the FlexRay IP is shown in *Figure 21*. The ECC engines are embedded into the IP, therefore separated from the external local memories. The FlexRay IP uses local memory to save the data structures used for their operations and the ECC is applied to the local connections to these memories. In addition the FlexRay is a master on the AHB system. The memory error protections are listed in *Table 23*. EDC/ECC errors are reported to both the FCCU and MEMU.

Figure 21. ECC protection scheme for FlexRay

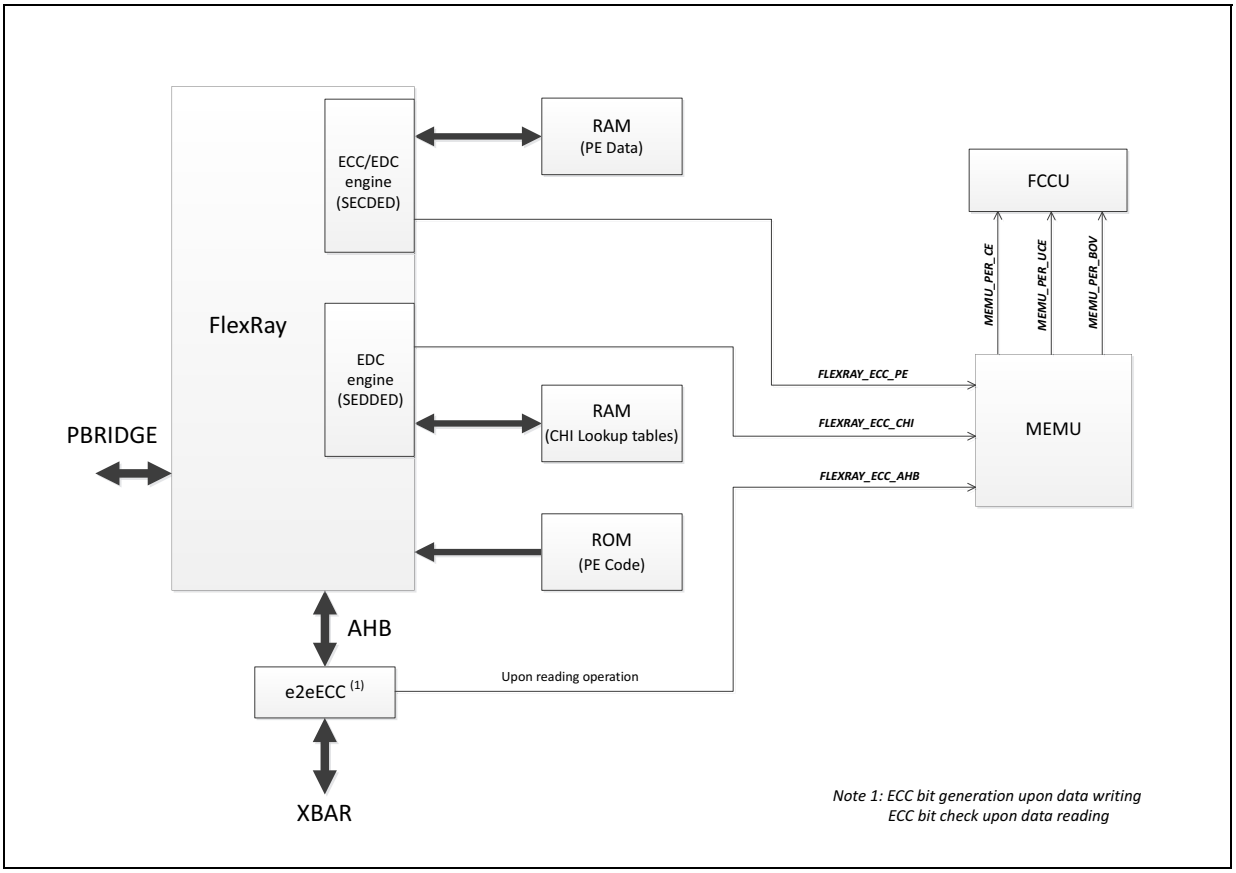


Table 23. FlexRay ECC/EDC protection

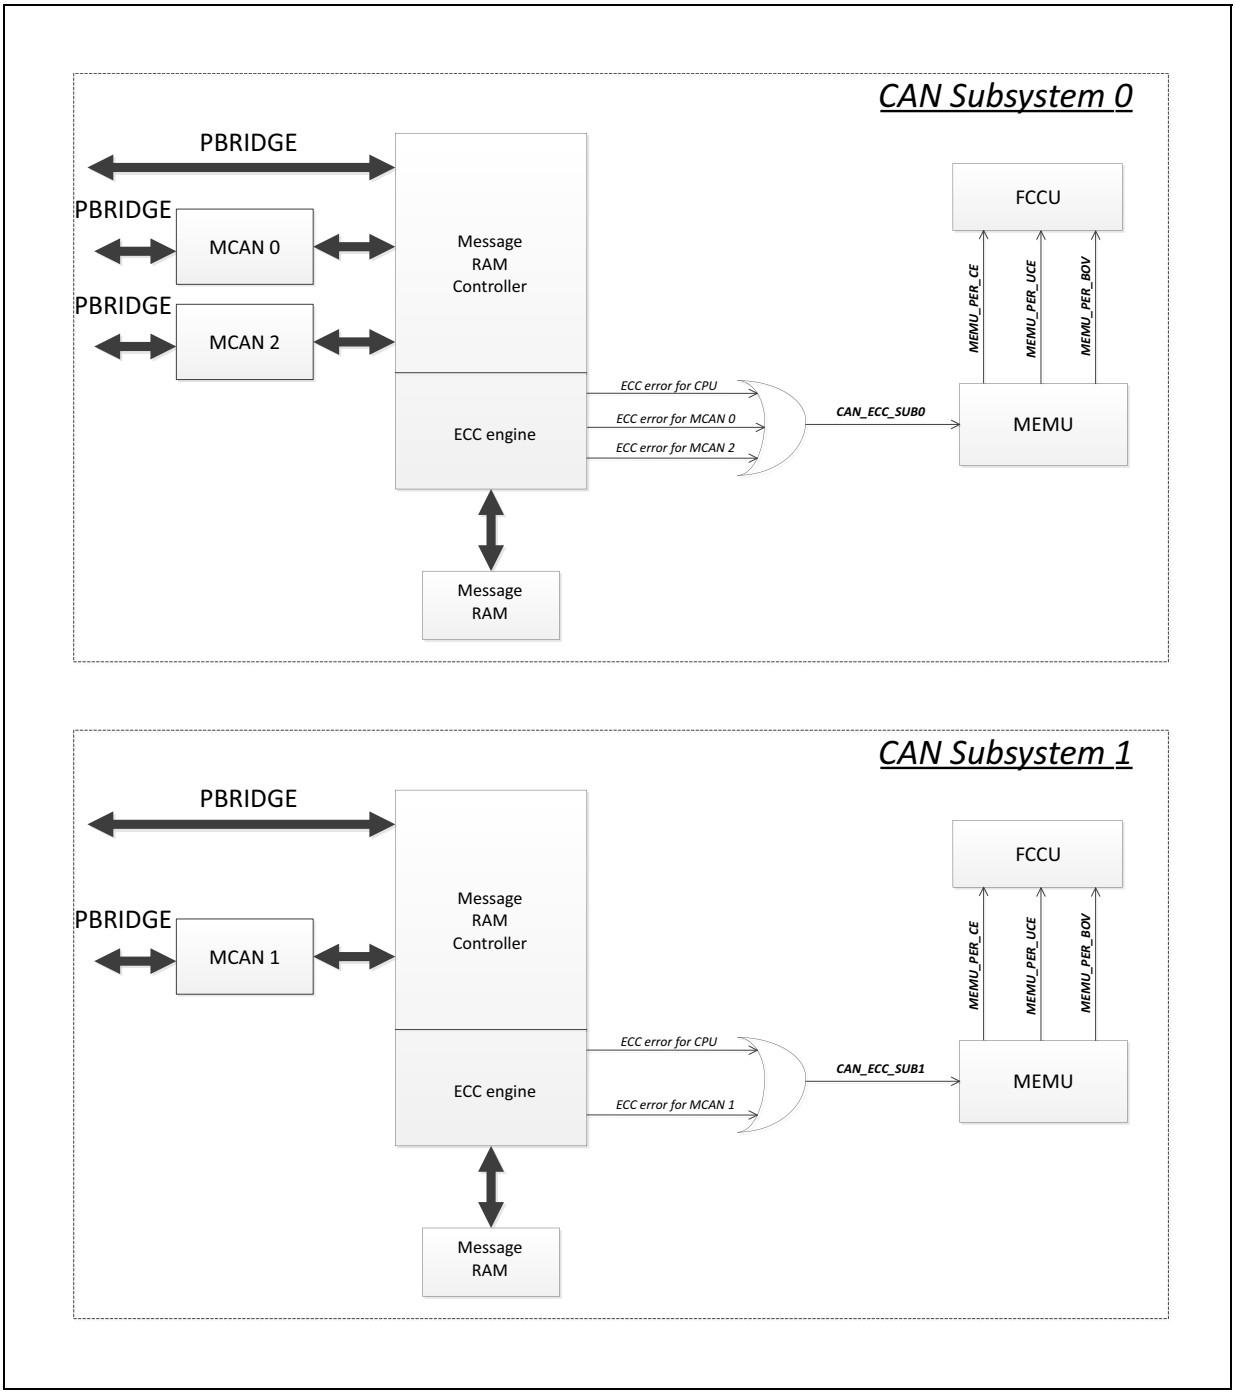

Path	Protection type
FlexRay AHB port	e2eECC on both data and address busses
FlexRay CHI connection to its local data memory	SEDDED on data bus only
FlexRay PE to its local data memory	SECDED on data bus only
PE connection to its local code memory	No protection

The ECC engine towards the FlexRay local memories make sure that if all data and code bits are all 0 or all 1, ECC/EDC do not report a correct word.

6.4.3.12 ECC protection for CAN subsystems

The message RAM access is regulated by the Message RAM Controller, which is part of the CAN subsystem. The ECC protection for the CAN subsystem is shown in *Figure 22*. The Message RAM Controller embeds an ECC engine. An ECC error is reported to the MEMU upon bit errors. The MEMU will in turn trigger the FCCU.

Figure 22. ECC protection scheme for CAN subsystems

The ECC engine towards the MCAN local memory makes sure that if all data and code bits are all 0 or all 1, ECC/EDC do not report a correct word.

6.4.3.13 ECC protection for SSCM configuration data reading

During the reset phase the device configuration data, stored in Test Flash and UTEST Flash, are read by the SSCM. The same ECC engine embedded into the Flash is used and it reports to the SSCM.

6.4.4 I/O safety

All I/O peripherals (except the SIUL2 and “hi-bandwidth” communication controllers such as CAN) used for safety purposes exist at least twice and the members of each pair are connected to different peripheral bridges. For example, DSPI provided by the MCU, two MCU IP modules (DSPI1, DSPI2) are included with different external pin connections. DSPI1 is internally connected to PBRIDGE_0 and DSPI2 to PBRIDGE_1 and is accessible via different addresses.

Redundant usage of I/O peripherals by software is possible.

6.4.5 Clock

The PLL provides error indications to the FCCU.

Clocks are supervised for correct frequency using CMU (Clock Monitoring Units).

CMU status is forwarded to the FCCU.

There is no element (specifically no flip flop) clocked by the supervised clock on the path from a CMU to FCCU and continuing on to the error_out pin.

The CMUs are driven by the IRCOSC to ensure independence from the monitored clocks.

Generally, in order to check the clock source and the clock path for any supervised clock, the CMU module is placed at the end of the clock path.

Modules are not directly clocked by the XOSC.

Diagnostic measures use a different clock to the function they are supervising. Particularly, FCCU and internal SWT run on a different clock than the system clock.

Master and checker channels have separate clock trees that conform as close as possible to the PLL-VCO.

One CMU is connected to the master channel clock path after the branch of the clock line for master and checker channel.

For other clock branches, one CMU is placed after the corresponding clock muxing logic.

CMUs are not required for clocks that can be considered implicitly supervised due to their failures affecting other supervised or diagnosed functionalities.

6.4.6 Power

There are two types of voltage supervisors on SPC574Sx, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion). For details on power monitoring, see *Chapter 10: Power management* and *Chapter 51: Power Control Unit (MC_PCU)*.

6.4.7 Failure handling

To prevent a failure of a safety related component (particularly the safety core) from affecting the appropriate reaction to the failure indication, failures are handled by dedicated modules (such as FCCU, MEMU, FOSU) as described below:

An independent module called Failure Collection and Control Unit (FCCU) is responsible for reacting to all failure indications.

For each failure source a different reaction is configurable.

Failure sources include:

- All failure indication signals from modules within the MCU
- Control logic and signals monitored by the FCCU itself (see *Chapter 65: Fault Collection and Control Unit (FCCU)*)
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Software can also directly influence the state of the F*n* pins

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, F0 and F1
- Disabling the transmission capabilities of communication controllers

Note: This is only possible in conjunction with changing the state of the failure indication pins.

- No reaction

It is possible for the software to read out the failure source which caused a failure reaction. This failure source storage is not influenced by functional (not Destructive, such as Power-on) resets.

In order to prevent FCCU failures from affecting the overall failure reaction capability, a secondary reaction path exists to supervise the FCCU reactions. This module is called FOSU (FCCU Output Supervisor Unit).

A Memory Error Management Unit (MEMU) provides information on where (which module) and at which address an error in the RAM or Flash was detected.

The MEMU receives data from ECC units according to the following interface per ECC unit connected:

- Single-Bit-Error (SBE) vs. Uncorrectable Error (UCE)
- Address of error (the accessed address)

Note: EDC logic does not report to the MEMU but failure indication is directly forwarded to the FCCU.

MBIST error address information is also stored in the MEMU.

In case an error is detected during MBIST, the following information is transmitted from the MBIST collar to the MEMU:

- Single-Bit-Error vs. Multi-Bit-Error
- Address of error (the tested address)
- Bit position of the error (if a single-bit error)

The MEMU stores the addresses at which ECC errors occurred in the following way:

- Uniqueness of the addresses in the buffer is ensured
- Software is able to read the buffers and remove individual entries from them (for example by marking them as invalid or free)
- If the buffer overflows, an additional signal is sent to the FCCU

The MEMU aggregates ECC failures and forwards them to the FCCU. For each of the SRAM, Peripheral RAM and Flash categories, the MEMU provides the following aggregated signals to the FCCU:

- Single-bit error corrected
- Uncorrectable error detected
- MEMU buffer overflow

Correctable errors which do not cause a new entry into the address table because they are known are not reported to the FCCU.

Uncorrectable errors always cause a report to the FCCU, even if they were already stored in the reporting table.

The following table lists the FCCU failure inputs.

Table 24. FCCU failure inputs

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
0	TEMP_ERROR	PMC	Temperature out of range	No reaction	Pulse, no SW intervention needed	—
1	LVD_ERROR		Voltage out of range from LVDs	No reaction	Pulse, no SW intervention needed	selftest by tap point manipulation
2	HVD_ERROR		Voltage out of range from HVDs	No reaction	Pulse, no SW intervention needed	selftest by tap point manipulation
3	DPMC_DCF_SAFETY_ERR		DCF read error (PMC trimming configuration)	No reaction	Persistent till error negation	LBIST
4	MEMORY_DCF_SAFETY_ERR	RAM	DCF read error (RAM redundancy data)	No reaction	Persistent till error negation	LBIST

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
5	SSCM_XFER_FLASH_ERR	SSCM	SSCM transfer error (during DCF reading used to configure the SSCM and the STCU) + Flash memory initialization error	No reaction	SSCM gets cleared by SW. Fatal error pulse no SW needed	Not testable (but wrong configuration can trigger other detection)
6	STCU_UF(1)	STCU2	STCU2 Unrecoverable Fault during the BIST execution, corresponding to the STCU_ERR_STAT.UFSF error bit	Functional Reset	Clear status through FCCU	SW check of BIST MISR
7	STCU_RF(1)		STCU2 Recoverable Fault during the BIST execution, corresponding to the STCU_ERR_STAT.RFSF error bit	No reaction	Clear status through FCCU	SW check of BIST MISR
8	STCU_LMBIST_USR_ERR		STCU2 fault in case LBIST or MBIST control signals go to wrong condition during user application	No reaction	—	STCU activation during User application running
9	JTAG_NPC_SSCM_MON	Debug logic(2)	JTAG, NPC, or SSCM not in reset or activation of dangerous debug functionality	No reaction	Clear status through FCCU	Feedback loop via FCCU Fake bit

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
10	RCCU_CPU_NON_AHB	RCCU	RCCU error trigger for the CPU non- AHB signals	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
11	RCCU_CPU_AHB		RCCU error trigger for the CPU AHB signals	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
12	SWT0_ResetReq	SWT	Software watchdog timer, 2nd timeout	Functional Reset	Cleared by reset only	LBIST + SW test by not triggering SWT during startup
13	SWT1_InterruptReq		Software watchdog timer, 1st timeout	No reaction	Needs to be cleared by SW, wc1 in SWT register	LBIST + SW test by not triggering SWT during startup

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
14	RCCU_AIPS_0	RCCU	RCCU error trigger for the AIPS 0 protocol checker	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
15	RCCU_AIPS_1		RCCU error trigger for the AIPS 1 protocol checker	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
16	MEMU_RAM_CE	MEMU	MEMU System RAM correctable error	No reaction	Clear Status in MEMU	LBIST + Injection of RAM ECC error via ECC bit access and later reading
17	MEMU_RAM_UCE		MEMU System RAM non-correctable error	No reaction	Clear Status in MEMU	LBIST + Injection of RAM ECC error via ECC bit access and later reading
18	MEMU_RAM_BOV		MEMU System RAM overflow(3)	No reaction	Clear Status in MEMU	LBIST + Injection of overflow error indication by MEMU debug register
19	MEMU_PER_CE		MEMU Peripheral RAM correctable error	No reaction	Clear Status in MEMU	LBIST + Injection of correctable error entry by writing one into the MEMU
20	MEMU_PER_UCE		MEMU Peripheral RAM non-correctable error	No reaction	Clear Status in MEMU	LBIST + Injection of uncorrectable error entry by writing one into the MEMU

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
21	MEMU_PER_BOV	MEMU	MEMU Peripheral RAM overflow(2)	No reaction	Clear Status in MEMU	LBIST + Injection of overflow error indication by MEMU debug register
22	MEMU_FLASH_CE		MEMU FLASH correctable Error	No reaction	Clear Status in MEMU	LBIST + Reading preprogrammed Correctable ECC error from UTESTFlash
23	MEMU_FLASH_UCE		MEMU FLASH non-correctable Error	No reaction	Clear Status in MEMU	LBIST + Reading preprogrammed uncorrectable ECC error from UTESTFlash
24	MEMU_FLASH_BOV		MEMU FLASH overflow(2)	No reaction	Clear Status in MEMU	LBIST + Injection of Overflow error indication by MEMU debug register

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
25	RCCU_INTC	RCCU	RCCU error trigger for the INTC	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
26	RCCU_DMA		RCCU error trigger for the DMA	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
27	SAR_012_WDG	ADC	SAR0/1/2 watchdog (or-ed signals)	No reaction	SW clear required in ADCDIG	LBIST + ADC conversion outside the wdg range
28	SAR_012_SPV_WDG		Supervisor SAR0/1/2 watchdog	No reaction	SW clear required in ADCDIG	LBIST + ADC conversion outside the wdg range
29	FM_PLL0	PLL	Loss of lock	No reaction	SW clear required in PLLDIG	Forced loss by PLL reconfiguration
30	FM_PLL1		Loss of lock	No reaction	SW clear required in PLLDIG	Forced loss by PLL reconfiguration

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
31	CMU_0_OSC	CGM (clock monitor units)(4)	Loss of XOSC clock	No reaction	Clear Status in CMU	—
32	CMU_0_PLL0		PLL0 frequency out of range	No reaction	Clear Status in CMU	Test by misconfiguration
33	CMU_1		AHB system clock out of range	No reaction	Clear Status in CMU	Test by misconfiguration
34	CMU_2		IPS clock out of range	No reaction	Clear Status in CMU	Test by misconfiguration
35	FLASH_REF_ERR	Flash	Flash Read Reference Error	No reaction	Clear status through FCCU	LBIST

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
36	FLASH_EDC_AFTER_ECC	Flash controller	EDC after ECC for Flash array	No reaction	Clear status through FCCU	LBIST
37	PFLASH_EDC_AFTER_ECC		EDC after ECC for FLASH Controller	No reaction	Clear status through FCCU	LBIST
38	FLASH_ENC_ERR		Flash encoding error(5)	No reaction	Clear status through FCCU	LBIST
39	PFLASH_ADDR_FDBK_ERR		Flash Controller Address Feedback Error	No reaction	Clear status through FCCU	LBIST

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
40	XBAR	XBIC	XBAR transaction monitor mismatch	No reaction	Clear status through FCCU	LBIST
41	PMC VD BIST	PMC	PMC Voltage Detectors BIST (enabled via SW)	No reaction	Clear status through FCCU	LBIST
42	SSCM_ACTIVE	SSCM	Indication of SSCM spurious activation during application run-time	No reaction	Pulse	Feedback loop via FCCU Fake bit
43	ADDR_FDBK_ERR_ PRAM + RAM_LWB_ERR	RAM controller	System RAM Address Feedback + RAM Late-Write Buffer mismatch	No reaction	Persistent till SW clearing from FCCU	LBIST
44	RCCU_DSMC	RCCU	DSMC RCCU checker	No reaction	Clear status through FCCU	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
45	PRAM_EDC_AFTER_ECC	RAM controller	EDC after ECC for RAM controller (read-modify-write ECC)	No reaction	Persistent till SW clearing from FCCU	LBIST
46	DFT1	TCU	Design For Test : Test circuitry Group 1 unexpected activation	No reaction	Persistent till reset	—
47	DFT2		Design For Test : Test circuitry Group 2 unexpected activation	No reaction	Persistent till reset	—
48	DFT3		Design For Test : Test circuitry Group 3 unexpected activation	No reaction	Persistent till reset	—
49	DFT4		Design For Test : Test circuitry Group 4 unexpected activation	No reaction	Persistent till reset	—
50	MACHINE_CHECK_EXC	CPU	Core machine check exception	No reaction	Pulse, no SW intervention needed	LBIST + Willfully cause an appropriate exception (that is, address a non-existing address)
51[6]	Lockstep Mode	SOC	Indication of disablement of Checker Core or RCCUs	No reaction	Persistent till HW negates it (comes out of debug mode)	Feedback loop via FCCU Fake bit

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
52	Safe Mode	MC_ME	Safe Mode entry indication	No reaction	Persistent till system remains in Safe mode	LBIST + (in principle requesting an RGM "safe mode" but that is not typically something want to do)
53	Compensation Disable	IO	Any of the macro-blocks, dedicated to guarantee that the IO control through the PVT (process, voltage, temperature) compensation cell, has been disabled	No reaction	Persistent till error negation from HW	—
54	CMU_3/4	CGM (clock monitor units)(7)	Peripheral clock out of range	No reaction	Clear Status in CMU	Test by misconfiguration
55	AIPS0_EDC	AIPS0	EDC fail	No reaction	Pulse, no SW intervention needed	LBIST
56	AIPS0_ECC_RCCU		ECC bit generation/correction failure	No reaction	Pulse, no SW intervention needed	LBIST

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
57	AIPS1_EDC	AIPS1	EDC fail	No reaction	Pulse, no SW intervention needed	LBIST
58	AIPS1_ECC_RCCU		ECC bit generation/correction failure	No reaction	Pulse, no SW intervention needed	LBIST
59	RCCU_DMA_MUX	RCCU	RCCU error trigger for the DMA Mux	No reaction	—	LBIST + Feedback loop via FCCU Fake bit and additional RCCU input
60	SAR_345_WDG	ADC	SAR3/4/5 watchdog (or-ed signals)	No reaction	—	LBIST + ADC conversion outside the watchdog range
61	SAR_345_SPV_WDG		Supervisor SAR3/4/5 watchdog	No reaction	—	LBIST + ADC conversion outside the watchdog range
62	ECTU0	CTU	CRC Mismatch output to FCCU	No reaction	—	Feedback loop via FCCU Fake bit

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
63	ECTU1	CTU	CRC Mismatch output to FCCU	No reaction	—	Feedback loop via FCCU Fake bit
64	DMA_GASKET_MON_ERROR	Platform	Monitor error from DMA frequency gasket	No reaction	—	Feedback loop via FCCU Fake bit
65	Flexray_GASKET_MON_ERROR	Platform	Monitor error from Flexray frequency gasket	No reaction	—	Feedback loop via FCCU Fake bit
66	AIPS0_GASKET_MON_ERROR	AIPS	Monitor error from AIPS0 frequency gasket	No reaction	—	Feedback loop via FCCU Fake bit

Table 24. FCCU failure inputs (continued)

67	AIPS1_GASKET_MON_ERROR	AIPS	Monitor error from AIPS1 frequency gasket	No reaction	—	Feedback loop via FCCU Fake bit
68	Flexray EDC after ECC	Platform	Alarm from flexray EDC after ECC	No reaction	—	Feedback loop via FCCU Fake bit
69	PLATFORM/CORE	Platform	CORE 0 D-Cache address ERR	No reaction	—	Feedback loop via FCCU Fake bit
70	PLATFORM/CORE	Platform	CORE 0 D-MEM address ERR	No reaction	—	Feedback loop via FCCU Fake bit

Table 24. FCCU failure inputs (continued)

FCCU input	Input trigger name	IP	Description	Default reaction after Reset	HW fault behaviour	Error reaction path check
71	PLATFORM/CORE	Platform	CORE 0 I-Cache address ERR	No reaction	—	Feedback loop via FCCU Fake bit
72	IMEM Acess monitor	Platform	Imem access monitor error	No reaction	—	Feedback loop via FCCU Fake bit
73	PMC_DIG	PMC	QVF FCCU error	No reaction	—	Feedback loop via FCCU Fake bit
74	PLATFORM/CORE	Platform	FCCU alarm from SMPU	No reaction	—	Feedback loop via FCCU Fake bit
75	PLATFORM/CORE	Platform	Monitor error from SMPU	No reaction	—	Feedback loop via FCCU Fake bit

1. The STCU2 error conditions can be configured as unrecoverable or recoverable. The effect is to trigger two different output triggers, which are are mapped to separate fault inputs of the FCCU.
2. This signal is driven by the “intg_debug” logic and it is asserted if the either TRST or TMS signals are high or if the Nexus or DCI controller report an operative status of the Nexus or debug resources.
3. This signal indicates that the correctable, non-correctable, or overflow error triggers are asserted at the same time. This signal is the result of a logical “OR” of “memu_xxxx_corr_err_oflw_flag”, “memu_xxxx_uncorr_err_oflw_flag”, and “memu_xxxx_err_buf_oflw_flag” done within the “intg_fccu” glue logic, put between the MEMU and the FCCU

4. For each CMU, the output alarm signals go through the “intg_fccu” where they are OR-ed together into one single FCCU input fault trigger.
5. The Flash re-calculate the ECC bits and compare them with the one received by the Flash controller. This signal is triggered in case of mismatch. The signal is also triggered by a mismatch between the latched address and the one rebuilt inside the Flash to address the memory array.
6. Since lockstep operation is not guaranteed in debug and stop mode, lockstep is disabled. When the debugger is connected to device this FCCU fault may set. It is suggested to Ignore this fault when operating in lockstep during debug mode.
7. For each CMU, the output alarm signals go through the “intg_fccu” where they are OR-ed together into one single FCCU input fault trigger.

6.4.8 Failure indication

Failure of the MCU is signaled via two pins: F0 and F1.

There are different configurable protocols to indicate a failure via the one or two pins.

At least one of the failure indication pins is high to indicate “operational”. This is true independent of the way the error output pins are configured to indicate a failure.

In case a two-pin bi-stable protocol with different outputs on both pins is implemented, the operational high pin is configurable.

In case of Time Switching protocol the default toggling frequency is less than 100 Hz.

Failure indication via the pin(s) is controlled by the FCCU.

After power-on the error out pins either have high impedance or are in a state that indicates an error. They go to “operational” state only on software request.

In case of a failure event or on software request for error indication, the pin(s) are set to “failure” for a minimum time T_min, even if software tries to release it before.
T_min = 250 µs + delta_T, with delta_T configurable by software up to 10 ms.

In case another failure event occurs within T_min after a previous failure, the “minimal failure indication time” is restarted.

Functional reset does not influence the failure indication state.

At the onset of a “failure” indication on an error pin, the duration of the low state since the last trigger is available to the system.

After the timer has expired (timer > T_min), software can set the error pin back to high.

Software can activate error pins to verify the integrity of the reaction path.

6.4.9 Latent fault detection

SPC574Sx supports some mechanisms to detect faults which can become latent. Two important mechanisms dedicated to this functionality are LBIST and MBIST.

If a safety measure cannot be tested by LBIST, a mechanism is included whereby software can detect its (in)correct function.

The LBIST (or other measures for all logic) targets at least 90% coverage of direct current (d.c.) faults at gate level for digital logic. (See ISO 26262-5 table D.1 for definition of d.c. faults). Coverage can be limited to 60% for peripheral modules.

If one of the built-in selftests fails, either hardware or software prevents normal operation from starting. Failure in this context means:

- Any error detected by the LBIST
- MBIST reports any multi-bit error or more than report the fault table depth single-bit
- Any error in any other selftest module including the selftest controller itself

Self tests can be executed during startup or during operation.

When detection is used, the availability of a safety mechanism and particularly of the corresponding fault reaction path is testable by software via “fake fault” injections following one of the following approaches:

- Memory content manipulation (for example, for Flash and RAM)
- Threshold manipulation (for example, for CMU, LVD/HVDs, SWT)
- Bit-level fault injection (for example, for RCCUs, protocol checkers, EDC, MEMU)

6.4.10 Common Cause Failures (CCFs)

Various prevention and/or detection measures have been included to cover CCFs. These include supervision of configuration registers, SW malfunction, internal signals related to test and debug, temperature and voltage, physical separation of modules on the die.

Configuration registers which can affect the execution of the MCU’s safety function and simultaneously disable the safety mechanism due to their change, are protected against bit flips or those flips are detected by independent measures.

Such registers are also protected against accidental software writes (software register protection).

Failures of control logic/signals do not cause similar failures in both channels or deactivate safety measures. At least the following logic/signals belong to this class:

- Debug circuitry (including on-die JTAG generators)
- Test circuitry
- Mode selection

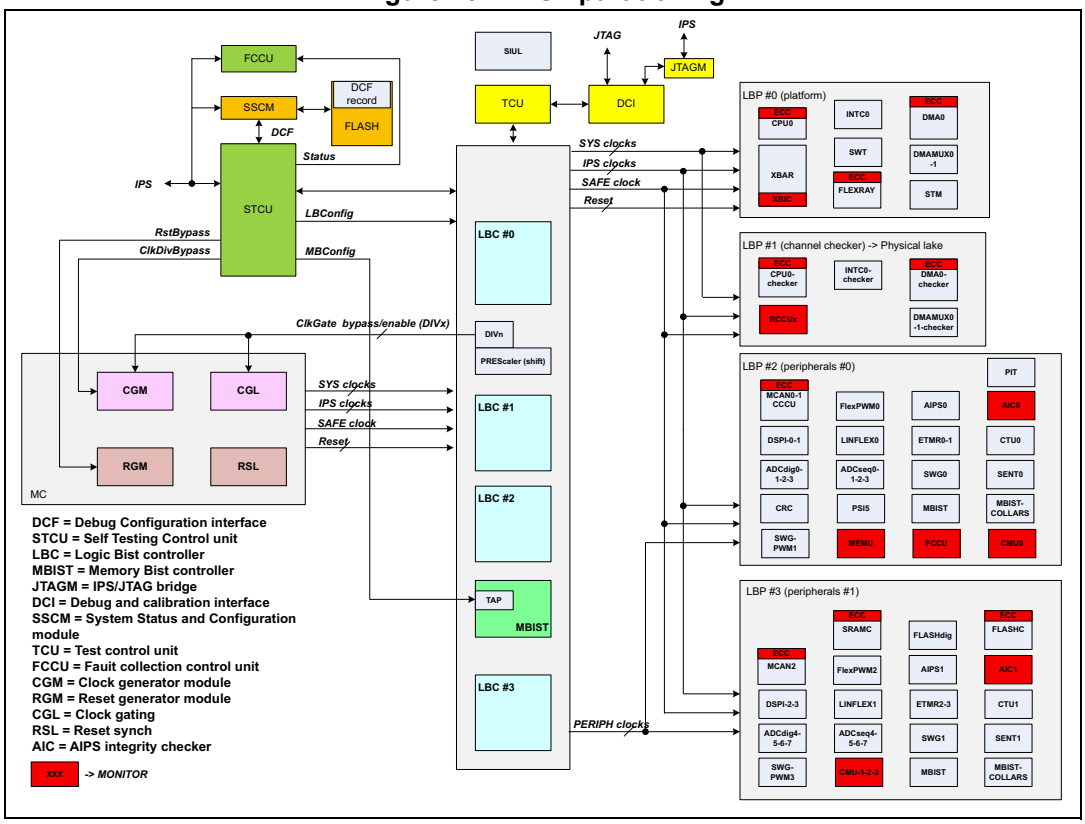
Pads for redundant signals are distributed over the pad ring as far as possible to avoid redundant signal inputs/outputs to be adjacent. The user will avoid configurations that place redundant signals on neighboring pads or pins.

6.4.11 Resets

A transient single point fault (specifically a single-bit flip in a register) can not cause a reset of an individual module (that is a partial reset).

Note: Resetting the whole MCU is acceptable.

There is a measure to detect a loop of functional resets and resolve it by causing a destructive escalation.



There is be a measure to detect a loop of destructive resets and keep the device in reset (for example by not releasing the reset signal) if detected.

Software is capable of resetting the device even if the IRCOSC has failed.

6.4.12 LBIST / MBIST architecture

The Logic BIST partitioning is provided in *Figure 23*.

Figure 23. LBIST partitioning

The Memory BIST partitioning is provided in *Table 25* :

Table 25. MBIST partitioning

M_BIST	Partition	start_address	end_address
0	dmem_0	0x5000_0000	0x5000_7FFF
1	dmem_1	0x5000_8000	0x5000_FFFF
2	icache_0	not addressable	
3	icache_1	not addressable

16	dcache-1	not addressable	
17	dcache-2	not addressable	
18	dcache-3	not addressable	
19	dtag	not addressable	
20	bam_rom	not addressable	

The settings of LBIST / MBIST configurations described as preliminary data in *Table 26* are provided *Section 7.11.6.1: BIST Configuration* of *Chapter 7: Device configuration*.

Note: All configurations can run both in offline and in online mode. The reader shall follow the configuration indicated below and take care about choosing the relevant STCU registers depending on online or offline mode

Process time considers the IRC as frequency source in offline and XOSC in online mode (time at nominal source clock frequency)

The power consumption data are enclosed in the final device datasheet release

Table 26. LBIST / MBIST configurations(1)

Number	Description	BIST	Mode	Frequency settings	Number of patterns	Process time (ms)	Configuration(2)
1	All MBISTs in parallel mode	MBIST	Parallel	40 MHz (PLL)	—	26.00	Mbist Conf_1_offline
				128 MHz (PLL)	—	9.00	Mbist Conf_1_online
2	All LBISTs in parallel mode	LBIST	Parallel	35 MHz (PLL)	5K (0x1388)	13.2	Lbist Conf_2_offline Conf_2_online

Table 26. LBIST / MBIST configurations(1) (continued)

Number	Description	BIST	Mode	Frequency settings	Number of patterns	Process time (ms)	Configuration(2)
3	Full self test (LBIST + MBIST)	LBIST	Parallel	16 MHz (RC)	5K (0x1388)	30.00	Full Selftest Conf_3_offline Conf_3_online

				128 MHz (PLL)	—	9.00	Mbist Conf_3_online
4	Full self test (LBIST + MBIST)	LBIST	Sequential	35 MHz (PLL)	5K (0x1388)	50.00	Full Selftest Conf_4_offline Conf_4_online
		MBIST			—	88.00	
5	Full self test (LBIST + MBIST)	LBIST	L0//L1 + L2//L3	35 MHz (PLL)	5K (0x1388)	27.00	Full Selftest Conf_5_offline Conf_5_online
		MBIST	Parallel		—	30.00	

1. The timing has been measured by programming only STCU related DCF clients. Timing may change based on actual DCF clients programmed.
2. For detail about the configuration see *Section 7.11.6.1: BIST Configuration* of *Chapter 7: Device configuration*.

6.5 Register classifications

- Safety Critical – Capable of causing a violation of the Safety Goal and disabling the safety mechanism at the same time
- Safety Latent – Capable of disabling a safety mechanism
- Safety Relevant – Capable of causing a violation of the Safety Goal
- Not Safety Relevant – Does not fall into any of the other three classifications

7 Device configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device,
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters, and
- Links for more information.

7.2 Core modules

The SPC574Sx has two z4 cores that perform various computational and control functions. The main core is a e200z420n3 core and is used for general computational functions. The second core, referred to as the Checker Core, uses an e200z419 core which is a true subset of the e200z420n3 core. When enabled, the Checker Core operates in lock step mode with the Main Core executing exactly the same instructions as the Main Core. Thus, the Checker Core checks to insure that the Main Core is executing correctly.

For more information, please see *Chapter 12: Core e200z420n3 Description*.

7.2.1 Core Reset Settings

Table 27 shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately following a system reset.

Table 27. Reset settings for Z resources

Resource	System reset setting

1. The levels that determine these bits are set by the factory and may change between revisions of the device.
2. Undefined on **m_por** assertion, unchanged on **p_reset_b** assertion
3. Reset by processor reset **p_reset_b** if DBCR0[EDM]=0, as well as unconditionally by **m_por**.
4. Read-only registers

7.2.2 Special Purpose Register Summary

PowerISA 2.06 and implementation-specific SPRs for the e200z420n3 and e200z419 cores are listed in *Table 28*. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in *Table 28*.

Table 28. Special Purpose Registers

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No
CTR	Count Register	9	R/W	No	No
SRR0	Save/Restore Register 0	26	R/W	Yes	No
SRR1	Save/Restore Register 1	27	R/W	Yes	No
PID0	Process ID Register	48	R/W	Yes	No
CSRR0	Critical Save/Restore Register 0	58	R/W	Yes	No
CSRR1	Critical Save/Restore Register 1	59	R/W	Yes	No

Table 28. Special Purpose Registers (continued)

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
DEAR	Data Exception Address Register	61	R/W	Yes	No
ESR	Exception Syndrome Register	62	R/W	Yes	No
IVPR	Interrupt Vector Prefix Register	63	R/W	Yes	No
SPRG0	SPR General 0	272	R/W	Yes	No

L1CSR1	L1 cache control and status register 1	1011	R/W	Yes	Yes
BUCSR	Branch Unit Control and Status Register	1013	R/W	Yes	Yes
MPUCSR0	MPU configuration register	1014	R/W	Yes	Yes
MMUCFG	MMU/MPU configuration register	1015	Read-only	Yes	Yes
L1FINV0	L1 cache flush and invalidate control register 0	1016	R/W	Yes	Yes
SVR	System Version Register	1023	Read-only	Yes	Yes

1. The Debug Status Register can be read using *mfspr RT,DBSR*. The Debug Status Register cannot be directly written to. Instead, bits in the Debug Status Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr DBSR,RS*.
2. The Machine Check Syndrome Register can be read using *mfspr RT,MCSR*. The Machine Check Syndrome Register cannot be directly written to. Instead, bits in the Machine Check Syndrome Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr MCSR,RS*.

7.3 System modules

7.3.1 SIUL2 configuration

The System Integration Unit Lite 2 (SIUL2) controls the MCU pad configuration, ports, general-purpose input and output (GPIO) signals and external interrupts with trigger event configuration.

For details please refer *Chapter 14: System Integration Unit Lite2 (SIUL2)*.

7.3.2 Crossbar switch

This device contains one crossbar switch module.

7.3.2.1 Crossbar switch (XBAR) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see *Chapter 13: Crossbar switch (XBAR)*.

Figure 24. Computational shell's crossbar switch integration

Crossbar switch slave	Flash memory controller	*Section 3.2.2: Flash memory*
	System RAM	*Section 3.2.1: SRAM*
System memory map	—	*Chapter 5: Memory map*

7.3.2.1.1 Crossbar switch master assignments

This device contains three masters connected to the crossbar switch.

Table 30 contains the master assignments.

Table 30. Crossbar switch master assignments

Master module	Physical master port number
Core_0 instruction bus	0
Core_0 data bus	1
DMA	2
FlexRay	3

7.3.2.1.2 Crossbar switch slave assignments

This device contains five slaves connected to the crossbar switch.

Table 31 contains the slave assignments.

Table 31. Crossbar switch slave assignments

Slave module	Physical slave port number
Flash memory controller port 0	0
CPU TCM backdoor	1
RAM controller	2
PBRIDGE_0	3
PBRIDGE_1	4

7.3.3 System Memory Protection Unit (SMPU) configuration

SPC574Sx contains one instance of the System Memory Protection Unit (SMPU). The following sections explain how SMPU_0 is configured on this chip.

7.3.3.1 SMPU_0 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the SMPU module itself, see the module's dedicated chapter.

Figure 25. SMPU_0 configuration

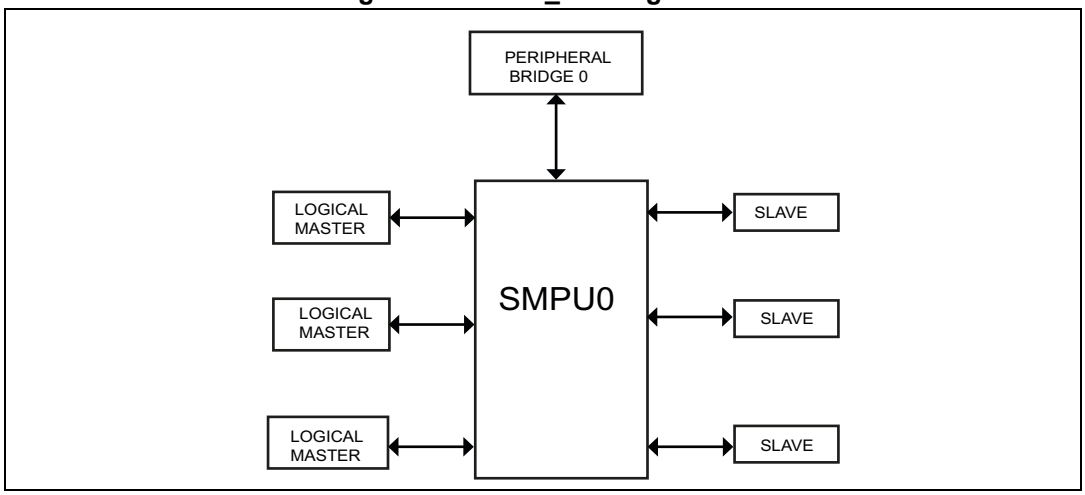

Table 32. Reference links to related information

Topic	Related module	Reference
Full description	System Memory Protection Unit (SMPU)	*Chapter 17: System Memory Protection Unit (SMPU)*
System memory map	—	*Chapter 5: Memory map*
Clocking	—	*Chapter 24: Clocking*
Power management	—	*Chapter 10: Power management*
Logical masters	—	*Section 7.3.3.2: SMPU_0 logical bus master assignments*
Region descriptors	—	*Section 7.3.3.3: Number of region descriptors supported by SMPU_0*
RGD_WORD2 formats	—	*Section 7.3.3.4: RGD_WORD2 formats supported by SMPU_0*

7.3.3.2 SMPU_0 logical bus master assignments

Table 33 contains the logical bus master assignments for the SMPU_0.

Table 33. SMPU_0 logical bus master assignments

SMPU logical bus master number	Bus master
0	Core_0
3	DMA
5	FlexRay
8	Core_0 Debug

7.3.3.3 Number of region descriptors supported by SMPU_0

This instance of the SMPU module supports up to eight region descriptors.

7.3.3.4 RGD_WORD2 formats supported by SMPU_0

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.3.5 Master Access permissions for SMPU_0

The only master allowed to access the SMPU_0 registers is Core_0. It is also required that the core be in supervisor mode.

7.3.4 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 26. Peripheral bridge configuration

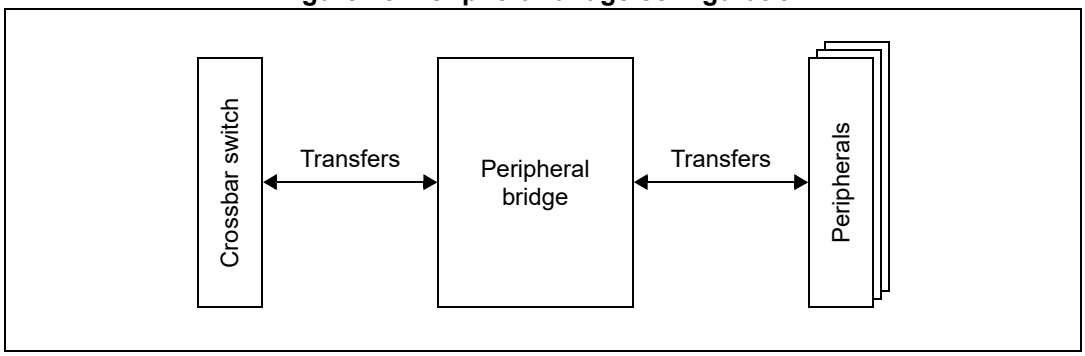

Table 34. Reference links to related information

Topic	Related module	Reference
Full description	Peripheral bridge	*Chapter 16: Peripheral bridge*
System memory map	—	*Chapter 5: Memory map*
Clocking	—	*Chapter 24: Clocking*
Crossbar switch	Crossbar switch	*Section 7.3.2: Crossbar switch*

7.3.4.1 Peripheral bridge instantiation

This device contains two identical peripheral bridges: PBRIDGE_0 and PBRIDGE_1.

7.3.4.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See *Chapter 5: Memory map* for the memory slot assignment for each module.

7.3.4.3 MPR registers

Each of the two peripheral bridges supports up to eight crossbar switch masters, each assigned to a MPROT*n* field in the MPRA registers. However, fewer are supported on this device. See *Section 7.3.2: Crossbar switch* for details of the master port assignments for this device.

7.3.4.4 PACR/OPACR registers

Each of the two peripheral bridges support up to 320 peripherals, each assigned to a PACR*n* or OPACR*n* field within the PACRA-H/OPACRA-AF registers. However, fewer peripherals are supported on this device. See *Chapter 5: Memory map* for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

7.3.5 Interrupt controller (INTC) configuration

7.3.5.1 INTC configurable parameters

The INTC on this chip supports 1 processor.

7.3.5.2 INTC implemented registers

Table 35 shows the registers implemented on the INTC on this chip.

Table 35. INTC implemented registers

Address offset	Register
0x0000	INTC Block Configuration Register (INTC_BCR)
0x0004	INTC Master Protection Register (INTC_MPROT)
0x0010	INTC Current Priority Register for Processor 0 (INTC_CPR0)
0x0020	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)
0x0030	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)
0x0040–0x005C	INTC Software Set/Clear Interrupt Register 0_3 (INTC_SSCIR0_3) – INTC Software Set/Clear Interrupt Register 28_31 (INTC_SSCIR28_31)
0x0060–0x085E	INTC Priority Select Register 0_1 (INTC_PSR0_1) – INTC Priority Select Register 1022_1023 (INTC_PSR1022_1023)

7.3.5.3 Interrupt channel map

Table 36 shows the list of interrupt channels.

Table 36. Interrupt channel map

Number	Description	Register bit / Signal name
0 - 31	Software interrupt flag 0 - 31	INTC_SSCIR0-7[SET/CLR0-3]

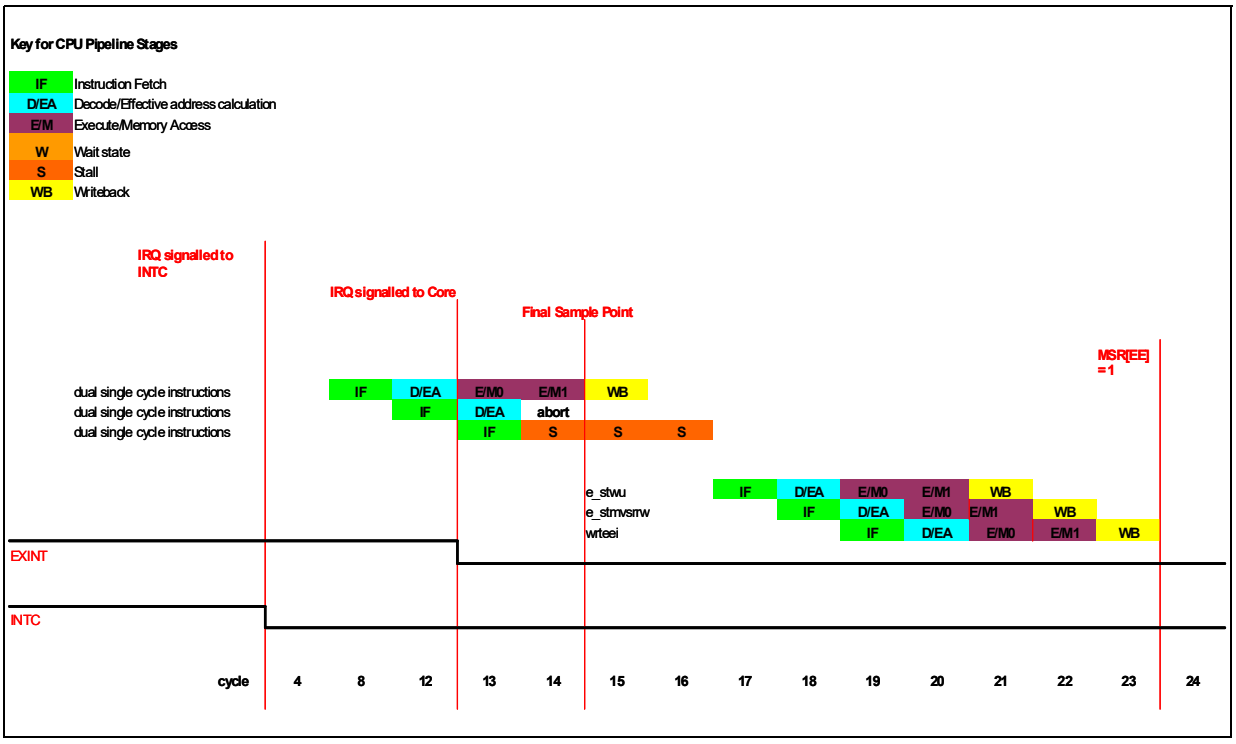
7.3.5.4 Interrupt latency

The Interrupt systems is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

The latency time is difficult to define exactly because it depends on what interrupts the INTC is processing and what the CPU is doing.



In general, the latency time is divided into three subsections:

- INTC Latency
  - 3 clock cycles (INTC clock domain) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency
  - 4 clock cycles (CPU clock domain) from the assertion of the interrupt request from the INTC to the execution of the first instruction
- Software Latency
  - 7 clock cycles (CPU clock domain) to execute the three instructions needed to save essential registers and enable interrupts

For the SPC574Sx, the INTC operates at 70 MHz and the CPU operates at 140 MHz. Interrupt latency is:

INTC Latency = 43 ns
CPU Latency = 28.6 ns
Software Latency = 50 ns
Interrupt Latency Total = 121.6 ns

Figure 27. Interrupt timing

7.3.6 DMA controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter in the device reference manual.

7.3.7 DMA channel multiplexer (DMACHMUX) configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.3.7.1 DMA channel assignment

SPC574Sx has two multiplexers. *Table 38* lists which channels apply to each multiplexer.

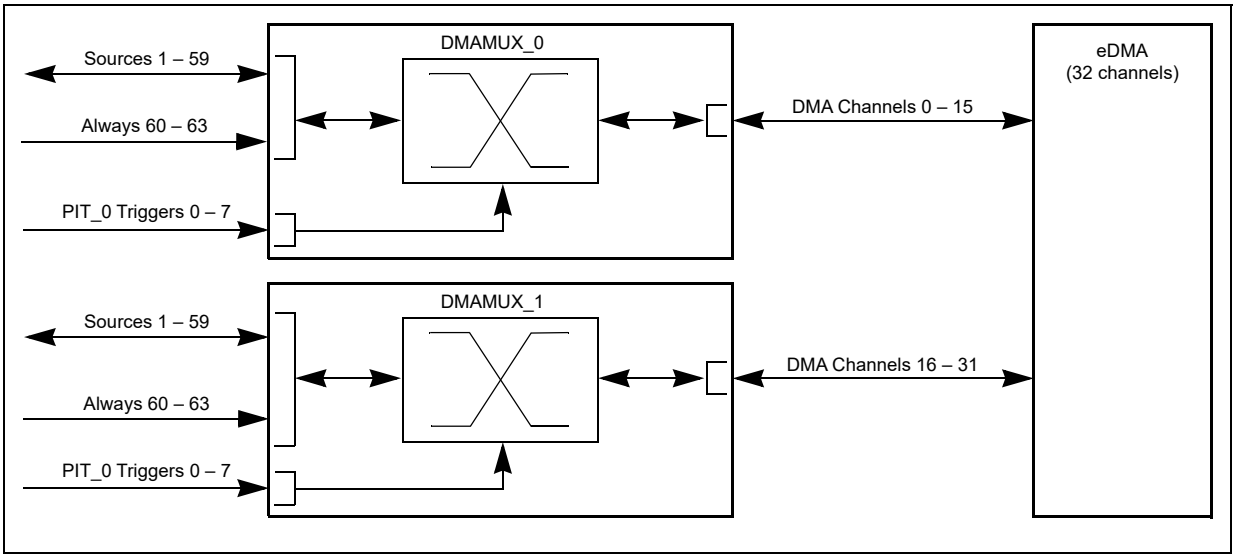

Table 38. SPC574Sx multiplexer and channel list

DMACHMUX instance	DMA channel
0	0–15
1	16–31

7.3.7.2 Block diagram

The connections of the DMA channel multiplexers to the eDMA are shown in *Figure 29*. One DMACHMUX is instantiated for every sixteen DMA channels.

Figure 29. DMA channel multiplexing

7.3.7.3 DMA request mapping

The mapping of the peripheral DMA requests to the DMA_CH_MUX input sources is shown in *Table 39*.

7.3.7.4 Platform Configuration Module (PCM)

The Platform Configuration Module (PCM) contains one register. This PCM register is used for controlling different aspects of the Platform functionality including the Frequency Gasket Configurations of the Intelligent Bus Bridging Gaskets.

The PCM module is mapped to PBRIDGE_0 on platform slot 10. Its base address is 0xFC02_8000.

7.3.8 Wakeup unit (WKPU) configuration

The WKPU supports 4 NMI sources. Please refer to *Chapter 22: Wakeup unit (WKPU)* for details.

In *Figure 31: Wakeup unit Block Diagram*, it has to be noted that only one filter is implemented.

Figure 31. Wakeup unit Block Diagram

NMI[0] and NMI[3] sources are tied together while NMI[1] and NMI[2] sources are tied to '1' (refer to *Section 22.2.2.1: NMI Status Flag Register (NSR)*).

Although access to all the bits in the *Section 22.2.2.2: NMI Configuration Register (NCR)* is read/write, writing is only effective for the bits corresponding to NMI[0] and NMI[3].

7.3.9 Crossbar integrity checker (XBIC)

- XBIC master definition follows the AHB master.
- XBIC slave definition follows the XBAR slave numbering (see *Section 7.3.2.1.2: Crossbar switch slave assignments*).

7.4 Clocking

See *Chapter 24: Clocking* for a description of the architecture for the system level clocks including clock generation, the clock sources and the peripheral clocks. The chapter also provides configuration details for the Clock Monitor Unit (CMU).

7.5 Memories and memory interfaces

See the following chapters for detailed information on memories and memory interfaces.

Embedded flash memory	—	*Chapter 32: Embedded Flash Memory*

7.5.1 Flash memory controller (PFLASH) configuration

The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on.

The master assignments are shown in the following table. Note that these are the same master assignments used elsewhere in the chip, e.g., the SMPU.

Table 43. Flash controller bus master assignments

7.5.2 Decorated Storage Memory Controller (DSMC)

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR, and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles

introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The DSMC is instantiated within the core platform and physically resides between the CPU data AHB bus and the associated crossbar master port.

Due to this architecture choice, the DSMC can access the whole addressing space.

7.6 Analog modules

This section highlights the following analog modules that are implemented on SPC574Sx:

Table 45. Reference links to related information

Module or Subsystem	Device-specific information	Block details
Temperature sensor	*Section 7.6.1: Temperature sensor configuration*	*Chapter 23: Temperature sensor (TSENS)*
ADC subsystem	*Section 33.2: Overview*	—
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	*Section 33.2: Overview*	*Chapter 33: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface*

7.6.1 Temperature sensor configuration

The temperature sensor is used to measure the temperature of the SPC574Sx devices. In general, the temperature sensor generates an analog voltage that is linearly proportional to temperature. Refer to *Section 23.5: Obtaining device temperature using TSENS* in *Chapter 23: Temperature sensor (TSENS)*

7.6.2 SARADC

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

SPC574Sx implements eight independent 12-bit successive approximation register analog-to-digital converters (SARADCs). The numbering scheme is aligned along the complete family of devices. The SARADCs on the device are referred to as SARADC_B and SARADC_B1(16:1 input mux) and SARADC_0, SARADC_1, SARADC_2, SARADC_3, SARADC_4, and SARADC_5 (maximum 8:1 input mux for each).

7.6.2.1 Register definitions

Each of the following sections shows register definitions for one SARADC instance:

- *Section 7.6.2.1.1: SARADC_B0 register definitions*
- *Section 7.6.2.1.2: SARADC_0 register definitions*
- *Section 7.6.2.1.3: SAR ADC_1 register definitions*
- *Section 7.6.2.1.4: SAR ADC_2 register definitions*
- *Section 7.6.2.1.5: SAR ADC_B1 register definitions*
- *Section 7.6.2.1.6: SAR ADC_3 register definitions*
- *Section 7.6.2.1.7: SAR ADC_4 register definitions*
- *Section 7.6.2.1.8: SAR ADC_5 register definitions*

Table 46: SARADC register descriptions provides a key for the register definition tables. Test channels are only used for SARADC_B.

Note: The following best configurations (in terms of timing) are supported for the SARADC (12 bits) at 12 MHz clock frequency:

1. ICDR[PCE] = 1 (pre-charge enabled)
   - CTRn[PRECHG] = 1 (1 pre-charge cycle)
   - CTRn[INPSAMP] = 6 (6 sampling cycles)
   - 19 clock cycles of total conversion time (1 + 6 + 12)
2. ICDR[PCE] = 0 (pre-charge disabled))
   - CTRn[PRECHG] = 0
   - CTRn[INPSAMP] = 6 (6 sampling cycles)
   - 18 clock cycles of total conversion time (6 + 12)

7.7 Motor control modules

7.7.1 ECTU

This device contains two ECTU, one per each ADC group, modules with the following features:

- Up to 4 ADCs can be controlled by each single CTU
- 8 sequential triggers based on trigger CMP registers (double buffered)
- Command list (64 descriptors double buffered)
- Up to 128 ADC channels per unit
- Single/multiple conversion
- Up to 8 FIFOs for data buffering
- Up to 8 + 1 DMA channels for data transfer and control

7.7.1.1 Cross triggering unit configuration status register 2

Offset: 0x051C Access: User Read

Figure 32. CTU_CFGSR2 register

7.7.1.2 Interaction with other peripherals

Figure 33. Module to module connections

1. For further details, refer to *Table 13: Peripheral multiplexing table description*.

7.7.2 eTimer

7.7.2.1 eTimer instantiation

SPC574Sx includes four 6-channel eTimer units. The following table provides the instantiation information for each module.

Table 64. eTimer instantiation

eTimer module	CH_NUM	AUX_NUM	FAULT_NUM	DMA_NUM	WDOG
eTimer_0	6	2	0	2	Yes
eTimer_1	6	2	0	2	Yes
eTimer_2	6	2	0	2	Yes
eTimer_3	6	2	0	2	Yes

The eTimer fault inputs are not connected to external pins but to ETC outputs. Refer to *Table 13: Peripheral multiplexing table description* for more details.

7.7.3 FlexPWM

7.7.3.1 FlexPWM configurable parameters

This device contains four FlexPWM modules with the following features:

- FlexPWM_0 and FlexPWM_2.
  - 4 Submodules
  - Support of PWM output capabilitites of third output channel per submodule (PWMX)
  - 4 Fault Inputs for each instantiation
- FlexPWM_1 and FlexPWM_3.
  - 2 Submodules
  - Support of PWM output capabilitites of first and second output channels per submodule (PWMA and PWMB)

Table 65 shows the parameters for all FlexPWM instantiations.

Table 65. FlexPWM Device Specific Parameters

Parameter Type	Description	FlexPWM_0 / FlexPWM_2	FlexPWM_1 / FlexPWM_3
SUB_NUM	Number of submodules	4	2
FNUM	Number of fault inputs	4	0
FIFO_DEPTH	Input capture FIFO depth	4	4
INPCAPT_AB	Include input capture on PWMA and PWMB pins	No	Yes
INPCAPT_X	Include input capture on PWMX pins	Yes	No
CYC_WIDTH	Capture value cycles reg width	3	3
FRAC	Include fine control logic	No	No

7.7.3.2 FlexPWM Interrupts

Table 66. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_comp0	CMPF_0	CMPIE_0	Submodule 0 compare interrupt	Compare event has occurred
ipi_int_capt0	CFX1_0, CFX0_0	CFX1IE_0, CFX0IE_0	Submodule 0 input capture interrupt	Input capture event has occurred
ipi_int_reload0	RF_0	RIE_0	Submodule 0 reload interrupt	Reload event has occurred
ipi_int_comp1	CMPF_1	CMPIE_1	Submodule 1 compare interrupt	Compare event has occurred
ipi_int_capt1	CFA1_1, CFA0_1, CFB1_1, CFB0_1,	CFA1IE_1, CFA0IE_1, CFB1IE_1, CFB0IE_1,	Submodule 1 input capture interrupt	Input capture event has occurred
ipi_int_reload1	RF_1	RIE_1	Submodule 1 reload interrupt	Reload event has occurred
ipi_int_comp2	CMPF_2	CMPIE_2	Submodule 2 compare interrupt	Compare event has occurred
ipi_int_capt2	CFA1_2, CFA0_2, CFB1_2, CFB0_2,	CFA1IE_2, CFA0IE_2, CFB1IE_2, CFB0IE_2,	Submodule 2 input capture interrupt	Input capture event has occurred
ipi_int_reload2	RF_2	RIE_2	Submodule 2 reload interrupt	Reload event has occurred
ipi_int_comp3	CMPF_3	CMPIE_3	Submodule 3 compare interrupt	Compare event has occurred
ipi_int_capt3	CFX1_3, CFX0_3	CFX1IE_3, CFX0IE_3	Submodule 3 input capture interrupt	Input capture event has occurred
ipi_int_reload3	RF_3	RIE_3	Submodule 3 reload interrupt	Reload event has occurred
ipi_int_rerr	REF_0	REIE_0	Submodule 0 reload error interrupt	Reload error has occurred
	REF_1	REIE_1	Submodule 1 reload error interrupt	
	REF_2	REIE_2	Submodule 2 reload error interrupt	
	REF_3	REIE_3	Submodule 3 reload error interrupt	
ipi_int_fault	FFLAG	FIE	Fault input interrupt	Fault condition has been detected

7.7.3.3 FlexPWM implemented registers

Each of the following sections shows register definitions for one FlewPWM instance:

- *Section 7.7.3.3.1: FlexPWM_0 register definitions*
- *Section 7.7.3.3.2: FlexPWM_1 register definitions*
- *Section 7.7.3.3.3: FlexPWM_2 register definitions*
- *Section 7.7.3.3.4: FlexPWM_3 register definitions*

7.7.3.3.1 FlexPWM_0 register definitions

FlexPWM_0 implements four submodules then the index n is from 0 to 3.

7.7.3.4 FlexPWM DMA

Table 71. DMA Summary

DMA Request	DMA Enable	Name	Description
Submodule 0 read request	CX0DE_0	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_0	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_0	Capture FIFO read request source select	Selects source of read DMA request
Submodule 0 write request	VALDE_0	VALx write request	VALx registers need to be updated
Submodule 1 read request	CA0DE_1	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_1	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_1	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_1	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_1	Capture FIFO read request source select	Selects source of read DMA request
Submodule 1 write request	VALDE_1	VALx write request	VALx registers need to be updated
Submodule 2 read request	CX0DE_2	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_2	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_2	Capture FIFO read request source select	Selects source of read DMA request
Submodule 2 write request	VALDE_2	VALx write request	VALx registers need to be updated
Submodule 3 read request	CA0DE_3	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_3	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_3	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_3	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_3	Capture FIFO read request source select	Selects source of read DMA request
Submodule 3 write request	VALDE_3	VALx write request	VALx registers need to be updated

7.8 Timers

Four types of timers and a complex timer subsystem are implemented on SPC574Sx.

7.8.1 System Timer Module (STM) configuration

SPC574Sx includes one STM.

Table 72. System Timer Module (STM) instances

Instance	Description	Number of channels	Number of registers (32-bit)
STM_0	Intended for Main Core_0 in the high-speed computational clock domain	4	14

7.8.2 Software Watchdog Timer (SWT) configuration

SPC574Sx includes one SWT.

Table 73. Software Watchdog Timer (SWT) instances

Instance	Description
SWT	Intended for Main Core in the high-speed computational clock domain.

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of system or internal oscillator clock for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.8.2.1 Reset assertion

The SWT can assert a reset when the watchdog timer expires. This reset causes a system reset equivalent to assertion of the RESET pin.

7.8.2.1.1 Default configuration

On SPC574Sx, the SWT comes out of reset with the default reset values summarized in *Table 74*. Minimum timeout value is 256 cycles.

Table 74. Register reset values

SWT instance	Register	Reset value
SWT2	SWT Control Register (SWT_CR)(1)	0xFF00_011B
SWT2	SWT Time-out (SWT_TO)	0x0003_FDE0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is ‘1’, but the DCI can override that default value by setting it to ‘0’. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT; it cannot enable it.) See the DCI chapter for details on the system watchdog control.

7.8.3 Periodic Interupt Timer (PIT) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

Figure 34. PIT configuration

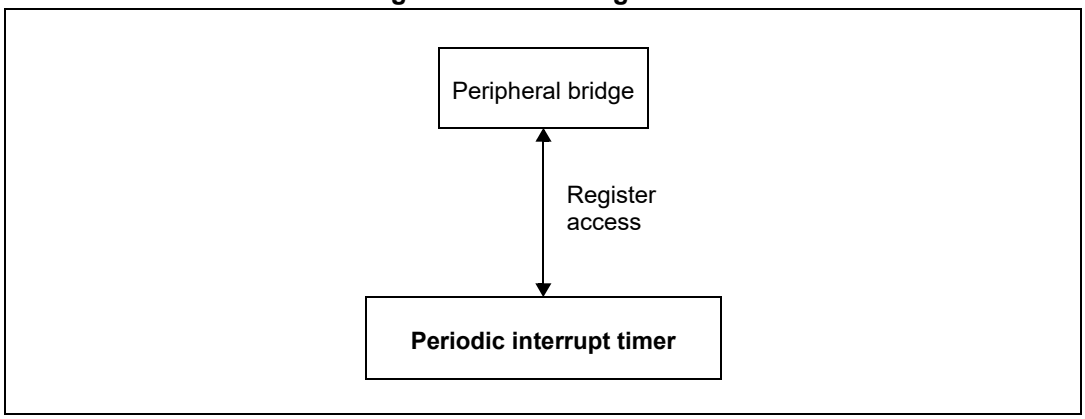

Table 75. Reference links to related information

Topic	Related module	Reference
Full description	PIT	*Chapter 41: Periodic Interrupt Timer (PIT)*
System memory map	—	*Chapter 5: Memory map*
Clocking	—	*Chapter 24: Clocking*
Power management	—	*Chapter 10: Power management*
DMA channel assignments	Direct memory access channel multiplexer	*Chapter 21: DMA channel multiplexer (DMACHMUX)*

7.8.3.1 PIT instantiation

Table 76. PIT information

PIT module instances	PIT channels	Description
1	8	The PIT has eight standard channels. All PIT registers are cleared by any reset.

7.8.3.2 PIT/DMA periodic trigger assignments

The PIT generates periodic trigger events to the DMACHMUX. To check the mapping of the PIT channel number with the corresponding DMA channel number, refer to the *Table 40: PIT_0 periodic trigger to DMA channel mapping*.

7.8.3.3 PIT clocking

The PIT standard channels are clocked with the peripheral clock (PER_CLK).

7.9 Communication interfaces

7.9.1 CAN subsystem configuration

7.9.1.1 CAN nodes

Table 77 lists the different CAN nodes.

Table 77. CAN bus controllers

Subsystem	Type	Instance	CAN FD support up to 64 data byte (M_CAN Rev 3.x)	Debug on CAN support	Clock calibration(1)
CAN_SUBSYS_0	M_CAN	MCAN_0	Yes	Yes	Yes
		MCAN_2	Yes	Yes	Yes
CAN_SUBSYS_1	M_CAN	MCAN_1	Yes	Yes	Yes

1. Clock calibration based on M_CAN_0 messages for CAN_SUBSYS_0.
Clock calibration based on M_CAN_1 messages for CAN_SUBSYS_1.

7.9.2 DSPI configuration

This section summarizes how the module has been configured in the chip.

DSPI module features:

- Transmission speed: 14 MHz
- Frame size: Programmable from 4-bits up to 32-bits in extended mode. Frame size is set inside the DSPI_CTARn descriptor. Extended DSPI mode is set inside the DSPI_MCR register
- Chip selects: 8
- FIFO depths: 4

The DSPI module operates in SPI configuration. The DSPI module cannot be configured to operate in DSI or CSI modes.

Figure 35. DSPI configuration

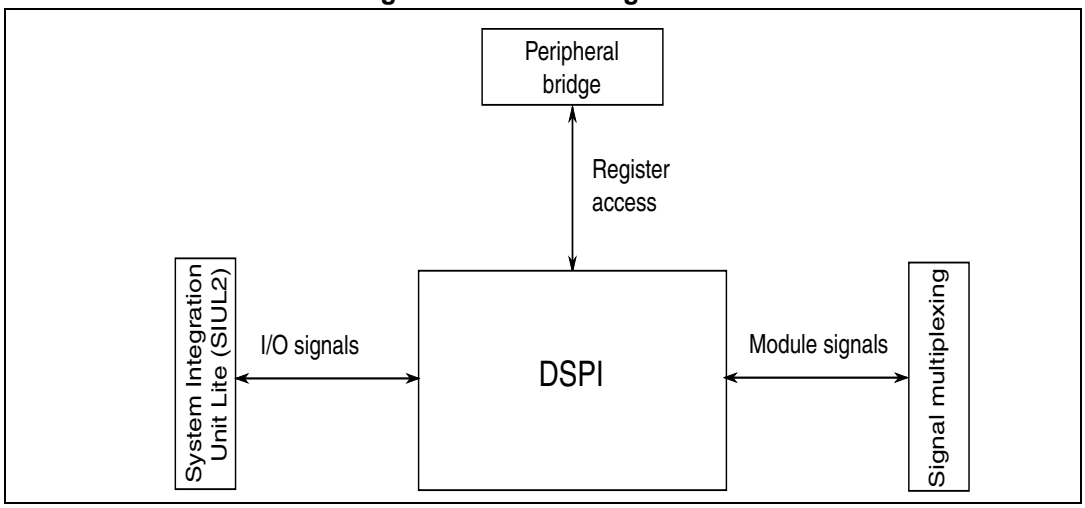

Table 78. Reference links to related information

Topic	Related module	Reference
Full description	DSPI	*Chapter 43: Deserial Serial Peripheral Interface (DSPI)*
System memory map	—	*Chapter 5: Memory map*
Clocking	—	*Chapter 24: Clocking*
Signal multiplexing	Port control	*Chapter 4: Signal description*
System module	System Integration Unit Lite	*Chapter 14: System Integration Unit Lite2 (SIUL2)*
DMA channel assignments	Direct memory access channel multiplexer	*Chapter 21: DMA channel multiplexer (DMACHMUX)*

7.9.2.1 DSPI instantiation

This device contains four DSPI modules. The following table provides the instantiation information for each module.

Table 79. DSPI instantiation

DSPI module	CTARs	TX FIFO depth	RX FIFO depth	PCS signals	Data Serialization Support
DSPI_0	8	4	4	PCS[7:0]	—
DSPI_1	8	4	4	PCS[7:0]	—
DSPI_2	8	4	4	PCS[7:0]	—
DSPI_3	8	4	4	PCS[7:0]	—

7.9.2.2 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all ‘1’s.

7.9.2.3 DSPI registers

The following table shows the absolute addresses of DSPI module registers in this MCU.

Table 80. DSPI registers memory map

Absolute address (hex)	Module
FBE7_0000	DSPI_2
FBE7_4000	DSPI_3
FFE7_0000	DSPI_0
FFE7_4000	DSPI_1

The following registers are **not** implemented on this MCU:

- DSPI DSI Configuration Register 0 (DSPIx_DSICR0)
- DSPI DSI Serialization Data Register 0 (DSPIx_SDR0)
- DSPI DSI Alternate Serialization Data Register 0 (DSPIx_ASDR0)
- DSPI DSI Transmit Comparison Register 0 (DSPIx_COMPR0)
- DSPI DSI Deserialization Data Register 0 (DSPIx_DDR0)
- DSPI DSI Configuration Register 1 (DSPIx_DSICR1)
- DSPI DSI Serialization Source Select Register 0 (DSPIx_SSR0)
- DSPI DSI Parallel Input Select Register 0 (DSPIx_PISR0)
- DSPI DSI Parallel Input Select Register 1 (DSPIx_PISR1)
- DSPI DSI Parallel Input Select Register 2 (DSPIx_PISR2)
- DSPI DSI Parallel Input Select Register 3 (DSPIx_PISR3)
- DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPIx_DIMR0)
- DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPIx_DPIR0)
- DSPI DSI Serialization Data Register 1 (DSPIx_SDR1)
- DSPI DSI Alternate Serialization Data Register 1 (DSPIx_ASDR1)
- DSPI DSI Transmit Comparison Register 1 (DSPIx_COMPR1)
- DSPI DSI Deserialization Data Register 1 (DSPIx_DDR1)
- DSPI DSI Serialization Source Select Register 1 (DSPIx_SSR1)
- DSPI DSI Parallel Input Select Register 4 (DSPIx_PISR4)
- DSPI DSI Parallel Input Select Register 5 (DSPIx_PISR5)
- DSPI DSI Parallel Input Select Register 6 (DSPIx_PISR6)
- DSPI DSI Parallel Input Select Register 7 (DSPIx_PISR7)
- DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPIx_DIMR1)
- DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPIx_DPIR1)

7.9.3 FlexRay Configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of safety system.

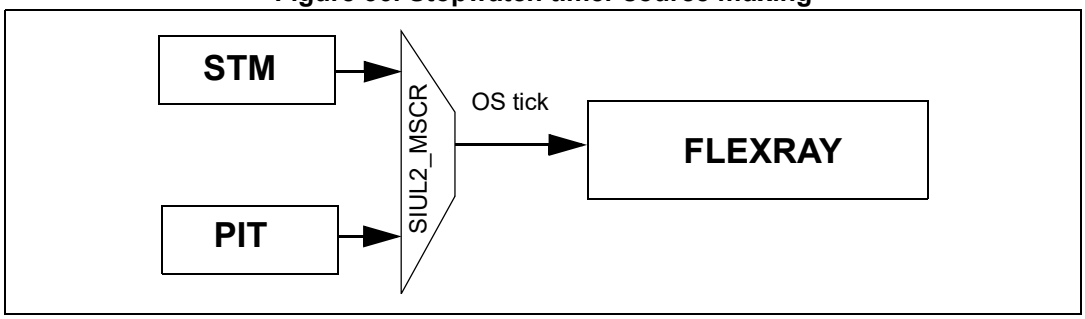
7.9.3.1 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 81. Flexray pin names

Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXDA
FR_A_TX (Transmit Data Channel A)	CA_TX
$\overline{\text{FR_A_TX_EN}}$ (Transmit Enable Channel A)	CA_TR_EN
FR_B_RX (Receive Data Channel B)	RXDB

Table 81. Flexray pin names (continued)



Signal description	Pin name
FR_B_TX (Transmit Data Channel B)	CB_TX
$\overline{\text{FR_B_TX_EN}}$ (Transmit Enable Channel B)	CB_TR_EN
FR_DBG[0] (Debug Strobe Signal 0)	DBG[0]
FR_DBG[1] (Debug Strobe Signal 1)	DBG[1]
FR_DBG[2] (Debug Strobe Signal 2)	DBG[2]
FR_DBG[3] (Debug Strobe Signal 3)	DBG[3]

7.9.3.2 FlexRay Stopwatch timer source muxing

Stopwatch timer input is routed to FlexRay module (selected by SIUL MSCR register) via:

- STM0_CMP0
- PIT1_CH0

Figure 36. Stopwatch timer source muxing

7.9.4 SENT Receiver (SRX) configuration

7.9.4.1 SRX channels

Table 82 shows the SENT receiver channels for each instance configured on this chip.

Table 82. SENT channel configuration

Instance	Channels (CH)
SENT 0	3
SENT 1	3

7.9.4.2 SRX registers

Table 83 lists the address offset and memory map for both SENT receiver (SRX) instances for this chip.

Table 83. SENT receiver memory map

Offset	Register name	SENT 0	SENT 1
0x0000	GBL_CTRL— Global Control Register	X	X
0x0004	CHNL_EN—Channel Enable Register	X	X

7.9.5 LinFlexD

7.9.5.1 LINFlexD – Configurations

SPC574Sx has four instances of LINFlexD. *Table 84* lists the configuration for each instance.

Table 84. LINFlexD configurations

Description	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3
Number of filters implemented	16	0		
Number of Tx DMA channels	1(1)			
Number of Rx DMA channels	1(2)			
LIN operation mode	Master/Slave (slave = 1)	Master (slave = 0)		
Value of autosynchronization	1	0		

1. TX_CH_NUM = 0, Number of TX DMA channels = $2^{TX_CH_NUM}$
2. RX_CH_NUM = 0, Number of RX DMA channels = $2^{RX_CH_NUM}$

7.9.5.2 LINFlexD implemented registers

Table 85 shows the registers implemented for each LINFlexD instance on the SPC574Sx chip.

Table 85. LINFlexD register comparison map

Register description	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3
	Address offset (hex)			
LIN Control register 1 (LINCR1)	00	00	00	00

7.10 Reset and Boot modules

7.10.1 BAF configuration

7.10.1.1 Search boot header and boot options

Refer to *Section 8.9: SW boot record search (BAF search)* in the *Chapter 8: Reset and boot*.

7.10.1.2 LINFlexD pins configuration

Table 86 shows the device pin configurations for the LINFlexD_0 module.

Table 86. LinFlexD pin configuration

Pads	Initial Serial Boot Mode		Serial Boot Mode after a valid LINFlexD message received
	Function	Pad Configuration	Function
PA[12]	LINFlexD_0 Rx	Input:— pull-down hysteresis TTL voltage level	LINFlexD_0 Rx
PA[13]	LINFlexD_0 Tx	Output:— Push/Pull medium drive no pullup/pulldown	LINFlexD_0 Tx

7.10.2 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the SPC574Sx device. For a comprehensive description of the SSCM, please refer to the SSCM's dedicated chapter.

7.10.2.1 SSCM instantiation

There is one SSCM instance in the SPC574Sx device.

7.10.2.2 Device-specific features

The device-specific reset values for the SSCM_MEMCONFIG register are shown in *Table 87*.

Table 87. SSCM_MEMCONFIG reset values

Field	Field definition	Value
MREV	Minor Revision	Minor silicon version
JPIN	JTAG Part ID	0A4h

Table 88 shows the address locations that the SSCM uses to search for startup information.

Table 88. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET)	0040_0000h
Location of the Boot Assist code in Flash (BAF)	0040_4000h

7.11 Safety modules

7.11.1 CRC – Number of contexts

Table 89 lists the number of contexts available for the current CRC computation of multiple data streams of CRC.

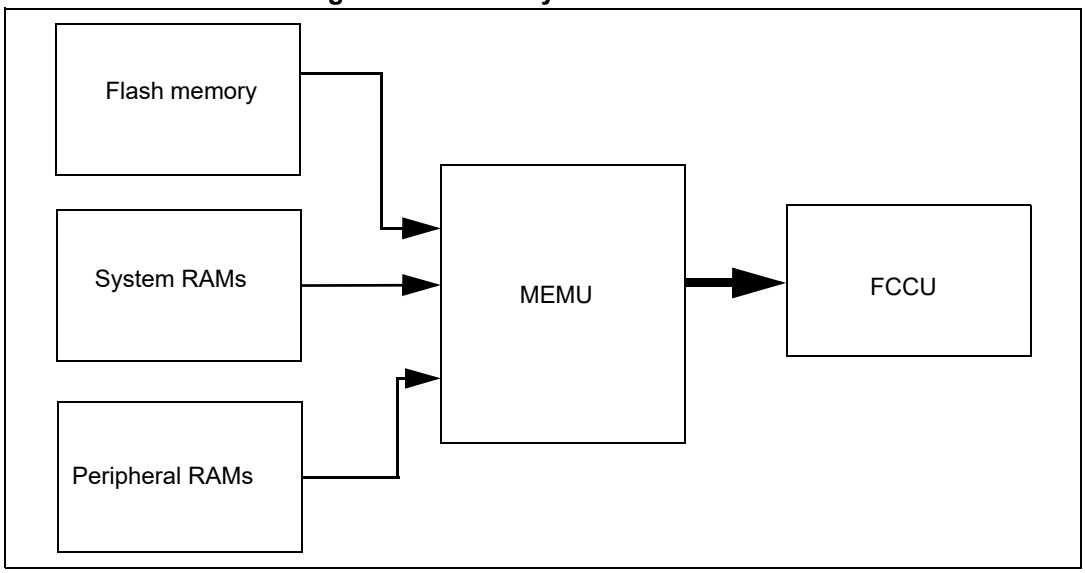

Table 89. CRC contexts

Signal name	Description
CRC_CNTX_NUM (N)	Number of contexts available for the current CRC computation of multiple data streams: 1

7.11.2 MEMU configuration

7.11.2.1 MEMU system connections

Figure 37. MEMU system connections

7.11.2.2 MEMU error sources

Table 90 shows the MEMU error sources for each instance configured on this chip.

Table 90. MEMU error sources

Instance	Value
Number of system RAM unique error sources	29
Number of peripheral RAM unique error sources	6
Number of flash memory unique error sources	2

7.11.2.3 Reporting tables implementation

There are three categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting
- Peripheral RAM error reporting

Each category of error reporting has two tables associated with it, these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

Table 91 describes the number of entries in each reporting table for the different error sources.

Table 91. Number of entries in each reporting table

Error source	Number of entries	
	Correctable error reporting table	Uncorrectable error reporting table
System RAM	10	1
Peripheral RAM	2	1
Flash memory	20	1

7.11.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from one of the three categories, Flash, System RAMs or Peripheral RAMs. In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Table 92. Corresponding error sources for system RAM OFLW0 register

7.11.3 FCCU configuration

7.11.3.1 Available FCCU output signals

Table 96 shows the available FCCU output signals implemented on this chip.

Table 96. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0](1), FI[0], ERROR0	FCCU_F0
EOUT[1](1), FI[1], ERROR1	FCCU_F1

1. FCCU_EOUT[0] and FCCU_EOUT[1] are both output and input pins.

7.11.3.2 FCCU register reset values

Table 97 shows the reset values of selected FCCU registers.

Table 97. Reset values of selected FCCU registers

Register	Reset value
FCCU_RF_CFG0	0xFFFF_FFFF
FCCU_RF_CFG1	0xFFFF_FFFF
FCCU_RF_CFG2	0x0000_0FFF
FCCU_RF_CFG3	0x0000_0000
FCCU_RFS_CFG0	0x0200_2000
FCCU_RFS_CFG1	0x0000_0000
FCCU_RFS_CFG2	0x0000_0000
FCCU_RFS_CFG3	0x0000_0000
FCCU_RFS_CFG4	0x0000_0000
FCCU_RFS_CFG5	0x0000_0000
FCCU_RFS_CFG6	0x0000_0000
FCCU_RFS_CFG7	0x0000_0000
FCCU_RF_S0	0x0000_0000
FCCU_RF_S1	0x0000_0000
FCCU_RF_S2	0x0000_0000
FCCU_RF_S3	0x0000_0000
FCCU_RF_E0	0x0000_1040
FCCU_RF_E1	0x0000_0000
FCCU_RF_E2	0x0000_0000
FCCU_RF_E3	0x0000_0000
FCCU_RF_TOE0	0x0000_0000
FCCU_RF_TOE1	0x0000_0000
FCCU_RF_TOE2	0x0000_0000
FCCU_RF_TOE3	0x0000_0000
FCCU_EOUT_SIG_EN0	0x0000_0000
FCCU_EOUT_SIG_EN1	0x0000_0000
FCCU_EOUT_SIG_EN2	0x0000_0000
FCCU_EOUT_SIG_EN3	0x0000_0000

7.11.3.3 FOSU parameters

The FOSU_COUNT, or FOSU timeout response time, is 1000 safe clock cycles.

7.11.4 Register protection (REG_PROT) configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the

module. This mechanism is software controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the *Chapter 67: Register Protection (REG_PROT)*.

FEE_TD	32	0x0718	32

7.11.4.4 PLL Digital Interface (PLL_DIG) protected registers

Certain PLL registers can be write-protected. The protected registers have write protection with both soft and hard locking. A soft lock can be unlocked by software after being previously locked. A hard lock is only unlocked by a reset once locked. *Table 102* lists the PLL_DIG registers that can be write-protected.

Table 102. Protected PLL_DIG registers

Register(1)	Register size (bits)	Offset from module base address	Protected size (bits)
PLL0_CR	32	0x0100	32
PLL0_DIVR	32	0x0108	32
PLL1_CR	32	0x0120	32
PLL1_DIVR	32	0x0128	32
PLL1_MR	32	0x012C	32
PLL1_CSR	32	0x0130	32

1. See *Chapter 67: Register Protection (REG_PROT)* for bit field details.

7.11.4.5 Oscillator Digital Interface (XOSC) protected registers

Certain XOSC registers can be write-protected.. The protected registers have write protection with both soft and hard locking. A soft lock can be unlocked by software after being previously locked. A hard lock is only unlocked by a reset once locked. *Table 103* lists the Oscillator Digital Interface registers that can be write-protected.

Table 103. Protected XOSC registers

Register(1)	Register size (bits)	Offset from module base address	Protected size (bits)
OSC_CTL	32	0x0080	32

1. See *Chapter 67: Register Protection (REG_PROT)* for bit field details.

7.11.4.6 Memory Error Management Unit (MEMU) protected registers

Table 104 lists the MEMU registers that can be protected.

Table 104. Protected MEMU registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)

Table 109 lists the JTAGM registers that can be protected.

Table 109. Protected JTAGM registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
JTAGM_MCR	32	0x000	32

7.11.5 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks on the SPC574Sx MCU. Up to four levels of password protection can be implemented for each flash block.

Note: The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See the Password and Device Security Module (PASS) chapter for further details.

7.11.5.1 PASS_LOCK*n*_PG*n* register bit mapping

Each password group defined in the DCF records has a set of four LOCKn registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note: The mapping of various LOCK register bits to flash blocks in the SPC574Sx microcontroller is very similar, but not identical. The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

7.11.5.2 PASS Module DCF Records (includes lifecycle state and censorship)

The records required to configure the initial values for the PASS module password group registers are shown in *Table 110*. These values provide the following capabilities:

- Set flash memory to censored/uncensored state (censorship also depends on lifecycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part.

Table 110. PASS DCF records

7.12 Debug and trace

SPC574Sx microcontrollers have a comprehensive feature set to assist debug and trace. *Chapter 55: Debug and Trace* contains full details as well as the top-level block diagram (*Figure 1132*) of the SPC574Sx debug architecture. The figure shows the general interconnection of functional debug modules.

7.12.1 NPC configuration

7.12.1.1 Parameter values

The following table provides the parameter values for this device.

Table 122. Device parameter values

Parameter	QFP100	QFP144
Number of MDO pins available in reduced-port mode	4	4
Number of MDO pins available in full-port mode	—	12

Table 122. Device parameter values (continued)

Parameter	QFP100	QFP144
Number of blocks that input an $\overline{\text{EVTO}}$	1	1
Number of $\overline{\text{MSEO}}$ pins available	2	2

7.12.1.2 Unavailable features

This device does not support an MCKO division factor of 3. Therefore, the setting PCR[MCKO_DIV] = 2 (see *Table 1130: MCKO_DIV Values*) is not available on this device.

Note: Due to package limitation of the TQFP100, the SWT enable feature driven by the EVTI external pad in DCI part is not possible. JCOMB signal is internally fix to high level.

8 Reset and boot

8.1 Introduction

The reset and boot chapter describes the device behavior from the time the external power is applied till the execution of the first instruction of the customer application.

8.1.1 Architecture

8.1.1.1 Reset and boot modules

There are several modules used to sequence through all the steps needed to properly reset the device and prepare it to fetch the first instruction of the user application code. These are the Power Management Controller (see *Chapter 50: Power management controller digital interface (PMC_Dig)*), the Reset generation Module (see *Chapter 47: Reset Generation Module (MC_RGM)*), the Mode Entry (see *Chapter 52: Mode Entry Module (MC_ME)*), the System Status and Configuration Module (see *Chapter 49: System Status and Configuration Module (SSCM)*) and the Self Test Configuration (see *Chapter 66: Self-Test Control Unit (STCU2)*). In addition, during the boot and reset phase some concepts are used. These are: the DCF record mechanism and the BAF code. This chapter gives a top-level overview about the reset functionality, while each module specific chapter goes more into the necessary details.

8.1.1.2 Reset and boot pins

Table 123 shows the pin used for the reset system functionality.

Table 123. Reset pins

Pin	Function	Direction	Active level	Notes
PORST	Destructive reset	Input	Low	—
ESR0	Reset monitor	Output	Low	This pin can be statically configured as a GPIO/AF or ESR0

8.1.2 Functionality

The boot and reset process is organized into two stages:

1. A hardware reset stage, initiated by a reset event, where the device executes the IP initialization
2. A software boot stage

The reset cause can be read from dedicated registers within the MC_RGM module. See *Chapter 47: Reset Generation Module (MC_RGM)* for further details. The next chapters describe in details the hardware and software reset and boot stages.

8.2 Hardware reset stage

Reset sources are organized into two categories: destructive and functional.

- A destructive reset source is associated with an event related to a critical error or dysfunction. A power on belongs to this category.
- A functional reset source is associated with an event related to a less critical error or dysfunction.

Table 124 shows the various destructive reset events and *Table 125* shows the various functional reset events.

The following symbols are used in the tables:

- X: Feature is disabled and cannot be enabled
- O: Feature is enabled and cannot be disabled
- P[D]: Feature is programmable; default is set to “disabled”
- P[E]: Feature is programmable; default is set to “enabled”

8.2.1 Destructive reset events

Table 124 shows the destructive reset sources.Some reset triggers can be programmed via software in order to generate a destructive reset or an alternate event. The choice is done by writing the corresponding bit in the RGM_DERD register. In case an alternate event has been programmed, then through the RGM_DEAR register is possible to define whether the trigger generates a SAFE mode change or an interrupt. After a reset event has occurred, the reset sources that triggered the event are recorded into the RGM_DES register (see chapter *Chapter 47: Reset Generation Module (MC_RGM)* for further details).

Table 124. Destructive reset events

RGM destructive reset sources					
Reset source		Configuration			
		Input	Reset or Alternate event(1)	Alternate event type(2)	
Module	Signal(s)			Safe mode	Interrupt
D_POR	Device PowerOn-Reset (POR)	POR	—	—	—
porst_gen	dest_rst_b: PORST pin reset	D[1]	P[E]	P[E]	P[D]
Reserved		D[2]	—	—	—
D_SOFT_DEST	Software destructive reset(3)	D[3]	O	X	X
fosu	fccu_failure_to_react_b: FCCU failure to react reset	D[4]	O	X	X
D_SUF	STCU2 failure	D[5]	O	X	X
Reserved		D[6:7]	—	—	—
D_EDR	Escalation destructive reset	D[8]	O	X	X
D_FIF	System watchdog timeout during Flash initialization	D[9]	O	X	X
D_JTAG	JTAG destructive reset request	D[10]	O	X	X

Table 124. Destructive reset events (continued)

RGM destructive reset sources					
Reset source		Configuration			
		Input	Reset or Alternate event(1)	Alternate event type(2)

D_TSR	Temperature sensor reset	D[23]	P[E]	P[E]	P[D]
D_VOR	Voltage out of range from LVDs and/or HVDs	D[24]	O	X	X
Reserved		D[25:31]	—	—	—

1. Set by RGM_DERD register
2. Set by RGM_DEAR register
3. Triggered by ME

8.2.2 Functional reset sources

Table 125 shows the functional reset sources.Some reset triggers can be programmed via software in order to generate a functional reset or an alternate event. The choice is done by writing the corresponding bit in the RGM_FERD registers. In case a functional reset event has been selected, then it is possible to select a Short or Long Functional Reset, by writing the corresponding bit in the RGM_FESS register. In case an alternate event has been programmed, then through the RGM_FEAR register is possible to define whether the trigger generates a SAFE mode change or an interrupt. After a reset event has occurred, the reset sources that triggered the event are recorded into the RGM_FES register (see chapter *Chapter 47: Reset Generation Module (MC_RGM)* for further details).

Table 125. Functional reset events

RGM functional reset sources							
Reset source		Configuration					
		Input	Reset or Alternate event(1)	Functional Reset type(2)		Alternate event type(3)	
Module	Signal(s)			Long	Short	Safe mode	Interrupt
Reserved		F[0]	—	—	—	—	—
F_WAKEUP	Wake-up unit(4)	F[1]	P[E]	P[E]	P[D]	P[E]	P[D]
F_ST_DONE	Self-test functional reset	F[2]	O	O	X	X	X
F_SOFT_FUNC	Online Self Test completion OR Software device reset(5)	F[3]	P[E]	P[E]	P[D]	X	X

Table 125. Functional reset events (continued)

RGM functional reset sources							
Reset source		Configuration					
		Input	Reset or Alternate event[1]	Functional Reset type[2]		Alternate event type[3]	
Module	Signal(s)			Long	Short	Safe mode	Interrupt
Reserved		F[4]	—	—	—	—	—
F_FCCU_HARD	Hard reaction request	F[5]	E	O	X	X	X
F_FCCU_SOFT	Soft reaction request	F[6]	P[E]	X	O	O	X
Reserved		F[7:9]	—	—	—	—	—

Reserved		F[11:22]	—	—	—	—	—
F_TSR_FUNC	Temperature sensor trigger	F[23]	P[E]	P[E]	P[D]	P[E]	P[D]
F_VOR_FUNC	Voltage out of range from LVDs and/or HVDs	F[24]	P[E]	P[E]	P[D]	P[E]	P[D]
Reserved		F[25:31]	—	—	—	—	—

1. Set by RGM_FERD register
2. Set by RGM_FESS register
3. Set by RGM_FEAR register
4. Triggered by NMI
5. Triggered by ME OR when ONLINE Self TEST completes

8.2.3 Functional reset escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' resets, triggered by any of the functional reset input signals, have occurred between software writes to a specific RGM register. This function is enabled by writing a non-zero value a specific RGM register[d].

Once 'functional' reset escalation has been enabled, the RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (that is entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to a specific RGM register and on any power-on or 'destructive' reset. If the counter reaches the value set into a specific RGM register, the RGM starts a reset sequence at PHASE0.

d. The default value at reset for this register is 4

8.2.4 Destructive reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets, triggered by any of the destructive reset input signals, has occurred between software writes to a specific RGM register. This function is enabled by writing a non-zero value to a specific RGM register [e]. Once 'destructive' reset escalation has been enabled, the RGM increases a counter on each 'destructive' reset which causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value a specific RGM register and on any power-on reset. If the counter reaches the value set into a specific RGM register, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

8.3 Reset sequence

The hardware reset stage is handled by the RGM module through a state machine. The RGM executes the device initialization through a sequence of phases. At the end of the hardware reset stage, the device starts software boot stage. The software boot stage is actually the very first code executed by the processor. This code, called BAF, is programmed by ST in a specific Flash location and cannot be modified.

e. The default value at reset for this register is 8

Figure 42. Reset sequence

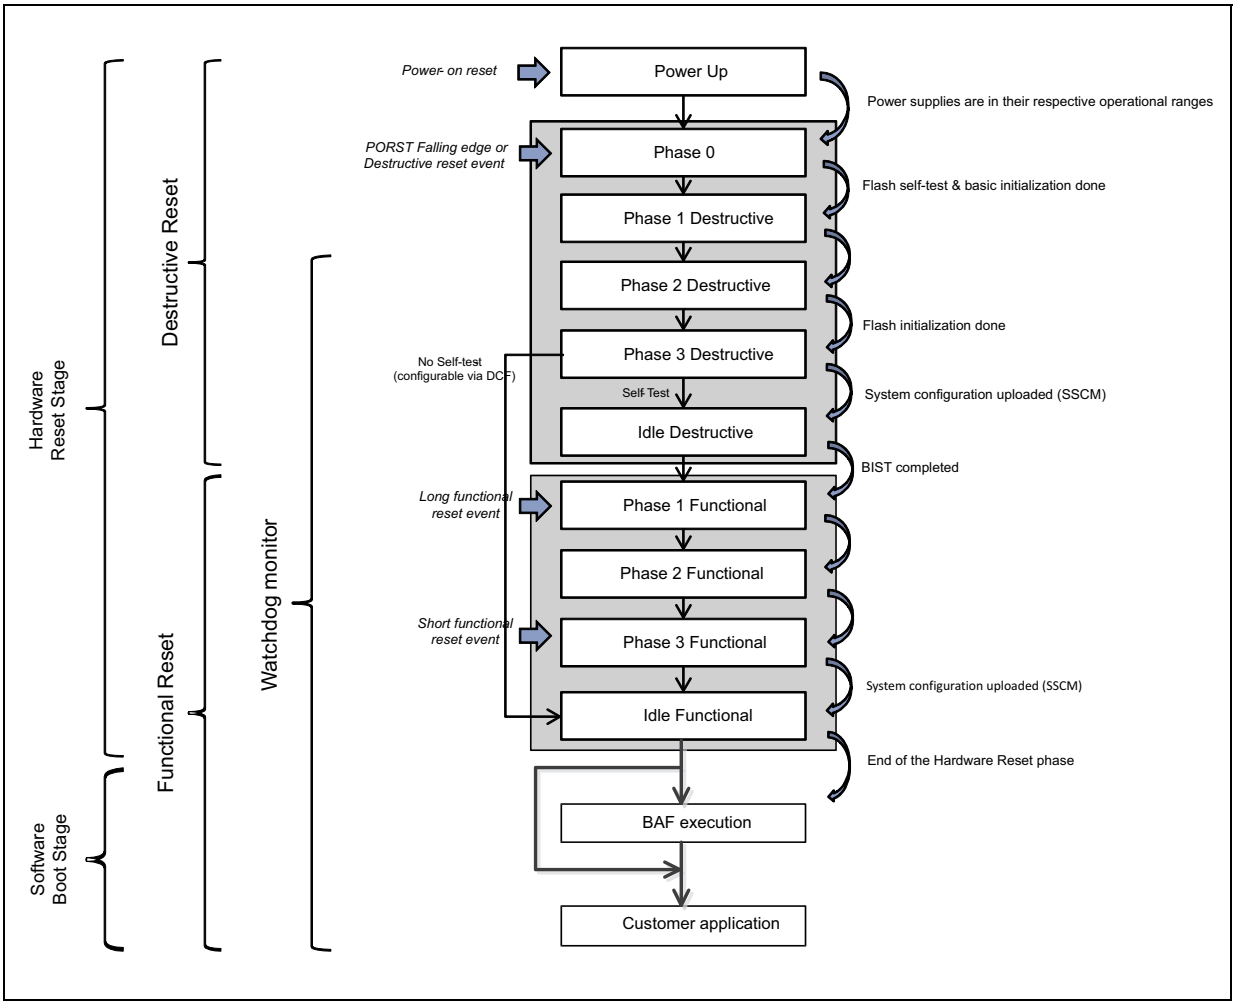

Table 126 summarizes the reset sequence phases.

Table 126. Reset sequence phases

Phase	Description
Power-up	The powerup phase can only be entered upon a power-on reset event. The device will remain in the power-up phase until the Power Management Controller module (PMC) determines that all power supplies are in their respective operational ranges. See *Chapter 10: Power management* for a detailed description of the power monitoring architecture.
Phase 0 DEST	The Reset Phase 0 Destructive is entered upon a falling edge of the PORST pin or a Destructive Reset event. During this phase, the Flash starts its initialization.
Phase 1 DEST	The Reset Phase 1 Destructive is entered after the Reset Phase 0 Destructive is completed.
Phase 2 DEST	The Reset Phase 2 Destructive is entered after the Reset Phase 1 Destructive is completed. During this phase the Flash executes its initialization. The whole operation is monitored by the Watchdog, which will trigger a destructive reset in case of Flash initialization failure.

Table 126. Reset sequence phases (continued)

Phase	Description
Phase 3 DEST	The Reset Phase 3 Destructive is entered after the Reset Phase 2 Destructive is completed. During this phase the SSCM module uploads the system configuration and dispatches to the proper clients (see *Chapter 49: System Status and Configuration Module (SSCM)* for more details). During this phase the CPU reset vector is written into the ME module and the trimming for the analog IPs (such as VR, LVD/HVD, temperature sensor, ADC, I/O, oscillator) are applied. In case no BIST is to be executed, the device can be kept into the Phase 3 DEST by keeping the PORST. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.
Idle DEST	The Idle Phase Destructive is entered after the Reset Phase 3 Destructive is completed in case a BIST execution is requested (see *Chapter 6: Functional safety* for further details). The BIST execution is monitored by a watchdog. In case of BIST failure, a destructive reset will be triggered.
Phase 1 FUNC	The Idle Phase Functional is entered after the Idle Phase Destructive is completed or when a Functional reset event is triggered, provided that the event itself is not configured to trigger a Short-Reset sequence. The system behavior during this phase is the similar to the Phase 1 Destructive.
Phase 2 FUNC	The Reset Phase 2 Functional is entered after the Reset Phase 1 Functional is completed. The system behavior during this phase is similar to the Phase 2 Destructive. The whole operation is monitored by the watchdog, which will trigger a reset in case of Flash initialization failure.
Phase 3 FUNC	The Reset Phase 3 Functional is entered after the Reset Phase 2 Functional is completed or in case a functional reset is triggered and the reset event has been configured as a Short-Reset. During Phase 3 Functional the information retrieved during the During Phase 3 Destructive is read again and compared with the value passed to the various clients. If a mismatch occurs, an error condition is signaled to the FCCU.
Idle FUNC	The Idle Phase Destructive is entered after the Reset Phase 3 Functional, or after the Reset Destructive Phase 3 is completed in case a BIST execution is not requested.

Table 127 shows the status of the various system modules during the hardware reset phase.

Table 127. Module status during the reset phase

1. RGM is reset only upon a power-on.

8.4 PORST pin functionality

The PORST pin acts as an input to initialize the device to a known start-up state. The detection of a falling edge on PORST will start the reset sequence. For safety reasons, a weak pull-down is always connected to the PORST pin. *Figure 43* shows the effect of keeping PORST low during the destructive reset phase. The effect depends on the BIST enabling status:

- In case the BIST is disabled, the reset sequence does not evolve and remains into the Phase 3 Destructive until the PORST pin is de-asserted low. Note that once the PORST pin is de-asserted low, the reset sequence evolves into the Idle Functional stage
- In case the BIST is enabled, the reset sequence evolves (notwithstanding the PORST pin level) and enters the Idle Phase Destructive once the BIST is completed

Figure 43. PORS Reset pin vs. Phase 3 Destructive

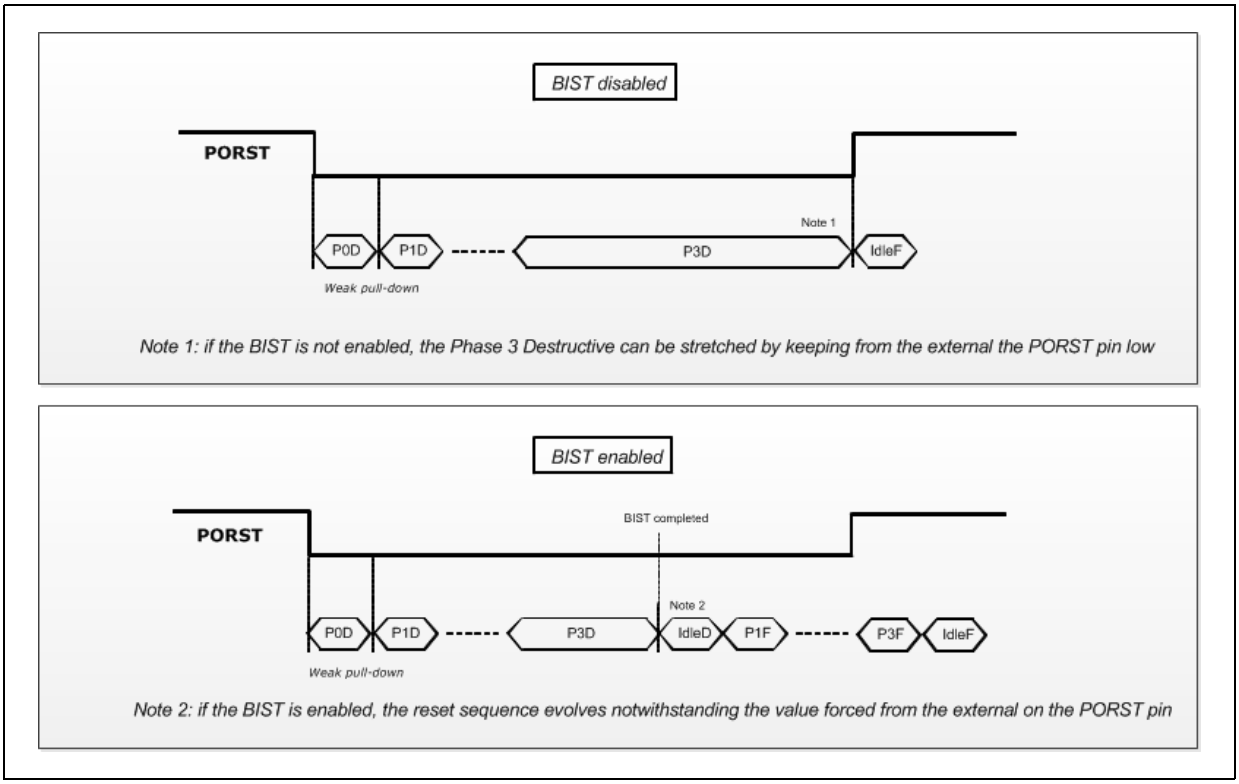

Figure 44 shows the effect of the PORST pin during the functional reset phase. It is possible to stretch the Phase 3 Functional by keeping PORST low. Note that this case is possible only when the BIST is enabled, otherwise the reset sequence would have been formerly stopped at the Phase 3 Destructive, as explained above.

Figure 44. PORS Reset pin vs. Phase 3 Functional

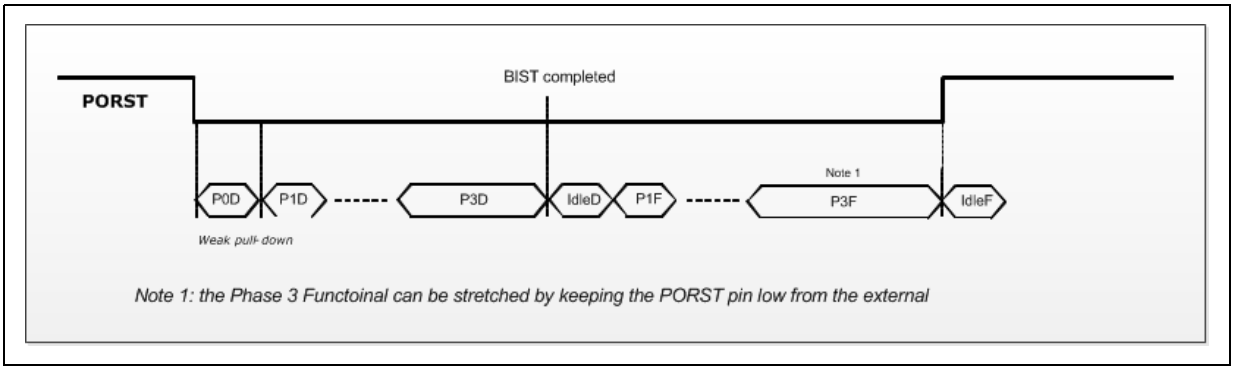

Table 128, *Table 129* and *Table 130* show PORST pin characteristics.

Table 128. PORST electrical characteristics

Type	Symbol	Description	Min	Max	Unit

Filtered pulses	2000	—	ns

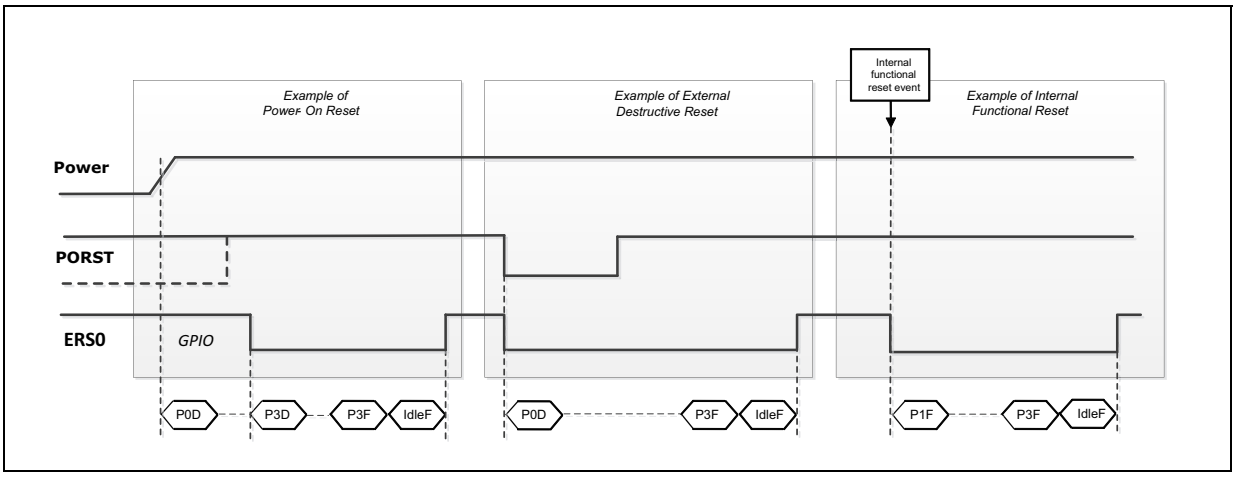
Table 130. PORST pull-down characteristics

Pull-down	Conditions	Min	Max	Unit
Weak	Vinput = VDD	30	80	uA

8.5 ESR0 pin functionality

This device does not implement a dedicated pin to output a reset signal. Nevertheless, it is possible to statically configure one pin to act as an output reset. The operation is done by reading a specific DCF record, which can be written one time only and it is assigned to a triple-voting set of flip-flops. The DCF is read during the reset phase 3 Destructive and the read value is maintained till the next power on reset. The following list summarizes the static pin configuration:

1. PAD 47 can have a double function (see *Chapter 4: Signal description* for the pad list):
   a) ESR0 reset output only
   b) GPIO/AF
2. The choice between a) or b) is done via DCF reading at every reset
3. The DCF is write-once and stored into a triple-voting set of flip-flops
4. The value read via DCF shall be available to the SW via a register read-only status bit, so that the application can always monitor the correct configuration
5. The value uploaded via DCF is maintained throughout the next Power-On-Reset
6. After a Power-On-Reset the default value is GPIO
7. After a Destructive or Functional reset, the default value is the last one being uploaded via DCF
8. In case the pin is configured as GPIO, during a reset phase the pin shall maintain the same under-reset safe configuration as for all the other GPIOs
9. In case the pin is configured as ESR0, during a reset phase the pin is driven to ‘0’ by the RGM module, while out of reset, the pin is weakly pulled-up. ESR0 is strongly driven during reset and it is weakly pulled up out of reset. So, out of reset , the rise of this pin will depend on the output load. Internal pull up resistance is 75 Kohm (worst case) , so outside resistance should be at least 10 times of this to have a output signal rising to the maximum value of IO supply.



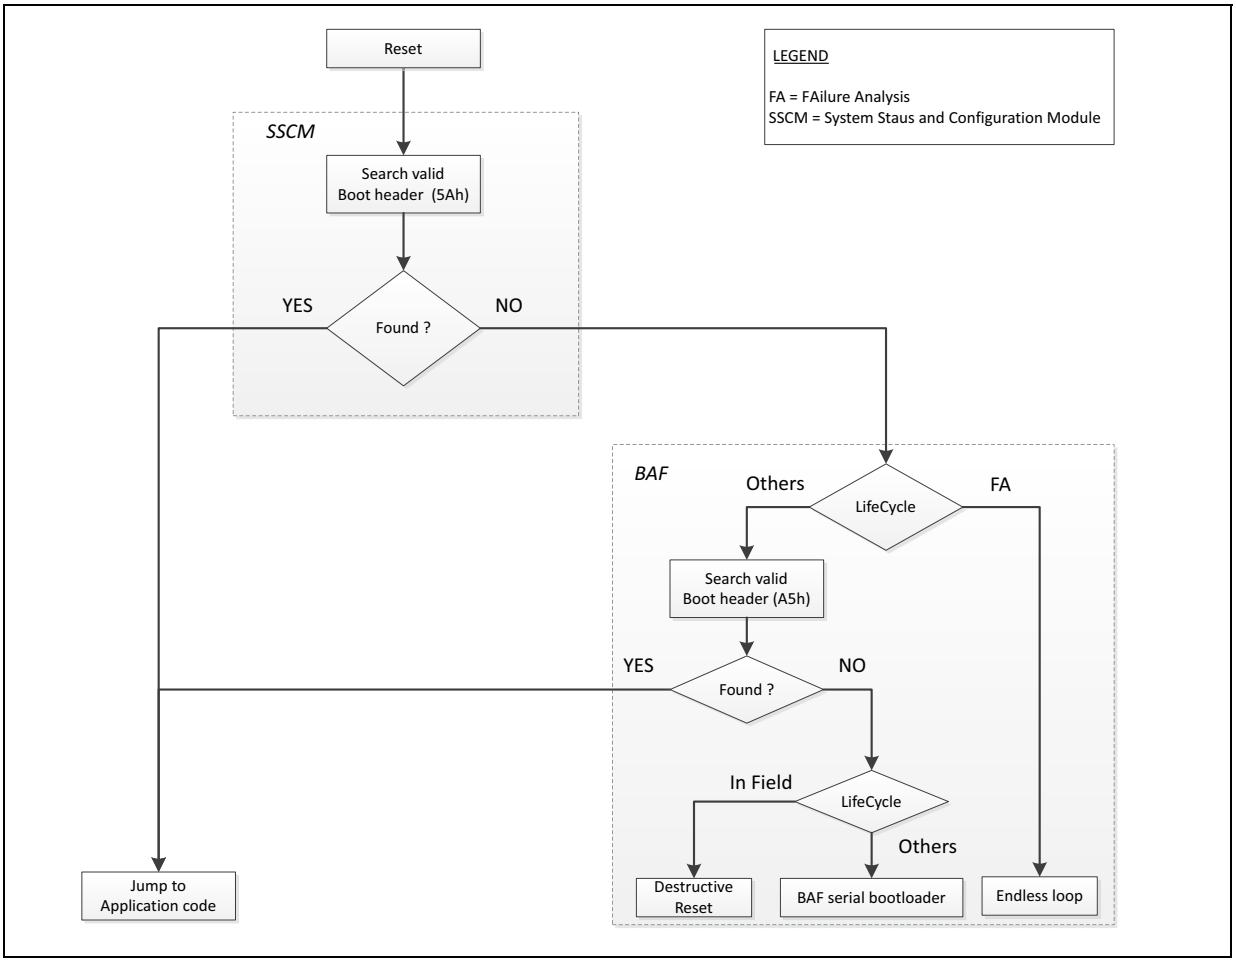
ESR0 pin characteristics: The ESR0 pin has the same electrical characteristic as a GPIO.

8.6 PORST and ESR0 pin status during power on, destructive and functional reset

Figure 45 shows the behavior of the PORST and ESR0/GPIO pins for three scenarios:

1. Power-on
2. PORST forced low from the external (the same case applies for an internal destructive reset)
3. Internal functional reset

Figure 45. PORST reset pin state during the reset sequence



8.7 System boot

After the reset phase is completed, the CPU starts executing at the start address provided by MC_ME peripheral, according to the value stored into the CADDR register. The default value (at the reset) of the CADDR register is forced by the SSCM, according to the system configuration, which is stored in Flash and read by the SSCM from the Flash during the reset.

The system configuration is set as application boot records and is programmed by the customer. It is used to set the customer application entry point after reset or after the BAF execution (if enabled)

Figure 46 shows the the various possible system boots.The application entry point can be retrieved both in HW (by the SSCM) or in SW (by the BAF). In both cases, the application entry point is retrieved by searching for a valid Boot Record, which shall programmed by the customer in one of the pre-determined Flash memory locations looked at by the SSCM or the BAF code. Next chapters give more details about the Boot Record structure and search operation.

Figure 46. System boot sequence

8.8 HW boot record search (SSCM search)

The SSCM module looks for a valid software entry point, called SSCM boot record. The SSCM boot record is organized as shown in the *Table 131*. The “Application start address“ value will be passed to the CADDR register of MC_ME, which is used to drive the CPU start address after the reset phase.

Table 131. SSCM boot record structure

Offset	Field description	
0x0	Boot Record Tag (5Ah)	Reserved
0x4	Application start address	
0x8	Reserved	
0xC	Reserved	

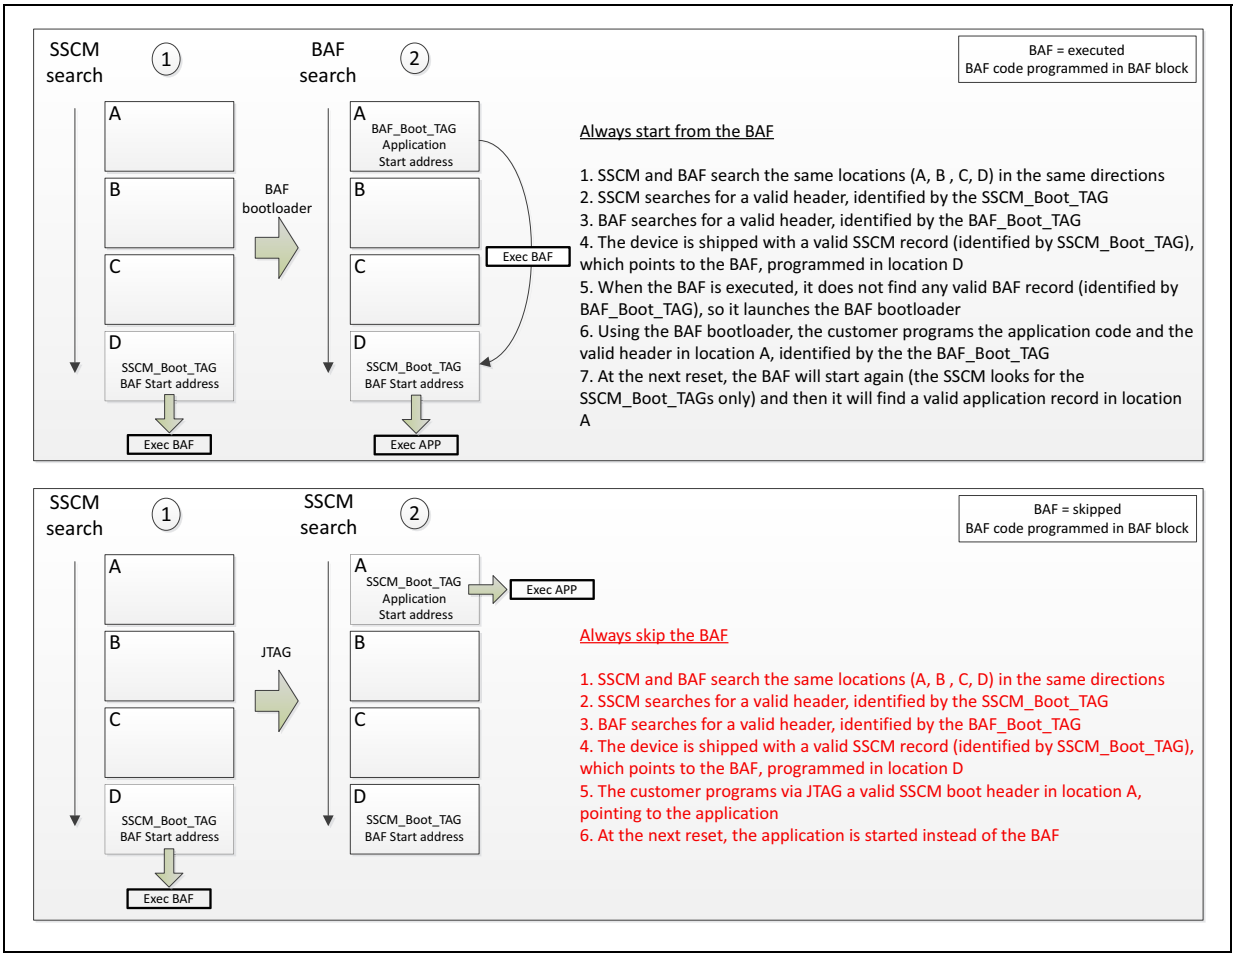
The SCCM searches for a valid boot record at the addresses specified in *Table 132*. A boot record is considered valid if it contains the value 5Ah in the “Boot Record Tag” field.

The “Search Order” column specifies which location is searched first. The SSCM stops the search as soon as a valid boot record is found.

Table 132. SSCM boot record search locations

Search order	Address[1]	Location	SSCM configuration parameter
1 (First)	0x00FC_0000	Flash 16 KB Code Block 0	RCHW_LOC_0
2	0x00FC_4000	Flash 16 KB Code Block 1	RCHW_LOC_1
3	0x00FC_8000	Flash 16 KB Code Block 2	RCHW_LOC_2
4	0x00FC_C000	Flash 16 KB Code Block 3	RCHW_LOC_3
5	0x0100_0000	Flash 256 KB Code Block 0	RCHW_LOC_4
6	0x0104_0000	Flash 256 KB Code Block 1	RCHW_LOC_5
7 (Last)	0x0040_4000	Flash 16 KB BAF block	RCHW_LOC_6

1. The addresses specified in this table refer to the system memory addresses (that is as “seen” by the CPU). In reality, the SCCM directly interfaces the Flash, so the exact addresses to be used in the SSCM RTL code are specified by the Flash block guide.



Depending upon the fact that a valid SSCM boot record is found and the content of the SSCM boot record, three scenarios can happens:

1. if a valid Boot Record is programmed by the customer, then the application is executed after the reset from the specified entry point address
2. if no valid Boot Record is programmed by the customer, then the default BAF Boot Record is retrieved and the BAF code is executed after the reset

Figure 47 shows the way to start the BAF or directly the customer application.

Note: For sake of simplicity, the picture shows only four boot record positions.

Figure 47. Valid boot header search

8.9 SW boot record search (BAF search)

The BAF is executed if no valid Boot Record (0x005A0000) is programmed by the customer. In this case a valid SSCM boot record pointing to the BAF code (programmed by factory at the location number 7) is found.

This boot record will point to the BAF entry point. Because the boot record number 7 is the last one being searched by the SSCM, this means that, if no other boot record is programmed, the software will start from the BAF. Notice that the location of the boot record nr. 7 is placed within the BAF block itself, making it not erasable (the BAF block is OTP).

When the BAF code is executed after the reset sequence is completed, a valid application Boot Record for the application entry point is searched. The mechanism is the same executed by the SSCM: a set of fixed locations are analyzed and, if a valid boot record is found, then, at the end of the BAF code, the CPU will start executing from the application entry point.

Note that the valid boot record is identified by a different tag: 5Ah for the SSCM; A5H for the BAF. This will make it possible to program the same boot record locations and launch the application directly after the reset or after the BAF code execution. *Table 133* shows the BAF boot record structure.*Table 134* shows the addresses of the location searched by the

BAF code. *Figure 46* shows a flow chart of the whole reset sequence, including the BAF search for a valid boot header. See *Chapter 48: Boot Assist Flash (BAF)* for additional information about the BAF code.

Table 133. BAF boot record structure

Offset	Field description	
0x0	BAF Boot Record Tag (A5h)	Reserved
0x4	Application start address	
0x8	Reserved	
0xC	Reserved	

Table 134. BAF boot record search locations

Search order	Address	Location
1 (First)	0x00FC_0000	Flash 16 KB Code Block 0
2	0x00FC_4000	Flash 16 KB Code Block 1
3	0x00FC_8000	Flash 16 KB Code Block 2

9 Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record consists of a pointer to the location of a register internal to the device and the data to be written to that register.

There are two broad categories of DCF records, TEST DCF Records and UTEST DCF Records. TEST DCF records are developed by the factory and are used mainly to program registers involved in trimming trip points for voltage comparators, adjusting analog to digital voltage supplies, trimming oscillator frequencies, and enabling RAM repair. However these records can also be used to write any DCF client. The TEST DCF Records are programmed into TEST flash during production and cannot be modified. TEST flash is not visible to the user.

The second set of DCF records are UTEST DCF records. Some UTEST DCF records are written by the factory and programmed during production testing (see “UTEST flash memory map” table in *Chapter 5: Memory map*). Others are written by the end user and programmed at the same time application code is programmed into the flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the UTEST DCF records programmed into the flash memory during factory production. The user-defined DCF records set up the initial memory map, assign memory blocks as OTP assign flash blocks to be associated with specific password groups.

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPU and the DCF records must be properly programmed into their respective flash memories.

When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device. After the system power supplies have reached predefined levels, the Power Management Controller signals the Reset Generation Module (RGM) to begin the boot sequence. During the boot sequence, the RGM enables another internal module, the System Status and Control Module (SSCM), to read the device configuration records and then write the configuration information to the specified registers.

9.2 DCF clients

DCF clients are 32-bit wide hardware registers inside a module, that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written, and may have special writing constraints, such as, ‘Write Once’ or allowing bits to be written from ‘1’ to ‘0’ only or vice versa. DCF clients need not implement all 32 bits. DCF clients maybe designated ‘TEST DCF record only’, which means that only DCF Records stored in TEST flash can write to the DCF Client.

A list of DCF clients is shown in *Table 138*. (TEST DCF Record Only Clients are not shown as these are not accessible by the user)

The DCF Records select the ‘target’ DCF client by a 30-bit field in the DCF Record consisting of a 15-bit ‘Chip Select’ field and a 15-bit Address field. Each module that

includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory beginning at 0x0040_0200.

The structure of a DCF Record is shown in *Figure 48*.

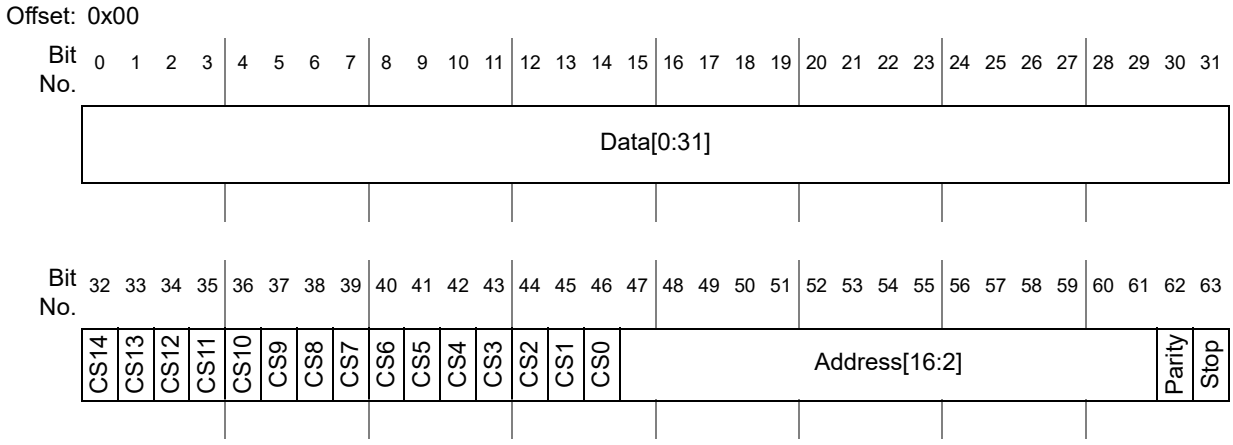

Figure 48. DCF record structure

Table 136. DCF record field description

Field	Description
0:31 Data[0:31]	32 bits of data that is to be written to the DCF Client
32:46 CSn	Chip Select n One Chip select is asserted (‘1’) per DCF record to select the target module for the DCF client. All other Chip Selects should be negated (‘0’)
47:61 Address[16:2]	Address of the DCF client within the selected module **Note:** Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter
62 Parity	Parity Bit for the DCF Record **Note:** This bit is NOT implemented for DCF Client written from UTEST
63 Stop	Stop bit This bit indicates the end the list of DCF Records. 0 Not the end of the list 1 End of the list **Note:** The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list

The following structure must be present:

- The first record must be a start record.
- DCF records containing configuration data must immediately follow the start record with no blank records between an unprogrammed record that is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a stop record.

Each record is 64 bits in length. *Figure 49* shows the DCF start record.

Warning: The start record must be placed at the beginning of the DCF area in UTEST flash memory to indicate to the device that the following data records must be processed.

Figure 49. DCF start record

0x00 0:31	**0x04 32:63**
0x05AA55AF	0x00000000

The stop bit designates the last device configuration record in a set of records. Normally, the stop bit is never set in a valid UTEST DCF record programmed during production, since this would prevent additional UTEST records from being appended to the factory programmed UTEST DCF records. However, the flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location. Therefore, that location's contents is 0xFFFF_FFFF_FFFF_FFFF. Thus, the stop bit location in this unprogrammed flash memory location is a logic 1, signifying that this is the last DCF record and it is not to be acted upon.

During the boot sequence, the SSCM uses the DCF records to program various registers before reset is released. Some device configuration records are calculated during production testing and programmed into the TEST flash memory area. Other DCF records are developed by the end user and programmed into the UTEST flash area. A device configuration record simply consists of an internal register address and a data field. During system boot, while the reset signal is asserted, the SSCM reads the device configuration records and writes the data to the appropriate internal module registers. Thus, many operational aspects of the device are properly configured when the reset signal is released and normal device operation begins.

The stop record indicates the end of DCF records to be processed. The general format of the stop record is shown in *Figure 50*. Only the stop bit needs to be 1 in order to form a stop record: all other bits are ignored. An unprogrammed location in UTEST flash is interpreted as a stop record.

Figure 50. DCF stop record

0:31	32:62	63
Reserved	Reserved	1

If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 137*.

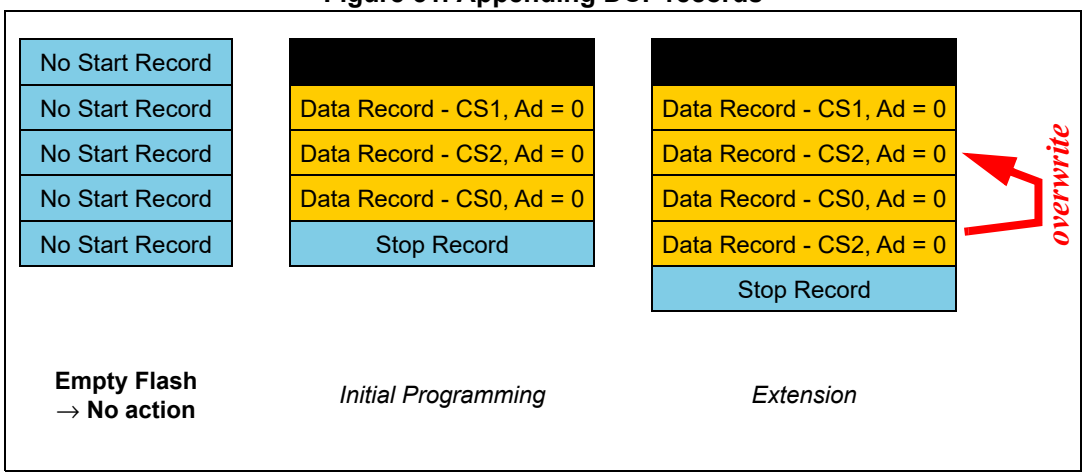

Table 137. Series of DCF records in UTEST flash memory

ADDR offset	DATA			
0x00	0x05AA55AF			
0x04	0x00000000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8n-1 + 0x0	Reserved			
8n-1 + 0x4	Reserved			**1**
8n + 0x0	—			
8n + 0x4				

Warning: There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored. This allows one to program the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 51*.

It is possible for more than one DCF Record to write to the same DCF client. In this case, as shown in the “Extension” part of *Figure 51*, the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

Figure 51. Appending DCF records

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST flash memory area (refer to UTEST flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory. The user may add additional USER DCF records beginning with the first unprogrammed location following the factory programmed UTEST DCF records. An unprogrammed location in flash memory contains 0xFFFF_FFFF.

When programming UTEST DCF records at the factory, the records must start at the first address in the UTEST flash memory area and be continuous; that is, one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module.

9.4 DCF client table

A list of DCF clients is shown in *Table 138*. Various attributes of the DCF clients are listed in these tables. The following list explains the meaning of the columns and give a description of the attributes of these DCF clients:

- DCF Chip Select

  The CS field is a 15-bit field with each bit in the field assigned to a particular module. These bits act as module select signals for the internal modules. Only one bit in this field should be set in a DCF record.
- DCF address

  The ADDR field is a 15-bit field that specifies an internal address for a DCF client. These addresses are used only by the SSCM when interpreting DCF records and writing the data to specified modules.
- DCF Client Description

  This field contains the name of the DCF clients.
- Reset value of DCF client

  This field contains the reset value of DCF client before being written by the SSCM with the associated DCF record.
- Typical value of DCF client

  This field contains a typical value that you might program into the various DCF clients. This field is for information only.
- IPS read

  This column specifies whether or not a DCF client can be read by user software after the release of reset.
- DCF client special strategy

  Though all DCF records have the same format, they can be used in different ways. As the device is being designed, registers must be designated as Device Configuration Format clients if they need to be written with a DCF record. There are other features that must be designated for DCF clients. For instance, DCF clients can have several different write strategies: Parity, Write Once, Triple Voted + Parity + Check with second write, Triple voted + Check with second write, or no strategy at all. The SSCM examines the DCF client to determine the correct special strategy to use and then

appropriately write a DCF record to that client. The following list defines the special strategies:

– None
No special DCF strategy is used.

– Parity
Not implemented for DCF clients. Only used for TEST only DCF clients not accessible by the user.

– Write Once
A register using the Write Once strategy can only be written once. The DCF client ignores subsequent writes.

– Triple Voted
DCF clients that use the Triple Voted strategy have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows for a 'bit-flip' error to occur without changing the DCF client output data.

– Triple Voted with second write
DCF clients that use the Triple Voted with 2nd write strategy have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. During the second execution of Phase 3 of the reset sequence, the SSCM attempts to write the DCF client again. At this time, the DCF client checks to see that the register contains the same data that is being written again.

– Write 0 only
A bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a bit with this attribute to a logic 1 is ignored.

– Write 1 only
A bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a bit with this attribute to a logic 0 is ignored.

– DCF order dependency in flash memory
This column details whether or not there are special conditions on the location of a particular DCF record in flash memory.

Table 138. DCF client list(1)

DCF CS [14:0]	DCF address [9:2] (binary)	DCF client			IP read direct access	Special strategy		DCF order dependencyi in flash memory	Estimated UTEST flash memory space (bytes)

Table 140. REE_BUS bits DCF client field descriptions

Field	Description
19 LVD14_ADL1	LVD14_ADL1 reset enable This bit defines whether an LVD assertion on the first supply of the ADC1 generates a system reset. The RES_HV1[RES14_ADL1] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the ADC1 does not cause system reset 1 Enabled. LVD assertion on the first supply of the ADC1 causes system reset
20 LVD14_ADL0	LVD14_ADL0 reset enable This bit defines whether an LVD assertion on the first supply of the ADC0 generates a system reset. The RES_HV1[RES14_ADL0] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the ADC0 does not cause system reset 1 Enabled. LVD assertion on the first supply of the ADC0 causes system reset
21 LVD14_IOL1	LVD14_IOL1 reset enable This bit defines whether an LVD assertion on the first supply of the IOL1 generates a system reset. The RES_HV1[RES14_IOL1] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the IOL1 does not cause system reset 1 Enabled. LVD assertion on the first supply of the IOL1 causes system reset

Table 140. REE_BUS bits DCF client field descriptions (continued)

Field	Description
22 LVD14_IOL0	LVD14_IOL0 reset enable This bit defines whether an LVD assertion on the first supply of the IOL0 generates a system reset. The RES_HV1[RES14_IOL0] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the IOL0 does not cause system reset 1 Enabled. LVD assertion on the first supply of the IOL0 causes system reset
23 HVD13_C	HVD13_C reset enable This bit defines whether an HVD assertion on the IOL0 supply generates a system reset. The RES_HV1[RES13_C] bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the IOL0 supply does not cause system reset 1 Enabled. HVD assertion on the IOL0 supply causes system reset
24 LVD11_ADL1	LVD11_ADL1 reset enable This bit defines whether an LVD assertion on the first supply of the ADC1 generates a system reset. The RES_HV0[RES11_ADL1] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the ADC1 does not cause system reset 1 Enabled. LVD assertion on the first supply of the ADC1 causes system reset
25 LVD11_ADL0	LVD11_ADL0 reset enable This bit defines whether an LVD assertion on the first supply of the ADC0 generates a system reset. The RES_HV0[RES11_ADL0] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the first supply of the ADC0 does not cause system reset 1 Enabled. LVD assertion on the first supply of the ADC0 causes system reset
26 LVD11_FL	LVD11_FL reset enable This bit defines whether an LVD assertion on the supply of the flash generates a system reset. The RES_HV0[RES11_FL] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the flash does not cause system reset 1 Enabled. LVD assertion on the supply of the flash causes system reset
27 LVD11_IOL1	LVD11_IOL1 reset enable This bit defines whether an LVD assertion on the supply of the IOL1 generates a system reset. The RES_HV0[RES11_IOL1] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the IOL1 does not cause system reset 1 Enabled. LVD assertion on the supply of the IOL1 causes system reset
28 LVD11_OSC	LVD11_OSC reset enable This bit defines whether an LVD assertion on the supply of the XOSC generates a system reset. The RES_HV0[RES11_XOSC] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the XOSC does not cause system reset 1 Enabled. LVD assertion on the supply of the XOSC causes system reset

Table 140. REE_BUS bits DCF client field descriptions (continued)

Field	Description
29 LVD11_C	This bit defines whether an LVD assertion on the IOL0 supply generates a system reset. The RES_HV0[RES11_C] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the IOL0 supply does not cause system reset 1 Enabled. LVD assertion on the IOL0 supply causes system reset
30 HVD_6C	HVD_6C reset enable This bit defines whether an HVD assertion on the core supply generates a system reset. The RES_LV1[RES6_C] bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the core supply does not cause system reset 1 Enabled. HVD assertion on the core supply causes system reset
31 LVD_3C	LVD_3C reset enable This bit defines whether an LVD assertion on the core supply generates a system reset. The RES_LV0[RES3_C] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the core supply does not cause system reset 1 Enabled. LVD assertion on the core supply causes system reset

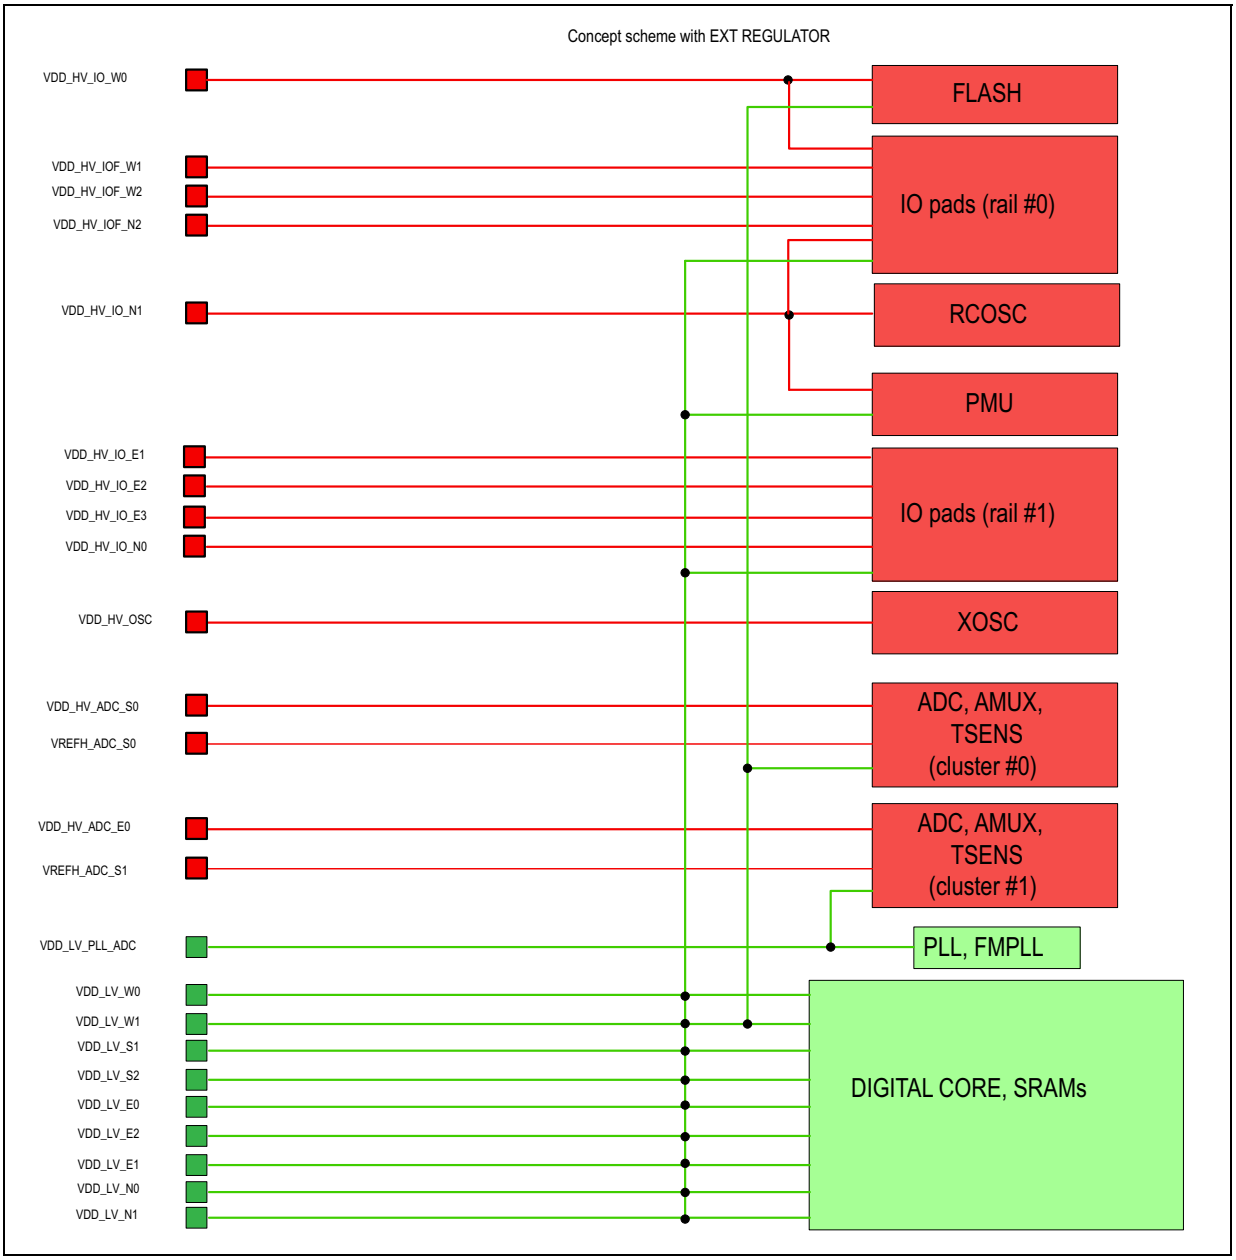
10 Power management

10.1 Overview

SPC574Sx microcontrollers include a robust power management infrastructure for applications to select various Operational and Low-power modes and monitor internal voltages for High- and Low-voltage conditions. This monitoring is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller leaves reset.

This chapter gives an overview of the built-in power management features.

The power management infrastructure encompasses the following modules:



- Power Control Unit (MC_PCU): provides a status register, and the Power Management Control Digital Interface (PMC_Dig) submodule, which provides an interface to configure and control internal voltages
- Clock Generation Module (MC_CGM): generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement Low-power modes
- Mode Entry Module (MC_ME): controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application
  - System modes RESET, SAFE, TEST and DRUN are entered automatically on system events or on application request
  - User modes RUN*x*, HALT, and STOP control performance and consumption during normal application operation. The modes are organized according to the performance provided. Each mode is entered via a dedicated key-protected register to avoid unwanted transition

See the respective module chapters for further details.

10.1.1 Power management framework

The power management framework supports a variety of configuration options (see *Figure 54*). SPC574Sx implements a unique core voltage power domain. There are no separate functional power domains.

Figure 54. Concept scheme of the power connections

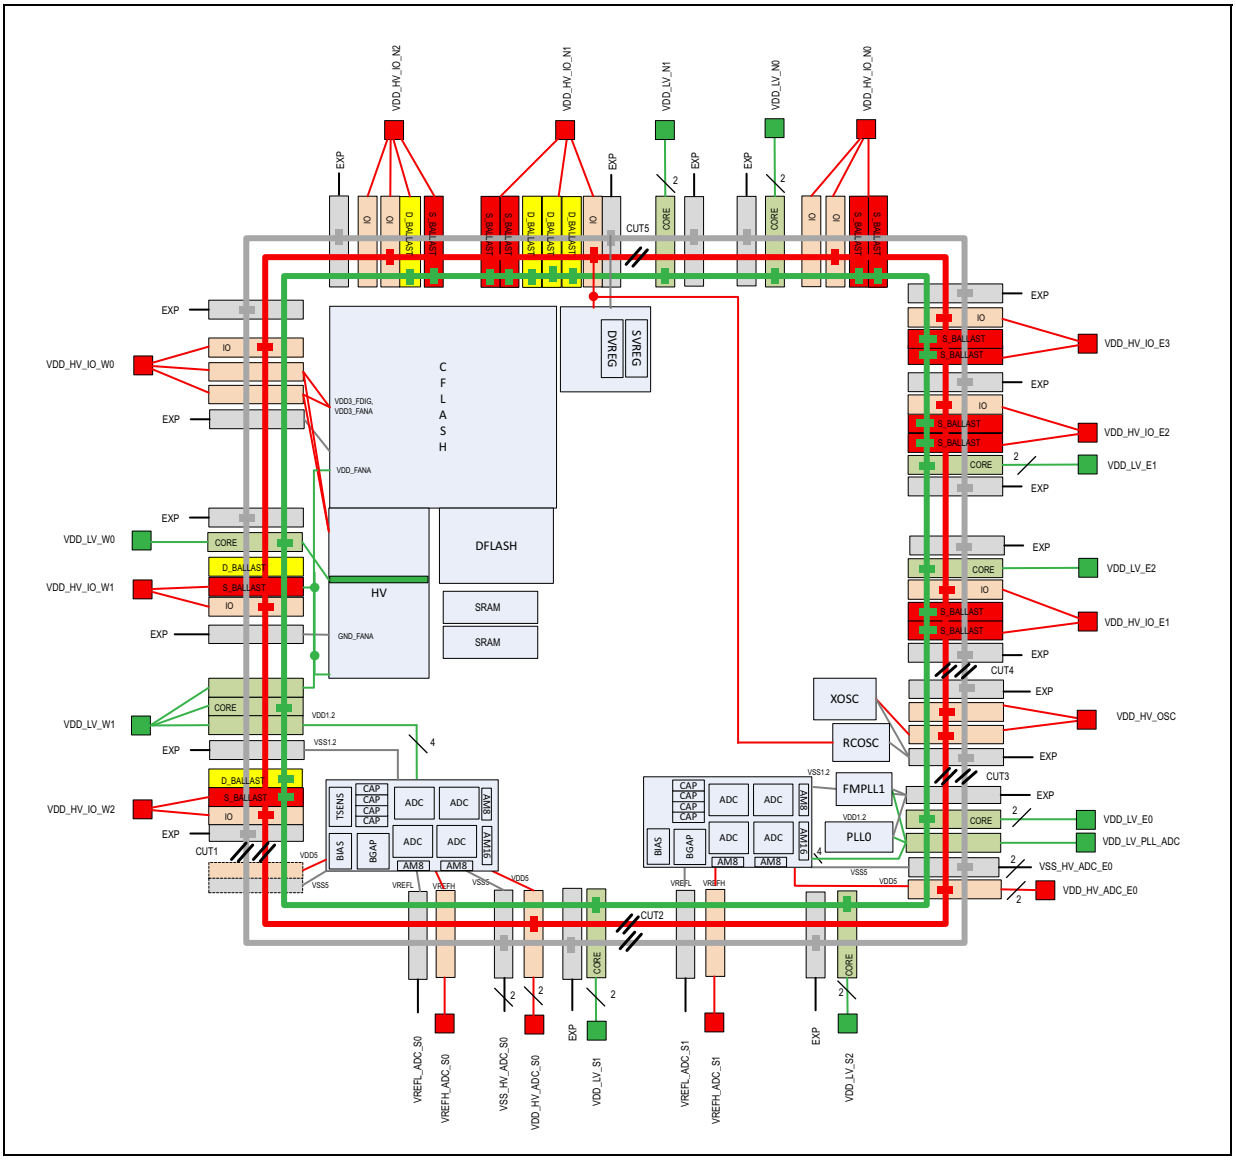
10.1.2 Power management supply description

Table 141 provides an overview of the PMC supply signals.

Table 141. Device power management controller external signals

Supply	Pad	Description
VSS_HV	Exposed pad	Common High voltage ground
VSS_LV	Exposed pad	Common Low voltage ground

Table 141. Device power management controller external signals (continued)



Supply	Pad	Description
VSS_HV_OSC_PMC	Exposed pad	Ground supply for the internal power management unit and the RCOSC
VDD_LV	VDD_LV_PLL_ADC VDD_LV_W0 VDD_LV_W1 VDD_LV_S1 VDD_LV_S2 VDD_LV_E0 VDD_LV_E2 VDD_LV_E1 VDD_LV_N0 VDD_LV_N1	Low voltage power supply for device
VDD_HV_IO0	VDD_HV_IO_W0 VDD_HV_IO_W1 VDD_HV_IO_W2 VDD_HV_IO_N2 VDD_HV_IO_N1	High voltage power supply for I/O rail #0, FLASH, Power Management Unit and RCOSC
VDD_HV_IO1	VDD_HV_IO_E1 VDD_HV_IO_E2 VDD_HV_IO_E3 VDD_HV_IO_N0	High voltage power supply for I/O rail #1
VDD_HV_OSC	VDD_HV_OSC	High voltage power supply for XOSC
VSS_HV_ADC_TSENS	Exposed pad	Ground supply for ADC and TSENS
VDD_HV_ADC_TSENS_0	VDD_HV_ADC_S0	High voltage supply for ADC group #0 and TSENS 0
VDD_HV_ADC_TSENS_1	VDD_HV_ADC_E0	High voltage supply for ADC group #1 and TSENS 1
VREFL_ADC	Exposed pad	Ground reference of ADCs
VREFH_ADC_0	VREFH_ADC_S0	Voltage reference of ADC group #0
VREFH_ADC_1	VREFH_ADC_S1	Voltage reference of ADC group #1

Warning: There are constraints on some input voltages relative to other input voltages. Please refer to the device data sheet for detailed information.

10.2 Architecture

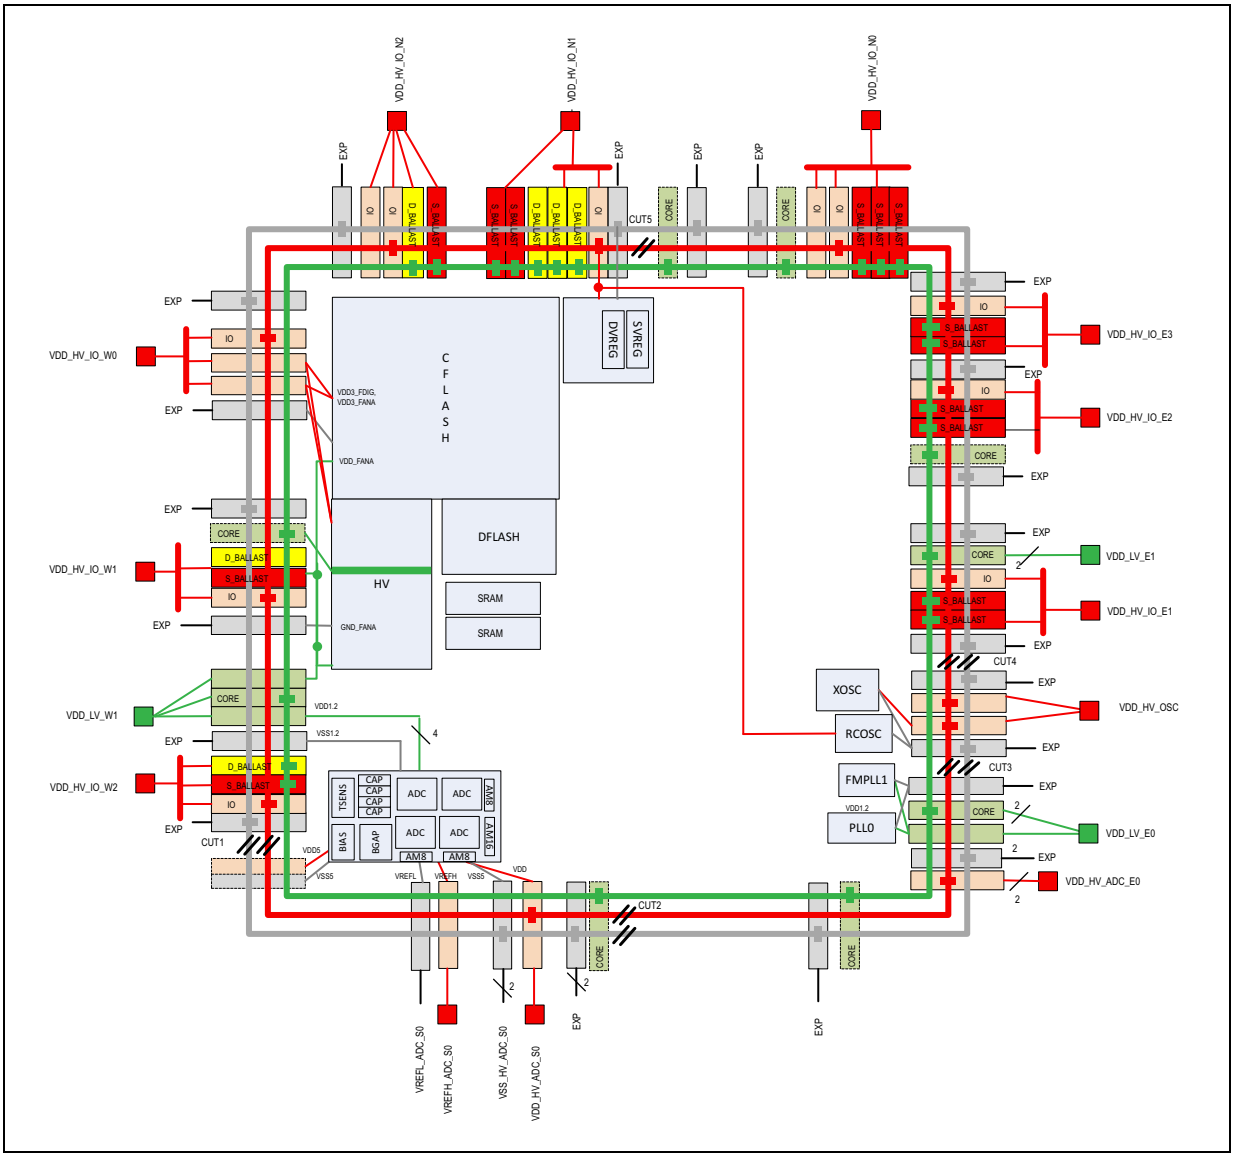


Figure 55 and *Figure 56* show the general power supply scheme for the BGA244/QFP144 package and QFP100 package respectively.

Figure 55. Power supply scheme BGA244 and QFP144(1)

1. GND is connected to GROUND BALLS for the BGA244.
   GND is connected to EXPOSED PAD for the TQFP144.

Figure 56. Power supply scheme QFP100

The HV ring is divided into 5 different physical domains:

- ADC group #0 and Temperature Sensor
- ADC group #1
- IO rail #0, Flash, PMU and RCOSC
- IO rail #1
- XOSC

From user point of view:

- 4 HV supplies are to be considered if the internal LV regulator is not used :
  - ADC group #0
  - ADC group #1
  - IO rail #0 + XOSC + PMU + Flash
  - IO rail #1
- 3 HV supplies are to be considered if the internal LV regulator is used (mandatory for the QFP100 package):
  - ADC group #0
  - ADC group #1[f]
  - IO rail #0 + XOSC + PMU + Flash + IO rail #1

The LV voltage is organized as one single domain. The LV can be generated internally (with internal ballast) or externally, depending on a pin setting. The exposed pad is used to connect the ground ring.

Figure 54 shows the concept scheme of the power connection.

10.2.1 Start-up sequence

There is no constraint on the power startup sequence for LV/HV.

10.2.2 Voltage regulator mode

The voltage regulator can be statically (bonding option) configured as internal or external.

A pin (PWMODE) determines the voltage regulator:

- if connected to GND, then external voltage regulator is used to generate the low voltage
- if connected to VDD, then internal voltage regulator is used to generate the low voltage

10.2.3 Ballast

Two types of ballast are included:

- S_BALLAST, which is a static (or digital) ballast
- D_BALLAST, which is a dynamic (or linear) ballast

The ballasts are circuits placed in the padring, similarly as other pad circuits (supply or input/output functions).

The S_BALLASTs are controlled by the digital regulator to source the static current. Total current capabily for the S_BALLAST on the LV domain is 325mA.

The D_BALLASTs are controlled by the linear regulator to source the dynamic current to support the the transient load response. Total current capability for all the D_BALLAST on the LV domain is 100mA.

Transient time for the dynamic regulation is 20 us for maximum 100mA on the LV.

The S_BALLASTs are enabled only in INTERNAL regulator mode (PWMODE = 1).

f. In case of TQFP100, ADC 1 is not available (refer to *Figure 56: Power supply scheme QFP100*)

The D_BALLASTs are always enabled in INTERNAL regulator mode (PWMODE = 1).

The D_BALLASTs are enabled in EXTERNAL regulator mode (PWMODE = 0) only if the LV supply is out of specs (+/- 5%) as tentative to avoid the device reset.

10.2.4 Reduced power modes

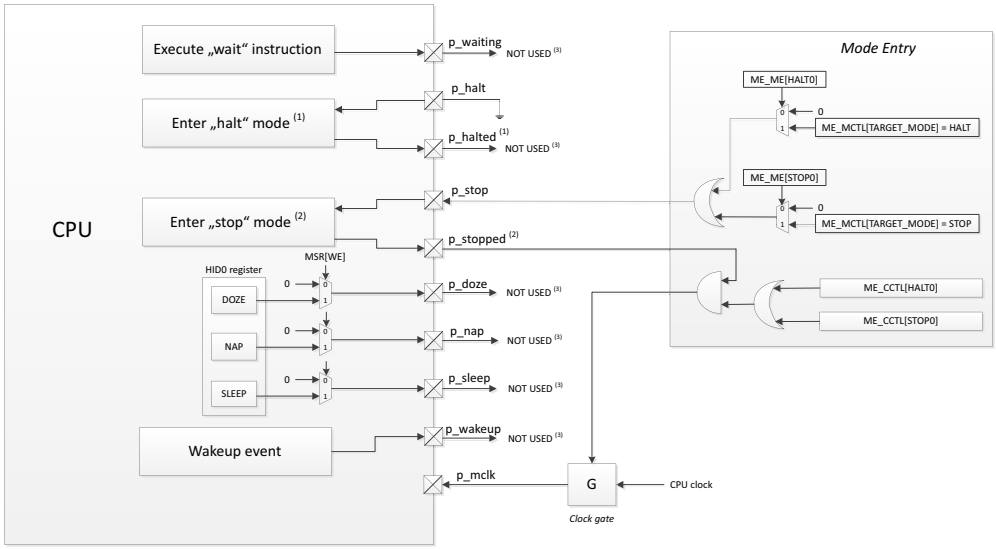

Table 142 shows which reduced power modes are available (as part of the Magic Carpet mode selection) and the corresponding effects.

Table 142. Reduced power mode summary

Mode	Enabled by	Effect
Wait	“wait” instruction execution	No effect
HALT	MC_ME mode change	– CPU enters in STOP mode – RCOSC enabled – PLL0, PLL1,XOSC clock on/off status configurable via ME_HALT0_MC register – Platform clock is stopped
STOP	MC_ME mode change	– CPU enters in STOP mode – RCOSC enabled – PLL0 and PLL1 stopped – XOSC clock on/off status configurable via ME_STOP0_MC register – System clock is forced to the internal RCOSC – Platform clock is stopped – I/O pin power can be disabled via ME_STOP0_MC register
NAP	CPU HID0[NAP] bit writing	No effect
DOZE	CPU HID0[DOZE] bit writing	No effect
SLEEP	CPU HID0[SLEEP] bit writing	No effect

Figure 57 gives a representation of the internal signals regulating the reduced power modes.

Figure 57. Reduced power modes

Note 1: HALT mode => RCOSC enabled; PLL0, PLL1, XOSC clock on/off status configurable via ME_HALT0_MC register
Note 2: STOP mode => RCOSC enabled; PLL0, PLL1 stopped; XOSC clock on/off status configurable via ME_STOP0_MC register; I/O pin power can be disabled via ME_STOP0_MC register; system clock is forced to the internal RCOSC
Note 3: Not used at SOC level but still used within the lockstep core signal comparison

10.2.5 Voltage monitors

The PMU block contains a set of monitors aimed to check the voltage and temperature operating conditions.

10.2.5.1 Nomenclature

- **POR** stands for Power On Reset. It is a circuit that manages the reset from very low voltage up to its threshold. Cannot be disabled
- **MVD** stands for Minimum Voltage Detector. It cannot be disabled by the user and generates a destructive Reset
- **LVD** stands for Low Voltage Detector. It can be disabled by the user
- **HVD** stands for High Voltage Detector. It can be disabled by the user
- **UVD** stands for Upper Voltage Detector. It cannot be disabled by the user and generates a destructive reset

Figure 58 shows the stack of coverage for the voltage monitor.

The operating ranges of the LV/HV for any static/dynamic/PVT/load conditions should be the following:

1. LV = 1.255V +/- 5%
2. HV = 4.5V to 5.5V or 3.0V to 3.6V

30mV of overshoot on the LV is allowed on the top of 1.255V + 5% in the transient time required to stabilize the supply. In case of violation of the allowed overshoot the HVD140_C and UVD145_C detectors can be triggered.

The HVD140_C reaction in case of failure is user defined.

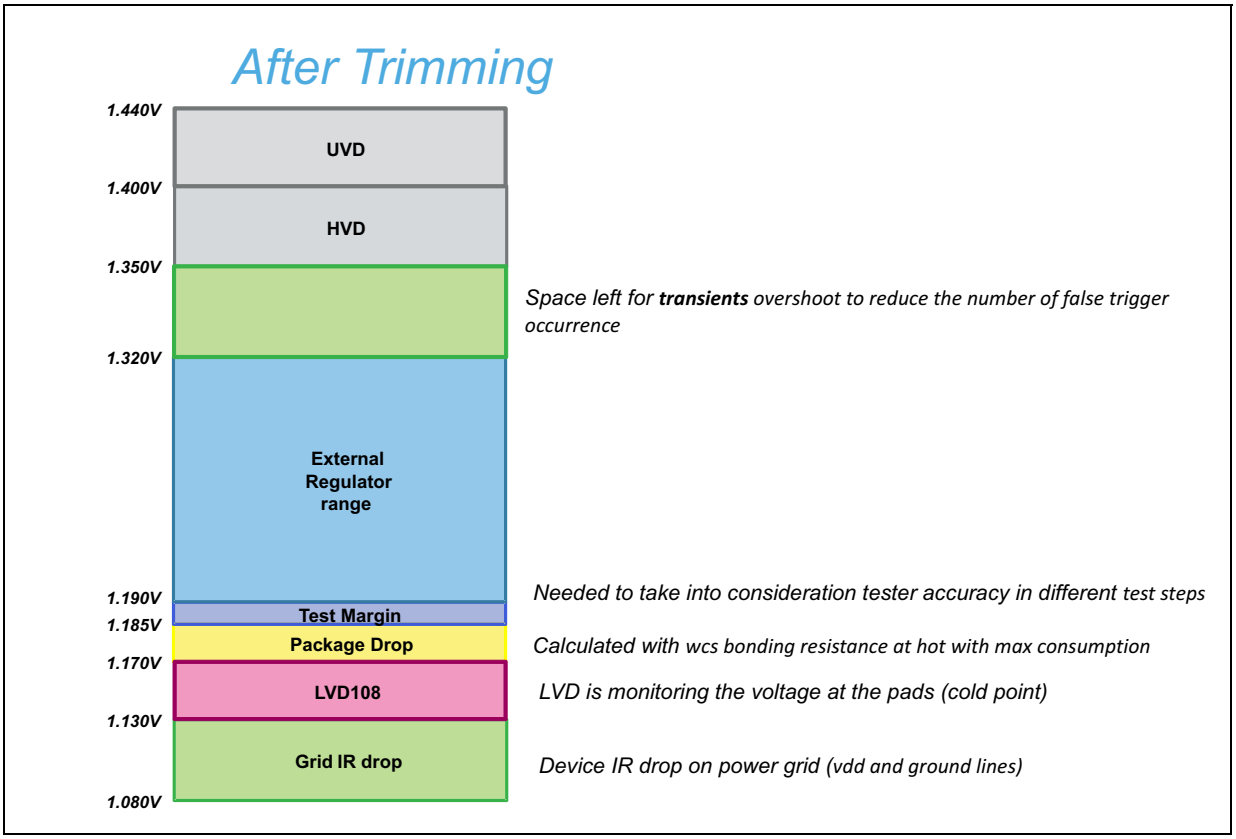
The UVD145_C reaction in case of failure is the destructive reset.

In terms of transient load response, the recommendation is to support 100mA in 20 µs on the LV (as done for the INTERNAL regulator).

On the HV the window is +/- 10%, therefore eventual overshoot must be enclosed in 500mV.

5.5V is the HV limit to operate without reliability degradation.

Figure 58. Voltage monitor coverage stack



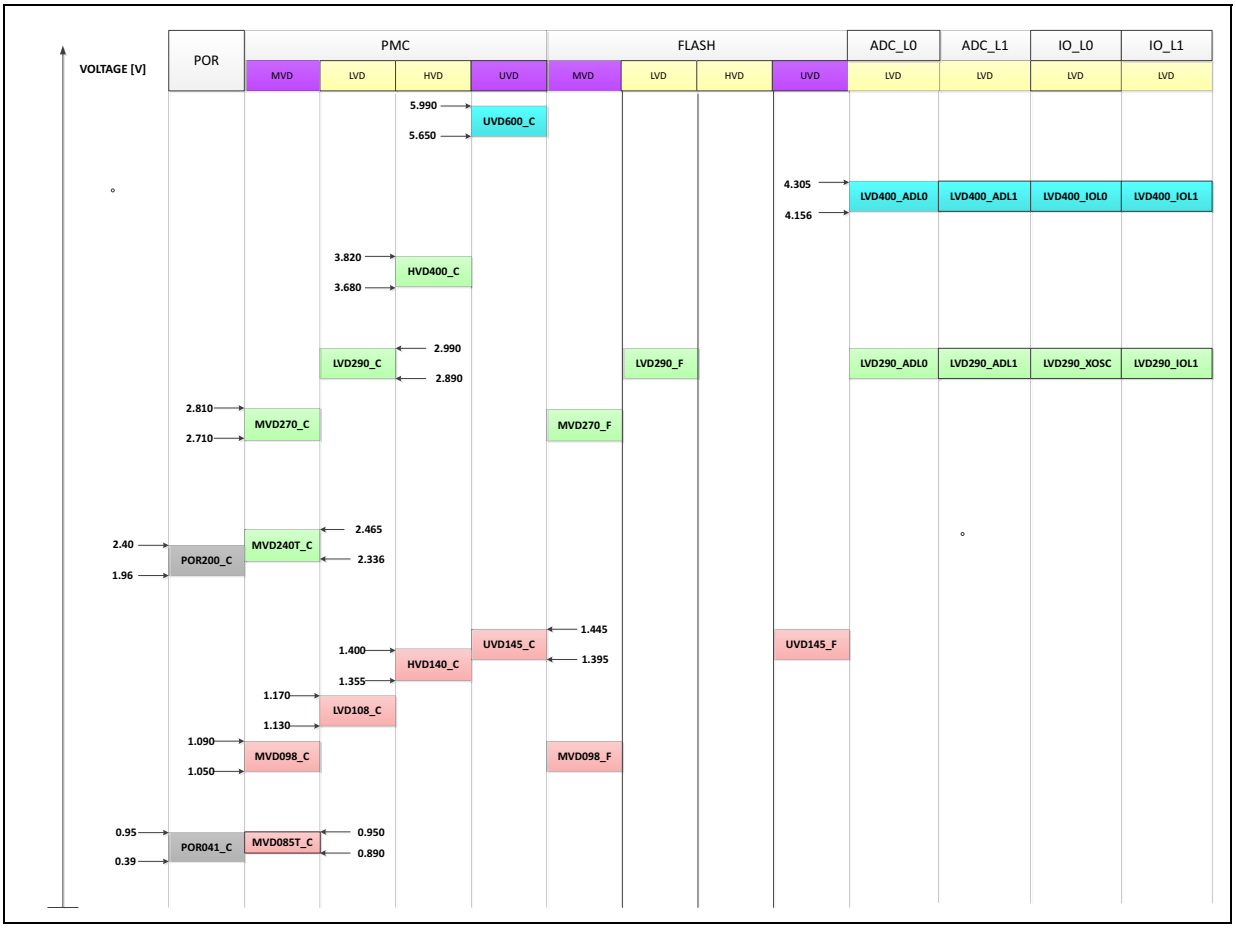


Figure 59 and *Figure 62* show the voltage monitor detailed coverage and functionality.

Figure 59. Voltage monitor coverage

Depending on the chosen power supply for the high voltage, some voltage detectors for the high voltage should be disabled by the user. *Table 143* shows which voltage monitors shall be used according to the high voltage value.

Table 143. Voltage Monitors for the High Voltage

HV = 3.3V	HV = 5V
LVD290_ADL0(1)	LVD400_ADL0(1)
LVD290_ADL1(1)	LVD400_ADL1(1)
—	LVD400_IOL0(2)
LVD290_IOL1(2)	LVD400_IOL1(2)
HVD400_C	—

1. L0 and L1 are equivalent to group #0 and group #1 respectively for the ADC
2. L0 and L1 are equivalent to rail #0 and rail #1 respectively for the IO

10.2.5.2 Voltage monitor reactions

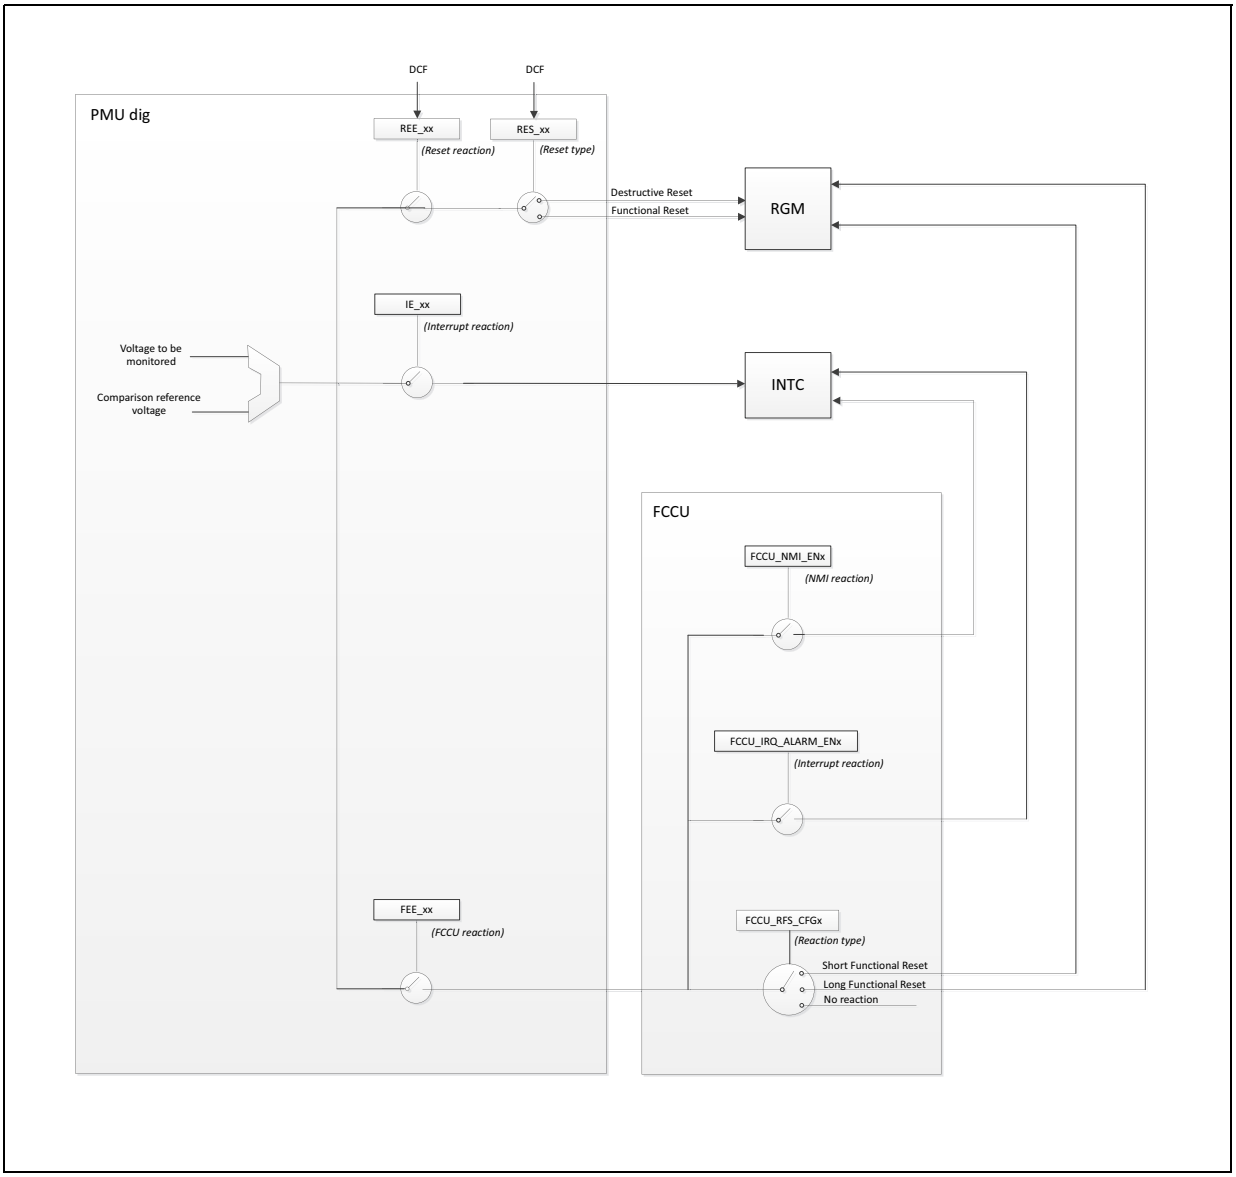

Figure 60 shows the architecture of a monitor in terms of generated trigger and system reaction.

The PMU digital interface makes it possible to enable one of the following reactions:

- destructive reset
- functional reset
- interrupt
- FCCU trigger

If the FCCU trigger reaction is enabled, them through the FCCU registers is it possible to set a system reaction as described in *Chapter 65: Fault Collection and Control Unit (FCCU)*.

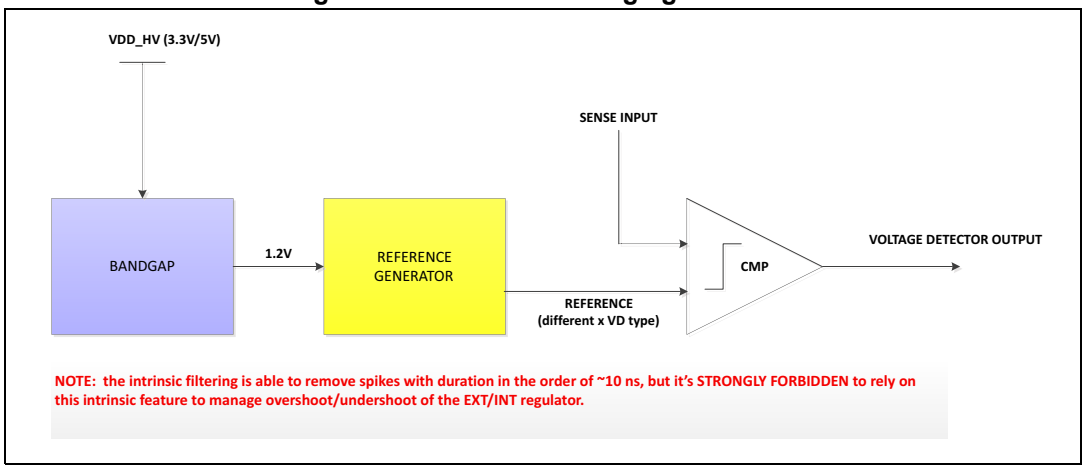

Figure 60. Monitor trigger and system reaction architecture

10.2.5.3 Reference Voltage

Figure 61 shows how is it generated the reference voltage used by the voltage monitor comparators.

Figure 61. Reference Voltage generation

10.2.5.4 Voltage Monitor activation

Figure 62 shows how the voltage monitors functionality and activation option.

Figure 62. Voltage monitor functionality

[1] : mandatory setting to be programmed in the TEST FLASH that cannot be overwritten (VD disabling) by the UTEST FLASH.
[2] : Destructive reset reaction can be set by UTEST or AIPS.
Functional reset reaction can be set by AIPS. AIPS can only modify the type of reaction (RES register -> destructive or functional) without to disable the REE setting by UTEST.
[3] IRQ/FCCU reaction type is USER defined (AIPS) according to the related application.
It's typically enabled if a destructive or functional reset reaction is disabled.

SW setting via AIPS registers init
Default setting (AIPS regs)
SW setting via DCF/AIPS regs init
Default setting w/o DCF init (user/test FLASH)

VD = voltage detector, SW = software (option bit), NA = not available, Y = available, MVD = min VD, LVD = low VD, HVD = high VD, UVD = ultra VD

10.2.6 Device operating status versus power conditions

Table 144 refers to the scenario when the external regulator is used to generate the internal LV supply. The table shows the device operating status and possible safety reaction respect to the eventuality that one or some of the supplies are out of the operating.

Table 144. Device operating status versus Power when the external regulator is used

LV CORE supply	HV supply IO rail #0 / RCOSC	HV supply IO rail #1	ADC supply rail #0	ADC supply rail #1	FLASH HV supply (connected to IO rail #0)	XOSC HV supply (connected to IO rail #0)	Device operating status	Safety reaction
1.2V	3.3V / 5V	3.3V / 5V	3.3V / 5V	3.3V / 5V	Correctly powered by HV rail #0	Correctly powered by HV rail #0	Device FULLY WORKING at 3.3V/5V on each IO/ADC rail	-

1.2V	Floating Ground Out of spec	Don´t care		Floating / Ground / Out of spec	Floating / Ground / Out of spec	DEVICE not WORKING	Destructive Reset

Table 145. Device operating status versus Power when the internal regulator is used (continued)

LV CORE supply	HV supply (IO rail #0 = IO rail #1)	ADC supply rail #0	ADC supply rail #1	FLASH HV supply (connected to IO rail #0)	XOSC/RCOSC HV supply (connected to IO rail #0)	Device operating status	Safety reaction
1.2V	Both 3.3V or both 5V	Floating Ground Out of spec	3.3V / 5V	Correctly powered by HV rail #0	Correctly powered by HV rail #0	Device FULLY WORKING at 3.3V or 5V (depending on the applied supply) on both IO rails and at 3.3V/5V on ADC rail #1. ADC rail #0 not working	User defined
1.2V	Both 3.3V or both 5V	3.3V / 5V	Floating Ground Out of spec	Correctly powered by HV rail #0	Correctly powered by HV rail #0	Device FULLY WORKING at 3.3V or 5V (depending on the applied supply) on both IO rails and at 3.3V/5V on ADC rail #0. ADC rail #1 not working	User defined
1.2V	Both 3.3V or both 5V	Floating Ground Out of spec	Floating Ground Out of spec	Correctly powered by HV rail #0	Correctly powered by HV rail #0	Device FULLY WORKING at 3.3V or 5V (depending on the applied supply) on both IO rails . Both ADC rails not working	User defined

10.2.7 BIST details

To detect failures in the monitoring structure of the Power Management Unit, an internal BIST is implemented which can be run by programming PMU_Dig registers.

The default values of the registers assume a 70 MHz clock (pbridge_clk). The BIST_TIME registers should be programmed accordingly if the BIST is required to run at a different clock frequency (see *Table 147*).

The timing diagram in *Figure 63* explains the sequence for checking three different monitors: LVD_290FL, LVD_290AD and LVD_290C. All inputs and outputs are controlled inside the PMC_Dig module.

Figure 63. Monitor checking timing diagram

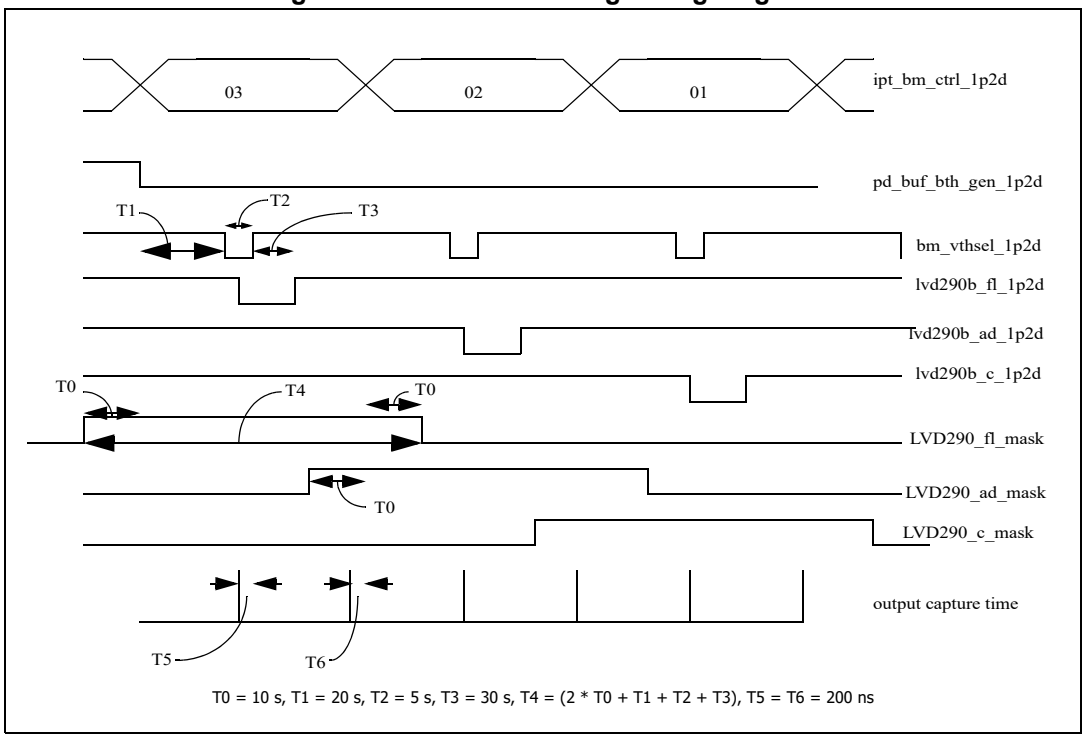

Table 146. Timing descriptions

Label	Description	Value
T0	the time that the monitor output is masked from the SoC before and after the monitor selection.	10 µs
T1	the wait time before the BIST testing for a specific LVD takes place. This is required to take care of the transients on the reference.	20 µs
T2	the time for which "bm_vthsel_1p2d" is kept logic 0.	5 µs
T3	the wait time before starting the testing of next monitor.	32 µs
T4	time for that the testing monitor output is kept masked from the SoC. T4 = 2 * T0 + T1 + T2 + T3	75 µs
T5	the time before "bm_vthsel_1p2d" becomes logic 1 such that the comparator logic 0 output can be checked	200 ns
T6	the time before the end of T3 phase to check logic 1 output of the comparator	200 ns

The BIST_TIME registers need to be programmed according to the following formula:

Equation 1 TIME_*x* = *T*x * pbridge_clk_freq - 1 where *x* is 0 to 3, 5 and 6.
See *Table 146* for the values of T*x*.

Table 147. Calculating the BIST_TIME values

PBRIDGE clock freq.	Base	TIME_0	TIME_1	TIME_2	TIME_3	TIME_5	TIME_6	BIST_TIME registers		
								TIME_10(1)	TIME_32(2)	TIME_65(3)
70 MHz	dec	699	1399	349	2099	14	14	0x057702BB	0x0833015D	0x000E000E

11 Security

This device has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access.

11.1 Basic security

All SPC574Sx devices have the following basic set of security features.

- Device censorship based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
  - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas.
- Monitoring of operating conditions
- Unique ID for each device: Each SPC574Sx device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device.
- Basic debugger restrictions (on/off via censorship mode)

11.2 Advanced security

Depending on the device configuration, the following features are available:

- Secure debugger interface
- Boot mode: Trusted/secure boot support

11.3 Detailed security information

Details of most of the SPC574Sx security features are published in a separate *SPC574Sx Microcontroller Security Reference Manual*, which is only available to qualified customers.

12 Core e200z420n3 Description

12.1 Overview of the e200z420n3 Core

e200z420n3 is a dual-issue 32-bit <asisitalic>PowerISA 2.06 VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z420n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in <asisitalic>PowerISA 2.06, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z420n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z420n3 contains a 8 KB Instruction Cache, and a 4 KB Data Cache and 32KB DMEM, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

Note: There is no IMEM memory support in this core (IMEM related registers are available but with no effect).

A Memory Protection Unit that protects various instruction and data memory areas is also included.

12.2 Register Model

This section describes the registers implemented in the e200z420n3 core. The <asisitalic>PowerISA 2.06 architecture defines register-to-register operations for all computational instructions.

e200z420n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 64 and *Figure 65* show the complete e200z420n3 register set, all of which are accessible in supervisor mode. *Figure 66* and *Figure 67* show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 64. e200z420n3 SUPERVISOR Mode Programmer's Model SPRs

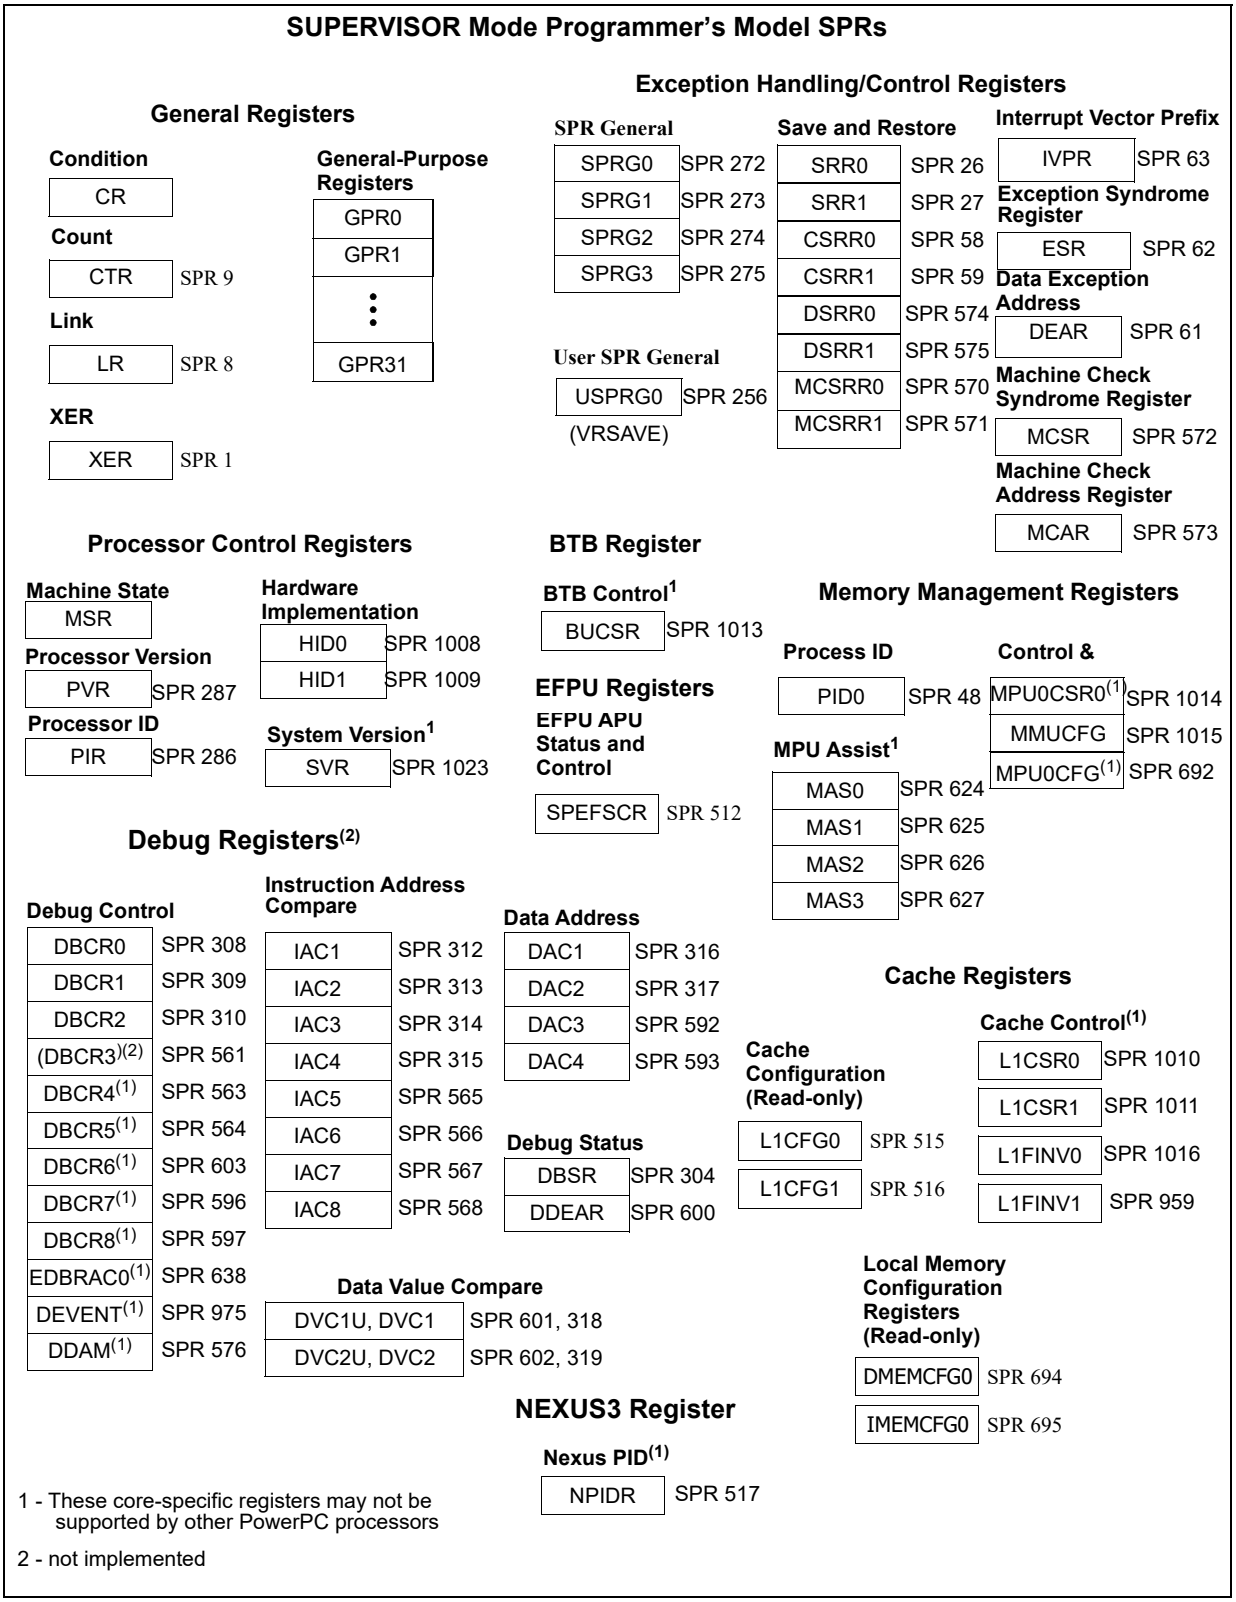

Figure 65. e200z420n3 Supervisor Mode Programmer's Model DCRs and PMRs

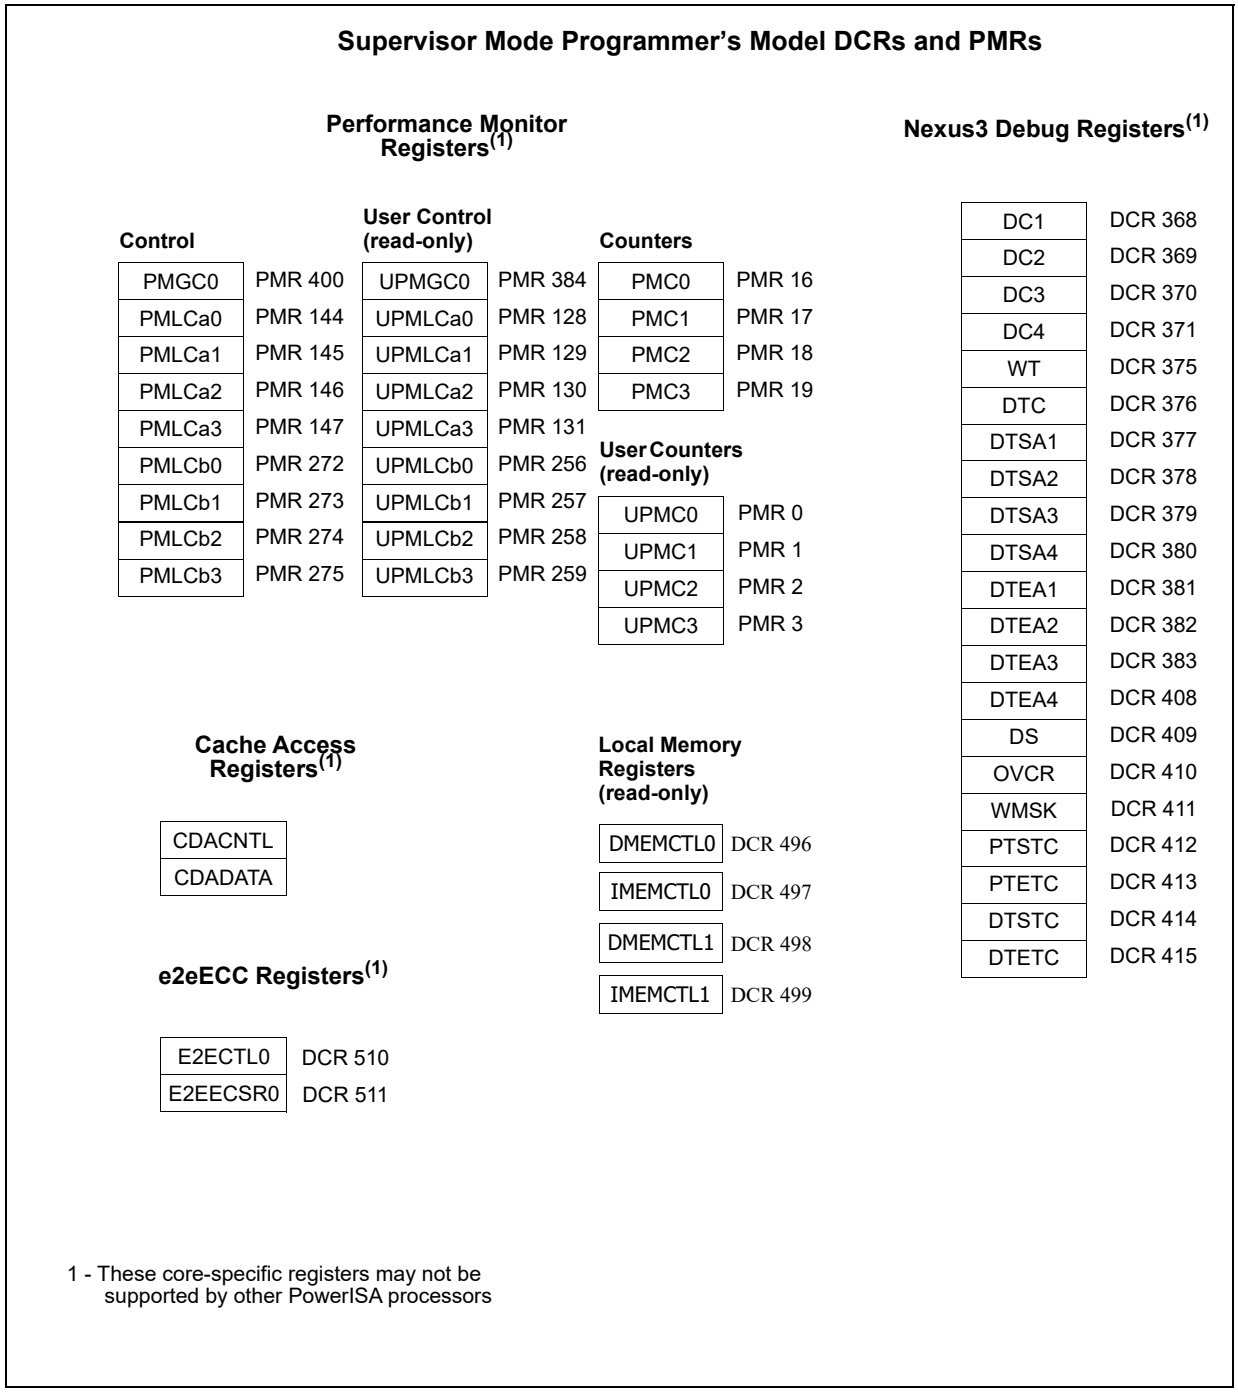

Figure 66. e200z420n3 User Mode Programmer's Model SPRs

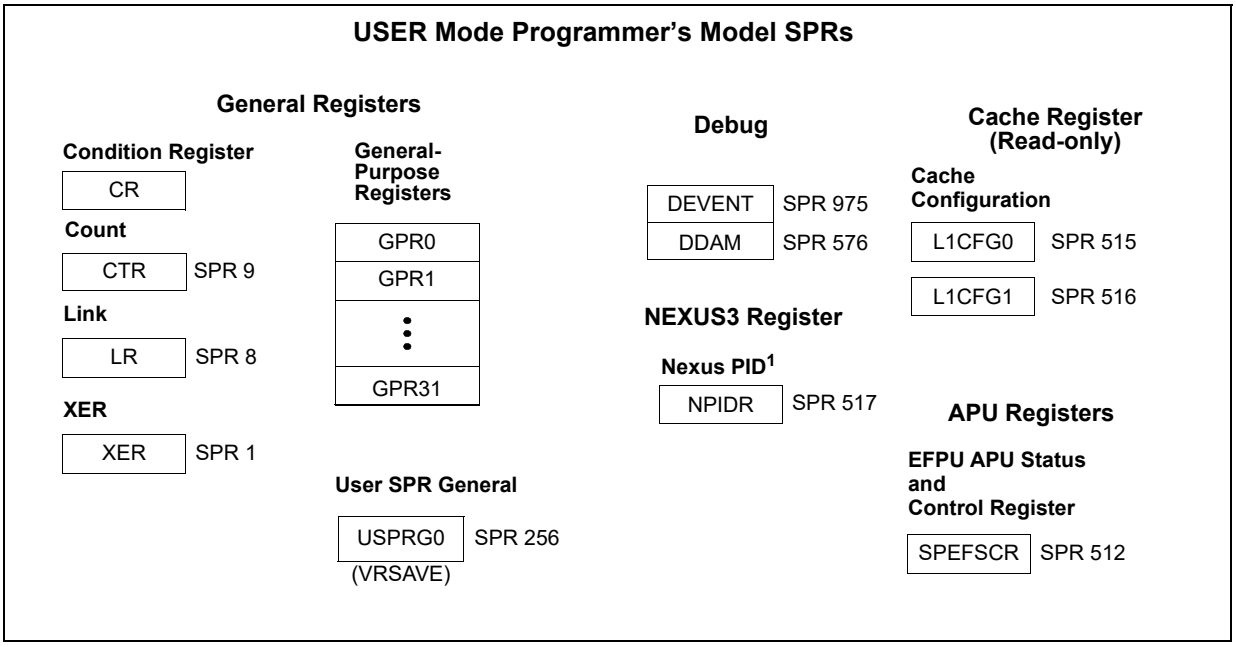

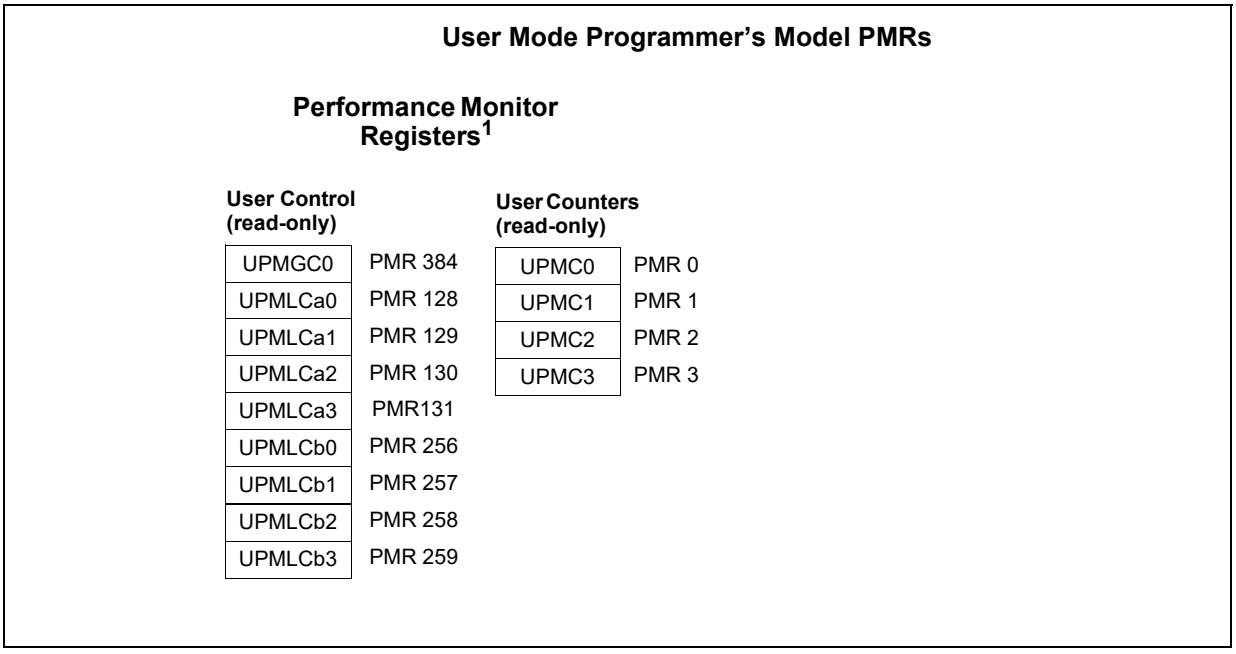

Figure 67. e200z420n3 User Mode Programmer's Model PMRs

12.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

Table 149 shows the e200z420n3 concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 149. Concurrent instruction issue capabilities for e200z420n3

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Special
Branch	—	yes	yes	yes	—
Load/Store	yes	—	yes	yes	—
Scalar integer	yes	yes	yes(1)	yes	—
Scalar float	yes	yes	yes	—	—
Special	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.

12.4 Reservation instructions and cache interactions

The CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx.**, **sthcx.**, and **stwcx.**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built which properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

12.5 Signal Processing Extension/ Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in *Figure 68*

Offset: Refer to *Figure 64* (SPR - 512) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 68. EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in *Table 150*.

Table 150. EFPU Status and Control Register fields description

Field	Description
10 FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z420n3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)

Table 150. EFPU Status and Control Register fields description (continued)

Field	Description
17 OV	Integer overflow Defined by LSP APU.
18 FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.
20 FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
25 FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

Table 150. EFPU Status and Control Register fields description (continued)

Field	Description
28 FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

12.6 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

12.6.1 Cache overview

The e200z420n3 processor supports an 8 KB 2-way set-associative instruction and 4 KB 2-way set-associative data cache with a 32-byte line size. The caches improve system performance by providing low-latency data to the e200z420n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z420n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

12.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in *Figure 69*.

Offset: Refer to *Figure 64* (SPR - 1010) Access: Read/Write

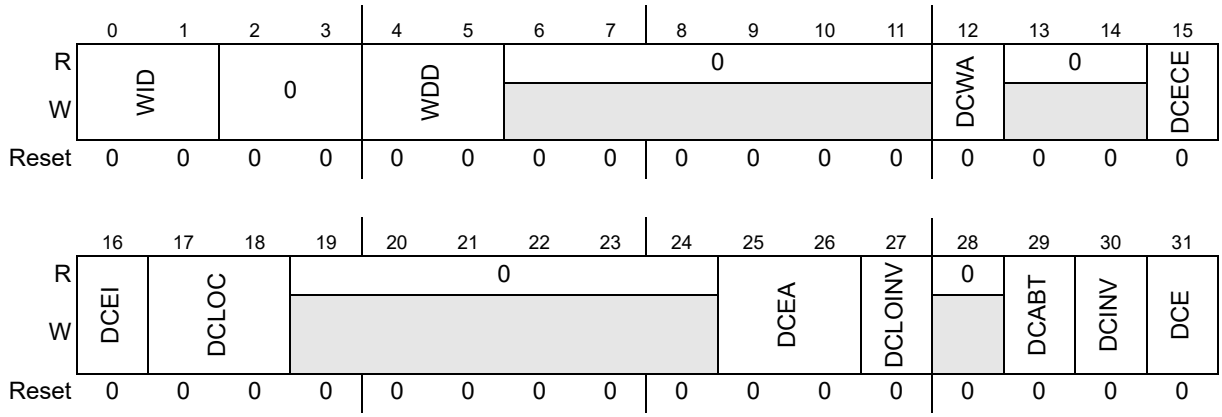

Figure 69. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in *Table 151*.

Table 151. L1CSR0 fields description

Field	Description
0:1 WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
4:5 WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
12 DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
15 DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled

Table 151. L1CSR0 fields description (continued)

Field	Description
16 DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18 DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. **Note:** When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
25:26 DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved

Table 151. L1CSR0 fields description (continued)

Field	Description
27 DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
29 DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30 DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31 DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

12.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in *Figure 70*.

Offset: Refer to *Figure 64* (SPR - 1011) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

27 ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
29 ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30 ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31 ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

12.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z420n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in *Figure 71*.

Offset: Refer to *Figure 64* (SPR - 515) Access: Read only

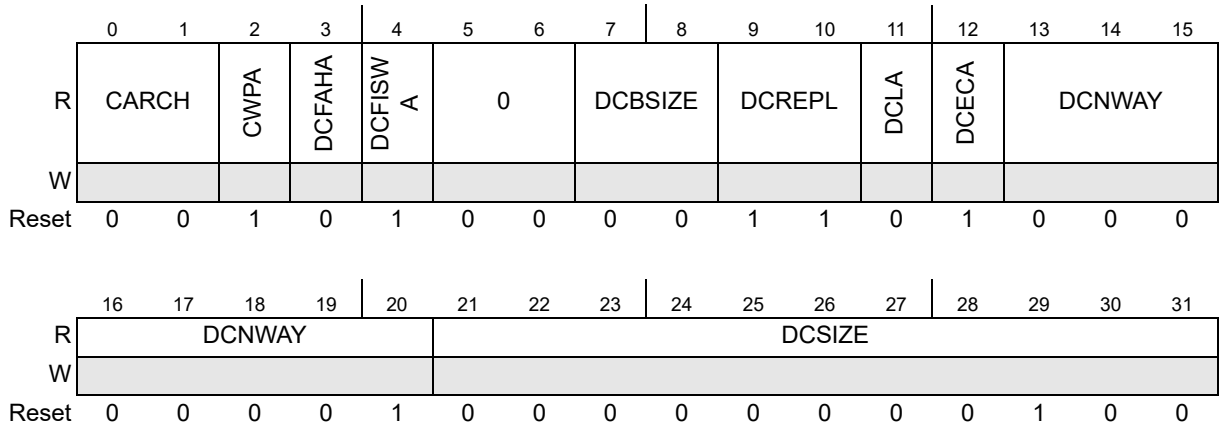

Figure 71. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in *Table 153*.

Table 153. L1CFG0 fields description

Field	Description
0:1 CARCH	Cache Architecture 00 The cache architecture is Harvard
2 CWPA	Cache Way Partitioning Available 1 The caches support partitioning of way availability for I/D accesses
3 DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4 DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0
5:6	Reserved - read as zeros
7:8 DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10 DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11 DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12 DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20 DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31 DCSIZE	Data Cache Size 0x004 The size of the data cache is 4 KB

12.6.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z420n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in *Figure 72*.

Offset: Refer to *Figure 64* (SPR - 516) Access: Read only

Figure 72. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in *Table 154*.

Table 154. L1CFG1 fields description

Field	Description
4 ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
7:8 ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10 ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11 ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12 ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20 ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31 ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

12.6.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

12.6.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

12.6.8 Cache Invalidate by Set and Way

e200z420n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

12.6.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in *Figure 73*.

Offset: Refer to *Figure 64* (SPR - 1016) Access: Read/Write

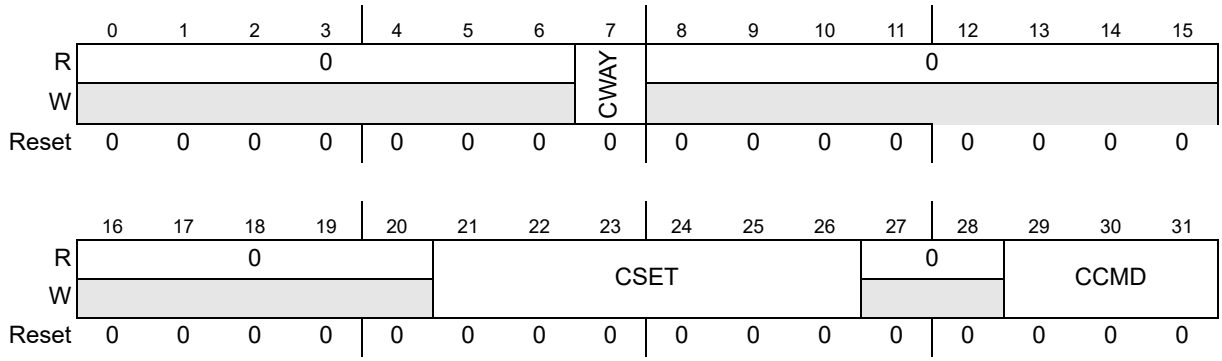

Figure 73. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in *Table 155*.

Table 155. L1FINV0 fields description

Field	Description
0:6	Reserved(1) for way extension
7 CWAY	Cache Way Specifies the data cache way to be selected
8:20	Reserved(1) for set extension
21:26 CSET	Cache Set Specifies the cache set to be selected

Table 155. L1FINV0 fields description (continued)

Field	Description
27:28	Reserved(1) for set/command extension
29:31 CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

12.6.8.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in *Figure 74*.

Offset: Refer to *Figure 64* (SPR - 959) Access: Read/Write

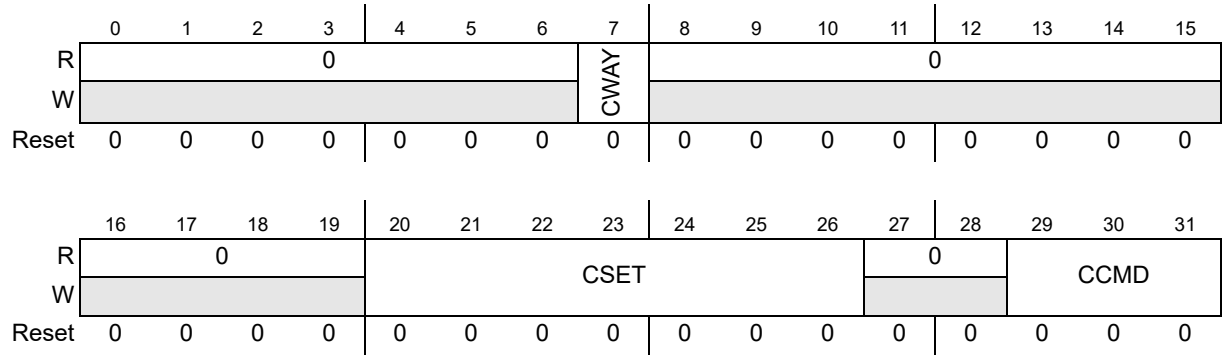

Figure 74. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in *Table 156*.

Table 156. L1FINV1 fields description

Field	Description
0:6	Reserved(1) for way extension
7 CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	Reserved(1) for set extension
20:26 CSET	Cache Set Specifies the instruction cache set to be selected

Table 156. L1FINV1 fields description (continued)

Field	Description
27:28	Reserved(1) for set/command extension
29:31 CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

12.6.9 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the $L1CSR0_{DCECE}$ and $L1CSR1_{ICECE}$ control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

12.6.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can be selectively set when certain errors occur in either the tag or data portion of the cache line. Use of the lockout function and control over error conditions which cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR\{0,1\}_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

12.6.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded.

Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV{0,1} invalidation operation.

12.7 Exceptions

Interrupts implemented in e200z420n3 and the exception conditions that cause them are listed in *Table 157*.

Table 157. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00(1)	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1) **p_mcp_b** transitions from negated to asserted 2)ISI or Bus Error on first instruction fetch for an exception handler 3)Parity Error signaled on Cache access 4)Parity Error signaled on Local Memory access 5)External bus error 6)Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40(2)	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1) **lmw**, **stmw** not word aligned 2) **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3) 4) dcbz
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1, MPU

Table 157. Exceptions and Conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
EFPU Data Exception	0xA0	See core specification about Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	See core specification about Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

12.7.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

Offset: Refer to *Figure 64* (SPR - 62) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0				PIL	PPR	PTR	FP	ST	0			0	0	BO	0

R	0								SPV	0	VLEMI	0			0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 75. Exception Syndrome Register (ESR)

The ESR bits are defined in *Table 158*.

Table 158. ESR fields description

Field	Description	Associated interrupt type
4 PIL	Illegal Instruction exception For Core (e200z225n3), PIL is used for both illegal and unimplemented instructions.	Program
5 PPR	Privileged Instruction exception	Program
6 PTR	Trap exception	Program
7 FP	Floating-point operation	Program
8 ST	Store operation	Alignment Data Storage

Table 158. ESR fields description (continued)

Field	Description	Associated interrupt type
14 BO	Byte Ordering exception Mismatched Instruction Storage exception (Not used by z4203n3. Implemented but not set by hardware.)	Instruction Storage
24 SPV	EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
26 VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call

12.7.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z420n3 MSR is shown in *Figure 76*.

Offset: Refer to *Figure 64* Access: Read/Write

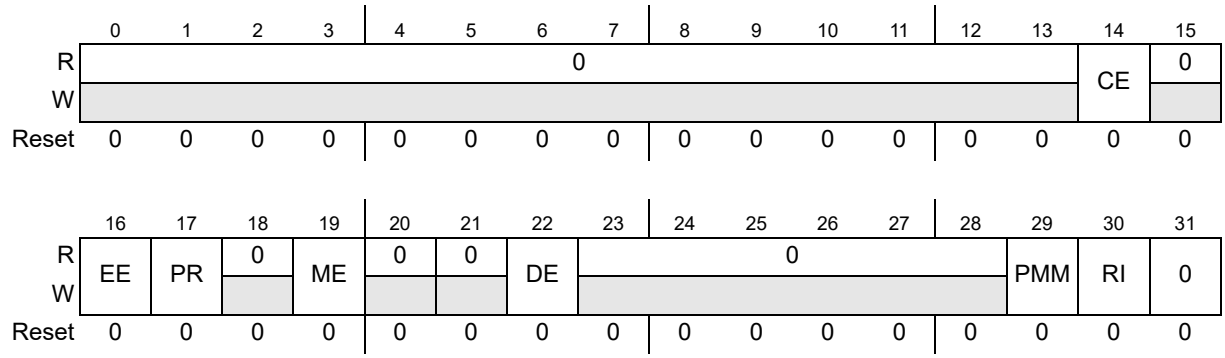

Figure 76. Machine State Register (MSR)

The MSR bits are defined in *Table 159*.

Table 159. MSR fields description

Field	Description
14 CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
16 EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17 PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (For example: GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
19 ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
22 DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
29 PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the Performance Monitor registers PMLCa n, the state for which monitoring is enabled, counting is enabled.
30 RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken

12.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 77*.

Offset: Refer to *Figure 64* (SPR - 572) Access: Read/Clear

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	LD	ST	G	0		STACK_ERR	IMEM_PERR	DMEM_RDPERR	DMEM_WRPERR	0		BUS_IRERR	BUS_DRERR	BUS_WRERR	BUS_WRDSI	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 77. Machine Check Syndrome Register (MCSR)

Table 160 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write 1 to clear.” Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME} = 1.

Table 160. Machine Check Syndrome Register (MCSR) fields description

Field	Description	Exception type(1)	Recoverable
0 MCP	Machine check input pin	Async Mchk	Maybe
1 IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
3 DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4 EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5 IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6 DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe

Table 160. Machine Check Syndrome Register (MCSR) fields description (continued)

Field	Description	Exception type(1)	Recoverable
7 IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8 DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
11 NMI	NMI input pin	NMI	—
12 MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13 MEA	MCAR holds Effective Address If MAV = 1,MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address(2)	Status	—
14 U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15 IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16 LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17 ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise

Table 160. Machine Check Syndrome Register (MCSR) fields description (continued)

Field	Description	Exception type(1)	Recoverable
18 G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
21 STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22 IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23 DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24 DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
27 BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28 BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29 BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30 BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely

1. The Exception Type indicates the exception type associated with a given syndrome bit.

   - “Error Report” indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   - “Status” indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   - “NMI” indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a ‘1’ to the bit position.

   - “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if $MSR_{ME} = 1$. If $MSR_{ME} = 0$, the machine check exception will remain pending. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

2. Note that since no address translation mechanism is present on Zen Z420n3, the MEA value is always set to `0'.

12.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 78*.

Offset: Refer to *Figure 64* (SPR - 63) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Vector Base[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Vector Base[16:23]								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 78. Zen Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in *Table 161*.

Table 161. IVPR fields description

Field	Description
0:23 Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.

12.7.5 Interrupt Definitions

12.7.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signalled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 162 lists register settings when a Critical Input interrupt is taken.

Table 162. Critical Input Interrupt: Register Settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0(1)	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13])** || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

12.7.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 163*.

Table 163. Machine Check Interrupt: Register Settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—(1)	PMM	0
	PR	0			RI	0

Table 163. Machine Check Interrupt: Register Settings (continued)

Register	Setting description
ESR	Unchanged
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.
Vector	$IVPR_{0:23}$ || 0x10

1. Clearing of DE is optionally supported by control in HID0.

12.7.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 164 lists register settings when a DSI is taken.

Table 164. Data Storage Interrupt: Register Settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access which caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

12.7.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

Table 165 lists register settings when an ISI is taken.

Table 165. Instruction Storage Interrupt: Register Settings

Register	Setting description
SRR0	Set to the effective address of the excepting instruction.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table 165. Instruction Storage Interrupt: Register Settings (continued)

Register	Setting description					
MSR	SPV	0	FP0	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

12.7.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signalled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 166 lists register settings when an External Input interrupt is taken.

Table 166. External Input Interrupt: Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt

12.7.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

Table 167 lists register settings when an alignment interrupt is taken.

Table 167. Alignment Interrupt: Register Settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0	—	—	RI	—
ESR	[ST], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	$IVPR_{0:23}$ || 0x50					

12.7.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z420n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z420n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR} = 1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5$ = 1 (even if the SPR is undefined)

The e200z420n3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any <asisitalic>PowerISA 2.06 floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause a illegal instruction program exception.

Table 168 lists register settings when a Program interrupt is taken.

Table 168. Program Interrupt: Register Settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt

MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x60					

12.7.5.8 Performance Monitor Interrupt (Offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 169 lists register settings when an performance monitor interrupt is taken.

Table 169. Performance Monitor Interrupt: Register Settings

Register	Setting description					
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.					
SRR1/ DSRR1(1)	Set to the contents of the MSR at the time of the interrupt.					
MSR	SPV	0	FP	0	FE1	0

DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x80					

12.7.5.10 Debug Interrupt (offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM}$ = 1 (internal debug mode) and MSR_{DE} = 1).

Table 171 lists register settings when a Debug interrupt is taken.

Table 171. Debug Interrupt: Register Settings

<table>
<tr><th>Register</th><th colspan="6">Setting description</th></tr>

12.7.5.11 Embedded Floating-point Data Interrupt (Offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

Table 172 lists register settings when a EFPU Floating-point Data interrupt is taken.

Table 172. Embedded Floating-point Data Interrupt: Register Settings

DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0xB0

12.7.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signalled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 174 lists register settings when a System Reset interrupt is taken.

Table 174. System Reset Interrupt: Register Settings

12.8 Memory Protection Unit (MPU)

12.8.1 MPU Overview

The e200z420n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

12.8.2 Access Protection Operation

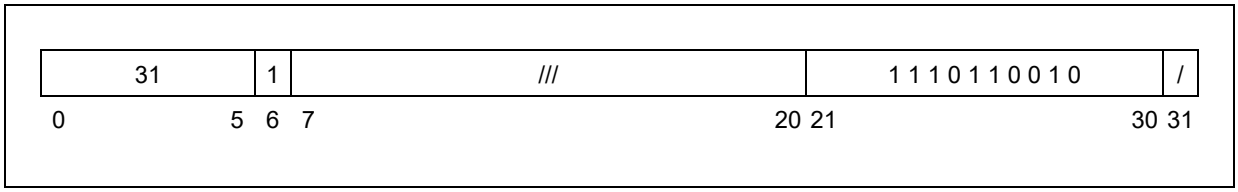
The Zen z420n3 Memory Protection Unit (MPU) provides access protection to memory regions using a set of region descriptors contained in a table structure. Each region descriptor defines an address range and a set of access protections and memory attributes. Individual region descriptors monitor either instruction accesses or data accesses. Independent access protection may be configured for supervisor-mode and user-mode reads, writes, and instruction accesses. In addition, any subset of these access types can bypass the protection system and instead rely on an external system MPU for enforcing access protections. This allows for an increased number of regions to be supported in a SoC, without requiring excessive processor resources.

Access addresses which fall within the address range(s) of one or more enabled region descriptors (a match) are allowed to proceed if the access permissions for any matching descriptor are set to allow the access. If no matching region descriptor is found, the access will not be allowed, and an Instruction Storage Interrupt (ISI) or Data Storage Interrupt (DSI) will be generated. If more than one matching descriptor is found, the access permissions enforced are the least restrictive access permissions defined by the matching entries.

Allowed accesses are based only on an address compare of the first byte of data being accessed; no checking is performed that the data associated with a single access is entirely contained in an allowed region.

For accesses which are not configured to bypass the protection system, a matching region descriptor with access permissions set to allow the type of access is required for the access to proceed without an access permission violation. An access permission violation results in the MPU signaling a protection violation via a DSI or an ISI, and the access is aborted.

Memory attributes of Guarded (for data accesses only) and Cache-Inhibited are provided in each descriptor, and are applied to matching accesses which pass permissions checking. In addition to controlling cache behavior, these attributes are used to control certain aspects of access ordering and buffering, and also to drive external system interface access attributes.

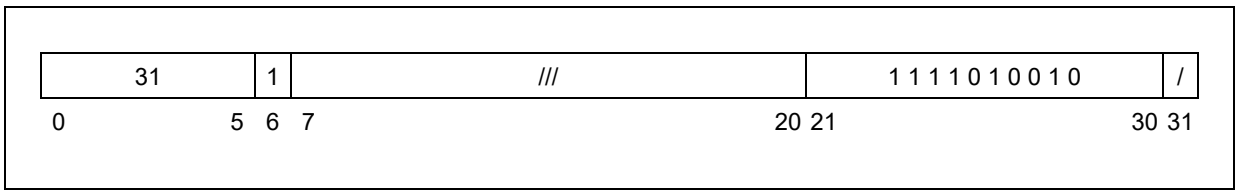


12.8.3 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

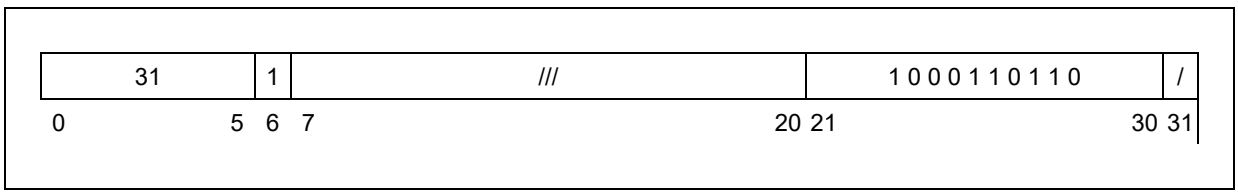
12.8.4 MPU Read Entry Instruction (mpure)



The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

12.8.5 MPU Write Entry Instruction (mpuwe)



The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

12.8.6 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z420n3.

12.8.7 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z420n3 MPU design. The MMUCFG register is shown in *Figure 79*.

Offset: Refer to *Figure 64* (SPR - 1015) Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 79. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 175*.

Table 175. MMUCFG fields description

Field	Function
8:14 RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
21:25 PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27 NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29 NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31 MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

12.8.8 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z420n3 MPU. The MPU0CFG register is shown in *Figure 80*.

Offset: Refer to *Figure 64* (SPR - 692) Access: Read Only

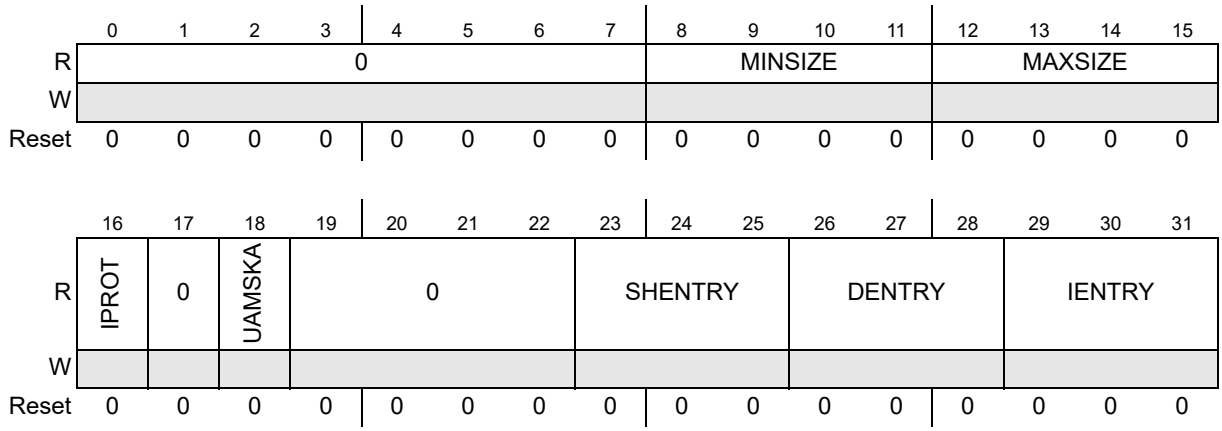

Figure 80. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in *Table 176*.

Table 176. MPU0CFG fields description

Field	Function
0 FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	Reserved for non-fully associative implementation use
8:11 MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15 MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16 IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
18 UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
23:25 SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28 DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31 IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

12.8.9 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in *Figure 81*.

Offset: Refer to *Figure 64* (SPR - 1014) Access: Read/Write

Figure 81. 32-bit register (REG NAME)

The MPU0CSR0 bits are described in *Table 177*.

Table 177. MPU0CSR0 fields description

Field	Description
16 BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17 BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18 BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19 BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses

Table 177. MPU0CSR0 fields description (continued)

Field	Description
20 BYPUW	Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21 BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
24 DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25 DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26 IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
28 TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode

Table 177. MPU0CSR0 fields description (continued)

Field	Description
30 MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. Note that entries which have the IPROT bit set will not be invalidated. 0 No flash invalidate 1 MPU1 invalidation operation
31 MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

12.8.10 MPU Assist Registers (MAS)

The e200z420n3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 82*. Fields are defined in *Table 178*.

Offset: Refer to *Figure 64* (SPR - 624) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Figure 82. MPU Assist Register 0 (MAS0)

Table 178. MAS0 (MPU Read/Write and Replacement Control) fields description

Name	Comments, or Function when Set
0 VALID	MPU Entry Valid 0 This MPU entry is invalid 1 This MPU entry is valid
1 IPROT	Invalidation Protect 0 Entry is not protected from invalidation 1 Entry is protected from invalidation
2:3 SEL	Selects MPU for access: 00 Reserved, no access 01 Reserved, no access 10 Select MPU 11 Reserved, no access
5 RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 This MPU entry is writable 1 This MPU entry is Read-only
6 DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7 INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 This MPU entry is used for matching data accesses only 1 This MPU entry is used for matching instruction accesses only
8 SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.

Table 178. MAS0 (MPU Read/Write and Replacement Control) fields description

Name	Comments, or Function when Set
12:15 ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
17:19 UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 No upper address bits are masked, address matching uses all 32 address bits for accesses 001 The most significant access address bit is forced to zero before matching 010 The two most significant access address bits are forced to zero before matching 101 The upper five access address bits are forced to zero before matching 11x Reserved, do not use
20 UW	User Mode Write Permission Determines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No User mode Write permission 1 User mode has Write permission
21 SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No Supervisor mode Write permission 1 Supervisor mode has Write permission
22 UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 No User mode Execute/ Read permission 1 User mode has Execute/ Read permission
23 SX/SR	Supervisor Mode Execute / Read Permission Determines Supervisor mode Execute (X) permission when INST = 1, or Supervisor mode Read (R) permission when INST = 0. 0 No Supervisor mode Execute/ Read permission 1 Supervisor mode has Execute/ Read permission
24 IOVR	Cache-Inhibit attribute Override Determines whether this matching entry overrides the I bit settings of other matching entries and the cache-inhibited region configuration signals 0 No override of I attribute by entry 1 Entry I bit overrides I attribute
25 GOVR/—	G attribute Override Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 No override of G attribute by entry 1 Entry G bit overrides G attribute

Table 178. MAS0 (MPU Read/Write and Replacement Control) fields description

Name	Comments, or Function when Set
28 I	Cache Inhibited This attribute may be overridden by the cache-inhibited region configuration input settings. 0 This region is considered cacheable 1 This region is considered cache-inhibited
30 G/—	Guarded This attribute may be overridden by the guarded region configuration input settings. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 All loads and stores to this region are performed without speculation (this means they are known to be required)

The MAS1 register is shown in *Figure 83*. Fields are defined in *Table 179*.

Offset: Refer to *Figure 64* (SPR - 625) Access: Read/Write

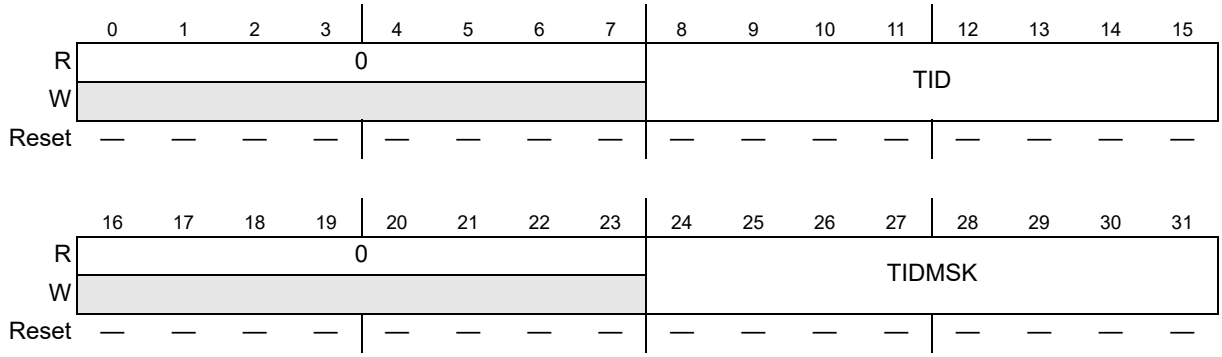

Figure 83. MPU Assist Register 1 (MAS1)

Table 179. MAS1 (Descriptor Context and Configuration Control) fields description

Name	Comments, or Function when Set
8:15 TID	Region ID bits This field is compared with the current process ID of the access address. A TID value of 0 defines an entry as global and matches with all process IDs.
24:31 TIDMSK	Region ID mask 0xxxxxxx TID[0] comparison to PID0[0] not masked 1xxxxxxx TID[0] comparison to PID0[0] is masked x0xxxxxx TID[1] comparison to PID0[1] not masked x1xxxxxx TID[1] comparison to PID0[1] is masked xx0xxxxx TID[2] comparison to PID0[2] not masked xx1xxxxx TID[2] comparison to PID0[2] is masked xxx0xxxx TID[3] comparison to PID0[3] not masked xxx1xxxx TID[3] comparison to PID0[3] is masked xxxx0xxx TID[4] comparison to PID0[4] not masked xxxx1xxx TID[4] comparison to PID0[4] is masked xxxxx0xx TID[5] comparison to PID0[5] not masked xxxxx1xx TID[5] comparison to PID0[5] is masked xxxxxx0x TID[6] comparison to PID0[6] not masked xxxxxx1x TID[6] comparison to PID0[6] is masked xxxxxxx0 TID[7] comparison to PID0[7] not masked xxxxxxx1 TID[7] comparison to PID0[7] is masked This field controls whether bits within the TID to PID0 comparison are masked for determining a range match. When a bit is masked, the value of that TID and PID0 bit is ignored for matching purposes.

The MAS2 register is shown in *Figure 84*. Fields are defined in *Table 180*.

12.8.11 MAS Registers Summary

The MAS registers are summarized in *Figure 86*.

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Figure 86. MPU Assist Registers Summary

12.9 Local memories

12.9.1 Local Instruction and Data Memory Overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

12.9.2 Local Memory Control and Configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs which are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

12.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z420n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 87*.

Offset: Refer to *Figure 64* (SPR - 694) Access: Read Only Privileged

Figure 87. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 182*.

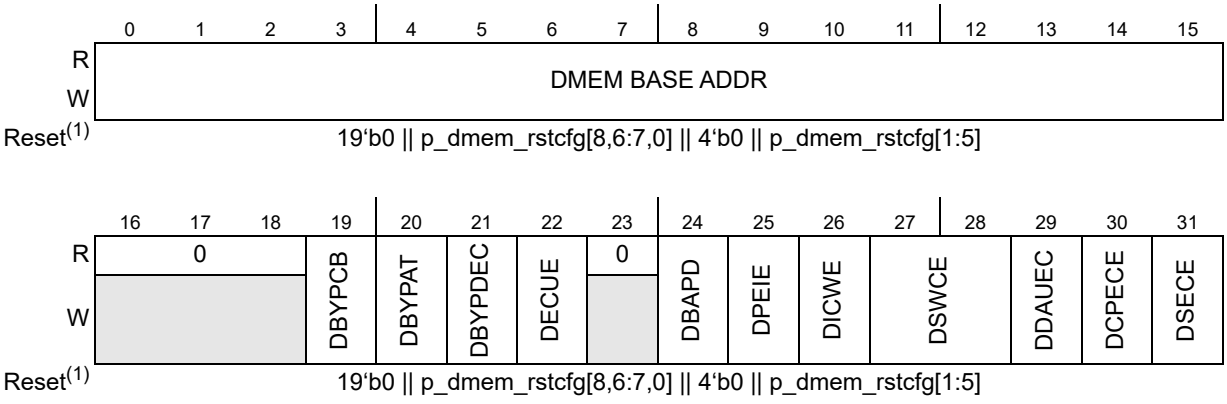

Table 182. DMEMCFG0 fields description

Field	Description
0:19 DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0's when the DMEM size is > 4 KB
21 DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access
22 DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available 1 Error Correction is available
24:29 DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB

12.9.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

Offset: Refer to *Figure 65* (DCR - 496) Access: Read/Write Privileged

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Figure 88. DMEM Control Register 0 (DMEMCTL0)

Table 183. DMEMCTL0 field descriptions

Field	Description
0:15 DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
19 DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses which target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.
20 DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems which support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input. 0 Atomic CPU accesses do not bypass the DMEM CPU port 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.
21 DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems which support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.

Table 183. DMEMCTL0 field descriptions (continued)

Field	Description
22 DECUE	DMEM Error Correction Update Enable DECUE can be used to provide an error scrubbing function for the DMEM. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM.
24 DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25 DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26 DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28 DSWCE	DMEM Slave port Write Check/Correct Enable **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs. 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors.

Table 183. DMEMCTL0 field descriptions (continued)

Field	Description
29 DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
30 DCPECE	DMEM CPU Port ECC Enable (CPU port) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input. 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated.
31 DSECE	DMEM Slave port Error Checking Enable (Slave port) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input. 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated.

12.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses which target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.

Figure 91. IMEM Control Register 0 (IMEMCTL0)

Table 186. IMEMCTL0 fields description

Field	Description
0:17 IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.
18:19	Reserved for Base Address extension
22 IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[0]** input. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
24 IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_imem_baseaddr[0:n]**) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
27:28 ISWCE	IMEM Slave port Write Check/Correct Enable **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_imem_rstcfg[1:2]** inputs. 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected.

Table 186. IMEMCTL0 fields description (continued)

Field	Description
29 IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[3]** input. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
30 ICPECE	IMEM CPU Port ECC Enable (CPU port) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[4]** input. 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated.
31 ISECE	IMEM Slave port Error Checking Enable (Slave port) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[5]** input. 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated.

12.9.2.6 IMEM Control Register 1 (IMEMCTL1)

Note: These locations are accessible by S/W and will not result in error if accessed.

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

12.10 End-to-End ECC Support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

12.10.1 End-to-End ECC Control and Configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

12.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

Offset: Refer to *Figure 65* (DCR - 510) Access: Read/Write Privileged

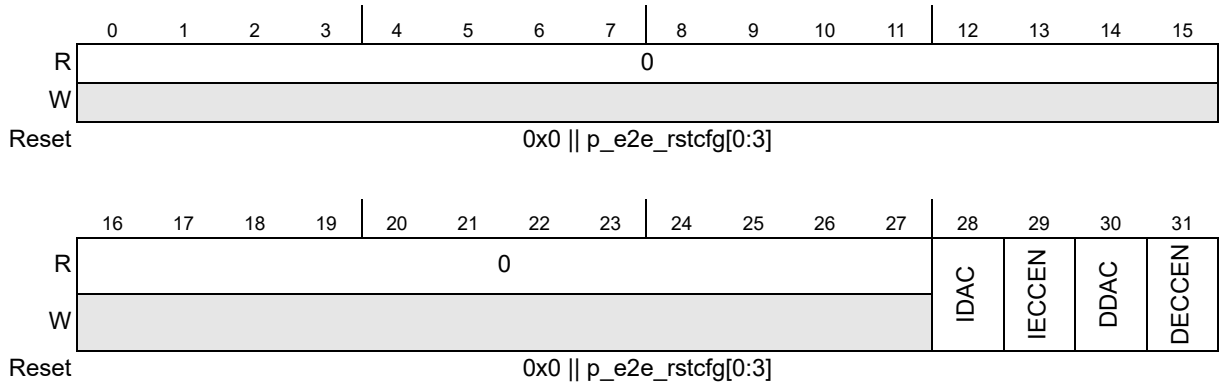

Figure 93. e2eECC Control Register 0 (E2ECTL0)

Table 188. E2ECTL0 fields description

Field	Description
28 IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
29 IECCEN	Instruction ECC Enable Field **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input. 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution.

Table 188. E2ECTL0 fields description (continued)

Field	Description
30 DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
31 DECCEN	Data ECC Enable Field **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input. 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for non-zero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

12.10.1.2 End-to-End ECC Error Generation by Software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 94 shows the layout of E2EECSR0.

Offset: Refer to *Figure 65* (DCR - 511) Access: Read/Write Privileged

Table 189. E2EECSR0 fields description

Field	Description
4:11 RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
16:17 WRC	Write Control **Note:** Checkbit substitution has priority over Error injection 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved

Table 189. E2EECSR0 fields description (continued)

Field	Description
18:19 INVC	Invert Control **Note:** Checkbit substitution has priority over Error injection 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved
24:31 WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

13 Crossbar switch (XBAR)

13.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

13.1.1 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
  - Concurrent accesses from different masters to different slaves
  - Configurable slave arbitration attributes on a slave-by-slave basis
- 32-bit datapath width
- Support for 8-, 16-, and 32-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

13.1.2 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require two bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the Chapter 7: Device configuration: Section 7.3.2.1: Crossbar switch (XBAR) configuration for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

Table 190. XBAR memory map

Offset address (hex)	Register name	Width (in bits)	Access	Location

13.1.2.1 XBAR Priority Registers Slave (XBAR_PRS*n*)

The priority registers (XBAR*x*_PRS*n*) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. The XBAR*x*_PRS*n* register is read-only; attempts to write to it have no effect on it and result in a bus-error response to the master initiating the write.

See *Chapter 7: Device configuration*: *Section 7.3.2: Crossbar switch* for XBAR*x*_PRS*n* priority values.

Offset: 0x0000 + *n**0x100 (*n* = 0 to 4) Access: Supervisor read-only

Figure 96. XBAR Control Register (XBAR_CRS*n*)

Table 192. XBAR_CRS*n* field descriptions

Field	Description
0 RO	Read only Forces both of the slave port's registers to be read-only. After set, only a hardware reset clears it. 0 The slave port's registers are writable. 1 The slave port's registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
1 HRP	Halt Request Priority Determines if a request to halt the crossbar is treated as the highest priority request, or the lowest priority request. 0 The halt request has the highest priority for arbitration on this slave port. 1 The halt request has the lowest initial priority for arbitration on this slave port.
12:15 HPE[3:0]	High Priority Enable Determines if Master x is able to temporarily elevate its request to the slave to high priority status. This can help reduce the amount of time the high priority requesting mster must wait to gain control of the slave. 0 High Priority requests from Master x are ignored and are treated the same as regular requests. 1 High Priority requests from Master x can temporarily elevate the priority level of the master's request to the slave.
22:23 ARB	Arbitration mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved
26:27 PCTL	Parking control Determines the slave port's parking control. The low-power park feature results in overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11 Reserved
30:31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **Note:** Only select master ports that are actually present on the device. If not, undefined behavior may occur. 00 Park on master port M0 01 Park on master port M1 10 Park on master port M2 11 Park on master port M3

13.2 Functional description

This section provides the functional details of the crossbar switch.

13.2.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes. When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being IDLEd by the crossbar, it can park the slave port on the master port indicated by the XBAR*x*_CRS*n*[PARK]. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using XBAR*x*_CRS*n*[PCTL].

13.2.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

13.2.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

13.2.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the XBAR*x*_PRS*n* (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master's priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

13.2.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

13.3 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

14 System Integration Unit Lite2 (SIUL2)

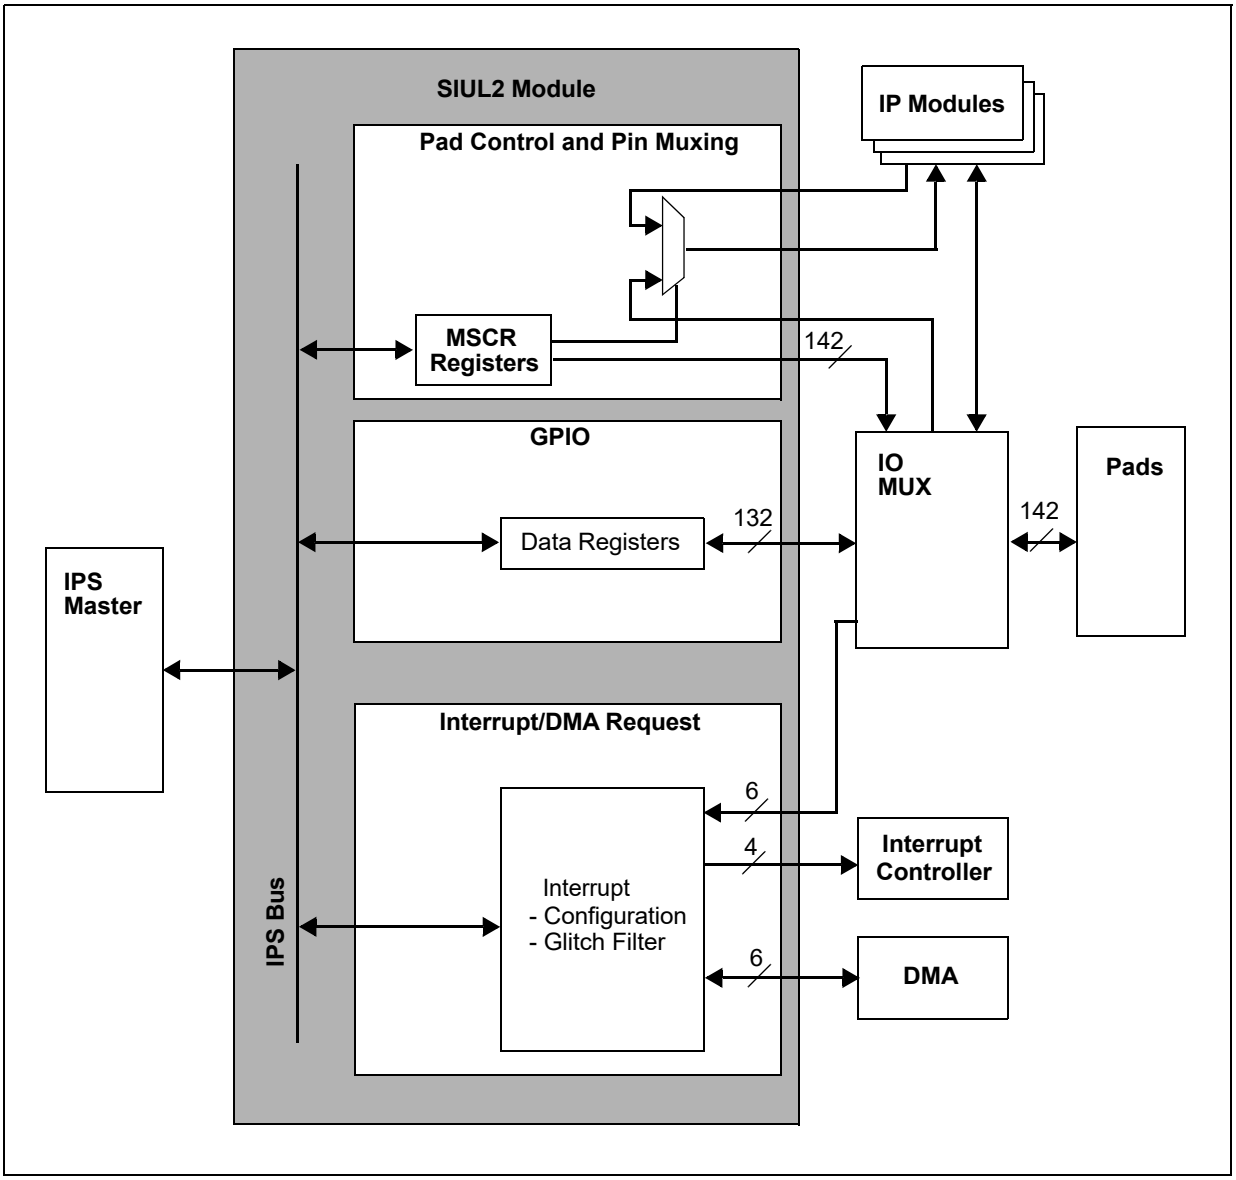
14.1 Introduction

14.1.1 Overview

The System Integration Unit Lite2 (SIUL2) provides control over all the I/O ports on this device and supports five ports with 16 bit of bidirectional, general-purpose input and output signals. It supports six external interrupts with independent trigger event configuration, that are combined to generate four internal interrupts versus the interrupt controller. For more details see *Section 14.3.4: External interrupts/DMA requests (EIRQ pins)*. *Figure 97* is the block diagram of SIUL2 and its interfaces to other system components for this device.

The module provides dedicated general-purpose pads that can be configured as either inputs or outputs.

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.



In order to assist in software development, there are three different access mechanisms to the GPIO data registers:

- Access to two 16-bits ports in one access
- Read/Write access to a single bit
- A 16-bits port write with a bit mask, using single 32-bits access

These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

The external interrupt sources can be configured on MCU level to be used with any chip pad. The six interrupt sources can be configured to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the six EIRQ pins in the device packages.

Figure 97. SIUL2 block diagram

14.1.2 Features

The SIUL2 supports these distinctive features:

- Five GPIO ports with data control
  - Drive data to up to 16 independent I/O channels
  - Sample data from up to 16 independent I/O channels
- Two 16-bits registers can be read/written with one access to a 32-bits port if needed.
- External interrupt/DMA request support with:
  - Four system interrupt vectors for 6 interrupt sources (six connected to EIRQ pins) with independent interrupt mask
  - Six programmable digital glitch filters (one for each EIRQ)
  - Independent DMA channels for each EIRQ pin
  - Edge detection

Additionally the SIUL2 contains the multiplexed signal configuration registers that configure the electrical parameters and settings of all functional pads (132 GPIO + 10 dedicated pads)[g]. These are used to configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control of JTAG pins
- Internal weak pull control
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration
- TTL or CMOS or Automotive input levels

14.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes.Details about the protected registers at specific addresses can be found in *Chapter 67: Register Protection (REG_PROT)* and *Chapter 7: Device configuration*.

14.2 Memory map and register description

14.2.1 Memory map

Table 193 gives an overview of the SIUL2 registers implemented.

g. Refer to the *Chapter 7: Device configuration* for details on package-specific pin and register implementation.

0x17A4–0x17FF	Reserved(4)						

1. Saf-Relv: Safety Relevant; Saf-Lat: Safety Latent.
2. For implemented registers MSCR, please refer to Pin Multiplexing table description table and Peripheral multiplexing table description in *Chapter 4: Signal description*.
3. 32-bit writes, 8/16/32-bit reads are allowed. (Only 8-bit and 16-bit writes are not supported and generate a transfer error.)
4. Writes are possible without having an impact on SoC functionality (No transfer errors are generated).

Note: Reserved registers will be read as 0. If supported and enabled in this MCU, a transfer error will be issued when trying to access completely reserved register space.

14.2.2 Register descriptions

This section describes in address order all the SIUL2 registers.

14.2.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register contains identification information about the device.

Offset: 0x0004 Access: Read-only

14.2.2.3 SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set irrespective of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) is enabled. The EIF bit remains set until cleared by software or through the servicing of a DMA request. The EIF bits are cleared by writing a ‘1’ to the bits. A write of ‘0’ has no effect.

This register contains the interrupt flags.

Table 196. SIUL2_DISR0 field descriptions

Field	Description
26:31 EIF[5:0]	External Interrupt Status Flag x This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

14.2.2.4 SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

Offset: 0x0018 Access: User read/write

Table 197. SIUL2_DIRER0 field descriptions

Field	Description
26:31 EIRE[5:0]	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR

14.2.2.5 SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

Figure 106. SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31)

Table 202. SIUL2_IFMCR0–SIUL2_IFMCR31 field descriptions

Field	Description
28:31 MAXCNT	Maximum Interrupt Filter Counter setting (MAXCNTx) MAXCNT can be 0 to 15 For MAXCNT = 0, 1, 2, the filter behaves as ALL PASS filter For MAXCNT = 3, 4, 5,…15, filter period = TCK * MAXCNTx + n * TCK (n= 0 to 4) TCK: Prescaled filter clock period, which is IRC clock prescaled to IFCP value, specified in SIUL2_IFCPR TIRC: Basic filter clock period 62.5 ns (f = 16 MHz) Note that filter delay is 2 TCK clock cycles more than filter period. In general, TFILTER and TDELAY are not integer multiples of TCK because DIN is asynchronous whereas DOUT is synchronous with respect to the CK clock, and the factor n accounts for this uncertainty in filter period calculation.

14.2.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler which is used to select the clock for all digital filters. Prescaler is applied to the input clock to the SIUL2, which is the system PBRIDGE clock counters in the SIUL2.

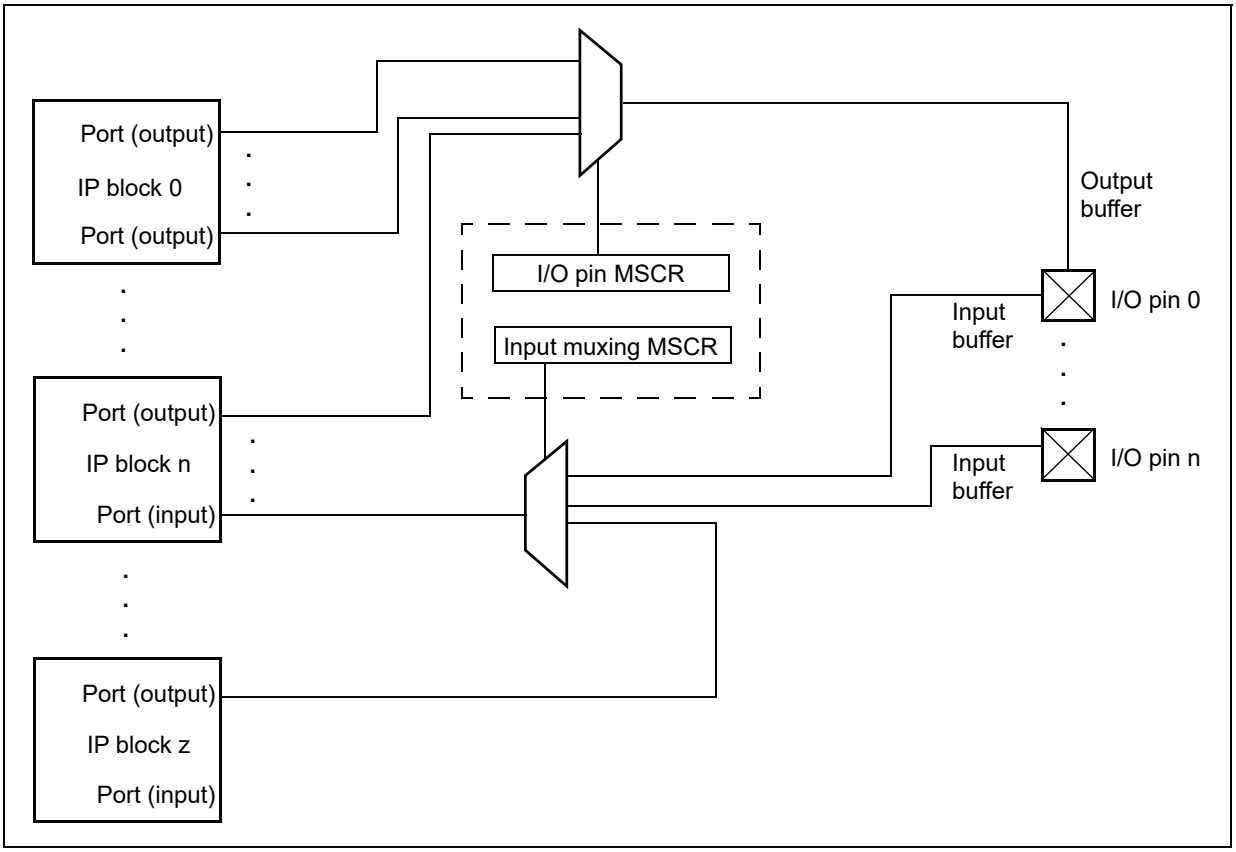
28:31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15.

14.2.2.11 SIUL2 Multiplexed Signal Configuration Registers (SIUL2_MSCR0–SIUL2_MSCR1023)



The MSCRs control the I/O pin function and electrical properties for each pin on the device, and are used to select the input signal for IP blocks on the device that have multiple input sources. There is a dedicated MSCR for each I/O pin on the device. Each MSCR is independent of the others, except in the case of an LVDS configuration, where two MSCRs must be configured together in this mode.

The MSCRs are divided into two sets:

- I/O pin control registers (SIUL2_MSCR0–SIUL2_MSCR511)
- Multiplexed input selection registers (SIUL2_MSCR512–SIUL2_MSCR1023)

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in *Figure 108*.

Figure 108. MSCR I/O pin and IP block port connectivity

14.2.2.12 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR0–SIUL2_MSCR511)

The I/O pin MSCR definition is given in *Figure 109*. These registers select the output function on the associated I/O pin. The I/O MSCRs control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, safe-mode operation, and analog input enable of the associated I/O pin.

Note that when an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs, and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

Table 204. SIUL2_MSCR0–SIUL2_MSCR511 field description

Field	Description
1:3 OERC	Output Edge Rate Control Used only when the associated destination is a chip pin. Specifies the output impedance, drive strength, and slew rate of the associated pin. 00 Weak 01 Medium 10 Strong 11 Very Strong Refer to Output Impedance column of Signal Description table earlier in document for associated pins.
6:7 ODC	Output Drive Control Used only when the associated destination is a chip pin. Specifies the type of output drive control for the associated pin. 00 Disabled (high impedance for turning off the pin or using it as an input) 01 Open-drain (Open drain low-side) 10 Push-pull 11 Open-source (Open drain high-side)

Table 204. SIUL2_MSCR0–SIUL2_MSCR511 field description (continued)

Field	Description
8 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
10:11 ILS	Input Level Selection Used only when the associated destination is a chip pin. Specifies the logic family for the associated pin, which determines its logic switching levels. 00 Automotive 01 TTL 10 LVDS 11 CMOS
12 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis Used only when the associated destination is a chip pin. Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. It is OK for both WPDE and WPUE to be enabled. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. It is OK for both WPDE and WPUE to be enabled. 0 Disabled 1 Enabled
16 INV	Invert Inverts the signal selected by SSS before transmitting it to the associated destination (chip pin or module port). 0 Don't invert 1 Invert
24:31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. See *Section 14.2.2.14* and *Section 14.2.2.15*.

All bits and fields in the I/O MSCRs are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV, and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The I/O state exceptions are given in *Table 205*.

14.2.2.13 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR512–SIUL2_MSCR1023)

The multiplexed input selection MSCR definition is given in *Figure 110*. These registers select the input source for IP blocks on the device that have inputs from multiple sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

14.2.2.18 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write.

Offset: 0x1700 + n*0x2 (n=0 to 8) Access: User read/write

Field	Description
0:15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit indexes define which PPDO register bit is equivalent to which PDO register bit according to the following equation: SIUL2_PGPDO[x].PPDO[y] = PDO[(x * 16) + y]

Note: The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

SIUL2_PGPDO0.PPDO[0] = PDO[0]

SIUL2_PGPDO2.PPDO[0] = PDO[32]

SIUL2_PGPDO8.PPDO[3] = PDO[131]

14.2.2.19 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read.

Address: 0x1740 + n*0x2 (n=0 to 8) Access: User read/write

0:15 MASK[0:15]	Mask Field Each bit corresponds to one data bit in the MPPDO at the same bit location. MASK[x] = 0 The associated bit value in the MPPDO field is ignored MASK[x] = 1 The associated bit value in the MPPDO field is written
16:31 MPPDO[0:15]	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO). The x and y bit indexes define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: SIUL2_MPGPDOx.MPPDO[y] = PDO[(x * 16) + y]

14.3 Functional description

14.3.1 General

This section provides a complete functional description of the SIUL2.

14.3.2 Pad control

The SIUL2 is capable of controlling the electrical characteristic of 80 pads on this device. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features will be supported on all devices or on all pads as this is dependent on the specific application needs and the pads implemented on the device.

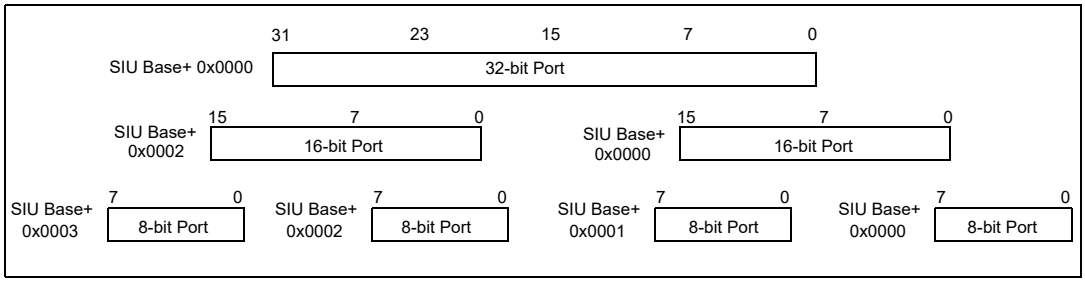
The required controls are:

- Drive strength control
  - This is needed to offer improved EMC performance.
- Internal weak pull capability
  - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
  - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Control of analog path switches
- Safe Mode behavior configuration
- Open drain/source enable
  - Needed to support different pads muxed (for example mux IIC, with non open drain pads)
- Pin Function Assignment
  - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

14.3.3 General purpose input or output pads (GPIO)



The SIUL2 allows each pad to be configured as either a General Purpose Input Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 203 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in *Figure 116*, all port accesses are identical with each read or write being performed only at a different location to access a different port width.

Figure 116. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

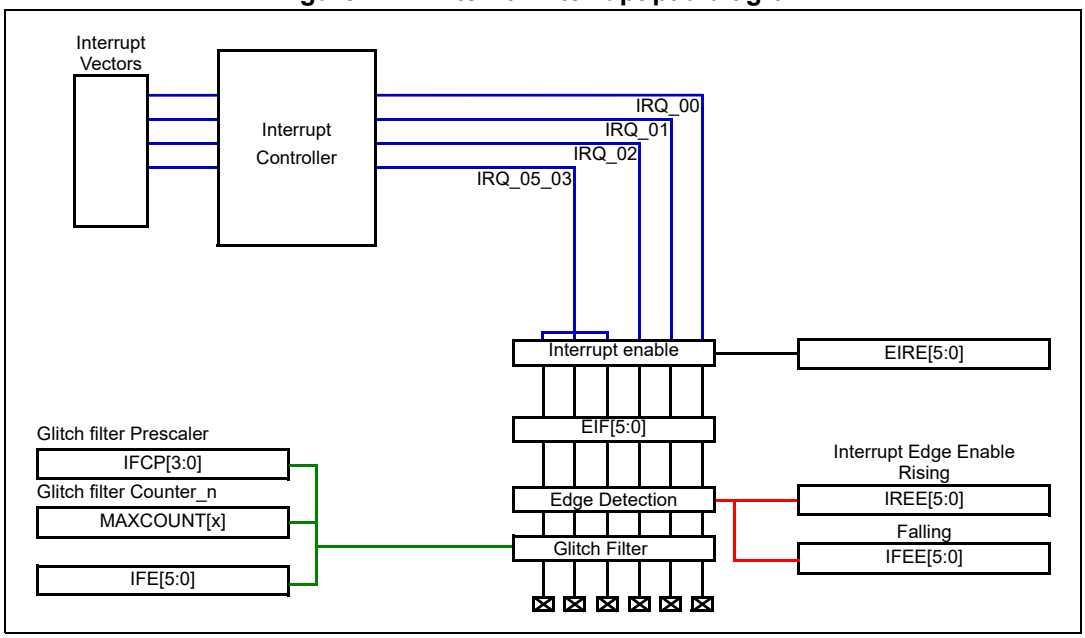
The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note: In case the bidirectional operation impacts some performances (for example ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only".



14.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports 6 external interrupts which can be allocated to any pad necessary at the MCU level. This allocation is fixed per MCU.

The SIUL2 supports 4 interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support six external interrupt sources from the device pads.

Refer to *Figure 117* for an overview of the external interrupt implementation.

Figure 117. External interrupt pad diagram

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

14.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

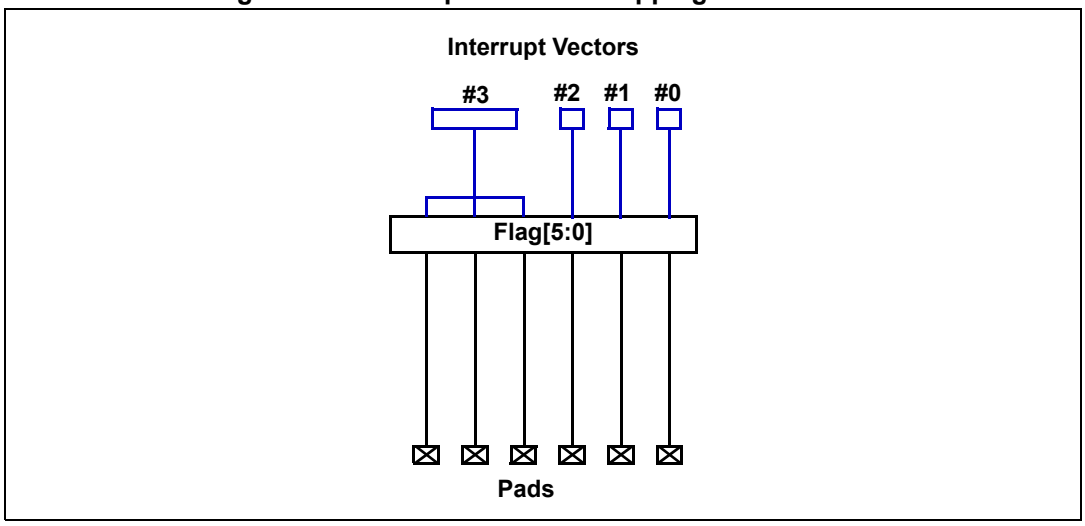
- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
  - Clear the ODC bits to do disable output.
  - Set the IBE bit to enable the pin's input buffer.
  - If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note: MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (so MSCR_ODC has to be configured as zero) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR.
  - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.
- Write to EIFn bits in DISR0 to as desired to clear any flags.
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

14.3.4.2 External interrupt management



Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (SIUL2_DIRER0 – *Figure 101*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

The SPC574Sx device supports 4 SIUL2 interrupt vectors aggregating a total of 6 external interrupt sources as shown in *Figure 118*.

Figure 118. Interrupt to vector mapping at MCU level

14.3.4.3 External interrupt request

The EIRQ input pins on the device are sources for interrupt or DMA requests. The 6 EIRQ pins for the device map to 4 interrupt requests. The mapping of interrupt requests and EIRQ pins is given in *Table 212*.

Table 212. Interrupt source mapping to SIUL2 interrupt request output

Interrupt requests	EIRQ pins
0	EIRQ0
1	EIRQ1
2	EIRQ2
3	EIRQ3 | EIRQ4 | EIRQ5

14.3.4.4 Interrupt Vector

The 6 EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note: See Section 7.3.5: Interrupt controller (INTC) configuration in the Chapter 7: Device configuration for the Interrupt Vector table.

14.3.4.5 DMA requests

The 6 EIRQ pins on the device map to an independent DMA request channel in the DMA controller.

Note: See the DMA controller configuration section in the Chapter Device Configuration for DMA request mapping table.

15 Crossbar Integrity Checker (XBIC)

15.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistence of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core's decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

15.2 Features

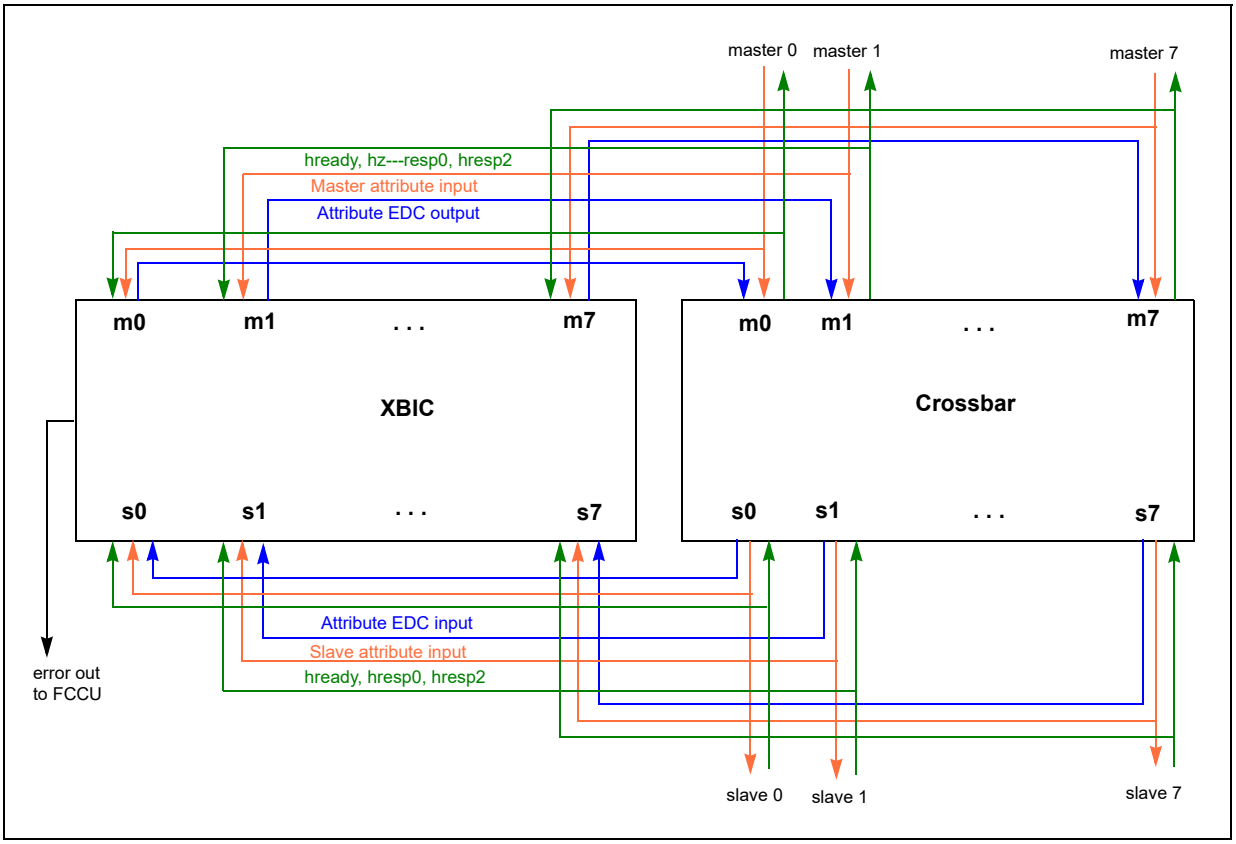
The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
  - hready, hresp0, and hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

15.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in *Figure 119* and *Figure 120*.

Figure 119. XBIC system block diagram



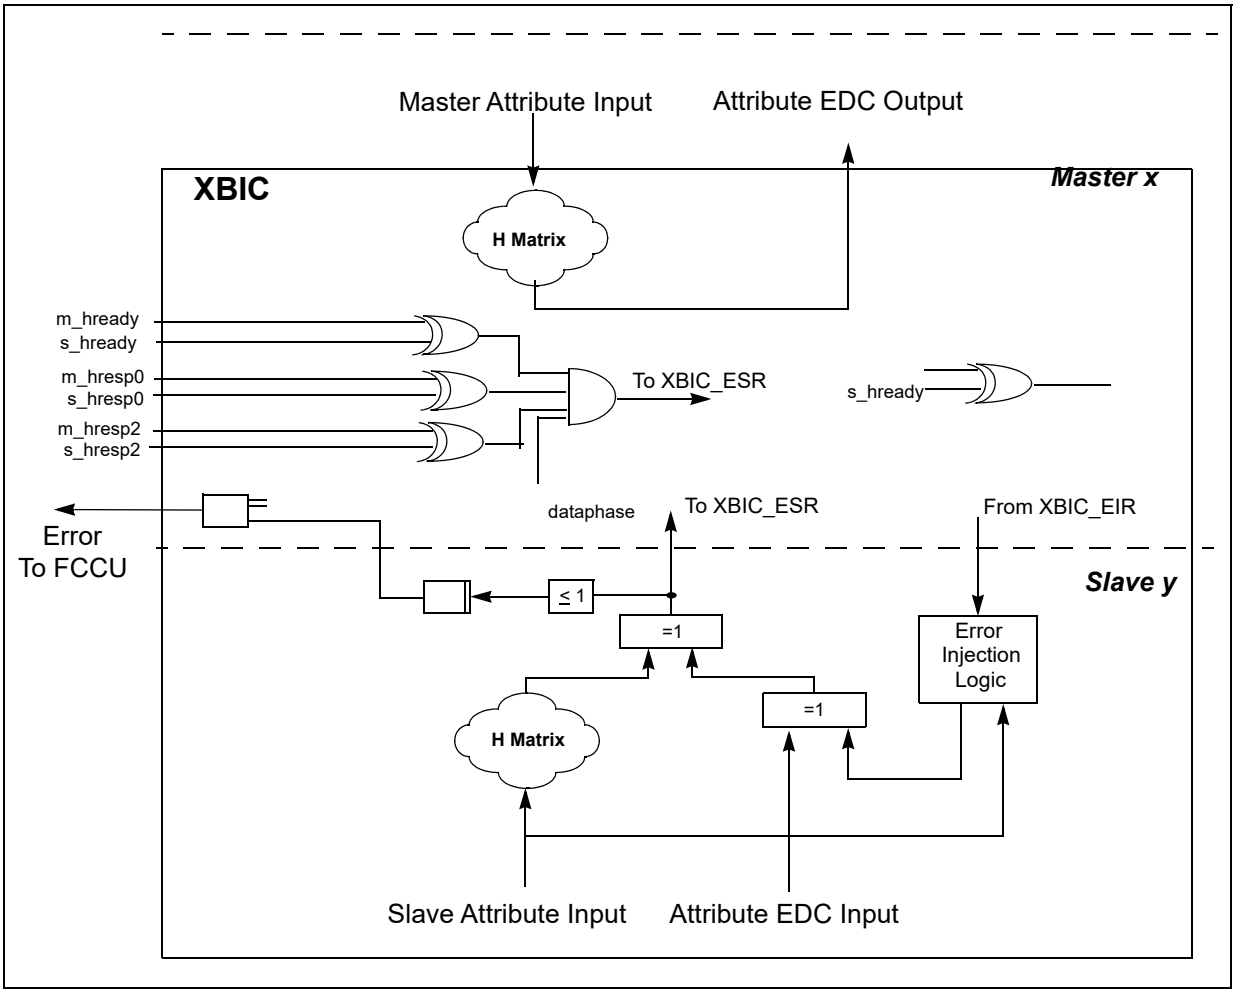


Figure 120. XBIC block diagram

15.4 External signal description

The XBIC has no external interface signals.

15.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

15.5.1 Memory map

The XBIC memory map is shown in *Table 213*.

Table 213. XBIC memory map

15.5.2.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Offset: 0x004 Access: Supervisor Read/Write

Figure 122. XBIC Error Injection Register (XBIC_EIR)

Table 215. XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable 0 Error injection disabled 1 Error injection enabled
17:19 SLV	Target Slave Port (1) Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20:23 MST	Target Master ID (2) Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24:31 SYN	Syndrome This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

1. For the list of the target slave ports refer to the table ‘Crossbar switch slave assignments’ in section ‘Crossbar switch’ from ‘Device Configuration’ chapter.
2. For the list of the target master IDs refer to the table ‘SMPU logical bus master assignments’ in section ‘Crossbar switch’ from ‘Device Configuration’ chapter.

15.5.2.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the *last* transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are captured in the DPSE0*x* and DPME*x* fields.

This register is cleared only on reset.

15.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the

settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. Error injection using XBIC_EIR register does not update the DPxxx bits in XBIC_ESR register, it only updates the syndrome information in XBIC_ESR register. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

Forwarding errors (master to slave) are detected during the AHB address phase. When a forwarding error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in *Table 218*. Any other syndrome indicates a multi-bit error.

XBIC also detects backward signal (slave to master) errors during AHB data phase. For the three slave driven signals (hready, hresp0, and hresp2), XBIC performs the comparison between the input of the slave port and output of the master port during the AHB data phase. When a mismatch occurs, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE*x*, and the current master port will be registered in XBIC_ESR bit field DSME*x*.

16 Peripheral bridge

16.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space. (Not all peripheral slots may be used. See *Chapter 7: Device configuration* or *Chapter 5: Memory map* for details on slot assignment.) The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

16.1.1 Features

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality

16.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map. Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots

All other 64-bit accesses result in an error response.

1. Access to this address space will terminate in an error.

2. The following address spaces when programmed, will not terminate in an error. Software should not program these address spaces

16.2.1 Master Privilege Registers (PBRIDGE_MPRA)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. See *Chapter 7: Device configuration* for details about the master assignments to these registers.

Field	Description
2 MTW	Master trusted for writes Determines whether the master is trusted for write accesses 0 This master is not trusted for write accesses 1 This master is trusted for write accesses.
3 MPL	Master privilege level Determines how the privilege level of the master is determined. 0 Accesses from this master are forced to user mode 1 Accesses from this master are not forced to user mode

16.2.2 Peripheral Access Control Registers (PBRIDGE_PACR*x*)

Each of the on-platform peripherals has a four-bit PACR*n* field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. See *Chapter 5: Memory map* for the assignments for your particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes, and writes are ignored.

Table 222 shows the top-level structure of the PACRs.

Table 222. PACR memory map

Each PACR*n* field is defined as shown in *Figure 128*.

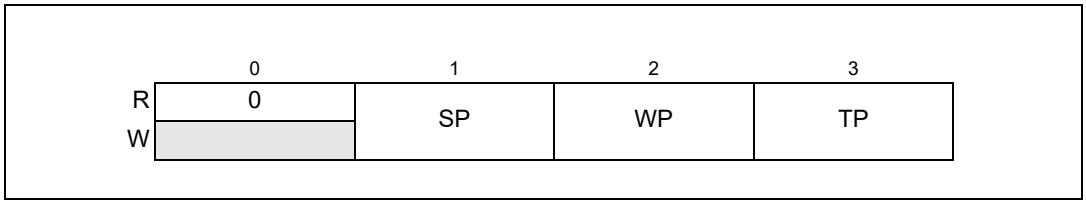

Figure 128. PACR*n* fields

Table 223. PACR*n* field descriptions

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT*n*[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

16.2.3 Off-Platform Peripheral Access Control Registers (PBRIDGE_OPACR*x*)

Each of the off-platform peripherals has a four-bit OPACR*n* field which defines the access levels supported by the given module. Eight OPACRs are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignments to each OPACR field are defined by the memory map slot to which the peripherals are assigned. See *Chapter 5: Memory map* for the assignments for your particular device. If a peripheral is absent, the corresponding OPACR is not implemented. Reads to the location return zeroes and writes are ignored.

Table 224 shows the top-level structure of the OPACR registers.

Table 225. OPACR*n* field descriptions

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT*n*[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.

Table 225. OPACR*n* field descriptions (continued)

Field	Description
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

16.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

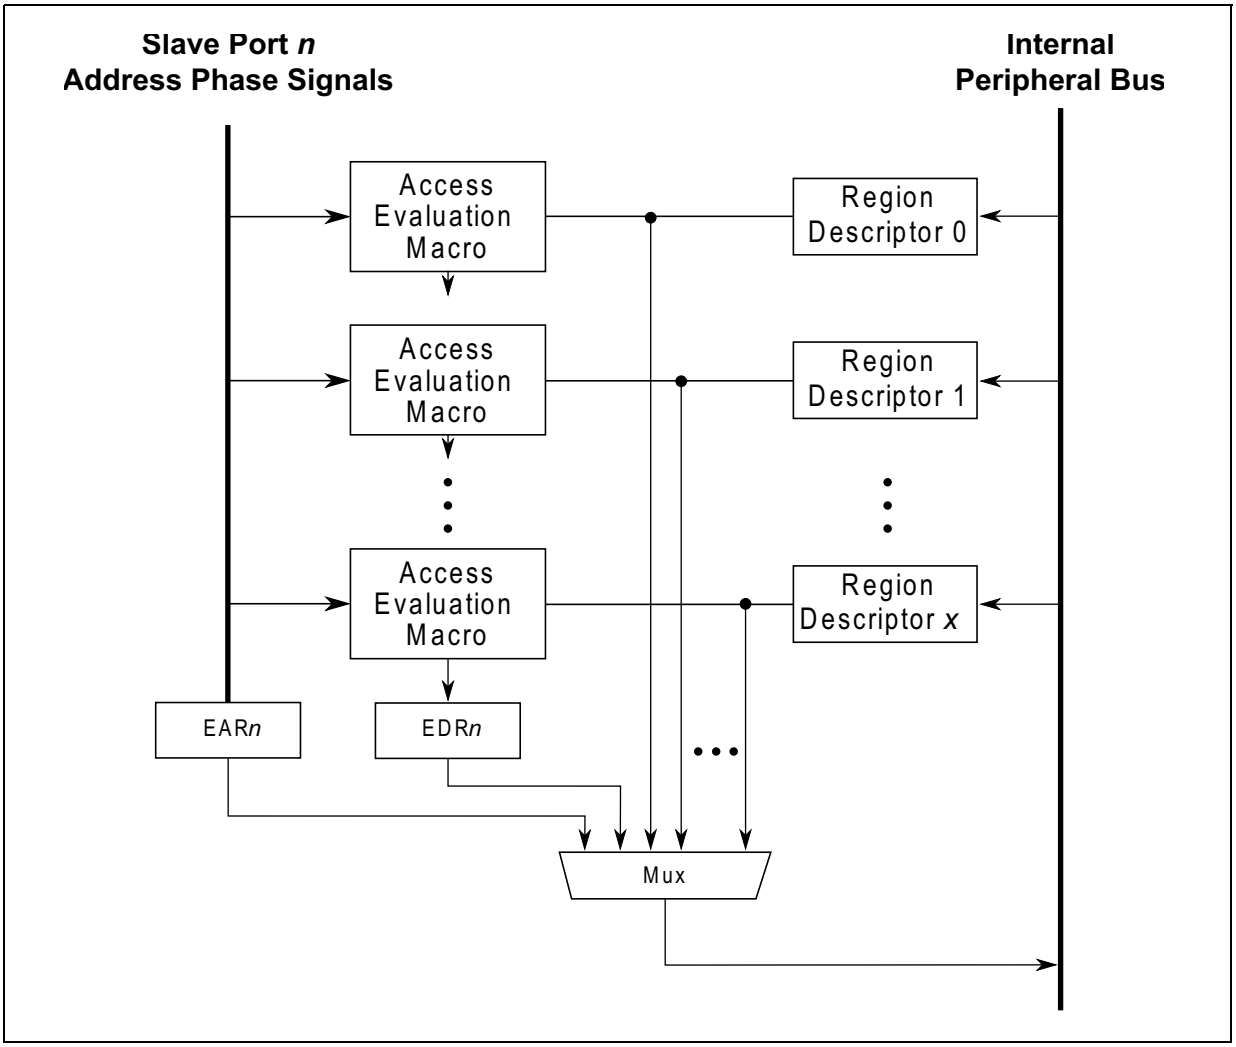
16.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

17 System Memory Protection Unit (SMPU)

17.1 Overview



The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

17.2 Block diagram

A simplified block diagram of the SMPU module is shown in *Figure 131*. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, see *Section 17.5.1: Access evaluation macro*.

Figure 131. SMPU block diagram

17.3 Features

The SMPU feature set includes:

- Supports up to 8 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24.)
  - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
    Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
  - Read/write access control permissions defined in region descriptor
  - Cache-inhibit attribute indicator per region descriptor
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
  - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24.)
  - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
    Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
  - Read/write access control permissions defined in region descriptor
  - Cache-inhibit attribute indicator per region descriptor
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
  - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports

- Detects access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (see the documentation related to the core for details).

- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit

17.4 Memory map and register definition

17.4.1 Memory map

The programming model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-

supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

The programming model can be accessed only in supervisor mode.

Note: See the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to 8 region descriptors.

Field	Description
0:15 MEOVR	Master *n* error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master *n* has occurred before the previous error was processed. The details of the first error are recorded in the EAR*n* and EDR*n* registers, and no information on subsequent errors is recorded until the associated CESR0.MERR flag is cleared. 0 No error overrun condition has been detected for bus master *n.* 1 An error overrun condition has been detected for bus master *n.*

Table 228. CESR1 field descriptions (continued)

Field	Description
16	Reserved This read-only bit is reserved and always has the value ‘1’.
28:31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

17.4.2.3 Error Address Register, Bus Master *n* (EAR*n*)

When the SMPU detects an access error on bus master *n*, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0.MERR is set. Additional information about the faulting access is captured in the corresponding EDR*n* at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Address: 0x0100 + *n**0x8 (*n* = 0 to 15) Access: Supervisor read-only

Table 229. EAR*n* field descriptions

Field	Description
0:31 EADDR	Error address Indicates the reference address from bus master *n* that generated the access error.

17.4.2.4 Error Detail Register, Bus Master *n* (EDR*n*)

When the SMPU detects an access error associated with bus master *n*, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0.MERR is

set. Information on the faulting address is captured in the corresponding EAR*n* register at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Address: 0x0104 + *n**0x8 (*n* = 0 to 15) Access: Supervisor read-only

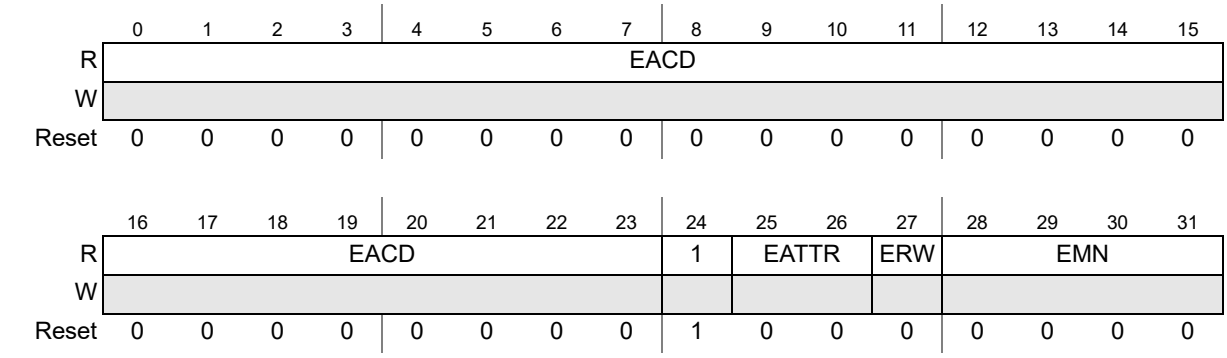

Figure 135. Error Detail Register, Bus Master *n* (EDR*n*)

Table 230. EDR*n* field descriptions

Field	Description
0:23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDR*n* contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24	Reserved This read-only bit is reserved and always has the value ‘1’.
25:26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28:31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

17.4.2.5 Region Descriptor *n*, Word 0 (RGD*n*_WORD0)

Address: 0x0400 + *n**0x10 (*n* = 0 to 1123) Access: Supervisor read/write

Field	Description
0:31 ENDADDR	End address Defines the byte end address of the memory region. **Note:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

17.4.2.7 Region Descriptor *n*, Word 2 Format 0 (RGD*n*_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3.FMT field.

Note: RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: 0x0408 + *n**0x10 (*n* = 0 to 1123) Access: Supervisor read/write

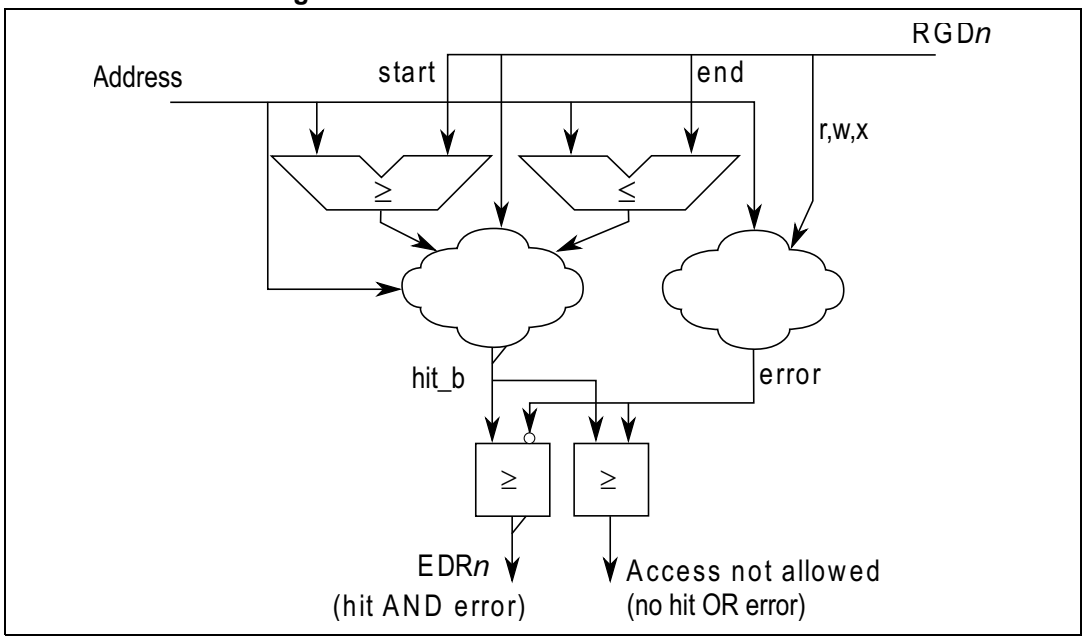
Figure 139. Region Descriptor n, Word 3 (RGDn_WORD3)

Table 234. RGD*n*_WORD3 field descriptions

Field	Description
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. **Note:** A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies. 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **Note:** Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect. 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **Note:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals that the region descriptor is valid. Any write to RGD*n*_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.



17.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

17.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in *Figure 140*, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD*n*), then performs two major functions: region hit determination and detection of an access protection violation. *Figure 140* shows a functional block diagram.

Figure 140. SMPU access evaluation macro

17.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
     (addr[0:31] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

where addr is the current reference address, RGDn_Word0.SRTADDR and RGDn_Word1.ENDADDR are the start and end addresses, and RGDn_Word3.VLD is the valid bit.

Note: The SMPU does not verify that ENDADDR ≥ SRTADDR.

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

17.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in *Table 235*.

Table 235. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

17.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see *Section 17.7*.

17.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGD*n*_Word3.VLD. Setting CESR0.GVLD enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0.GVLD = 0). Next, load the appropriate region descriptors (RGD*n*), including the setting of the RGDn_Word3.VLD bits. Finally, set CESR0.GVLD to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

17.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region: Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the

maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Modifying a region descriptor: Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor: Clearing RGD*n*_Word3.VLD deletes an existing region descriptor.
- Accessing the SMPU: Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error: The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0.MERR signals. The error registers contain the captured fault data.
- Overlapping region descriptors: Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters: the two processors (CP0, CP1) and two DMA engines (DMA1, a traditional data movement engine transferring data between RAM and peripherals, and DMA2, a second engine transferring data to/from the RAM only). Consider the following region descriptor assignments:

Table 236. Overlapping region descriptor example

Region description	RGDn	CP0	CP1	DMA1	DMA2	System memory map space
CP0 code	0	rwx	r--	—	—	Flash
CP1 code	1	r--	rwx	—	—	
CP0 data & stack	2	rw-	—	—	—	RAM
CP0 → CP1 shared data	2–3	r--	r--	—	—	
CP1 → CP0 shared data	4					
CP1 data & stack	4	—	rw-	—	—	
Shared DMA data	5	rw-	rw-	rw	rw	
SMPU	6	rw-	rw-	—	—	Peripheral space
Peripherals	7	rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map (flash, RAM, and peripheral space). Each region indicates the specific permissions for each of the four bus masters, and this definition provides an assigned set of shared, private, and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1, and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the peripheral bus is partitioned into two regions: one containing the SMPU's programming model accessible only to the two processor cores and the remaining peripheral region accessible to both processors and the traditional DMA1 master.

This simple example is intended to show one possible application of the capabilities of the SMPU in a typical system.

18 Intelligent AHB Gasket (IAHBG)

18.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 237 lists the available operation modes.

Table 237. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

18.2 Timing modes

18.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

18.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

18.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master.The 1:4 mode is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write.

19 Interrupt Controller (INTC)

19.1 Introduction

Note: For the chip-specific implementation details of this module's instances, please refer to the Section 7.3.5.

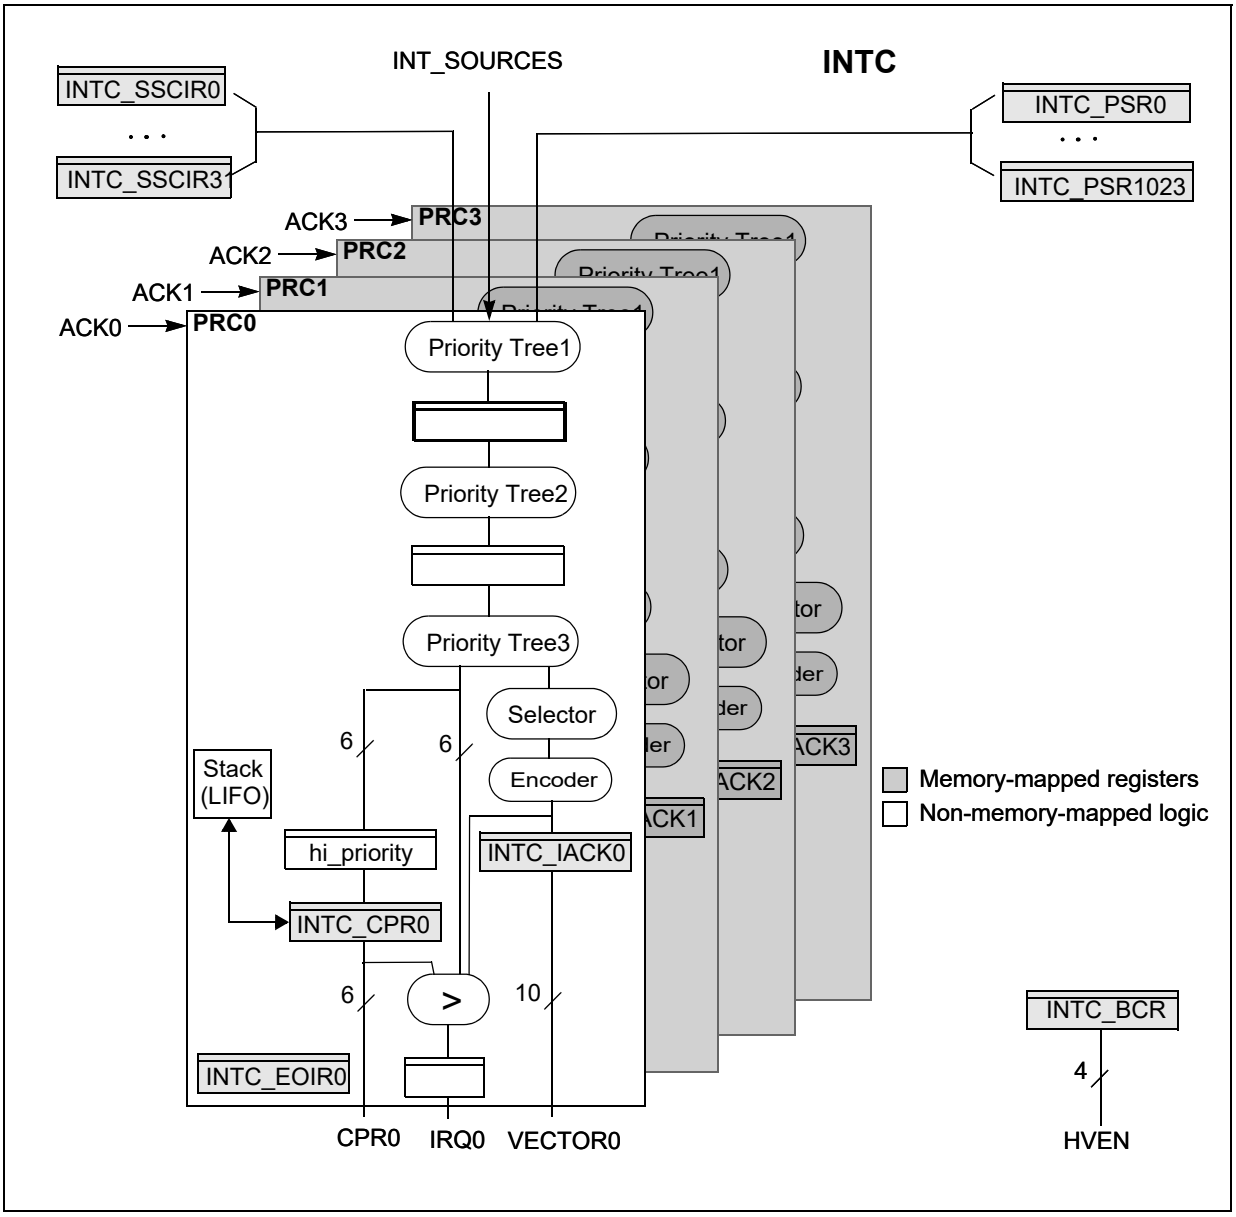
The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to the processor (PRC)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.



When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

The software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

19.2 Block diagram

The block diagram for the INTC is shown in *Figure 141*.

Figure 141. INTC block diagram

19.3 Features

- Each peripheral interrupt source is software-steerable to processor 0
- 32 software-settable interrupt request sources
- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request

19.4 Modes of operation

The interrupt controller operates with the following handshaking modes: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN0], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ). In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

19.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for the processor when the HVEN0 bit in INTC_BCR (see *Section 19.5.2.1*) is negated. The hardware vector enable signal to the processor is driven as negated when the HVEN0 bit is negated. The vector is read from the INTC_IACKR0 register (see *Section 19.5.2.3*). Reading the INTC_IACKR0 negates the interrupt request to the processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in INTC_CPR0 (see *Section 19.5.2.2*) onto the LIFO, and updates PRI in INTC_CPR0 with the new priority.

19.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for the processor when the HVEN0 bit in INTC_BCR is asserted. The hardware vector enable signal to the processor is driven as asserted.

When the interrupt request to the processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKR0.

The assertion of the interrupt acknowledge signal for the processor pushes the PRI value in the INTC_CPR0 register onto the LIFO and updates the PRI in the INTC_CPR0 register with the new priority. This pushing of the PRI value onto the LIFO and updating PRI in INTC_CPR0 does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs (see *Section 19.5.2.5*) is written at a time such that the PRI value in the INTC_CPR0 register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in INTC_CPR0 is updated with the new priority, and the LIFO is neither pushed or popped.

19.5 Memory map and register definition

19.5.1 Memory map

Table 238 is the INTC memory map.

The actual availability and number of registers are chip-specific. For this information, see the chapter that describes how modules are configured and connected.

Table 238. INTC memory map

Address offset	Register	Location

0x0860–0x0FFF	Reserved	

1. Access to this location will not result in transfer error.

Note: A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

19.5.2 Register descriptions

With the exception of the INTC_SSCIR*n* and INTC_PSR*n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR0) are the same regardless of the size of the read. In software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR0) does not affect the operation of the write.

19.5.2.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

19.5.2.2 INTC Current Priority Register for Processor 0 (INTC_CPR0)

The INTC_CPR0 masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR0[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR0) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR0) is written, the LIFO is popped into the INTC_CPR0 PRI field. An exception case in hardware vector mode to this behavior is described in *Section 19.4.2*.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See *Section 19.7.5*.

Note: A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Section 19.7.5.2, for example code to ensure coherency.

19.5.2.3 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor 0 provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR0 has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKR0 does not have side effects in hardware vector mode.

0:19 VTBA	Vector table base address Must be set with the base address of the vector table prior to enabling interrupts.
20:29 INTVEC	Interrupt vector Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.

19.5.2.4 INTC End of Interrupt Register for Processor 0 (INTC_EOIR0)

Writing to the INTC_EOIR0 signals the end of the servicing of the interrupt request. When the INTC_EOIR0 is written, the priority last pushed on the LIFO is popped into INTC_CPR0. The values and size of data written to the INTC_EOIR0 are ignored. Those values and sizes written to this register neither update the INTC_EOIR0 contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

19.5.2.5 INTC Software Set/Clear Interrupt Register *n* (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a

pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Figure 146 shows the structure of the first INTC_SSCIR. The other registers follow the same structure.

7 CLR	Clear flag bit CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

19.5.2.6 INTC Priority Select Register *n* (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSR*n* is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32–1023, and their priorities are configured in INTC_PSR32–1023, respectively.

Figure 147 and *Figure 148* show the structure and numbering scheme of the first and last PSRs, respectively. The other registers follow the same numbering scheme.

Note: Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

Interrupts are not detected while the PSRs are being written.

Figure 148. INTC Priority Select Register *n* (INTC_PSR*n*)

Table 245. INTC_PSR*n* field descriptions

Field	Description
0 PRC_SEL0	Processor 0 select bit If an interrupt source is enabled, PRC_SEL0 selects whether the interrupt request is to be sent to processor 0.
7 SWT	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared.
10:15 PRI	Priority select Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

19.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

19.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI value in INTC_PSR*n* is higher than the PRI value in INTC_CPR0, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in INTC_CPR0 is updated with the corresponding PRI value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

19.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

19.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

The processor will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the processor which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR*n*[PRC_SEL0] bit.

19.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

19.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL0 values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in INTC_CPR0. The results of those comparisons are used to manage the priority of the ISR being executed by the processor. The LIFO also assists in managing that priority.

19.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in *Figure 141* are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for the processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for INTC_IACKR0, and if in hardware vector mode, for the interrupt vector provided to the processor.

19.6.2.1.1 Priority tree

The priority tree for the processor compares all the priorities of all of the asserted interrupt requests assigned to the processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to the processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the selector logic.

19.6.2.1.2 Selector

If only one interrupt request from the priority tree is asserted, then it is passed as asserted to the encoder logic. If multiple interrupt requests from the priority tree are asserted, then only the one with the lowest vector is passed as asserted to the encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

19.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the processor.

19.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the priority arbitrator subblock with PRI in INTC_CPR0. If the comparator detects that this highest priority is

higher than the current priority, then it asserts the interrupt request to the processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in INTC_CPR0, or the PRI value in INTC_CPR0 is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in INTC_CPR0 when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI in INTC_PSR*n* are zero will not cause a preemption because their PRI will not be higher than PRI in INTC_CPR0.

Another function of the comparator is to signal an update of INTC_IACKR0 with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of INTC_CPR0 occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

19.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from INTC_CPR0. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in INTC_CPR0 does not need to be loaded from INTC_CPR0 and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored in INTC_CPR0.

The PRI value in INTC_CPR0 is pushed onto the LIFO when INTC_IACKR0 is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode. The priority is popped into PRI in INTC_CPR0 whenever INTC_EOIR0 is written. An exception case in hardware vector mode to this behavior is described in *Section 19.4.2*.

Although the INTC supports up to 64 priorities, an ISR executing with PRI in INTC_CPR0 equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

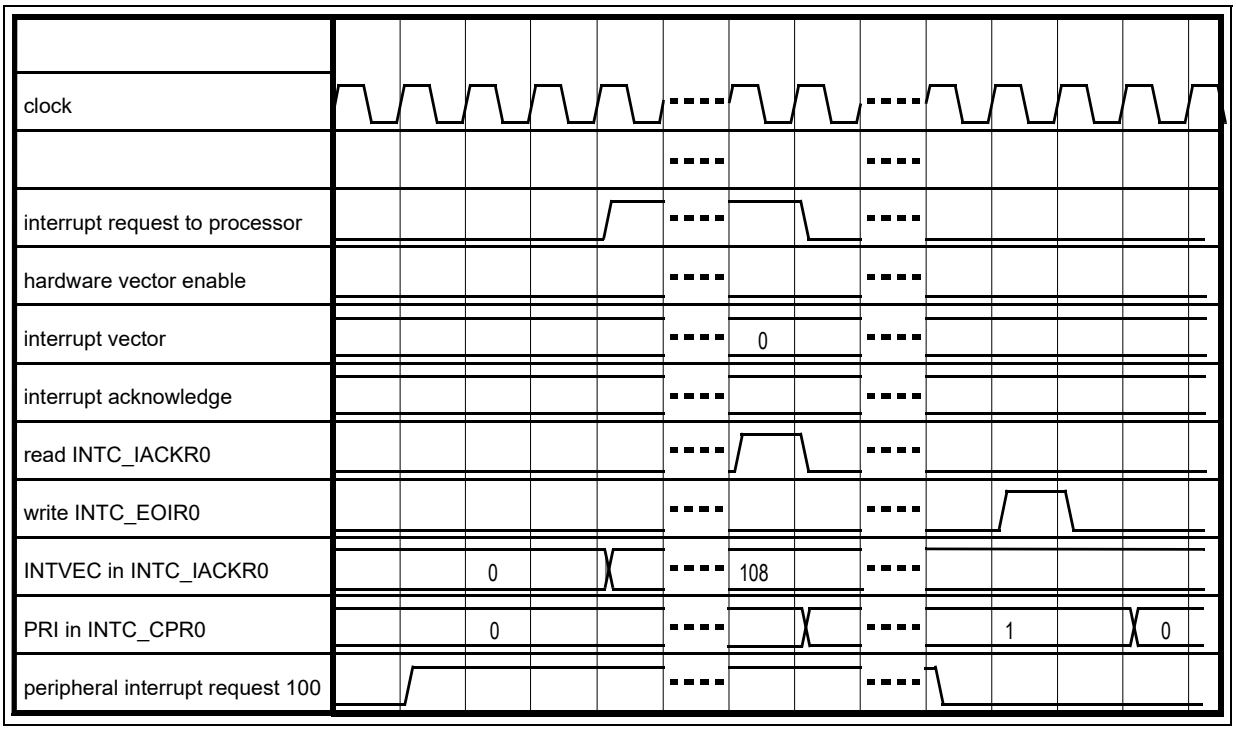
19.6.3 Handshaking with processor

19.6.3.1 Software vector mode handshaking

19.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to *Figure 149*.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 149*. The INTC examines the peripheral and software-settable interrupt requests.



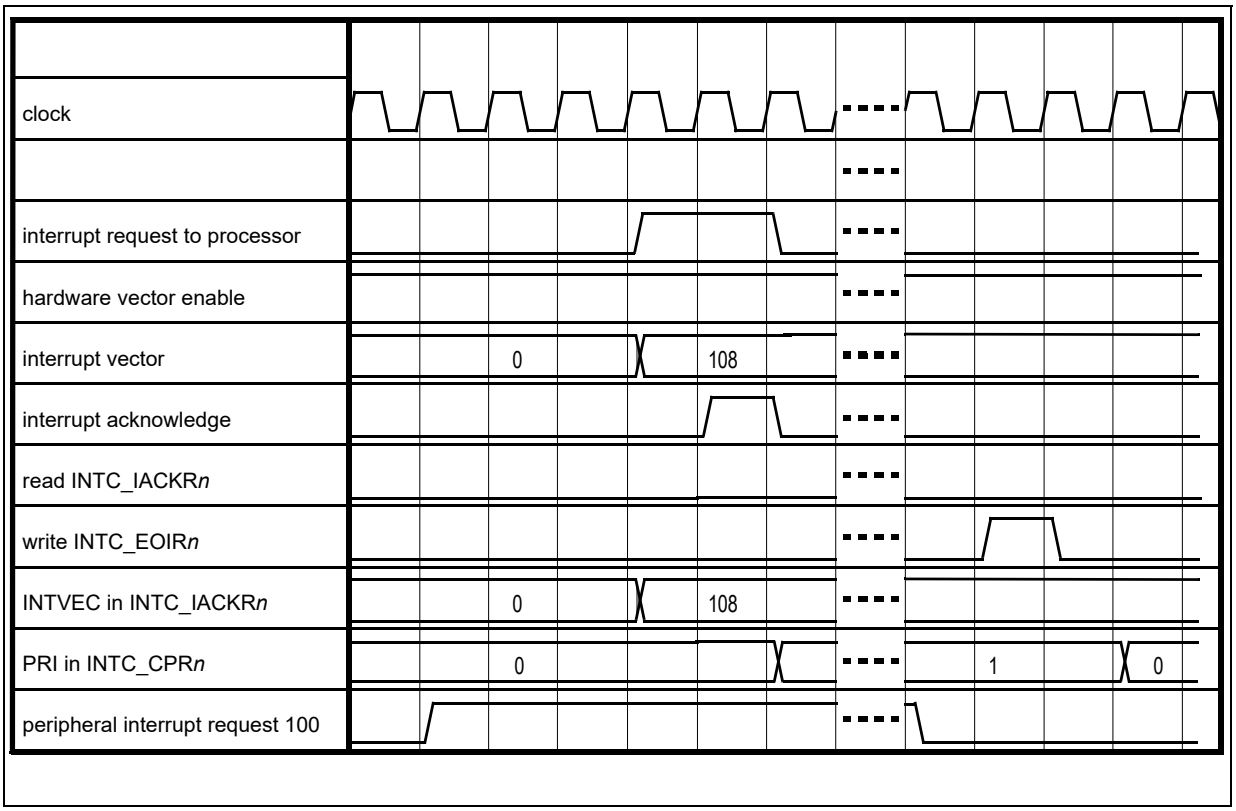
When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in INTC_CPR0, it asserts the interrupt request to the processor. The INTVEC field in INTC_IACKR0 is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in *Section 19.4.1*.

19.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR0 must be written. When it is written, the LIFO is popped so that the preempted priority is restored into PRI of INTC_CPR0. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in INTC_CPR0 is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 149. Timing diagram of software vector mode handshaking



19.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 150*. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in INTC_CPR0, it asserts the interrupt request to the processor. The INTVEC field in INTC_IACKR0 is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. In addition, the value of the interrupt vector to the processor matches the value of the INTVEC field in INTC_IACKR0. The rest of the handshaking is described in *Section 19.4.2*.

The handshaking near the end of the interrupt exception handler, that is the writing to INTC_EOIR0, is the same as in software vector mode. See *Section 19.6.3.1.2*.

Figure 150. Timing diagram for hardware vector mode handshaking

19.7 Initialization/application information

19.7.1 Initialization flow

After exiting reset, all of the PRI and PRC_SEL0 fields in INTC_PSR*n* are zero, and PRI in the INTC_CPR0 register is 31. These reset values will prevent the INTC from asserting the interrupt request to the processor. The enable or mask bits in the peripherals are reset such

that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- Interrupt_request_initialization:
  - Configure HVEN0 in INTC_BCR.
  - Configure VTBA in INTC_IACKR0.
  - Raise the PRI fields and set the PRC_SEL0 fields in INTC_PSR*n*.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC_CPR0 to zero.
  - Enable processor recognition of interrupts.

19.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

19.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

19.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR0 having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR0 priority 0 and outside the control of the RTOS while RTOS executes at INTC_CPR0 priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPR0 priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR0 while the shared resource is being accessed.

An ISR whose PRI in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless

called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

19.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in *Table 246* shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 246. Order of ISR execution example

		Code executing at end of step						
Step#	**Step Description**	**RTOS**	**ISR108(1)**	**ISR208**	**ISR308**	**ISR408**	**interrupt exception handler**	**PRI in INTC_CPR at end of step**
1	RTOS at priority 0 is executing.	X						0

11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR0.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

19.7.5 Priority ceiling protocol

19.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR0) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR2, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR0 to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

19.7.5.2 Ensuring coherency

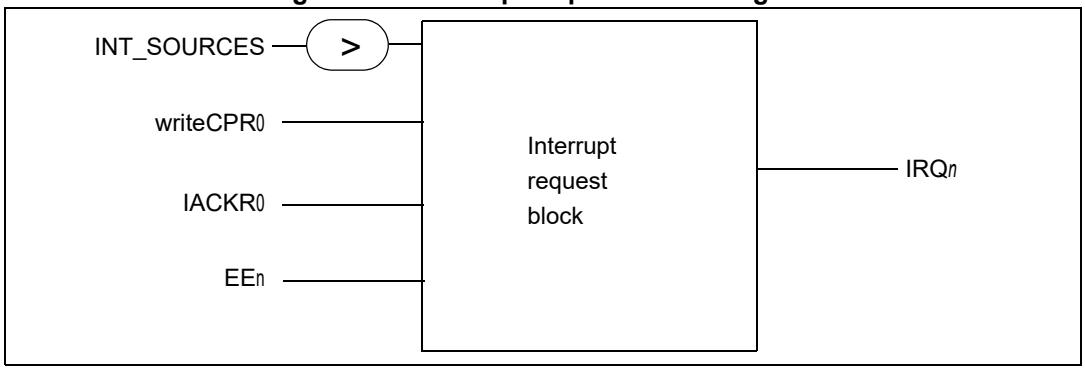
19.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR0. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby

assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR0 can be made by those system services with the code sequence:

Figure 151. OSEK Code Sequence



```
GetResource:
   wrteei  0       # disable external interrupts to the Processor
   raise   PRI     # Write to CPR, cache inhibit, guarded
   mbar            # flush out writes from store buffer
   wrteei  1       # enable external interrupts to the Processor
   isync           # re-fetch Processor pipeline

ReleaseResource:
   mbar            # flush out writes from store buffer
   wrteei  0       # disable external interrupts to the Processor
   lower   PRI     # Write to CPR, cache inhibit, guarded
   wrteei  1       # enable external interrupts to the Processor
```

19.7.5.2.1.1 Interrupt request to processor

Referencing *Figure 141*, the interrupt request logic to the processor is shown in *Figure 152*.

Figure 152. Interrupt request block diagram

Assuming that there are no IRQ*n* deasserted (no pending interrupt requests to the processor), if one of the external interrupt sources (INT_SOURCES) has a priority higher than INTC_CPR0, then interrupt request to the processor (IRQ*n*) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACKR0) is asserted
- If the EE*n* bit has been cleared by the wrteei instruction (see *Figure 151*), IRQ*n* will be re-evaluated when the processor writes to INTC_CPR0 while the processor ignores IRQ*n*

This provides a safe way to guarantee that no interrupts will be recognized by the processor while updating INTC_CPR0.

19.7.5.2.2 Raised priority preserved

Before the instruction and after the GetResource system service executes, all pending transactions are complete. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in INTC_CPR0. The shared coherent data block now can be accessed coherently. *Figure 153* shows the timing diagram for this scenario, and *Table 247* explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 153. Timing diagram of raised priority preserved

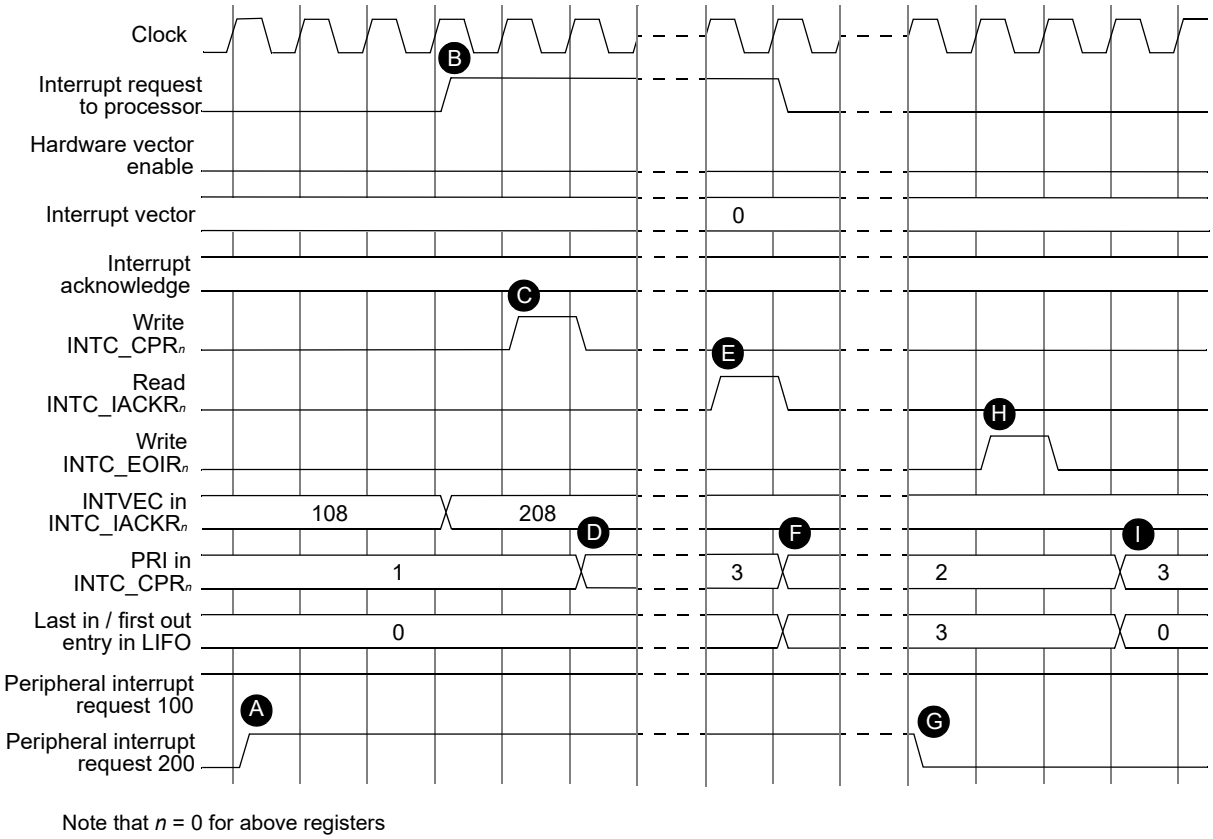


Table 247. Raised priority preserved events

Event	Description
A	Peripheral interrupt request with name equal to 200, asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKR0 updates with vector for that peripheral interrupt request.
C	ISR108 writes to INTC_CPR0 to raise priority to 3 before accessing shared coherent data block.

Table 247. Raised priority preserved events (continued)

Event	Description
D	PRI in INTC_CPR0 now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
E	Interrupt exception handler prolog acknowledges interrupt by reading INTC_IACKR0.
F	PRI of 3 pushed onto LIFO. PRI in INTC_CPR0 updates to 2, the priority of ISR208.
G	ISR208 clears its flag bit, deasserting its peripheral interrupt request.
H	Interrupt exception handler epilog writes to INTC_EOIR0.
I	LIFO pops 3, restoring the raised priority onto PRI in INTC_CPR0. Next value to pop from LIFO is the priority from before peripheral interrupt request with name equal to 100 interrupted. ISR108 now can access data block coherently after interrupt exception handler executes rfi instruction.

19.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

19.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR.

19.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR0 with the interrupt acknowledge. The ISR, however, can have a portion of it which need not be executed at this higher priority. Therefore, executing this later

portion which need not be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit in INTC_SSCIR*n*. Writing a 1 to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

19.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in *Section 19.7.7.1*) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note: Lowering the PRI value in INTC_CPR0 within an ISR to below the ISR's corresponding PRI value in INTC_PSRn allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

19.7.9 Negating an interrupt request outside of its ISR

19.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

19.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

19.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to *Section 19.6.3.1.2* for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI value in INTC_PSR*n*.

19.7.10 Examining LIFO contents

Normally the user does not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR0). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
pop_lifo:
   store to INTC_EOIR0
   load INTC_CPR0, examine PRI, and store onto stack
   if PRI is not zero or value when interrupts were enabled, branch to
pop_lifo
```

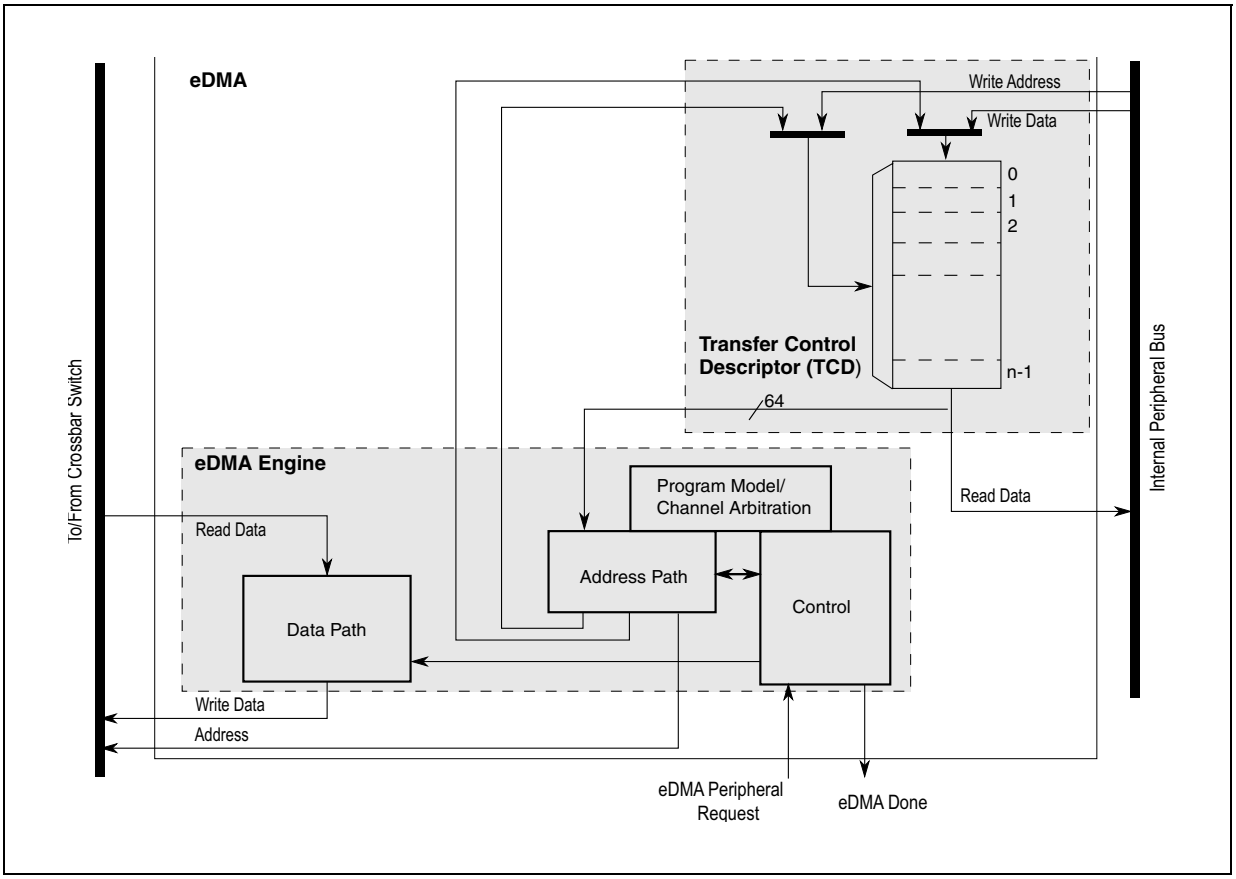
When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
   load stacked PRI value and store to INTC_CPR0
   load INTC_IACKR0
   if stacked PRI values are not depleted, branch to push_lifo
```

Note: Reading the INTC_IACKR0 acknowledges the interrupt request to the processor and updates the INTC_CPR0[PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, because the peripheral or software-settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPR0[PRI] is lower than the priorities of those peripheral or software-settable interrupt requests.

19.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chapter that describes how modules are configured and connected.



20 Enhanced Direct Memory Access (eDMA)

20.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 32 channels.

Figure 154 illustrates the eDMA module.

Figure 154. eDMA block diagram

20.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data

size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination:
  Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  – Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers
  – Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  – 32-byte TCD stored in local memory for each channel
  – An inner data transfer loop defined by a minor byte transfer count
  – An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  – Explicit software initiation
  – Initiation via a channel-to-channel linking mechanism for continuous transfers
  – Peripheral-paced hardware requests (one per channel)
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
  – One interrupt per channel, optionally asserted at completion of major iteration count
  – Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing
- Support for complex data structures
- Support to cancel transfers via software

Throughout this chapter, *n* is used to reference the channel number.

20.2 Modes of operation

The eDMA supports the following modes of operation.

20.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

20.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

20.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

20.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. *Table 248* provides a 32-bit view of the eDMA's memory map.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

20.3.1 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in two groups (0, 1) of 16 channels each: Group 1 contains channels 31 to 16, and group 0 contains channels 15 to 0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (see the DCHPRI*n* registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

Note: Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRP*n*PRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

1. Bit 20 is always set to 0 and not writable.
2. Bit 22 is always set to 0 and not writable.

Table 249. DMA_CR field descriptions

Field	Description
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt
20:21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22:23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCD*n*.word2 is defined as a 32-bit NBYTES field 1 Enabled. TCD*n*.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before eing activated again 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection. 1 Round-robin arbitration is used for channel selection.

Table 249. DMA_CR field descriptions (continued)

Field	Description
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.
31 EBW	Enable Buffered Writes 0 The bufferable write signal (hprot[2]) is not asserted during AMBA AHB writes. 1 The bufferable write signal (hprot[2]) is asserted on all AMBA AHB writes except for the last write sequence.

20.3.2 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

See *Section 20.4.3*, for more details.

Table 250. DMA_ES field descriptions

Field	Description
0 VLD	ERRL status bits 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
14 UCE	Uncorrectable ECC error 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error.
15 ECX	Transfer cancelled 0 No cancelled transfers 1 The last recorded entry was a cancelled transfer by the error cancel transfer input.

Table 250. DMA_ES field descriptions (continued)

Field	Description
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18:23 ERRCHN	Error channel number or cancelled channel number GPE and/or last recorded error cancelled transfer.
24 SAE	Source address error 0 No source address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SADDR field. TCD*n*_SADDR is inconsistent with TCD*n*_ATTR[SSIZE].
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SOFF field. TCD*n*_SOFF is inconsistent with TCD*n*_ATTR[SSIZE].
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DADDR field. TCD*n*_DADDR is inconsistent with TCD*n*_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DOFF field. TCD*n*_DOFF is inconsistent with TCD*n*_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_NBYTES or TCD*n*_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD*n*_CSR[ESG] is enabled. TCD*n*_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read.
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write.

20.3.3 Enable Request Register Low (DMA_ERQL)

The ERQL registers provide a bit map for the 32 implemented channels to enable the request signal for each channel. EQRL covers channels 31–00.

The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQL.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

31 ERQ0	Enable DMA Request 0 0 The DMA request signal for the corresponding channel is disabled 1 The DMA request signal for the corresponding channel is enabled

20.3.4 Enable Error Interrupt Register Low (DMA_EEIL)

The Enable Error Interrupt Register Low (DMA_EEIL) provides a bit map for the 32 channels to enable the error interrupt signal for each channel. EEIL covers channels 31–00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEIL registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

20.3.5 Set Enable Request Register (DMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQL to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQL to be set.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x0018 Access: User write-only

	0	1	2	3	4	5	6	7
R	0	0	0					
W	NOP	SAER	SERQ					
Reset	0	0	0	0	0	0	0	0

Field	Description
0 NOP	0 Normal operation 1 No operation, ignore bits 1:7 of this register
1 SAER	Set all enable requests 0 Set only those ERQ bits specified in the SERQ field 1 Set all bits in ERQL
2:7 SERQ	Set enable request Sets the corresponding bit in ERQL

20.3.6 Clear Enable Request Register (DMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQL to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQL to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x0019 Access: User write-only

2:7 CERQ	Clear enable request Clears the corresponding bit in ERQL

20.3.7 Set Enable Error Interrupt Register (DMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEIL to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be set. Setting the SAEE bit provides a global set function, forcing the entire EEIL contents to be set.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

2:7 SEEI	Set enable error interrupt Sets the corresponding bit in EEIL

20.3.8 Clear Enable Error Interrupt Register (DMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEIL to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEIL contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x001B Access: User write-only

1 CAEE	Clear all enable error interrupts 0 Clear only those EEI bits specified in the CEEI field 1 Clear all bits in EEI
2:7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEIL

20.3.9 Clear Interrupt Request Register (DMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INTL to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INTL to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INTL to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x001C Access: User write-only

1 CAIR	Clear all interrupt requests 0 Clear only those INT bits specified in the CINT field 1 Clear all bits in INTL
2:7 CINT	Clear interrupt request Clears the corresponding bit in INTL

20.3.10 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERRL to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERRL to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERRL contents to be cleared, clearing all channel error indicators.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x001D Access: User write-only

1 CAEI	Clear all error indicators 0 Clear only those ERR bits specified in the CERR field 1 Clear all bits in ERR
2:7 CERR	Clear error indicator Clears the corresponding bit in ERRL

20.3.11 Set START Bit Register (DMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x001E Access: User write-only

1 SAST	Set all START bits (activates all channels) 0 Set only those TCD*n*_CSR[START] bits specified in the SSRT field 1 Set all bits in TCD*n*_CSR[START]
2:7 SSRT	Set START bit Sets the corresponding bit in TCD*n*_CSR[START].

20.3.12 Clear DONE Status Bit Register (DMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeros.

Address: 0x001F Access: User write-only

2:7 CDNE	Clear DONE bit Clears the corresponding bit in TCD*n*_CSR[DONE]

20.3.13 Interrupt Request Register Low (DMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the lower half of the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INTL.

Field	Description
30 INT1	Interrupt request 1 0 The interrupt request for corresponding channel is cleared. 1 The interrupt request for corresponding channel is active.
31 INT0	Interrupt request 0 0 The interrupt request for corresponding channel is cleared. 1 The interrupt request for corresponding channel is active.

20.3.14 Error Register Low (DMA_ERRL)

The ERRL provides a bit map for the 32 channels, signaling the presence of an error for each channel. ERRL covers channels 31–00. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

20.3.15 Hardware Request Status Register Low (DMA_HRSL)

The HRSL provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. HRSL covers channels 31–00. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQL fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQL bits.

20.3.16 Channel *n* Priority Register (DMA_DCHPRI*n*)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities

with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRI*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRI*n* registers. The group priority is assigned in the DMA control register.

Address: 0x0100 + *n**0x1 (*n* = 0 to 31) Access: User read/write

Table 264. DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel *n* cannot be suspended by a higher priority channel's service request 1 Channel *n* can be temporarily suspended by the service request of a higher priority channel
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel *n* can suspend a lower priority channel. 1 Channel *n* cannot suspend any channel, regardless of channel priority.
2:3 GRPPRI	Channel *n* current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4:7 CHPRI	Channel *n* arbitration priority Channel priority when fixed-priority arbitration is enabled. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.

20.3.17 Channel *n* Master ID Register (DMA_DCHMID*n*)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (for example a core) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID*n* registers.

Figure 173. TCD Transfer Attributes (DMA_TCD*n*_ATTR)

Table 267. DMA_TCD*n*_ATTR field descriptions

Field	Description
0:4 SMOD	Source address modulo 0x00 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range
5:7 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte 110 Reserved 111 Reserved
8:12 DMOD	Destination address modulo See the SMOD definition.
13:15 DSIZE	Destination data transfer size See the SSIZE definition.

20.3.20 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)

1. x = Undefined at reset.

Figure 175. TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCD*n*_NBYTES_MLNO)

Table 269. DMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **Note:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

20.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if Minor loop mapping is enabled (CR[EMLM] = 1) and SMLOE = 0 and DMLOE = 0

Address: 0x1008 + *n**0x20 (*n* = 0 to 31) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 270. DMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.

Table 270. DMA_TCD*n*_NBYTES_MLOFFNO field descriptions (continued)

Field	Description
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

20.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)

TCD Word 2 is defined as follows if Minor loop mapping is enabled (CR[EMLM] = 1) and Minor loop offset enabled (SMLOE or DMLOE = 1)

Address: 0x1008 + *n**0x20 (*n* = 0 to 31) Access: User read/write

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2:21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

20.3.24 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST)

Address: 0x100C + *n**0x20 (*n* = 0 to 31) Access: User read/write

Figure 180. TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES)

Table 274. DMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
1:6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.
7:15 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (for example final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **Note:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

20.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)

Field	Description

0:31
DLASTSGA
	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).
	If (TCD*n*_CSR[ESG] = 0) then
	– Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure
	else
	– This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, else a configuration error is reported

20.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

Figure 184. TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

Table 278. DMA_TCD*n*_BITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
1:6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.
7:15 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

Reset(1)	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

1. x = Undefined at reset.

Figure 186. TCD Control and Status (DMA_TCD*n*_CSR)

Table 280. DMA_TCD*n*_CSR field descriptions

Field	Description
0:1 BWC	Bandwidth control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBS). **Note:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each R/W 11 eDMA engine stalls for 8 cycles after each R/W

2:7
MAJORLINKCH
	Link channel number
	If (MAJORELINK = 0) then
	– No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted
	else
	– After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.

8 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **Note:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
9 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. **Note:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled

Table 280. DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
11 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **Note:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable request 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **Note:** If BITER is set, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled .
14 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
15 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request;

20.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

20.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
  - Address path:

    This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

    When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n* _{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the TCD*n* _CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
  - Data path:

    This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

    The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
  - Program model/channel arbitration:

    This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
  - Control:

    This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-

bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

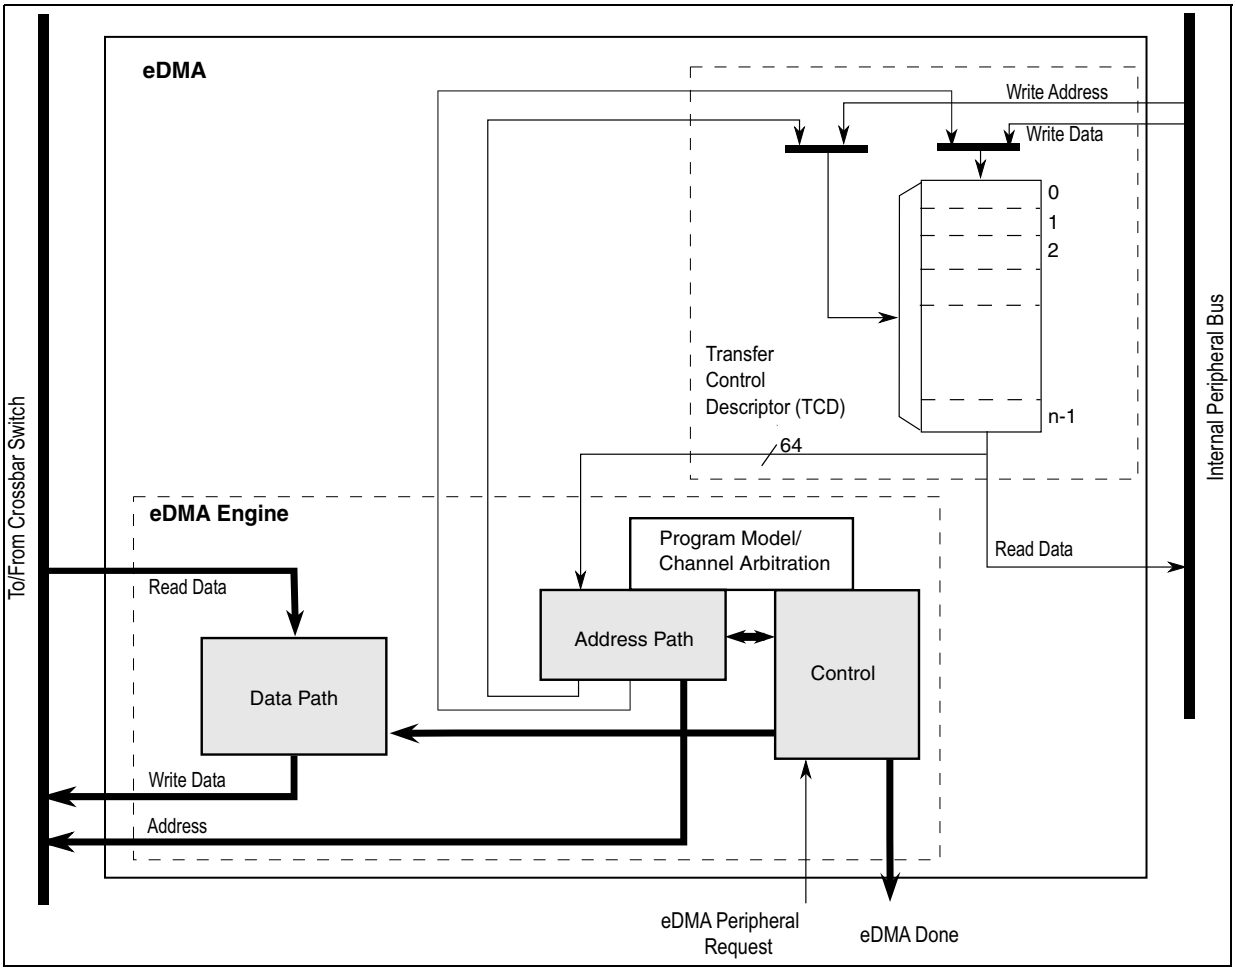
- Transfer control descriptor memory
  - Memory controller:

    This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

    As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
  - Memory array:

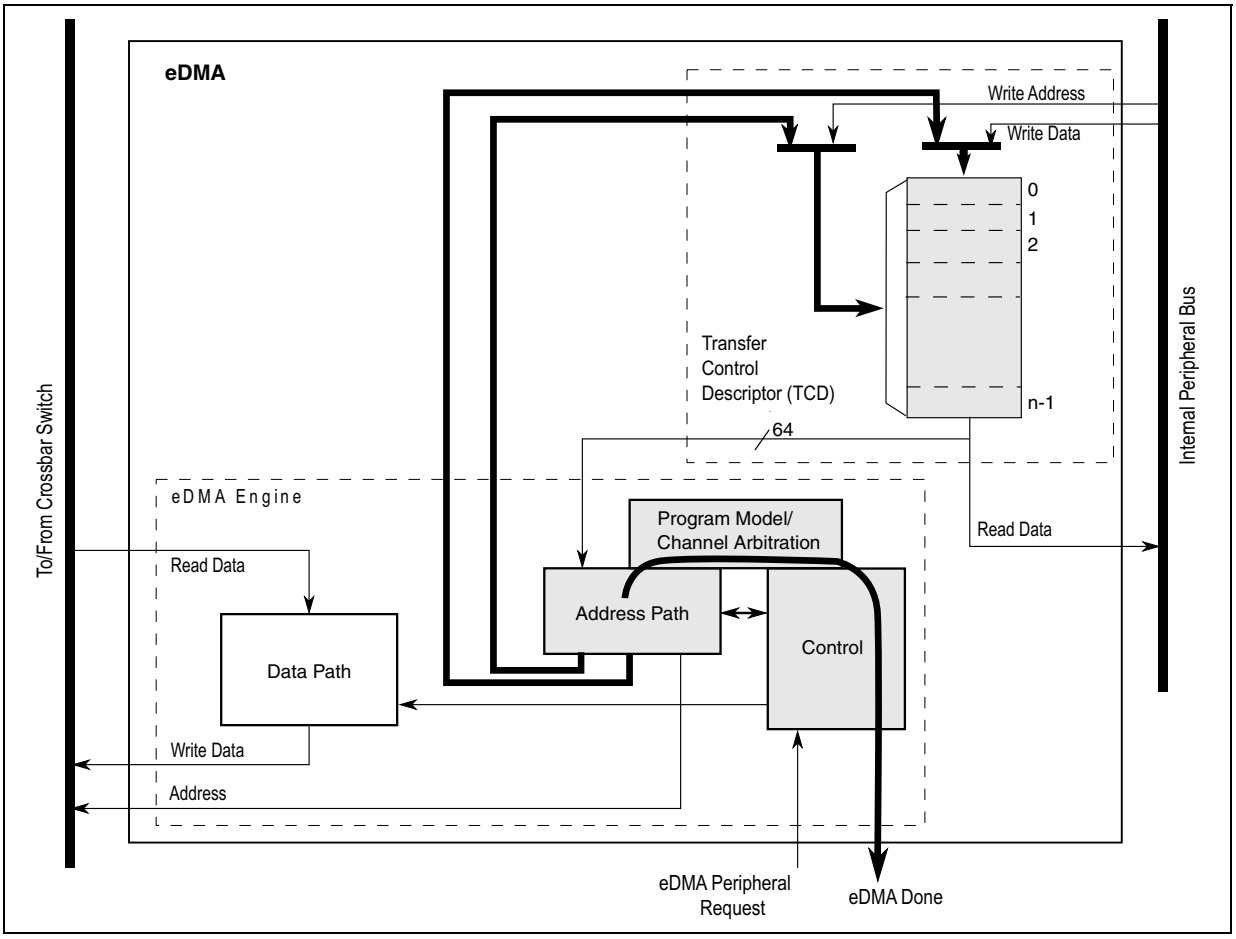
    TCD storage is implemented using a single-port, synchronous RAM array.

20.4.2 eDMA basic data flow



The basic flow of a data transfer can be partitioned into three segments. As shown in *Figure 187*, the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

Figure 187. DMA operation, part 1



In the second part of the basic data flow as shown in *Figure 188* the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

Figure 188. DMA operation, part 2

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in *Figure 189*.

Figure 189. DMA operation, part 3

20.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries
- The minor loop byte count must be a multiple of the source and destination transfer sizes
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively
- In Fixed Arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups.

All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when Fixed Arbitration mode is enabled

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD*n*_CITER[E_LINK] bit does not equal the TCD*n*_BITER[E_LINK] bit

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

20.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRI*n*[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRI*n*[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

20.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in *Table 281* and *Table 282*. The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase
- All internal peripheral bus accesses are 32 bits in size
- All internal SRAM accesses are 64 bits in size

Table 281 presents a peak transfer rate comparison, measured in megabytes per second.

Table 281. eDMA peak transfer rates (Mbyte/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0

Table 281. eDMA peak transfer rates (Mbyte/s) (continued)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD*n* _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* Word 7)
- Cycle 3: Channel arbitration begins
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here
- Cycles 8 to x[(h)]: The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

  The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles.

h. "*x*" represents an undefined cycle value dependant on transfer sizes and response times for the channel's read and write accesses.

For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles

- Cycle $x^{(h)}$ + 1: This cycle represents the data phase of the last destination write
- Cycle $x^{(h)}$ + 2: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* Word 7 is read and checked for channel linking or scatter/gather requests
- Cycle $x^{(h)}$ + 3: The appropriate fields in the first part of the TCD*n* are written back into the local memory
- Cycle $x^{(h)}$ + 4: The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start
- Cycle $x^{(h)}$ + 5: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles (4 + (3 + 3)/2 + 3). This is the time from Cycle 4 to Cycle *x* + 5. The resulting peak request rate, as a function of the system frequency, is shown in *Table 282*. This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

Table 282. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

Equation 2 PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example, consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase
- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer:

Equation 3 PEAKreq = 150 MHz / [4 + (1 + 0) + (1 + 1) + 3] cycles = 15.0 Mreq/s

For an internal peripheral bus-to-SRAM transfer:

Equation 4 PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 0) + 3] cycles = 15.0 Mreq/s

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCD*n*_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

20.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

20.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired
2. Write the channel priority levels into the DCHPRI*n* registers if a configuration other than the default is desired
3. Enable error interrupts in the EEI registers if so desired
4. Write the 32-byte TCD for each channel that may request service
5. Enable any hardware service requests via the ERQ register
6. Request channel service by software (setting the TCD*n*_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal)

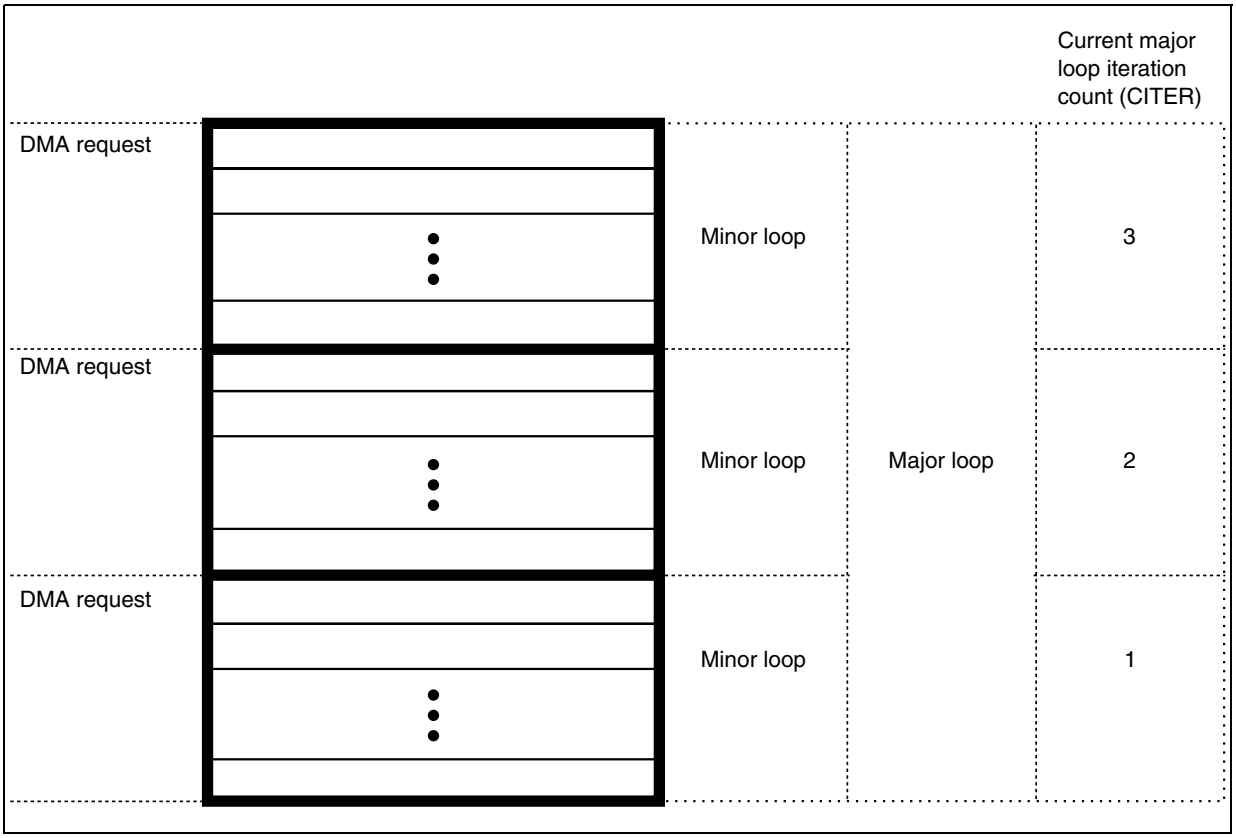
After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in *Table 283*) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD*n*_SADDR) to the destination (as defined by the destination address, TCD*n*_DADDR) continue until the specified number of bytes (TCD*n*_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

Table 283. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

Figure 190 shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 190. Example of multiple loop iterations



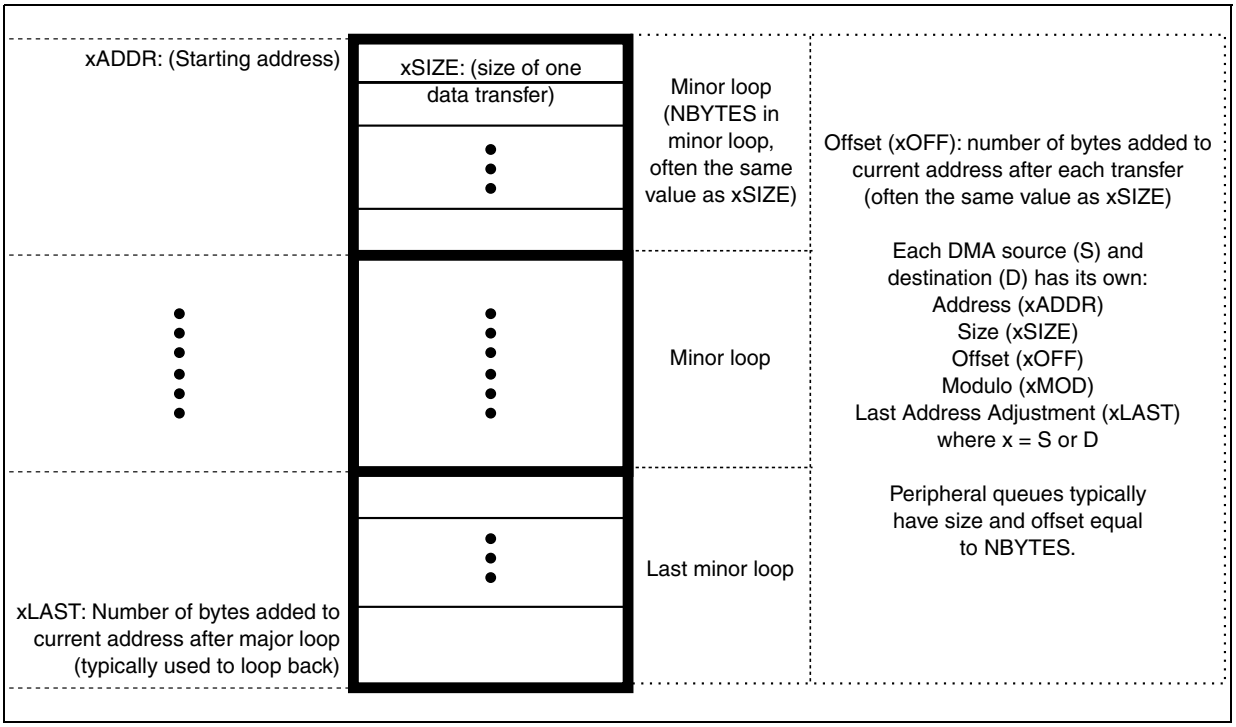


Figure 191 lists the memory array terms and how the TCD settings interrelate.

Figure 191. Memory array terms

20.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: group priority error (ES[GPE]) and channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes
2. Group 1 is the highest priority and all channels are unique in that group
3. Group 0 is the next highest priority and has two channels with the same priority level
4. If Group 1 has any service requests, those requests will be executed
5. Once all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur
7. This repeats until all of the Group 0 requests have been removed or a higher priority Group 1 request comes in

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the

selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

20.5.3 DMA Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

20.5.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller: that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

20.5.3.2 Round-robin group arbitration, fixed-channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with an service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

20.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in *Section 20.5.3.2: Round-robin group arbitration, fixed-channel arbitration*, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel

service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

20.5.3.4 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in *Section 20.5.3.1: Fixed-group arbitration, fixed-channel arbitration* but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get very much longer and longer as the group priority decreases.

20.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

20.5.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have
been initialized)
```

```
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service
2. The channel is selected by arbitration for servicing
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file
5. The source-to-destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F
   h) Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER)
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1
8. The channel retires and the eDMA goes idle or services the next channel

20.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as previous. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service
2. The channel is selected by arbitration for servicing
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file
5. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F
   h) Write 32 bits to location 0x200C → last iteration of the minor loop
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel
9. Second hardware (eDMA peripheral) requests channel service
10. The channel is selected by arbitration for servicing
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1
12. eDMA engine reads: channel TCD data from local memory to internal register file
13. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013
   b) Write 32 bits to location 0x2010 → first iteration of the minor loop
   c) Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017
   d) Write 32 bits to location 0x2014 → second iteration of the minor loop
   e) Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B
   f) Write 32 bits to location 0x2018 → third iteration of the minor loop
   g) Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F
   h) Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2(TCD*n*_BITER)
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel

20.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

Table 284 shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 284. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

20.5.5 eDMA TCD*n* status monitoring

This section discusses how to monitor eDMA status.

20.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute a sequence for a software activated channel as shown in the following table:

Table 285. TCD status sequence – software activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing

Table 285. TCD status sequence – software activated channel (continued)

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute a sequence for a hardware-activated channel as shown in the following table:

Table 286. TCD status sequence – hardware activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit. The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

20.5.5.2 Active channel TCD*n* reads

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

20.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in Fixed-Group, Fixed-Channel Arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal (constantly rotating) when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting

channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

20.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note: The TCDn_CITER[E_LINK] bit and the TCDn_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

Table 287 summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 287. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	

Table 287. Channel linking parameters (continued)

Desired link behavior	TCD control field name	Description
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

20.5.7 Dynamic programming

20.5.7.1 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode
2. Disable all channels, change the group priorities, then enable the appropriate channels

20.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in *Table 288* is recommended when executing a dynamic channel link request.

Table 288. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit
2	Read back the TCD.major.e_link bit
3	Test the TCD.major.e_link request status: – If TCD.major.e_link = 1b, the dynamic link attempt was successful – If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring)

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

20.5.7.3 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

20.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in *Table 289* may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 289. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather
2	Write 1b to theTCD.d_req bit *Note: Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.*
3	Write theTCD.dlast_sga field with the scatter/gather address
4	Write 1b to the TCD.e_sg bit

Table 289. Coherency model for method 1 (continued)

Step	Action
5	Read back the 16 bit TCD control/status field
6	Test the TCD.e_sg request status and TCD.major.linkch value: – If e_sg = 1b, the dynamic link attempt was successful – If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring) – If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit)

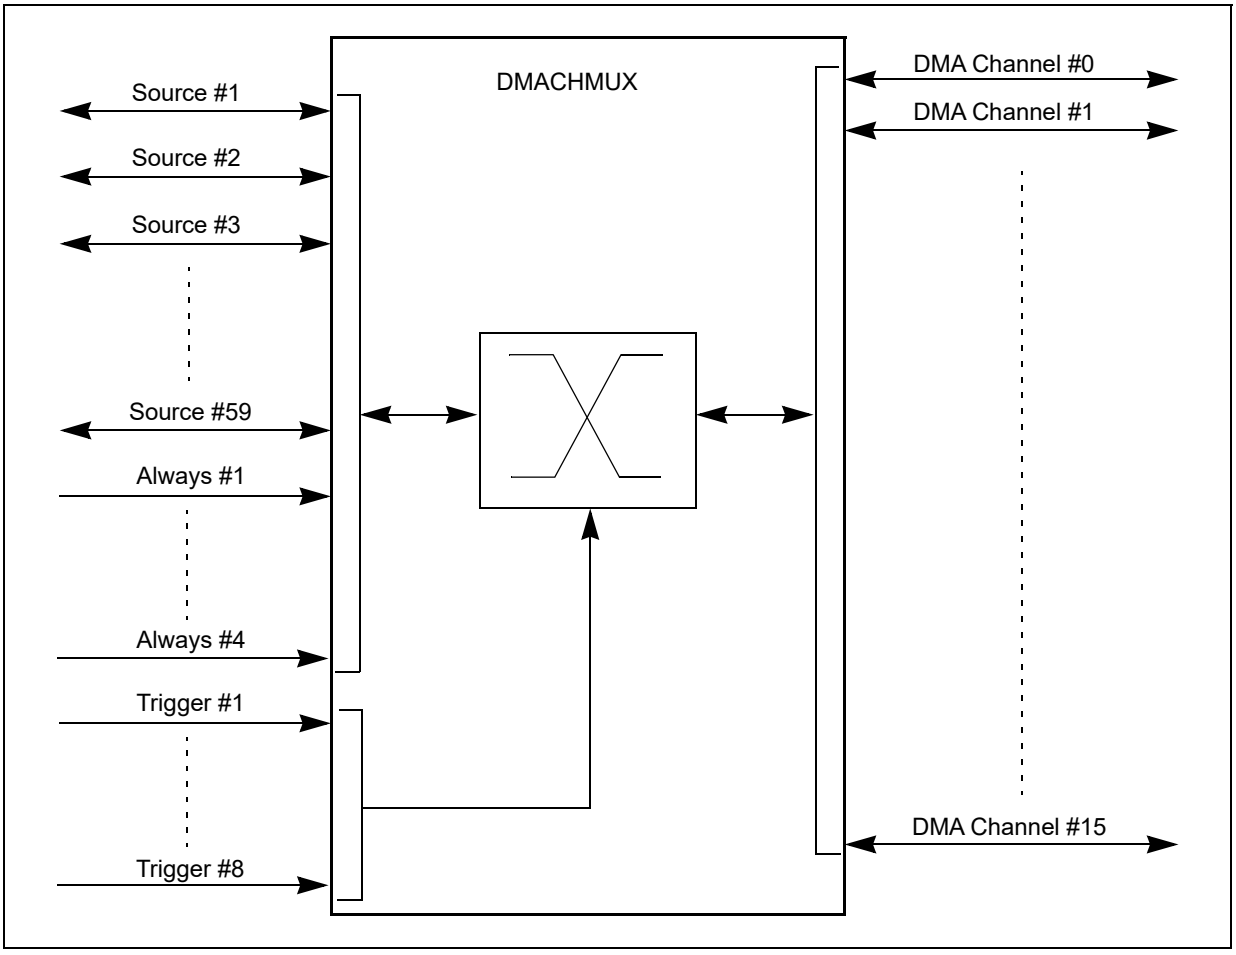
20.5.7.3.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in *Table 290* may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 290. Coherency model for method 2

Step	Action
1	Write 1b to theTCD.d_req bit **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
2	Write theTCD.dlast_sga field with the scatter/gather address
3	Write 1b to the TCD.e_sg bit
4	Read back the TCD.e_sg bit
5	Test the TCD.e_sg request status: – If e_sg = 1b, the dynamic link attempt was successful – If e_sg = 0b, read the 32 bit TCD dlast_sga field – If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring) – If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit)

21 DMA channel multiplexer (DMACHMUX)



21.1 Introduction

Note: For the chip-specific implementation details of this module's instances, see the chip configuration information.

21.1.1 Overview

The DMA channel multiplexer (DMACHMUX) allows to route 59 DMA peripheral sources (called slots) to 16 DMA channels. This is illustrated in *Figure 192*.

Figure 192. DMACHMUX block diagram

21.1.2 Features

The DMACHMUX provides these features.

- 59 peripheral slots + four always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channels routers.
  - The first 8 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of 59 possible peripheral DMA slots or to one of the 4 always-on slots.

21.1.3 Modes of operation

The following operation modes are available.

- Disabled Mode
  In this mode, the DMA channel is disabled. Since disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMACHMUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place (for example, changing the period of a DMA trigger).
- Normal Mode
  In this mode, a DMA source (such as DSPI transmit or DSPI receive for example) is routed directly to the specified DMA channel. The operation of the DMACHMUX in this mode is completely transparent to the system.
- Periodic Trigger Mode
  In this mode, a DMA source may only request a DMA transfer (such as when a transmit buffer becomes empty or a receive buffer becomes full) periodically. Configuration of the period is done in the registers of the Periodic Interrupt Timer (PIT). This mode is only available for channels 0–7 of each DMACHMUX instance.

21.2 External signal description

21.2.1 Overview

The DMACHMUX has no external pins.

21.3 Memory map and register definition

Table 291 lists the DMACHMUX memory-mapped registers. All addresses are offsets; the absolute address can be computed by adding the specified offset to the base address of the DMACHMUX.

Table 291. DMACHMUX memory map

Address offset	Register	Access	Location
eDMA channel registers per channel (*n* = 0 to 15)			
0x0000 + *n* * 0x1	Channel *n* Configuration registers (CHCFG*n*)	R/W	*Section 21.3.1.1*

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, CHCFG0 through CHCFG3 are accessible by a 32-bit READ/WRITE to address ‘Base + 0x00’, but performing a 32-bit access to address ‘Base + 0x01’ is illegal.

21.3.1 Register descriptions

This section provides a detailed description of the memory-mapped registers in the DMACHMUX.

21.3.1.1 Channel *n* Configuration registers (CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMACHMUX slots (peripheral slots or always-on slots) in the system.

Address: 0x0000 + *n* * 0x1 (*n* = 0 to 15) Access: User read/write

	0	1	2	3	4	5	6	7
R W	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

Figure 193. Channel Configuration registers (CHCFG*n*)

Table 292. CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable ENBL enables the DMA Channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMACHMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable (for triggered channels only) TRIG enables the periodic trigger capability for the DMA Channel. 0 Triggering is disabled. If triggering is disabled, and the ENBL bit is set, the DMA Channel will simply route the specified source to the DMA channel 1 Triggering is enabled
2:7 SOURCE	DMA Channel Source (DMACHMUX slot) SOURCE specifies which DMA source, if any, is routed to a particular DMA channel. Please refer to “Device configuration” chapter for further details about the peripherals and their slot numbers

Table 293. Channel and trigger enabling

ENBL	TRIG	Function	Mode
0	X	DMA Channel is disabled	Disabled Mode
1	0	DMA Channel is enabled with no triggering (transparent)	Normal Mode
1	1	DMA Channel is enabled with triggering	Periodic Trigger Mode

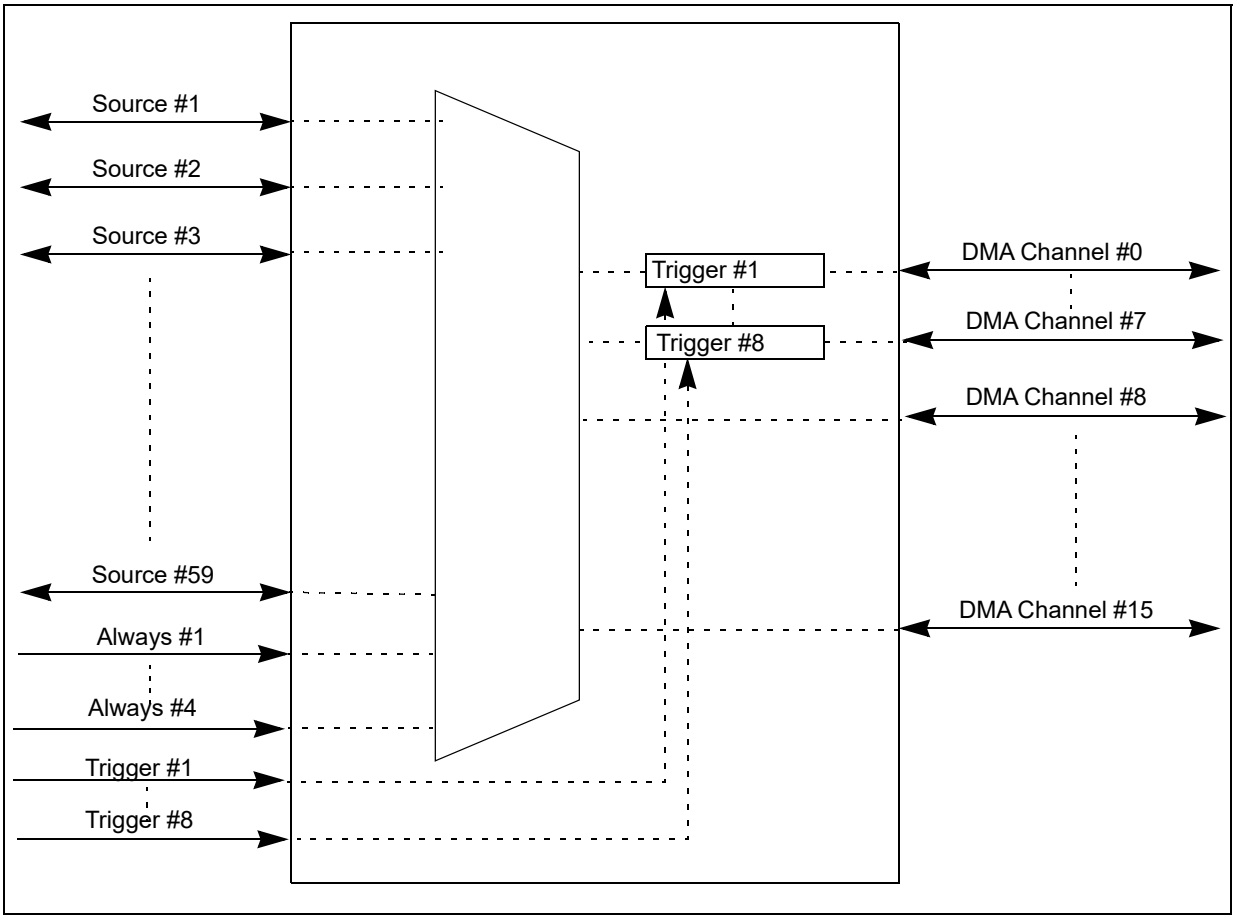
Note: Setting multiple CHCFG registers with the same source value will result in unpredictable behavior.

Before changing the trigger or source settings a DMA channel must be disabled via the CHCFG[n].ENBL bit.

21.4 Functional description

This section provides a functional description of the DMACHMUX. The primary purpose of the DMACHMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMACHMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in *Section 21.5.2* is followed, the configuration of the DMACHMUX may be changed during the normal operation of the system.

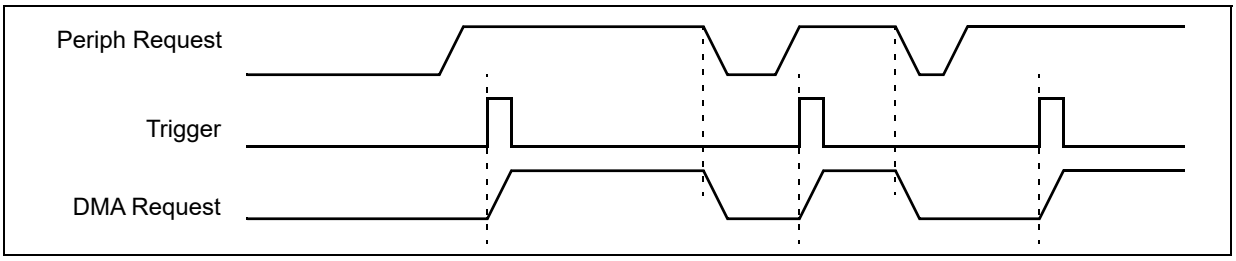
Functionally, the DMACHMUX channels may be divided into two classes.



- Channels which implement the normal routing functionality plus periodic triggering capability.
- Channels which implement only the normal routing functionality.

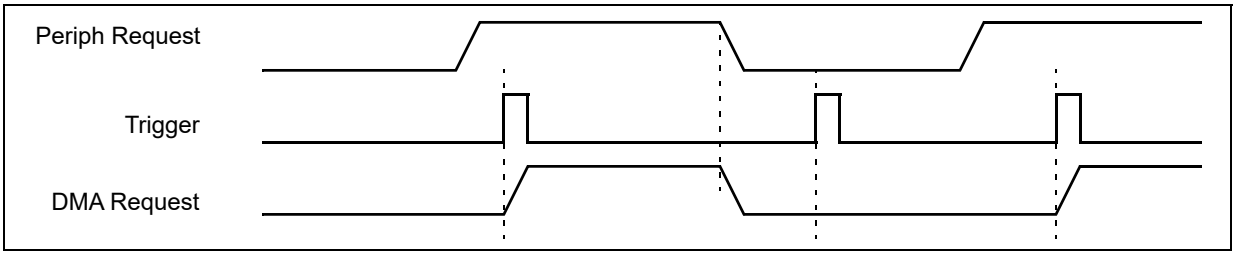
21.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 8 channels of the DMACHMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames or packets at fixed intervals without the need for processor intervention. The trigger is generated by the Periodic Interrupt Timer (PIT): such as the configuration of the periodic triggering interval is done via configuration registers in the PIT. Please refer to the Periodic Interrupt Timer (PIT) chapter for more information on this topic.



Note: Because of the dynamic nature of the system (such as DMA channel priorities, bus arbitration, interrupt service routine lengths), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 194. DMACHMUX triggered channels



The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the Peripheral to the DMA until a trigger event has been seen. This is illustrated in *Figure 195*.

Figure 195. DMACHMUX channel triggering: normal operation

Once the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral re-asserts its request AND the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, that trigger will be ignored. This situation is illustrated in *Figure 196*.

Figure 196. DMACHMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations.

- Periodically polling external devices on a particular bus. As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. Once setup, the SPI will request DMA transfers (presumably from memory) as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO Ports to drive or sample waveforms. By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger (such as resolution, range of values) may be found in Periodic Interrupt Timer (PIT) chapter.

21.4.2 DMA channels with no triggering capability

The other channels of the DMACHMUX provide the normal routing functionality as described in *Section 21.1.3*.

21.4.3 “Always Enabled” DMA sources

In addition to the peripherals that can be used as DMA sources, there are 4 additional DMA sources that are “always enabled”. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the *“always enabled”* sources provide no such “throttling” of the data transfers. These sources are most useful in the following cases:

- Doing DMA transfers to/from GPIO: Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Doing DMA transfers from memory to memory: Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Doing DMA transfers from memory to the external bus (or vice-versa): Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation: Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, a *“always enabled”* DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require a new “*start*” event be sent. This

can either be a new software activation, or a transfer request from the DMACHMUX. The options for doing this are:

- Transfer all data in a single minor loop. By configuring the DMA to transfer all of the data in a single minor loop (that is major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will incur on the system. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use explicit software reactivation. In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel (by writing to the DMA registers) *after every minor loop*. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use a *"always enabled"* DMA source. In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMACHMUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an *"always enabled"* source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

21.5 Initialization/Application information

21.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 21.3.1*). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

21.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 2 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

Note: The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

Example 1 Configure source #5 Transmit for use with DMA Channel 2, with periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #4 above:

In file **registers.h:**

```
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
#include "registers.h"
   :
   :
*CHCFG2 = 0x00;
*CHCFG2 = 0xC5;
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 8 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

Note: The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

Example 2 Configure source #5 Transmit for use with DMA Channel 2, with no periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #3 above:

In File **registers.h:**

```
  #define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
  /* Following example assumes char is 8-bits */
  volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
  volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
  volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
  volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
  volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
  volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
  volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
  volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
  volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
  volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
  volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
  volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
  volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
```

```
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG2 = 0x00;
  *CHCFG2 = 0x85;
```

Disabling a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module specific configuration may be necessary. Please refer to the appropriate section for more details.

Switching the source of a DMA Channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the ENBL and TRIG bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the ENBL and TRIG bits are set.

Example 3 Switch DMA Channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 does not have triggering capability.
2. Write 0x00 to CHCFG8 (Base Address + 0x08).
3. Write 0x87 to CHCFG8 (Base Address + 0x08). (In this example, setting the TRIG bit would have no effect, due to the assumption that channels 8 does not support the periodic triggering functionality).

The following code example illustrates steps #2 and #3 above.

In File **registers.h:**

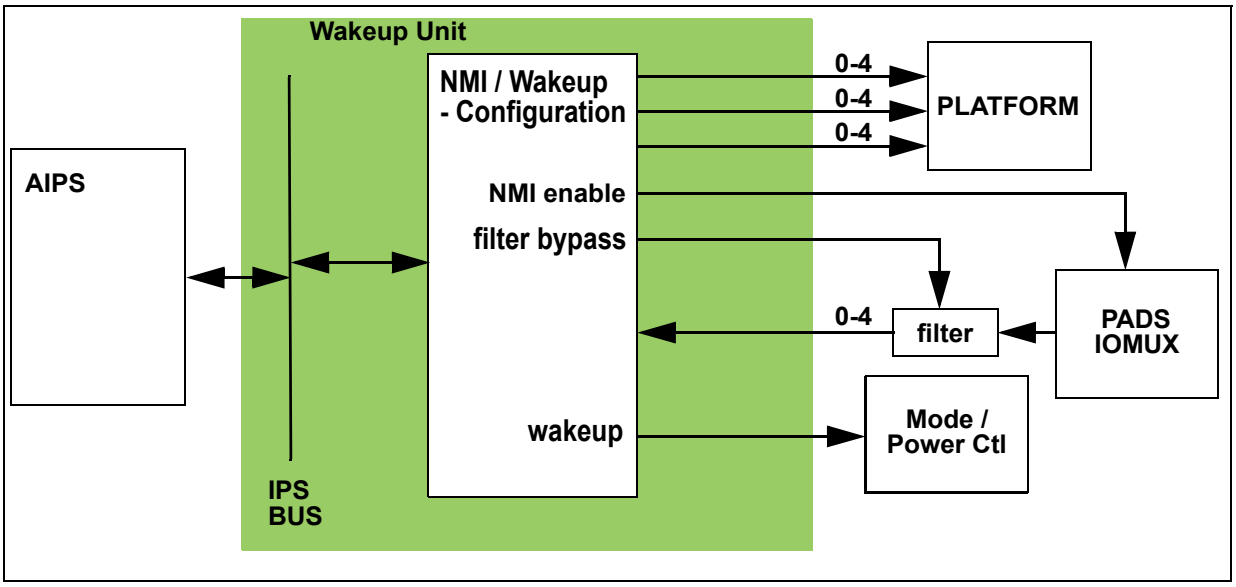
```
  #define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
  /* Following example assumes char is 8-bits */
  volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
  volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
  volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
  volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
  volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
```

```
  volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
  volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
  volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
  volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
  volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
  volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
  volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
  volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG8 = 0x00;
  *CHCFG8 = 0x87;
```

22 Wakeup unit (WKPU)



22.1 Introduction

22.1.1 Overview

The Wakeup unit supports up to 3 external sources that can cause non-maskable interrupt requests or wakeup events. In addition, it combines its wakeup events to supply a single wakeup to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 197* is a block diagram of the Wakeup unit and its interfaces to other system components.

Note: For the chip-specific implementation details of this module see the "Device Configuration" chapter.

Figure 197. Wakeup unit Block Diagram

22.1.2 Features

The Wakeup unit supports these distinctive features:

Non-maskable Interrupt support with:

- Up to four NMI sources
- Up to four analog glitch filters
- Independent CPU exceptions destination: non-maskable interrupt, critical interrupt, or machine check request
- Edge detection
- Configurable system wakeup triggering from all NMI sources

22.2 Memory Map and Register Description

This section provides a detailed description of all registers accessible in the WKPU module.

22.2.1 Memory Map

Table 294 gives an overview on the WKPU registers implemented.

Table 294. WKPU Memory Map

Address Offset	Registers	Supported Access Sizes	Location
0x0000	NMI Status Flag Register (NSR)	32/16/8	*Section 22.2.2.1*
0x0004–0x0007	Reserved		
0x0008	NMI Configuration Register (NCR)	32/16/8	*Section 22.2.2.2*
0x000C–0x3FFF	Reserved		

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

22.2.2 Register Descriptions

This section describes in address order all the Wakeup unit registers.

22.2.2.1 NMI Status Flag Register (NSR)

This register holds the non-maskable interrupt status flags.

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NIF0	NOVF0	0	0	0	0	0	0	NIF1	NOVF1	0	0	0	0	0	0	NIF2	NOVF2	0	0	0	0	0	0	RIF	ROVF	0	0	0	0	0	0
W	w1c	w1c							w1c	w1c							w1c	w1c							w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 198. NMI Status Flag Register (NSR)

Table 295. NSR Field Descriptions

Field	Description
0 NIF0	NMI Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE0 and NFEE0 has occurred. 0 No event has occurred on the pad.
1 NOVF0	NMI Overrun Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 1 An overrun has occurred on NMI input 0. 0 No overrun has occurred on NMI input 0.
8 NIF1	NMI Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE1 and NFEE1 has occurred. 0 No event has occurred on the pad.
9 NOVF1	NMI Overrun Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 1 An overrun has occurred on NMI input 1. 0 No overrun has occurred on NMI input 1.
24 RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (that is if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An event as defined by RREE and RFEE has occurred. 0 No event has occurred on the pad.
25 ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An overrun has occurred on NMI input. 0 No overrun has occurred on NMI input.

Note: Refer to the Chapter 7: Device configuration to see how the Figure 198: NMI Status Flag Register (NSR) is used in the device.

22.2.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

Figure 199. NMI Configuration Register (NCR)

1. Writing this bit has no functional impact.

Table 296. NCR Field Descriptions

Field	Description
0 NLOCK0	NMI Configuration Lock Register 0 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
1:2 NDSS0	NMI Destination Source Select 0 This value is reset on system reset. 00 non-maskable interrupt 01 critical interrupt 10 machine check request 11 reset request
3 NWRE0	NMI Wakeup Request Enable 0 1 NMI0 wakeup is enabled. A set NIF0 bit or set NOVF0 bit causes a system wakeup request. 0 NMI0 wakeup is disabled. System wakeup requests from the corresponding NIF0 bit are disabled.
5 NREE0	NMI Rising-edge Events Enable 0 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
6 NFEE0	NMI Falling-edge Events Enable 0 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
7 NFE0	NMI Filter Enable 0 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
8 NLOCK1	NMI Configuration Lock Register 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.

Table 296. NCR Field Descriptions (continued)

Field	Description
9:10 NDSS1	NMI Destination Source Select 1 This value is reset on system reset. 00 non-maskable interrupt 01 critical interrupt 10 machine check request 11 reset request
11 NWRE1	NMI Wakeup Request Enable 1 1 NMI1 wakeup is enabled. A set NIF1 bit or set NOVF1 bit causes a system wakeup request 0 NMI1 wakeup is disabled. System wakeup requests from the corresponding NIF1 bit are disabled
13 NREE1	NMI Rising-edge Events Enable 1 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
14 NFEE1	NMI Falling-edge Events Enable 1 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
15 NFE1	NMI Filter Enable 1 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
16 NLOCK2	NMI Configuration Lock Register 2 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
17:18 NDSS2	NMI Destination Source Select 2 This value is reset on system reset. 00 non-maskable interrupt 01 critical interrupt 10 machine check request 11 reset request
19 NWRE2	NMI Wakeup Request Enable 2 1 NMI2 wakeup is enabled. A set NIF2 bit or set NOVF2 bit causes a system wakeup request. 0 NMI2 wakeup is disabled. System wakeup requests from the corresponding NIF2 bit are disabled.
21 NREE2	NMI Rising-edge Events Enable 2 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
22 NFEE2	NMI Falling-edge Events Enable 2 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
23 NFE2	NMI Filter Enable 2 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Table 296. NCR Field Descriptions (continued)

Field	Description
24 RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
25:26 RDSS	Reset Destination Source Select This value is reset on system reset. 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request. 0 System wakeup requests from the corresponding RIF bit are disabled.
29 RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
30 RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
31 RFE	Reset Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Note: Refer to the Chapter 7: Device configurationto see how the Figure 199: NMI Configuration Register (NCR) is used in the device.

Note: Writing a '0' to both NREEx and NFEEx disables the NMI functionality completely (no system wakeup or interrupt will be generated on any pad activity).

22.3 Functional Description

22.3.1 General

This section provides a complete functional description of the Wakeup unit.

22.3.2 Non-Maskable Interrupts

The Wakeup unit supports up to 4 non-maskable interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports the generation of 3 types of interrupts per NMI input to the SoC. The Wakeup unit supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a bypassable analog glitch filter.

Note: Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

22.3.2.1 NMI Management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 199*). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

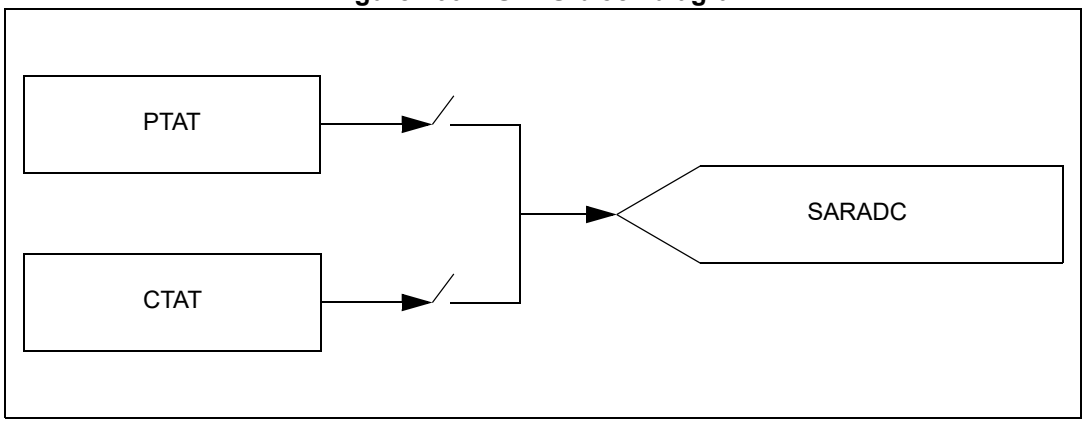
Note: After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 296* for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see *Figure 198*). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (it has not yet been cleared).

Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.



23 Temperature sensor (TSENS)

23.1 Introduction

The TSENS module provides an analog voltage that is proportional to the internal temperature of the SPC574Sx. This voltage can be sampled by the ADC and converted to an actual temperature by using factory-programmed calibration constants.

Figure 200 shows a block diagram of the TSENS module. The module operates on the principles of a basic silicon bandgap sensor that measures the difference in base-emitter voltages of multiple transistors, which can be related to the absolute temperature of the device.

Figure 200. TSENS block diagram

23.2 Features

The TSENS has the following features:

- Temperature monitoring range: –40 to +150 °C
- Sensitivity: approximately 5.14 mV/°C

23.3 Signals

The TSENS does not use any input signals external to the device.

23.4 TSENS outputs

TSENS produces two outputs from separate sources:

- Proportional to absolute temperature (PTAT). PTAT channel number is TCH120 (test channel).
- Complementary to absolute temperature (CTAT). CTAT channel number is TCH121 (test channel).

23.5 Obtaining device temperature using TSENS

In order to obtain the device temperature using TSENS, you must do the following:

- Extract the necessary TSENS calibration constants from the SPC574Sx test flash memory (see *Section 23.5.1*).
- Measure PTAT and CTAT voltages through the ADC.
- Calculate the device temperature using the equations in *Section 23.5.2*.

The need for the measurements in two different modes is driven by the fact that although the TSENS output is linear in either mode, the intercept of the V_{TSENS}-T plot varies significantly based on the ADC reference voltage. Performing the two measurements allows the resulting equations to be independent of this reference voltage.

23.5.1 TSENS calibration constants

The equations needed to convert V_{TSENS} into device temperature information depend on four calibration constants as described in *Table 297*. These constants are determined during factory testing and stored in the test flash memory.

Table 297. TSENS calibration constants (1)

Constant	Description
P_1	Code from the ADC converting PTAT voltage at 150 °C
P_2	Code from the ADC converting PTAT voltage at –40 °C
C_1	Code from the ADC converting CTAT voltage at 150 °C
C_2	Code from the ADC converting CTAT voltage at –40 °C

1. Flash locations for P2, C2, P1, and C1 are 0x400000, 0x400002, 0x400004, and 0x400006 respectively for Temperature Sensor 0. Flash locations for P2, C2, P1, and C1 are 0x4000F0, 0x4000F2, 0x4000F4, and 0x4000F6 respectively for Temperature Sensor 1.

23.5.2 Equations for converting TSENS voltage to device temperature

In the equations below:

- P_n and C_n are the calibration constants described in *Section 23.5.1*
- T is the device temperature in °C
- P_x is the code from the ADC converting the PTAT voltage output at a generic temperature T
- C_x is the code from the ADC converting the CTAT voltage output at a generic temperature T
- $T_2 = -40$
- $T_1 = +150$

Given that:

Equation 5

$$A = P_x C_2 - P_2 C_x$$

Equation 6

$$B = C_x P_1 - P_x C_1$$

The temperature is calculated as:

Equation 7

$$T = T_2 + \frac{(T_1 - T_2) \cdot A}{A + B}$$

23.6 Equations for converting CTAT and PTAT voltages into constant reference code

By converting the two outputs of CTAT and PTAT through ADC, one can find out a constant reference code which does not change with temperature.

- Pn and Cn are the calibration constants described in *Table 297*
- ref_code is the value of the constant reference code
- Px is the code from the ADC converting PTAT voltage output at any temperature T with any ADC reference voltage Vref
- Cx is the code from the ADC converting CTAT voltage output at the same temperature T with the same ADC reference voltage Vref

Equation 8

$$\text{ref_code} = P_x + \left(\frac{(P_2 - P_1)}{(C_1 - C_2)}\right) . Cx$$

Note: It is mandatory to measure Px and Cx at the same ADC reference voltage and at the same temperature.

24 Clocking

24.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers

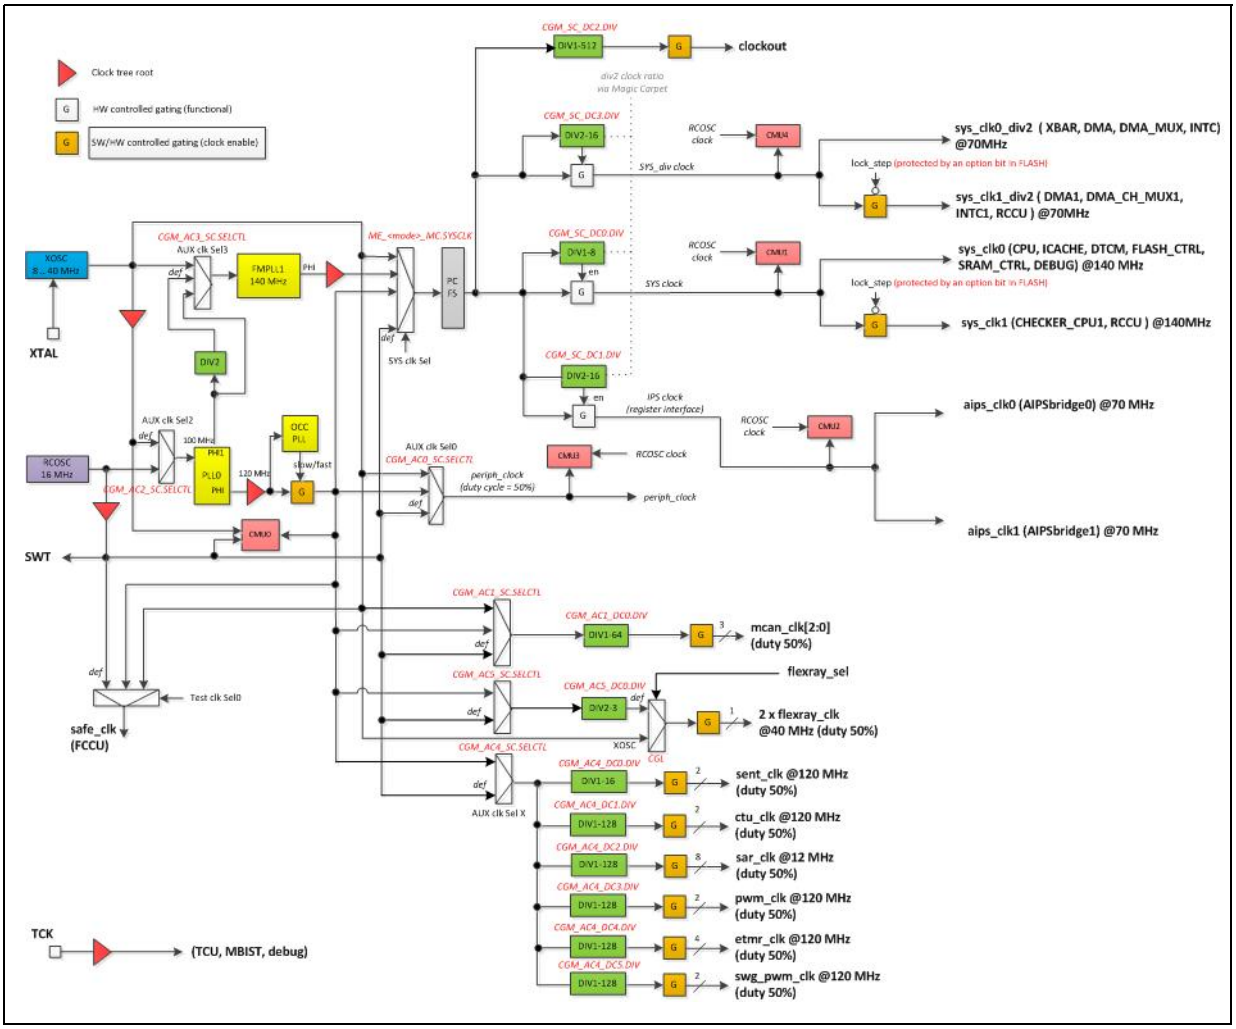
The system clock (SYSCLK) for the platform (which includes the two CPUs (Main Core_0 and Checker Core_0s), memories, and debug logic is independent from the peripheral clocks. This allows SYSCLK to be a frequency modulated clock to reduce electromagnetic emissions, while having a precise clock for the peripheral timer and communication functions. It also allows the system clock to be reduced during low computational activity periods to help reduce power consumption, while providing a fixed frequency to the communication interfaces and timers.

This device boots from the internal 16 MHz RC oscillator (IRCOSC), and uses this as a backup clock in the event of a PLL or oscillator failure (if backup clock is enabled). The backup clock can be enabled in the Mode Entry Module (MC_ME). See *Chapter 52: Mode Entry Module (MC_ME)* for details.

There are two possible ways to provide the source clock:

- External oscillator/External crystal
- Internal 16 MHz RC oscillator

From one of these input sources, the internal clocks are generated from both PLLs, PLL0 and PLL1, using PLL0_PHI and PLL1_PHI outputs, respectively. These two clocks, along with the XOSC and IRCOSC, can be selected to drive system peripherals depending on the configuration of the Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM). The PHI1 output of PLL0 can also be used as the clock source for PLL1. Six Auxiliary Clock Selectors are utilized, allowing developers to select an independent clock source for each of the system peripherals.



Each of the outputs of the module clock selectors have individual dividers that allow for more clock frequency granularity with the ability to divide the clock selector outputs by up to 512 for a given peripheral. Clock Monitor Units (CMUs) are connected to outputs of clock dividers as shown in *Figure 201: Clock generation architecture* to verify that their clock frequencies stay within necessary operating limits. The action taken when a CMU detects an issue with the monitored clock depends on the CMU configuration. When an issue with a clock is found, the CMUs can signal an interrupt or initiate a system reset.

24.2 Clock generation

The top-level clock generation architecture can be seen in *Figure 201*. All clock selectors and dividers are located and programmed in the MC_CGM. All dividers are integer dividers (1, 2, 3, …, *n*) with the ranges shown in the divider blocks in *Figure 201*.

Note: CMU_1, CMU_2 ,CMU_3 and CMU_4 in Figure 201 use IRCOSC for their reference clock, whereas the user can select either IRCOSC or XOSC for the reference in CMU_0.

Figure 201. Clock generation architecture

24.2.1 MC_CGM registers

Table 298 shows the relationship between the clocks in *Figure 201* and the MC_CGM registers.

Table 298. MC_CGM relationship to clocks(1)

MC_CGM register(s)	Register description	Output clock	CMU(2)
CGM_SC_DC0	System(3) Clock Divider Configuration 0	Core/XBAR (XBAR_CLK)	CMU_1
CGM_SC_DC1	System Clock Divider Configuration 1	PBRIDGE (PBRIDGE_CLK)	CMU_2
CGM_SC_DC2	System Clock Divider Configuration 2	Clock out divisor	—
CGM_SC_DC3	System Clock Divider Configuration 3	SYS_CLK/2 (INTC, DMA)	CMU_4

Table 298. MC_CGM relationship to clocks[1] (continued)

MC_CGM register(s)	Register description	Output clock	CMU[2]
CGM_AC0_DC0 CGM_AC0_SC	Aux Clock 0 Divider Configuration 0 Aux Clock 0 Select Control	PIT clock divisor	—
CGM_AC0_DC1 CGM_AC0_SC	Aux Clock 0 Divider Configuration 1 Aux Clock 0 Select Control	DSPI	—
CGM_AC0_DC2 CGM_AC0_SC	Aux Clock 0 Divider Configuration 2 Aux Clock 0 Select Control	LinFlexD	—
CGM_AC1_DC0 CGM_AC1_SC	Aux Clock 1 Divider Configuration 0 Aux Clock 1 Select Control	MCAN clock divisor	—
CGM_AC2_SC	Aux Clock 2 Select Control	PLL0	—
CGM_AC3_SC	Aux Clock 3 Select Control	PLL1	—
CGM_AC4_DC0	Aux Clock 4 Divider Configuration 0	SENT_CLK	—
CGM_AC4_DC1	Aux Clock 4 Divider Configuration 1	CTU_CLK	—
CGM_AC4_DC2	Aux Clock 4 Divider Configuration 2	SAR_CLK	—
CGM_AC4_DC3	Aux Clock 4 Divider Configuration 3	PWM_CLK	—
CGM_AC4_DC4	Aux Clock 4 Divider Configuration 4	ETMR_CLK	—
CGM_AC4_DC5	Aux Clock 4 Divider Configuration 5	SWG_PWM_CLK	—
CGM_AC5_DC0	Aux Clock 5 Divider Configuration 0	FLEXRAY_CLK	—

1. See the *Chapter 27: Clock Generation Module (MC_CGM)* for specifics on register implementation.
2. CMU_0 not shown in table since it does not monitor an output clock from the MC_CGM.
3. This clock is used for the following modules: CPU, XBAR, PFlash controller, PRAM controller, Debug.

24.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in *Table 299*.

Table 299. Maximum system level clock frequencies

System clock	Max frequency (MHz)[1]
Core	140
XBAR, system RAM	140
PBRIDGE_0	70
DMA	70
Interrupt controller	70
DSPI_CLK, LIN_CLK	120
Peripheral clock	120
PLL0_PHI	120
PLL0_PHI1	100

Table 299. Maximum system level clock frequencies (continued)

System clock	Max frequency (MHz)[1]
PLL1_PHI	140
ADCs	12
FlexRay	40
Max protocol clock	40
Max host clock	70
SENT	120
CTU	120
SAR	12
FlexPWM	120
eTimer	120
SWG_PWM	120
CCCU	120
TCK (JTAGM)	70
TCK (PAD)	35

1. The user must ensure that these values are not exceeded.

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

Note: CORE_CLK and PBRIDGE0_CLK are not required to be at the same frequency.

CORE_CLK and PBRIDGE0_CLK could be at the same frequency in the range from 0 Hz to the PBRIDGE_0 maximum frequency (70 MHz).

The ratio between CORE_CLK and PBRIDGE0_CLK shall not be greater than 2.

In order to maintain synchronization between divider clocks on auxiliary clock 4, there are limitations on the clock frequencies of its dividers. The ratio between each divider should always be an integer value.

24.3.1 JTAG frequencies

Table 300 shows the maximum frequencies of the JTAG interface.

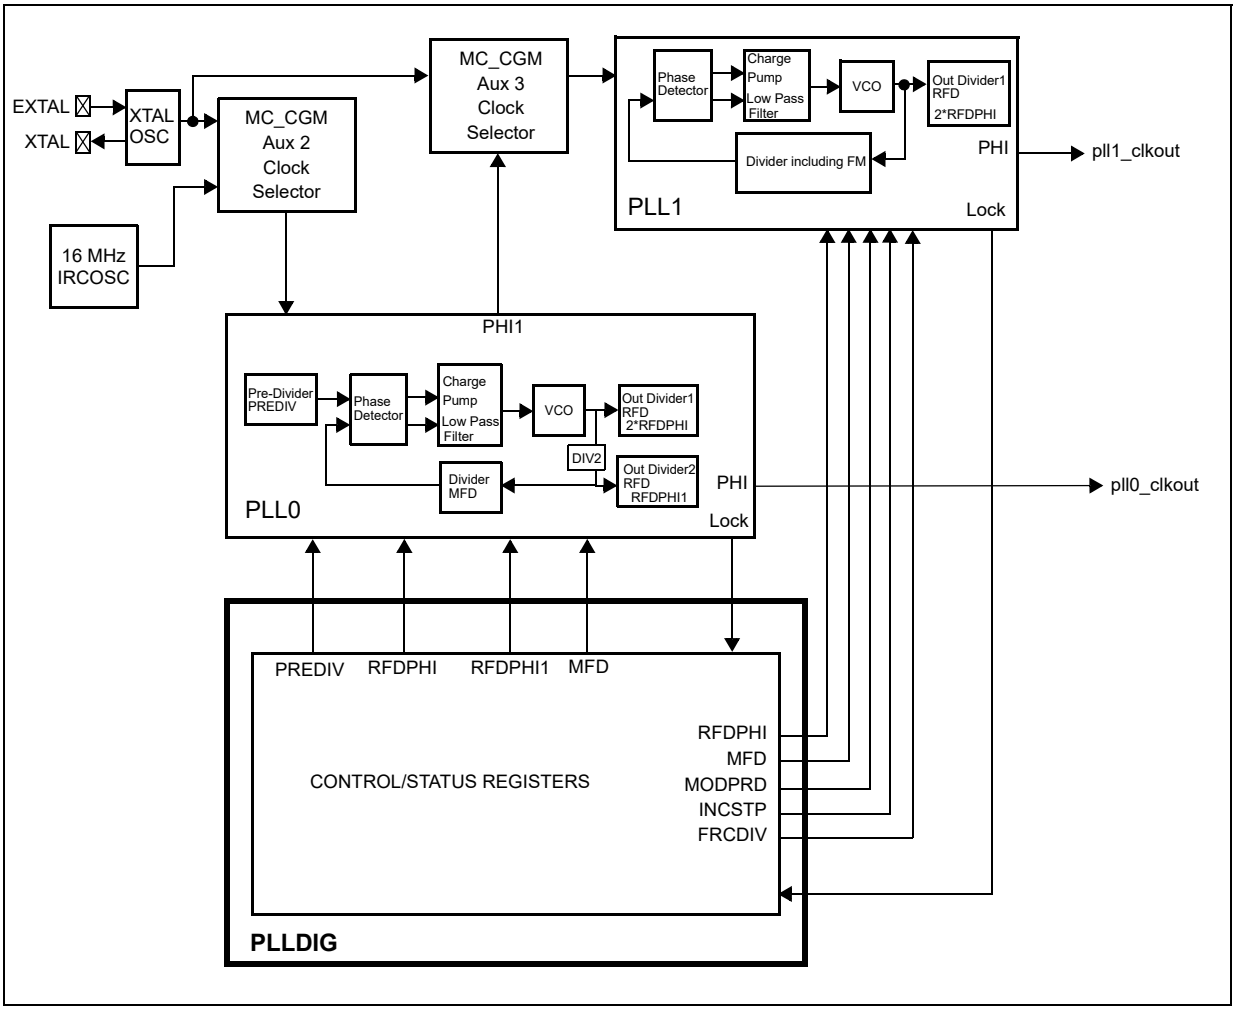
Table 300. JTAG frequencies

Configuration	e200z420n3 max. internal JTAG frequency	Max. external JTAG frequency	Notes
Unconfigured clock	—	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock (IRCOSC) with ± 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
Clock configured to 140 MHz	70 MHz		JTAG usable at 1/2 CPU frequency

24.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to ‘1’ at power on reset.

24.5 Clock sources



The following clock sources are described in this section:

- PLL0_PHI
- PLL1_PHI (FMPLL)
- External oscillator (XOSC)
- External clock (EXTAL bypass)
- 16 MHz internal RC oscillator (IRCOSC)

24.5.1 PLL

The PLL is a dual-PLL providing separate system and peripheral clocks as shown in *Figure 201*. The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in *Figure 202*.

Figure 202. SPC574Sx dual PLL digital interface block diagram

24.5.1.1 PLL0 — base PLL (non-FM)

PLL0 is the primary PLL. This PLL0 provides a non-Frequency Modulated clock to the peripheral IPs and the reference clock to PLL1.

24.5.1.1.1 PLL0 input clocks

The input clock sources for PLL0 are the XOSC, IRCOSC, and external reference clock. The external reference clock is input on the EXTAL pin.

24.5.1.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1. The PHI output clock drives the peripheral clock and the system clock when PLL1 is not locked or active. The PHI1 output clock provides the input reference clock for PLL1.

24.5.1.2 PLL1 — FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

24.5.1.2.1 PLL1 input clocks

The input clocks to PLL1 are the PHI1 output clock from PLL0, PHI1 output clock from PLL0 divided by 2 and the external reference clock.

24.5.1.2.2 PLL1 output clocks

The output clock from PLL1 is the PHI clock, which drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

24.5.1.2.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the Dual PLL Digital Interface (PLLDIG) chapter.

Note: Certain PLL registers can be write-protected. Refer to Section 7.11.4.4: PLL Digital Interface (PLL_DIG) protected registers of the Chapter 7: Device configuration for details.

24.5.1.3 PLL register reset values

All reset values for the PLL_DIG registers that are device-specific are shown in *Table 301*. All other register reset values are shown in the *Chapter 25: Dual PLL Digital Interface (PLLDIG)*.

Table 301. Dual PLL Digital Interface register reset values

Offset	Register	Reset value
0008h	PLL0DV — PLL0 Divider Register	0000_0000h
0028h	PLL1DV — PLL1 Divider Register	0000_0000h

24.5.1.4 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition. An optional backup clock is implemented within the PLL that software may enable or disable.

24.5.2 External oscillator (XOSC)

The external oscillator (XOSC) is provided as a reference for the on-chip PLLs. It can also be used as a clock source to the ADCs, timer, serial interfaces, and as a system clock source. It is available for observation on either of the CLKOUT pins, and is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators
- Automatic Loop Control (ALC) to remove need for external series resistor
- Gain selection for <= 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues
- Reference clock to PLL0 and to PLL1
- Reference clock to CMU_0 (IRCOSC trimming)
- Option to drive the CAN protocol clock directly from the XOSC

The XOSC provides support for 8 – 40 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor.

Note: The user must take care when using 16 MHz crystals or lower, because the S_XOSC flag in the ME_GS register will not be set if the CMU_PLL (CMU 0) default configuration is used. Indeed CMU_PLL (CMU 0) is programmed by default to use crystal frequencies greater than IRC (16 MHz) + 0.5 MHz and this condition is no longer valid with XOSC <= 16 MHz. In this case, to use an XOSC frequency less than or equal to 16 MHz, an RCDIV value (CMU_0.CSR register) that respects the previous formula (CMU_CSR.B.RCDIV = 3) must be used. This setting has to be done before enabling XOSC in the user code.

24.5.2.1 XOSC startup

Enabling of the oscillator at startup is determined by a bit in the UTEST row of flash memory (UTEST DCF Miscellaneous row, bit 24). The default value has the XOSC disabled (UTEST Misc bit 24 = 0 (XOSC EN)).

If enabled, the oscillator is started in phase 3 of the reset sequence, after negation of the internal POR circuits, but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors (UTEST Misc bit 25 = 1 (XOSC EXT LOAD)). Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. See the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During phase 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module. Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values (UTEST Misc bit 26:30 = 00000b (XOSC LOAD CAP SEL)).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value, and thus an undetectable error in the system.

The XOSC has the ability to be started with either 8 MHz to 20 MHz, or 40 MHz to 44 MHz crystal. The XOSC EN_40 MHz bit in the UTEST Misc row selects which crystal source will be used. The default value of this field is for an 8 MHz to 20 MHz crystal (UTEST Misc bit 21 = 0).

See the flash memory chapter for more information on the UTEST row programming.

Note: Certain XOSC registers can be write-protected. Refer to Section 7.11.4.5: Oscillator Digital Interface (XOSC) protected registers of the Chapter 7: Device configuration for details.

24.5.2.2 XOSC reset value

Table 302 shows the default reset value for the XOSC registers.

Table 302. XOSC register reset values

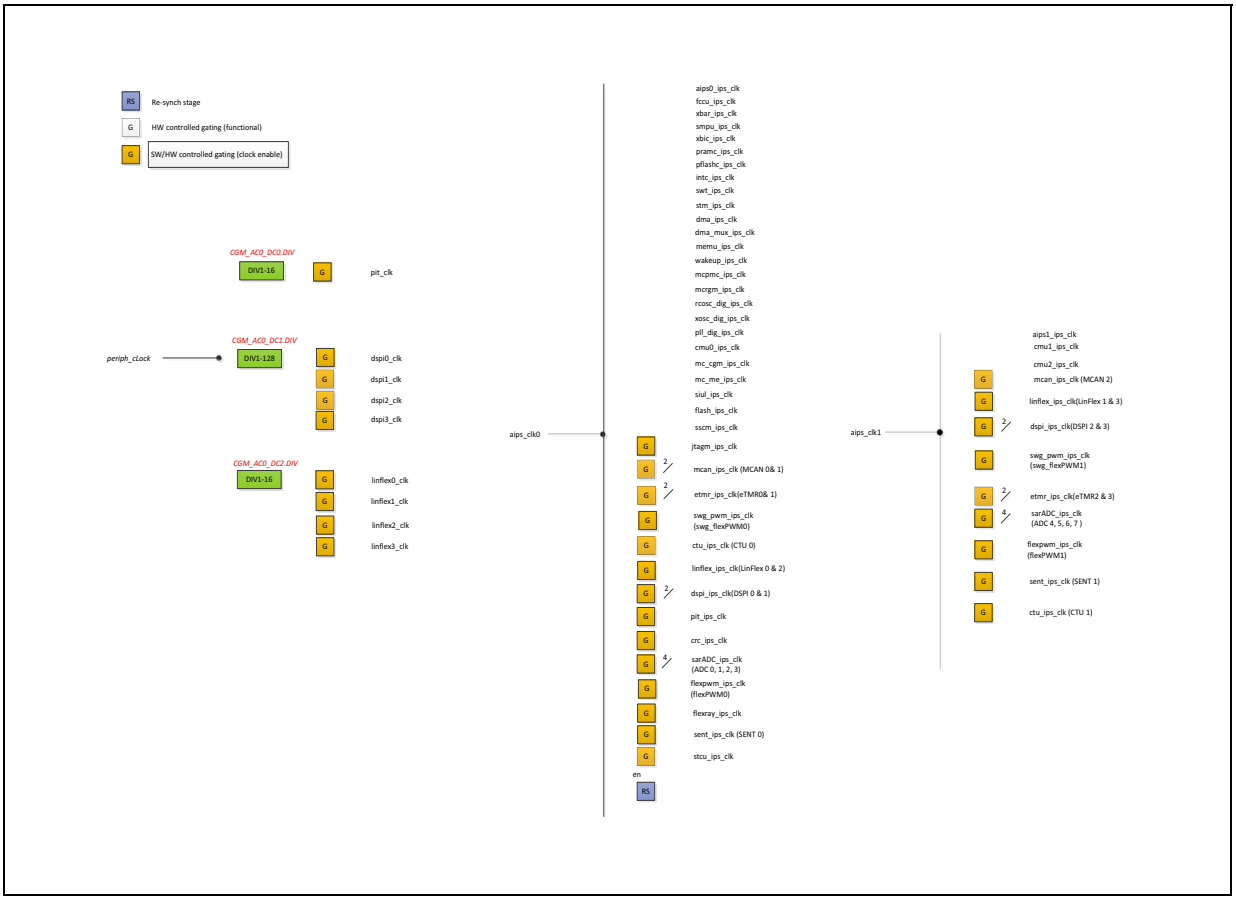
Offset	Register	Reset value
00h	XOSC_CTL—XOSC Control Register	0030_0000h

24.5.3 16 MHz internal RC oscillator (IRCOSC)

The microcontroller has a 16 MHz internal RC oscillator that is always enabled and can be used as the clock source for the PLLs. The IRCOSC is the default clock after reset. The register interface is used for user trimming of the oscillator and dividing the output from 1 to 32.

24.5.3.1 IRCOSC register interface

This device has a dedicated digital interface for the IRCOSC. The digital interface provides a register for fine tuning the IRCOSC frequency by the user. The IRCOSC is always enabled when the device is powered.



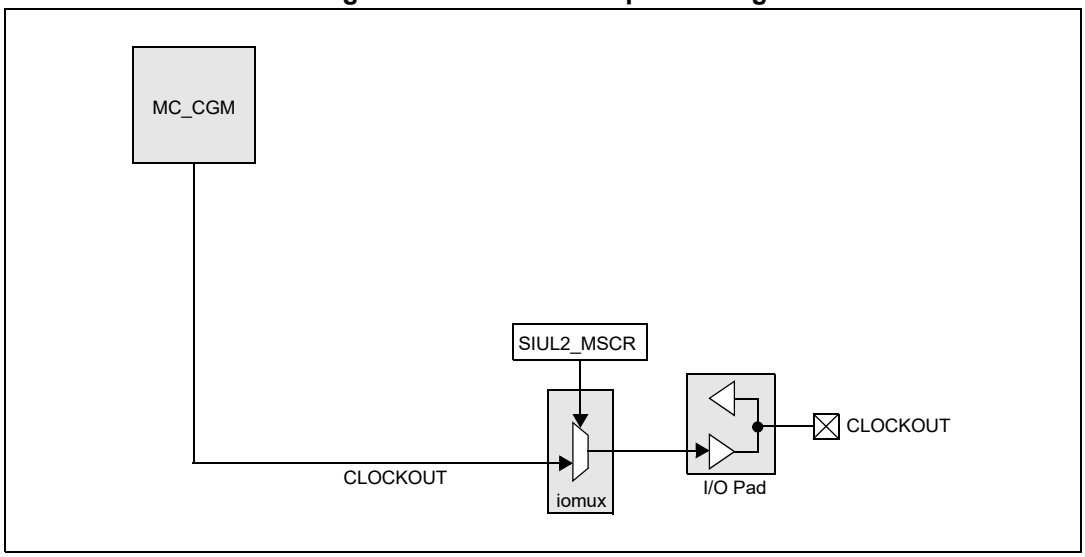
24.5.3.2 IRCOSC register write-protection

The IRCOSC registers do not utilize write-protection.

24.6 Peripheral clocks

Figure 203 shows the clock distribution to the cores and peripheral modules.

Figure 203. Clock distribution



24.6.1 MCAN clocking

The CAN_CLK is generated from either the XOSC or PLL0:PHI clocks, depending on the configuration of CGM_AC1_SC in the MC_CGM. The CAN_CLK can also be reduced by configuring the dividing factor in the CGM_AC1_DC0 (divide by 1 to 64).

24.6.1.1 System clock

There is one system clock output pin on the device: CLOCKOUT. This is a divided version of device's system clock and can be observed outside the device by programming CGM_SC_DC2 register. See *Figure 201*.

Figure 204. CLOCKOUT pin muxing

24.7 Clock monitoring

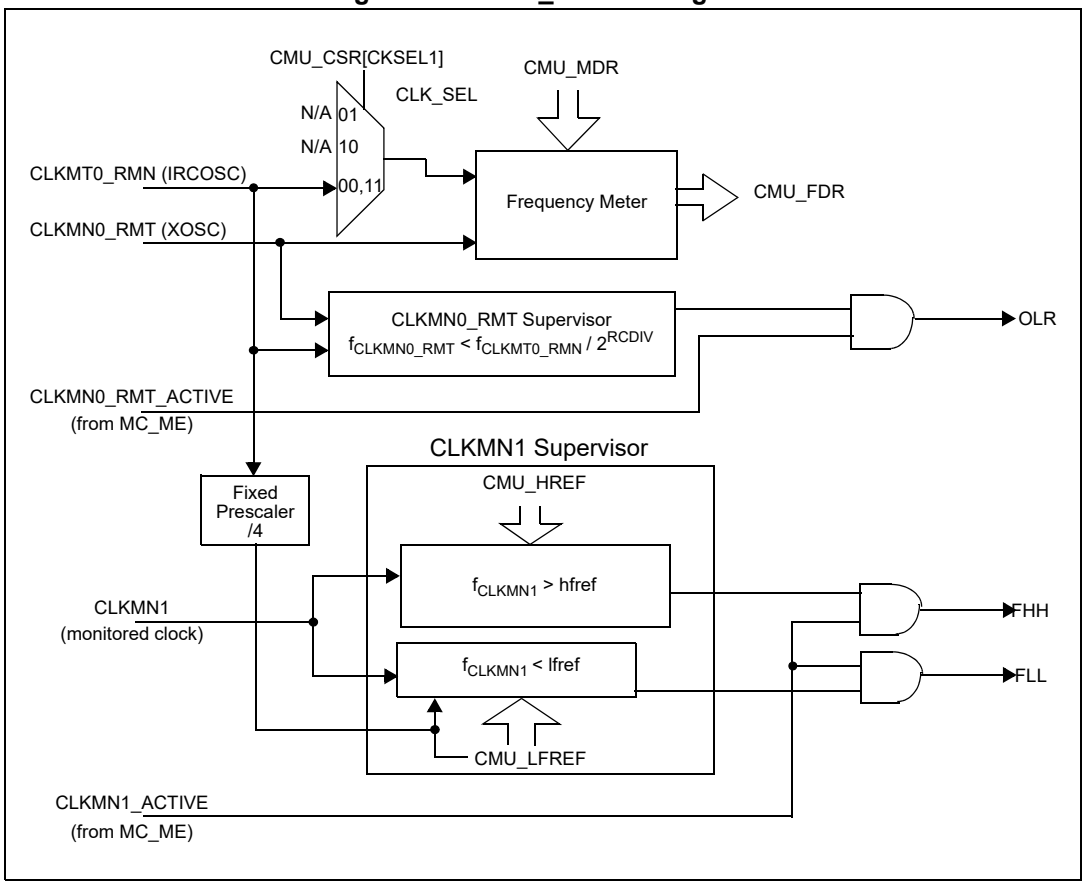
For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency. Each CMU is programmed independently (see *Figure 201* for CMU distribution). The IRCOSC and XOSC are used as the clock monitor references. Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

24.7.1 CMU configuration

This section explains the CMU configuration.

Figure 205 shows the block diagram for CMU_0 on the SPC574Sx.

Figure 205. CMU_0 block diagram



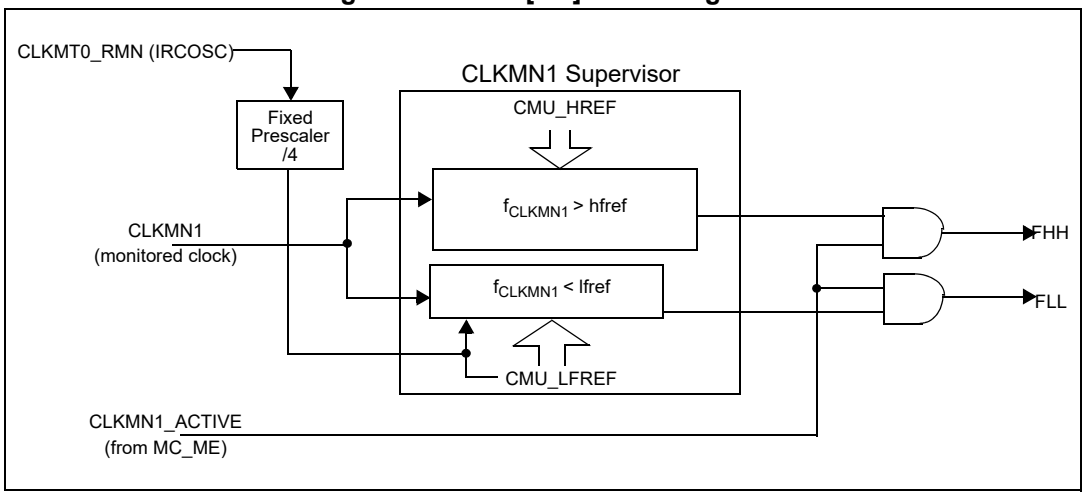


Figure 206 shows the block diagram for CMU[1:4] on the SPC574Sx.

Figure 206. CMU[1:4] block diagram

24.7.1.1 Clock input sources

Table 303 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU_0 implements the XOSC

monitor. CMU_0 uses the IRCOSC clock to measure if the XOSC is too low. CMU_0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 303. Clock input sources

Clock module	Monitored clock
CMU_0	PLL0:PHI, XOSC, IRCOSC
CMU_1	Main Core_0, Safety Core (Main Core_0, Checker Core_0s), XBAR_CLK
CMU_2	PBRIDGE_CLK
CMU_3	PERIPH_CLOCK
CMU_4	DMA, INTC

24.7.1.2 CMU registers and field availability

Table 304 specifies which registers and fields are available on a given CMU for this device.

Table 304. CMU registers availability

Address offset	Register	CMU	Notes
0x0000	CMU_CSR	All	Fields CMU_CSR[SFM] and CMU_CSR[CKSEL1] are present in CMU_0 only
0x0004	CMU_FDR	CMU_0	—
0x0008	CMU_HFREFR	All	—
0x000C	CMU_LFREFR	All	—
0x0010	CMU_ISR	All	Fields CMU_ISR[FLCI] and CMU_ISR[OLRI] are present in CMU_0 only.
0x0014	Reserved	—	—
0x0018	CMU_MDR	All	—

Note: Certain CMU registers can be write-protected. Refer to Section 7.11.4.2: Clock Monitor Unit (CMU) protected registers of the Chapter 7: Device configuration for details.

24.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

24.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

24.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU_0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

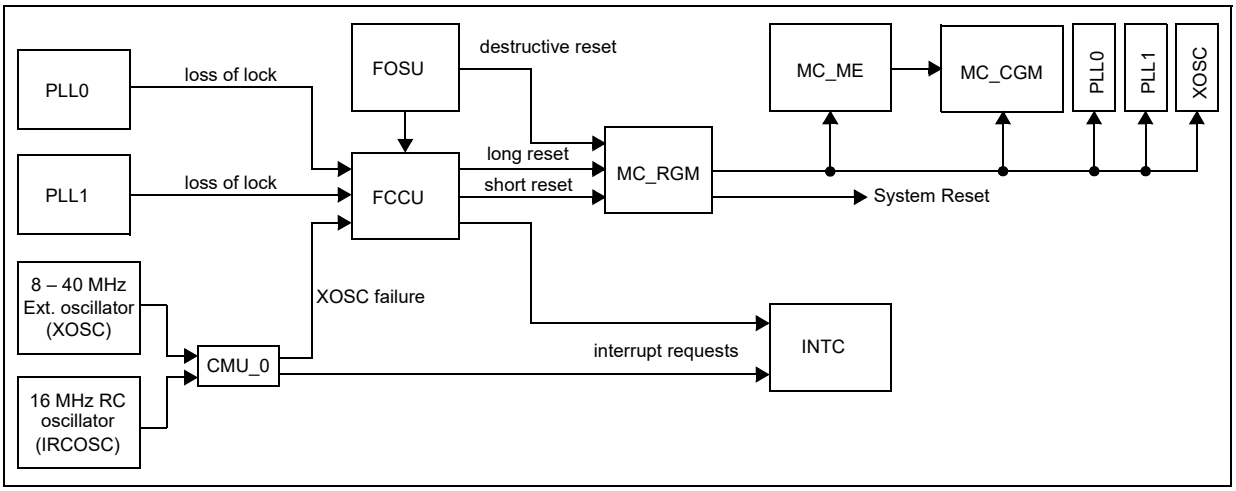
24.7.5 System clock monitors

A CMU is assigned to monitor the frequency of the core, XBAR, and both peripheral bridges (refer to *Figure 201*).

24.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. *Figure 207* gives a high-level view of the loss of clock logic.

24.8.1 Loss of PLL/XOSC clock



As shown in *Figure 207*, each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU. The FCCU can be programmed to generate a short or long reset sequence when a clock failure occurs, or simply to generate an interrupt. In the case of the interrupt, only the backup clock in the PLL can provide clocks to the system in order to perform a system clock switch. There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

If a long reset is selected the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the IRCOSC. If a short reset is selected, the clock configuration is maintained, but again, the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.

24.8.2 Loss of IRCOSC clock

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure (a loss of IRCOSC clock) is a catastrophic failure.

Figure 207. Loss of clock logic

25 Dual PLL Digital Interface (PLLDIG)

25.1 Introduction

The MCU provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 blocks (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1 as shown in *Chapter 24: Clocking*. The key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1 PHI frequency modulated output.

25.2 Block Diagram

The block diagram of the PLLDIG block is found in the *Chapter 24: Clocking* of the *SPC574Sx Reference Manual*.

25.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for reducing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- The frequency range after the prescaler is required to be 8-20MhzLock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
  - User-selectable ability to generate an interrupt request upon loss of lock.
  - The loss of lock indication is sent to the FCCU via the system glue logic.

Note: Please refer to the Device Data sheet for information on the input and output clock frequency range.

25.4 Modes of operation

The operating modes of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The various modes of operation for the PLL are:

- Normal mode with reference, and either PLL0 or both PLLs enabled

Note: Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<mode>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

When PLL0 is powered down and working in Bypass mode, PLL1 should be bypassed and powered down. PLL1 should be configured to work in normal mode only after PLL0 has

achieved lock (for example, bypass with PLL0 running or PLL0 in normal mode, PLL*n*SR[LOCK] = 1).

25.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In the normal mode, PLL0 receives an input clock from the reference and the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0_PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, output divider (Reduced Frequency Divider) and whether the PLL1 is modulated or not can be programmed by writing to the PLL1FM register, *Section 25.5.2.7: PLL1 Frequency Modulation Register (PLL1FM)*.

Note: While powering down the PLLs, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Note: Only when the PLL0 achieves lock should PLL1 be configured to work in either mode by programming the appropriate MC_ME_<mode>_MC register.

25.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs.

25.5.1 Memory map

Table 305 shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

Table 305. Dual PLL Digital Interface memory map

Offset (hex)	Register	Section
0x0000	PLL0 Control Register (PLL0CR)	*Section 25.5.2.1*
0x0004	PLL0 Status Register (PLL0SR)	*Section 25.5.2.2*

Figure 209. PLL0 Status Register (PLL0SR)

Table 307. PLL0SR field descriptions

Field	Description
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
28 LOLF	Loss of lock flag This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested 1 Loss of lock detected. Interrupt service requested
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

25.5.2.3 PLL0 Divider Register (PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. The values of PREDIV and MFD should not be changed when the PLL is on and locked (working in Normal mode). If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled. The reduced frequency divider fields (RFDPHI, RFDPHI1) can

be modified at anytime, but the changes only become effective after PLL0 is disabled, then reenabled.

29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

25.5.2.6 PLL1 Divider Register (PLL1DV)

The PLL1DV register provides the output clock reduced frequency dividers and loop divider values. The value of MFD should not be changed when the PLL is on and locked (working in Normal mode). If the field is changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled. The reduced frequency divider field (RFDPHI) can be modified at anytime, but the changes only become effective after PLL1 is disabled, then reenabled .

Field	Description
10:15 RFDPHI	PHI reduced frequency divider This 6-bit field determines the VCO clock post divider for driving the PHI output clock. 00 Reserved 01 Divide by 1 02 Divide by 2 ... 3E Divide by 62 3F Divide by 63
25:31 MFD	Loop multiplication factor divider This 7-bit field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. 10 Divide by 16 11 Divide by 17 .... 21 Divide by 33 22 Divide by 34 All other settings are Reserved

25.5.2.7 PLL1 Frequency Modulation Register (PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of PLL1FM[MODEN] and PLL1FM[MODSEL] fields once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock, however, the output clock from PLL may have an incorrect frequency for a few cycles after either of these updates (as defined in the Data Sheet).

Figure 214. PLL1 Frequency Modulation Register (PLL1FM)

Table 312. PLL1FM field descriptions

Field	Description
1 MODEN	Modulation enable This bit enables the frequency modulation. 0 Frequency modulation disabled 1 Frequency modulation enabled
2 MODSEL	Modulation selection This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Modulation centered around nominal frequency 1 Modulation spread below nominal frequency
3:15 MODPRD	Modulation period This 13-bit field is the binary equivalent of the modulation period variable derived from the formula: $MODPRD = round(\frac{f_{ref}}{4 \times f_{mod}})$ where f_{ref} represents the frequency of the feedback divider and f_{mod} represents the modulation frequency (see equation in *Section 25.6.4*).
17:31 INCSTP	Increment step This 15-bit field is the binary equivalent of the INCSTP variable derived from the formula: $INCSTEP = round(\frac{(2^{15} - 1) \times MD \times PLL1CR[MFD]}{100 \times 5 \times MODPRD})$ where *md* represents the peak modulation depth in percentage (+/- *MD* for centered modulation, -2**MD* for modulation below nominal frequency), and MFD represents the nominal value of the feedback loop divider (see equation in *Section 25.6.4*).

25.5.2.8 PLL1 Fractional Divider Register (PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The dither disable and fractional divider fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates .

Figure 215. PLL1 Fractional Divider Register (PLL1FD)

Table 313. PLL1FD field descriptions

Field	Description
1 FDEN	Fractional Divide Enable This bit enables the fractional divider in the loop divider for PLL1. 0 Fractional divide disabled 1 Fractional divide enabled
14:15 DTHDIS	Dither Disable Bit 14 and bit 15 control noise of SSCG and Fractional Controller. 00 Increase PLL multiplication factor by 1/2^13 and has maximum noise control of SSCG and Fractional Controller. 01 Increase PLL multiplication factor by 1/2^13 and has some noise control of SSCG and Fractional Controller. 10 No influence on PLL multiplication factor and has some noise control of SSCG and Fractional Controller. 11 No influence on PLL multiplication factor and no noise control of SSCG and Fractional Controller.
20:31 FRCDIV	Fractional divide input When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV[MFD]} + (\text{FRCDIV} \div 2^{12}))$ where FRCDIV is the decimal equivalent of the FRCDIV bits (see *Section 25.6.2*). **Note:** Depending of DTHDIS value the multiplication factor can change as described in DTHDIS field description.

25.5.3 Register classification for safety requirements

This module is classified as a safety Vital Module (ViMo). Hence, the registers of this module have been classified as shown in the SPC574Sx Reference Manual “Functional Safety” chapter.

25.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

25.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for each PLL are discussed in detail in the *SPC574Sx Data Sheet*.

25.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV and PLL1FD registers, and calculated according to the following equations:

Equation 9

$$f_{pll0_phi} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]}$$

Equation 10

$$f_{pll0_phi1} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]}$$

Equation 11

$$f_{pll1_phi} = f_{pll1_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Note: Depending of DTHDIS value the multiplication factor of *Equation 11* can change as described in PLL1DV[DTHDIS] field description (see *Table 313*).

The relationship between the VCO frequency f_{VCO} and the output frequency of the PLLs is determined by the configuration of the PLL0DV, PLL1DV and PLL1FD registers, according to the following equations:

Equation 12

$$f_{pll0_VCO} = \frac{f_{pll0_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

Equation 13

$$f_{pll1_VCO} = f_{pll1_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} \right)$$

Note: Depending of DTHDIS value the multiplication factor of *Equation 13* can change as described in PLL1DV[DTHDIS] field description (see *Table 313*).

Note: *f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1.*

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification for PLL0 or PLL1 (refer to the device datasheet). Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of PLL*n*DV are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

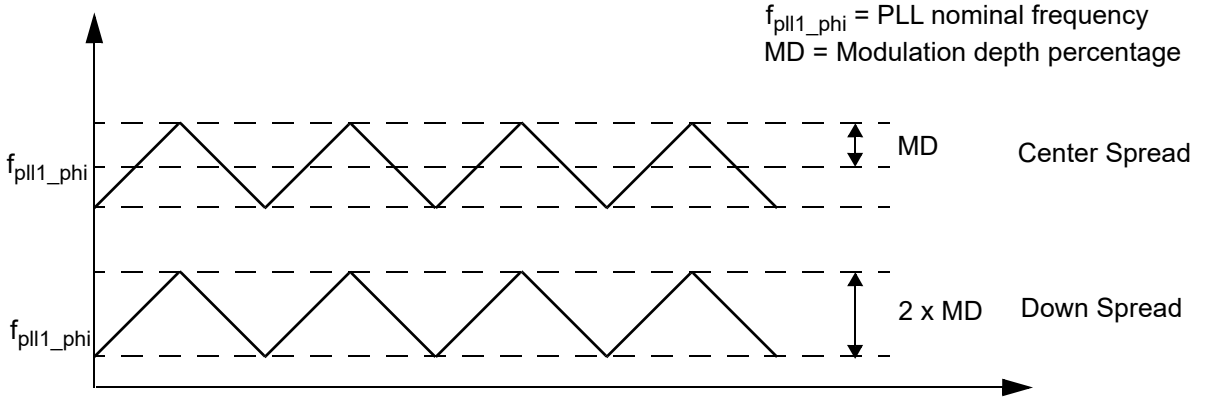
Note: *The PLL must be powered down and powered up by configuring MC_ME_<mode>_MC before PLL0CR[PREDIV], PLL0CR[MFD], PLL1CR[MFD] or the input reference clock values are modified.*

The recommended procedure to program the PLLs and engage normal mode is shown in *Section 25.7*.

25.6.3 Loss of lock

The PLL digital interface registers provide the flexibility to select whether to generate an interrupt assert system reset or do nothing in the event that the PLL loses lock according to the available PLL*n*CR options.

Loss of lock reset and interrupt are only generated when the PLL is operating in normal mode. The PLLDIG_PLL*n*SR[LOLF] bits are not asserted by a loss of lock condition detected during Bypass mode, although going to Bypass mode from normal mode does not automatically clear the flag if it was previously asserted while the PLL was in normal mode.



The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, it will be immediately indicated in the status register (after synchronization time).

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. Once the PLL has locked, the counters continue to monitor the reference and feedback clocks and report whether the PLL has lost lock. The lock status is indicated in the status register.

25.6.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in *Figure 216*. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 216. Triangular frequency modulation

Note: The device maximum operating frequency includes the frequency modulation. If center modulation is selected, the fsys must be below fmax by MD percentage such that fmax = fsys(1 + MD%). Please refer to the Analog PLL Chapter for more details.

The following equations define how to calculate PLL1FM[MODPRD] (*Equation 14*) and PLL1FM[INCSTP] (*Equation 15*) based on the frequency of the feedback divider (f_{pll1_ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD):

Equation 14

$$PLL1FM[MODPRD] = round\left(\frac{f_{pll1_ref}}{4 \times f_{mod}}\right)$$

Equation 15

$$PLL1FM[INCSTP] = round\left(\frac{(2^{15} - 1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

Equation 16

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is given by the following formula:

Equation 17

$$\text{ModulationDepth} = \text{round}\left(\frac{\text{PLL1FM[MODPRD]} \times \text{PLL1FM[INCSTP]} \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV[MFD]}}\right)$$

As an example, suppose the following configuration:

- Input frequency: 40 MHz
- Loop divider (PLL1DV[MFD]): 20
- Input divider: 1
- Output divider RFD: 5
- VCO frequency: 40 MHz × 20 = 800 MHz
- PLL output frequency: 800 MHz / 2*RFD = 800 MHz / 10 = 80 MHz
- Center spread (PLL1FM[MODSEL] = 0)
- Modulation frequency: 200 kHz
- Modulation depth: ± 1.9% (3.8% peak-to-peak)
- PLL1FM[MODPRD] = Round[(40 × 10^6) / (4 × 200 × 10^3)] = Round[50] = 50
- PLL1FM[INCSTP] = Round[((2^{15} – 1) × 1.9× 20) / (100 × 5 × 50)] = Round[49.8] = 50
- PLL1FM[MODPRD] × PLL1FM[INCSTP] = 50 × 50 = 2500 (which is less than 2^{15})
- MD (quantized) = ((50 × 50 × 100 × 5) / ((2^{15} – 1) × 20) = 1.90740%

In this example, the modulation error is 0.00740%.

The FM parameters do not get reset when PLL0 looses its lock. These parameters get reset on destructive reset. Whenever PLL0 gets relocked FM modulation starts with the previous values. The sequence for reprogramming the FM is:

1. Power down PLL1[i]
2. Program the PLL1FM while PLL1 is powered down
3. Power up the PLL1[j]

25.7 Initialization information

Coming out of reset the PLLs are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The recommended procedure to program the PLLs and enter normal mode is:

i. By writing MC_ME_<*mode*>_MC[PLL1ON] = 0b.

j. By writing MC_ME_<*mode*>_MC[PLL1ON] = 1b.

1. Configure PLL0 and related modules.

   Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   a) With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.

   b) Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   c) If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).

   d) If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

2. Turn on XOSC and PLL0.

   a) Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<mode>_MC[XOSCON] = 1 and MC_ME_<*mode*>_MC[PLL0ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0 PHI output) as the sysclk.

   b) Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if re-entering the same mode.

3. Wait for the mode transition to complete.

   a) Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

   - XOSC counter expires (if the new mode configuration changes MC_ME_<*mode*>_MC[XOSCON] to 1), and

   - PLL is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL0ON] = 1).

   b) Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

4. Configure PLL1 and related modules

   a) With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = which selects XOSC.

   b) Program PLL1DV[MFD] and PLL1DV[RFDPHI].

   c) If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

5. Turn on PLL1

   a) Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL0 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<*mode*>_MC[XOSCON] = 1, MC_ME_<*mode*>_MC[PLL0ON] = 1 and MC_ME_<*mode*>_MC[PLL1ON] = 1. If desired, also set

MC_ME_<*mode*>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.

b) Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if re-entering the same mode.

6. Wait for the mode transition to complete.

a) Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

XOSC counter expires (if the new mode configuration changes MC_ME_<*mode*>_MC[XOSCON] = 1), and PLL1 is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL1ON] = 1).

b) Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Note: See the Chapter 52: Mode Entry Module (MC_ME) for more details.

26 Clock Monitor Unit (CMU)

26.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock sources CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and also detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the division factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate events when the CLKMN1 frequency is less than the CLKMT0_RMN frequency divided by four or if CLKMN1 leaves an upper or lower frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of one clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note: See the Chapter 24: Clocking for the number of instances of the CMU in this device.

26.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as the reference clock.
- Event generation for various failures detected inside monitoring unit.

26.2 Block diagram

The block diagram of the CMU module(s) is shown in the *Chapter 24: Clocking*.

26.3 Signals

Table 314 describes the signals on the boundary of the CMU (in alphabetical order).

Table 314. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference: Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1: Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference: Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

Note: See the "Chapter 24: Clocking for device specific clock sources of each CMU.

26.4 Memory map and register definition

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in *Table 315*.

Table 315. CMU memory map

Figure 217. CMU Control Status Register (CMU_CSR)

Table 316. CMU_CSR field descriptions

Field	Description
8 SFM	Start Frequency Measure The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR register. MDR[MD] must be written before enabling frequency measurement (CSR[SFM] = 1). Do not write MDR[MD] while CSR[SFM] = 1. Software should only read the value of CMU_FDR[FD] bits once the hardware has cleared the CMU_CSR[SFM] bit. 0 Frequency measurement is completed or not yet started. 1 Frequency measurement is not completed.
22:23 CKSEL1	Frequency measure clock selection bit CKSEL1 selects the clock to be measured by the frequency meter. This only effects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected. 01 Reserved 10 Reserved. 11 CLKMT0_RMN is selected.

Table 316. CMU_CSR field descriptions (continued)

Field	Description
29:30 RCDIV	CLKMT0_RMN division factor These bits specify the CLKMT0_RMN division factor. The output clock frequency is f_{CLKMT0_RMN} divided by the factor 2^{RCDIV}. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV]. The clock division coding is as follows: 00 CLKMT0_RMN divided by 1 (No division). 01 CLKMT0_RMN divided by 2. 10 CLKMT0_RMN divided by 4. 11 CLKMT0_RMN divided by 8.
31 CME	CLKMN1 monitor enable CMU_HFREF and CMU_LFREF registers must be written before enabling the clock monitoring (CSR[CME] =1) 0 CLKMN1 monitor is disabled. 1 CLKMN1 monitor is enabled.

26.4.1.2 CMU Frequency Display Register (CMU_FDR)

The FDR is used to determine the measured frequency being monitored by the CMU.

2. Field is read only.

Figure 221. CMU Interrupt Status Register (CMU_ISR)

Table 320. CMU_ISR field descriptions

Field	Description
29 FHHI	CLKMN1 frequency higher than high reference event status This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred

Table 320. CMU_ISR field descriptions (continued)

Field	Description
30 FLLI	CLKMN1 frequency less than low reference event status This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than f_{CLKMT0_RMN} / 2^{RCDIV} event status This bit is set by hardware when the f_{CLKMN0_RMT} is less than f_{CLKMT0_RMN} / 2^{RCDIV} frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No OLR event 1 OLR event occurred

Note: All the flags in CMU_ISR are set asynchronously. This register must be read only after an interrupt (safe mode entry) is triggered by the CMU as confirmed by MC_RGM. Otherwise, the read access on this register may fetch an incorrect value.

Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

26.4.1.6 CMU Measurement Duration Register (CMU_MDR)

Figure 222. CMU Measurement Duration Register (CMU_MDR)

Table 321. CMU_MDR field descriptions

Field	Description
12:31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

26.5 Functional description

This section describes the functionality of the CMU.

26.5.1 Frequency meter

The purpose of frequency meter is to evaluate the deviation from the nominal metered source (such as, CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the Clocking chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

Equation 18 $f_{sel} = (f_{CLKMN0_RMT} \times MDR[MD]) / FDR[FD]$

26.5.2 CLKMN0_RMT supervisor

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

26.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

Note: An example of determining the HFREFActual value is as follows. Assume a fCLKMT0_RMN = 16 MHz with an accuracy of +/-5%. In order to monitor fCLKMN1 = 200 MHz, the ideal HFREFIdeal = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration (HFREFActual = (HFREFIdeal + 2) × 1.05).

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note: The low reference value must be programmed considering the following factors:

- *2 cycles of f_{CLKMN1} which is the built-in tolerance of the monitor implementation*
- *Frequency variation % of f_{CLKMT0_RMN} across PVT*

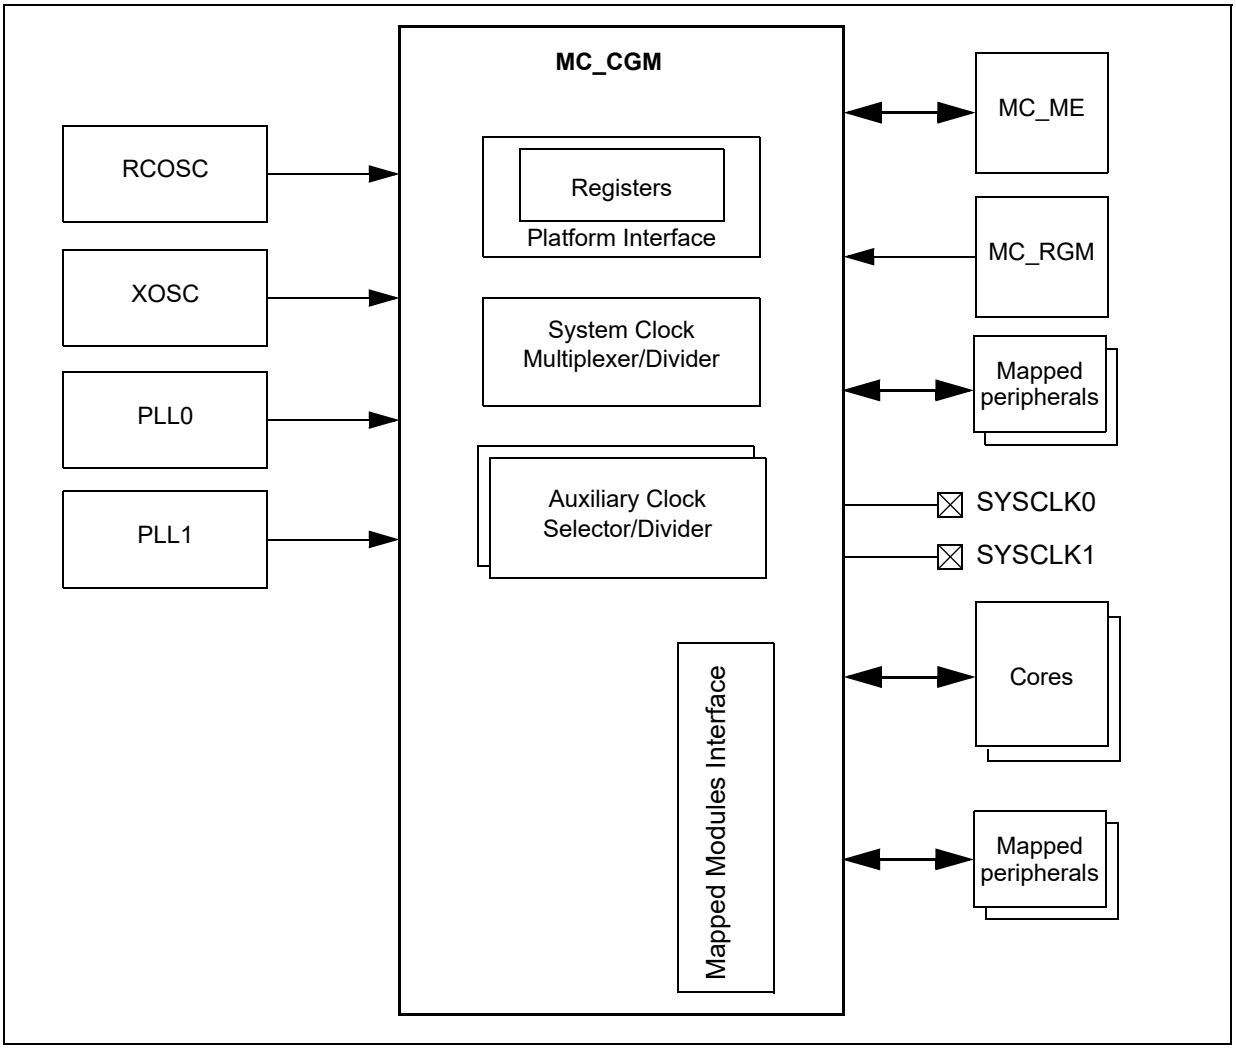
For example, assuming f_{CLKMT0_RMN} is 16 MHz with +/-5% variation, in order to monitor the f_{CLKMN1} (200 MHz), the ideal $LFREF_{Ideal}$ is 800. The adjusted value considering the tolerances will be 758 ($LFREF_{Actual}$ = ($LFREF_{Ideal}$ - 2) x 0.95).

The minimum value that can be programmed in CMU_LFREFR[LFREF] is 3. The minimum frequency that can be monitored using the CLKMN1 supervisor must be >= f_{CLKMT0_RMN} / 16.

27 Clock Generation Module (MC_CGM)

27.1 Introduction

This chapter describes the Clock Generation Module (MC_CGM) which includes, but is not limited to, the funtionality, pin descriptions, and registers of the MC_CGM module.



27.1.1 Overview

The Clock Generation Module (MC_CGM) generates reference clocks for all the chip blocks and enables the system clock from one of the available system clock sources. System clock selection is handled in the Mode Entry control module, see the MC_ME chapter for more details.

The addressable memory spaces of system and peripheral clock are accessed through the MC_CGM memory space.

Figure 223 shows the MC_CGM block diagram.

Figure 223. MC_CGM block diagram

27.1.2 Features

The MC_CGM:

- Generates system and peripheral clocks
- Selects and enables/disables the system clock supply from system clock sources according to MC_ME control
- Performs progressive system clock frequency change depending on MC_ME mode configuration
- Contains a set of registers to control clock dividers for divided clock generation
- Supports multiple clock sources and maps their address spaces to its memory map
- Guarantees glitch-free clock transitions when changing the system clock selection
- Supports 8, 16, and 32-bit wide read/write accesses

27.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use and/or observation.

27.3 Memory map and register definition

Note: Any access to unused registers as well as write accesses to read-only registers:

- *Does not change register content*
- *Causes a transfer error*

27.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes.

The bytes are ordered according to big endian.

For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0004, as a half-word at address offset 0x0006, or as a byte at address offset 0x0007.

27.3.1.1 PCS Switch Duration Register (CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See *Section 27.4.1.2: Progressive System Clock Switching* for details on how to set this value.

Address: 0x0000 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7
R W	SDUR							
Reset	0	0	0	0	0	0	0	0

Table 323. CGM_PCS_SDUR field descriptions

Field	Description
0:7 SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of 16 MHz Internal RC oscillator (RCOSC) cycles.

27.3.1.2 PCS Divider Change 1 Register (CGM_PCS_DIVC1)

This register relates to the external crystal oscillator (XOSC).

When the system clock source switches to this clock or from this clock on ramp-up or ramp-down, the register defines the rate of frequency change and the initial change value for progressive system clock switching.

See *Section 27.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte write accesses are not allowed for the INIT field of this register. Such attempts do not result in an exception, however the new value is not loaded.

Address: 0x0004 Access: User read/write, Supervisor read/write, Test read/write

24:31 RATE	Divider Change Rate Controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to or from this clock

27.3.1.3 PCS Divider End 1 Register (CGM_PCS_DIVE1)

This register relates to the external crystal oscillator (XOSC).

When switching the system clock source away from this clock on ramp-down, the register defines the final division value for progressive system clock switching.

See *Section 27.4.1.2* for details on how to set this value.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

Address: 0x0008 Access: User read/write, Supervisor read/write, Test read

27.3.1.4 PCS Divider Start 1 Register (CGM_PCS_DIVS1)

This register relates to the external crystal oscillator (XOSC).

When switching the system clock source to this clock on ramp-up, the register defines the initial division value for progressive system clock switching.

See *Section 27.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

Field	Description
0:15 INIT	Divider Change Initial Value The initial change value of the clock divider for the clock ramp-up phase when switching to this clock.
24:31 RATE	Divider Change Rate Controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to or from this clock.

27.3.1.9 PCS Divider End 4 Register (CGM_PCS_DIVE4)

This register relates to PLL1_PHI.

When switching the system clock source away from this clock on ramp-down, the register defines the final division value for progressive system clock switching.

See *Section 27.4.1.2: Progressive System Clock Switching* for details on how to set this value.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

Address: 0x002C Access: User read/write, Supervisor read/write, Test read

Field	Description
12:31 DIVE	Divider End Value The clock divider end value for the clock ramp-down phase when switching from this clock.

27.3.1.10 PCS Divider Start 4 Register (CGM_PCS_DIVS4)

This register relates to PLL1_PHI.

When switching the system clock source to this clock on ramp-up, the register defines the initial division value for progressive system clock switching.

See *Section 27.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

Address: 0x0030 Access: User read/write, Supervisor read/write, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
12:31 DIVS	Divider Start Value The start value of the clock divider for the clock ramp-up phase when switching to this clock.

27.3.1.11 System Clock Divider Ratio Change Register (CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations. An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3. The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

Caution: Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

27.3.1.12 Divider Update Type Register (CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.

Address: 0x00D4 Access: User read/write, Supervisor read/write, Test read

Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type 0 The configuration for each system clock divider is updated immediately on writing to the corresponding CGM_SC_DCi register 1 The configuration for each system clock divider is pre-loaded on writing to the corresponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register
26 AUX5_UPD_TYPE	Auxiliary Clock 5 Divider Update Type 0 The configuration for each auxiliary clock 5 divider is updated immediately on writing to the corresponding CGM_AC5_DCi register 1 The configuration for each auxiliary clock 5 divider is pre-loaded on writing to the corresponding CGM_AC5_DCi register, and the pre-loaded configurations of all the auxiliary clock 1 dividers are updated on writing to the CGM_DIV_UPD_TRIG register
27 AUX4_UPD_TYPE	Auxiliary Clock 4 Divider Update Type 0 The configuration for each auxiliary clock 4 divider is updated immediately on writing to the corresponding CGM_AC4_DCi register 1 The configuration for each auxiliary clock 4 divider is pre-loaded on writing to the corresponding CGM_AC4_DCi register, and the pre-loaded configurations of all the auxiliary clock 1 dividers are updated on writing to the CGM_DIV_UPD_TRIG register

Table 334. CGM_DIV_UPD_TYPE field descriptions (continued)

Field	Description
30 AUX1_UPD_TYPE	Auxiliary Clock 1 Divider Update Type 0 The configuration for each auxiliary clock 1 divider is updated immediately on writing to the corresponding CGM_AC1_DCi register 1 The configuration for each auxiliary clock 1 divider is pre-loaded on writing to the corresponding CGM_AC1_DCi register, and the pre-loaded configurations of all the auxiliary clock 1 dividers are updated on writing to the CGM_DIV_UPD_TRIG register
31 AUX0_UPD_TYPE	Auxiliary Clock 0 Divider Update Type 0 The configuration for each auxiliary clock 0 divider is updated immediately on writing to the corresponding CGM_AC0_DCi register 1 The configuration for each auxiliary clock 0 divider is pre-loaded on writing to the corresponding CGM_AC0_DCi register, and the pre-loaded configurations of all the auxiliary clock 0 dividers are updated on writing to the CGM_DIV_UPD_TRIG register

27.3.1.13 Divider Update Trigger Register (CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to '1' in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

Address: 0x00D8 Access: User write, Supervisor write, Test read

Field	Description
0:31 DIV_UPD_TRIGGER	Writing any value to this register will cause all dividers that have corresponding bits set to '1' in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

27.3.1.14 Divider Update Status Register (CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the CGM_DIV_UPD_TYPE[i] is '0', CGM_DIV_UPD_STAT[i] is set to '1' immediately on writing to one of the corresponding divider configuration registers. Otherwise,

CGM_DIV_UPD_STAT[i] is set to ‘1’ immediately on writing to the CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. CGM_DIV_UPD_STAT[i] is cleared to ‘0’ as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

14:15 DIV	Divider Division Value The resultant clock has a period 'DIV + 1' times the selected auxiliary clock source. If the divider is disabled (DE = '0'), writes to the DIV field are ignored.

27.4 Functional Description

27.4.1 System Clock Generation

Figure 266 shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the RCOSC as the system clock and ignore the system clock select.

Figure 266. MC_CGM System Clock Generation Overview

27.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled:

- On a SAFE mode or reset event, by the MC_RGM.
- Otherwise, by the MC_ME.

27.4.1.2 Progressive System Clock Switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency up or down based on the power level values of the current and target modes.

During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVEn registers, where n corresponds to the current system clock source selection.

During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVSn registers, where n corresponds to the target system clock source selection.

27.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in *Equation 19*.

Equation 19

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

27.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of RCOSC cycles. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

27.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value *d* to be programmed into the PCS_DIVCn[RATE] register is given in *Table 365*.

Table 365. MC_CGM CGM_PCS_DIVCn[RATE] values

a_{max}	d = CGM_PCS_DIVCn[RATE]
0.05	0.012
0.10	0.048
0.15	0.112
0.20	0.184
0.25	0.334
0.30	0.429
0.35	0.539
0.40	0.667
0.45	0.819
0.50	1.000

27.4.1.2.4 Generic Clock Change Properties

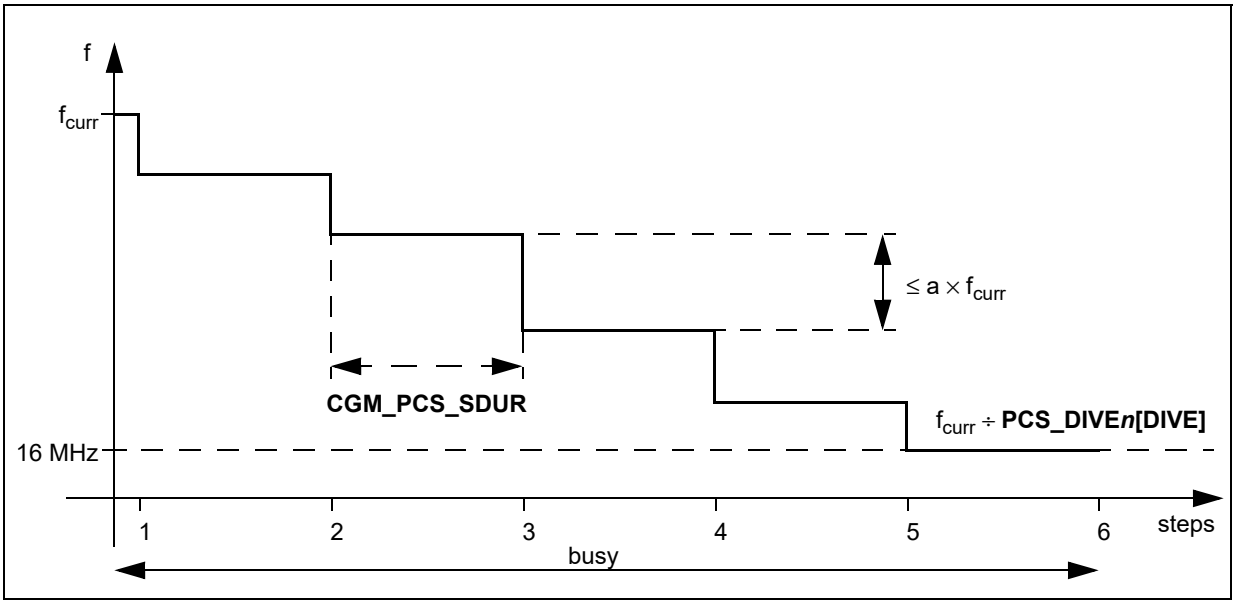
The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in *Equation 20*.

Equation 20

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

27.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and the given divider increment value PCD_DIVCn[RATE], and ends with the given divider value PCS_DIVEn[DIVE].



The divider end value for clock ramp-down is given in *Equation 21*.

Equation 21

$$\textbf{PCS_DIVEn[DIVE]} = \frac{f_{src}}{16MHz} \times 1000 - 1$$

Where f_{curr} is the frequency of the currently selected system clock source.

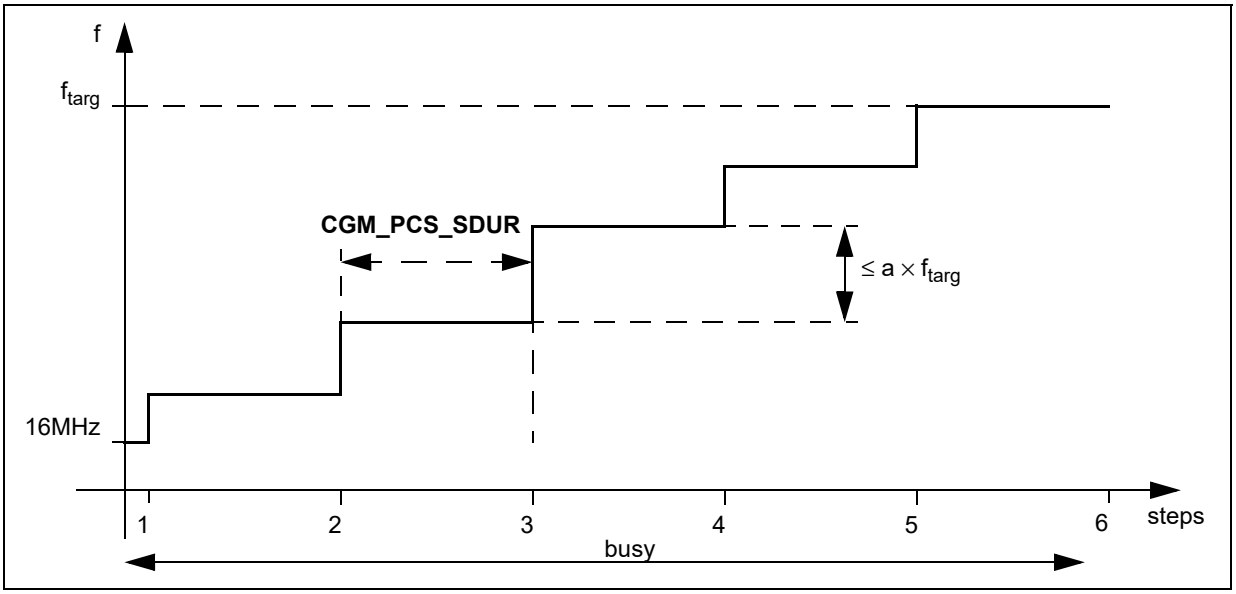
Figure 267. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

27.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in *Equation 22*.

Equation 22



$$\textbf{PCS_DIVCn[INIT]} = d \times k \times 1000 - 1$$

Where *k* is calculated from *Equation 20* using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in *Equation 23*.

Equation 23

$$\textbf{PCS_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Figure 268. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

27.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC_ME.

27.4.1.4 System Clock Dividers

The MC_CGM generates the following derived clocks from the system clock:

- Core clock - controlled by the CGM_SC_DC0 register
- IPS clock - controlled by the CGM_SC_DC1 register
- CLKOUT clock - controlled by the CGM_SC_DC2 register
- DMA, INTC clock - controlled by the CGM_SC_DC3 register

27.4.1.4.1 System Clock Divider Synchronization

The system clock dividers are synchronized such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This imposes limitations on the division factors which can be used:

- Each division factor must be an integer multiple of each division factor that has a lower value.

Example 1 Correct System Clock Divider Configuration

Table 366. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** = 6b000000
1	2	**CGM_SC_DC1[DIV]** = 6b000001
2	6	**CGM_SC_DC2[DIV]** = 6b000101

The above example is correct because:

- System clock divider 1 has a division factor greater than divider 0; 2 is an integer multiple of 1.
- System clock divider 2 has a division factor greater than dividers 0 and 1; 6 is an integer multiple of 1 and 2.

Example 2 Incorrect System Clock Divider Configuration

Table 367. MC_CGM Example System Clock Division Values Incompatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** = 6b000000
1	4	**CGM_SC_DC1[DIV]** = 6b000011
2	6	**CGM_SC_DC2[DIV]** = 6b000101

The above example is incorrect because:

- System clock divider 1 has a division factor greater than divider 0; 4 is an integer multiple of 1.
- System clock divider 2 has a division factor greater than dividers 0 and 1; 6 is not an integer multiple of 4.

Warning: Configuring the system clock dividers incorrectly causes the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the system clock divider division factors without first disabling them or performing a reset.

Note: The same rule applicable on system clock dividers for system clock divider synchronization is applicable on Dividers present on Auxiliary clock4 dividers. This means The auxiliary clock4 dividers are synchronized such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. The impacted registers are: CGM_AC4_DC0–5

27.4.1.4.2 System Clock Divider Update Triggering

System clock dividers are updated only with the next software triggered mode change (This is applicable to auxilliary mux 4 as well). This ensures that the system clock dividers are updated simultaneously without inconsistent intermediate configurations, and that the divider configurations are aligned with the system clock selection of the target mode.

The system clock divider configuration update sequence is:

1. Configure the target mode in the MC_ME to select the desired system clock source.
2. Configure the CGM_SC_DC0–3 registers as desired but aligned with the target system clock source frequency and compatible with divider synchronization described in *Section 27.4.1.4.1: System Clock Divider Synchronization*.
3. Request a mode change in the MC_ME to the desired target mode.
4. The new system clock divider configuration is effective on mode change completion and successful switching of system clock.

See the MC_ME chapter for details on how to configure modes and make mode change requests.

27.4.2 Auxiliary Clock Generation

Figure 269 through *Figure 274* show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- *Section 27.3.1.20: Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)*
- *Section 27.3.1.25: Auxiliary Clock 1 Select Control Register (CGM_AC1_SC)*
- *Section 27.3.1.28: Auxiliary Clock 2 Select Control Register (CGM_AC2_SC)*
- *Section 27.3.1.30: Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)*
- *Section 27.3.1.32: Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)*
- *Section 27.3.1.40: Auxiliary Clock 5 Select Control Register (CGM_AC5_SC)*

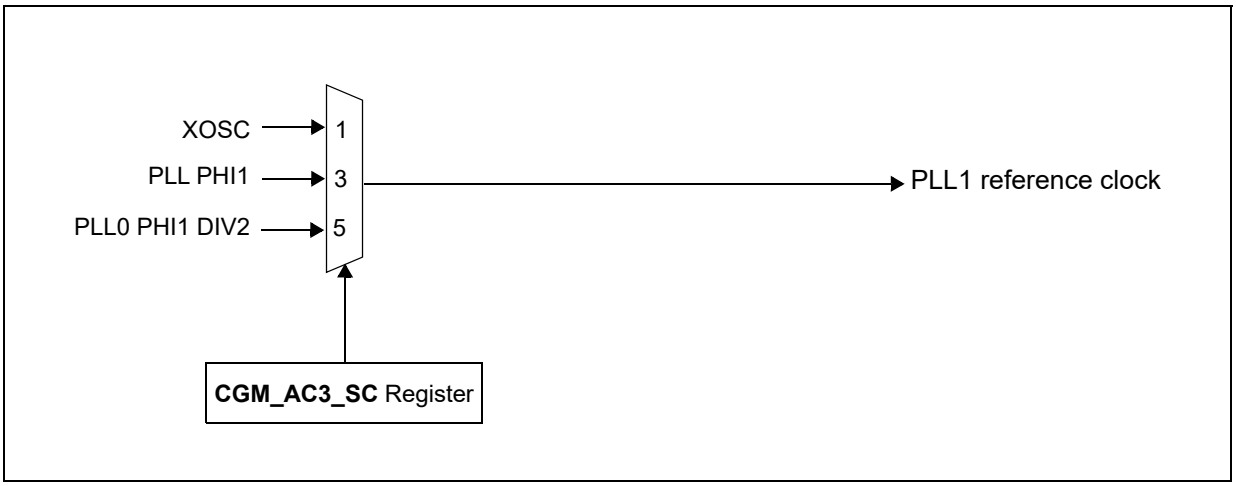

Figure 273. MC_CGM Auxiliary Clock 4 Generation Overview

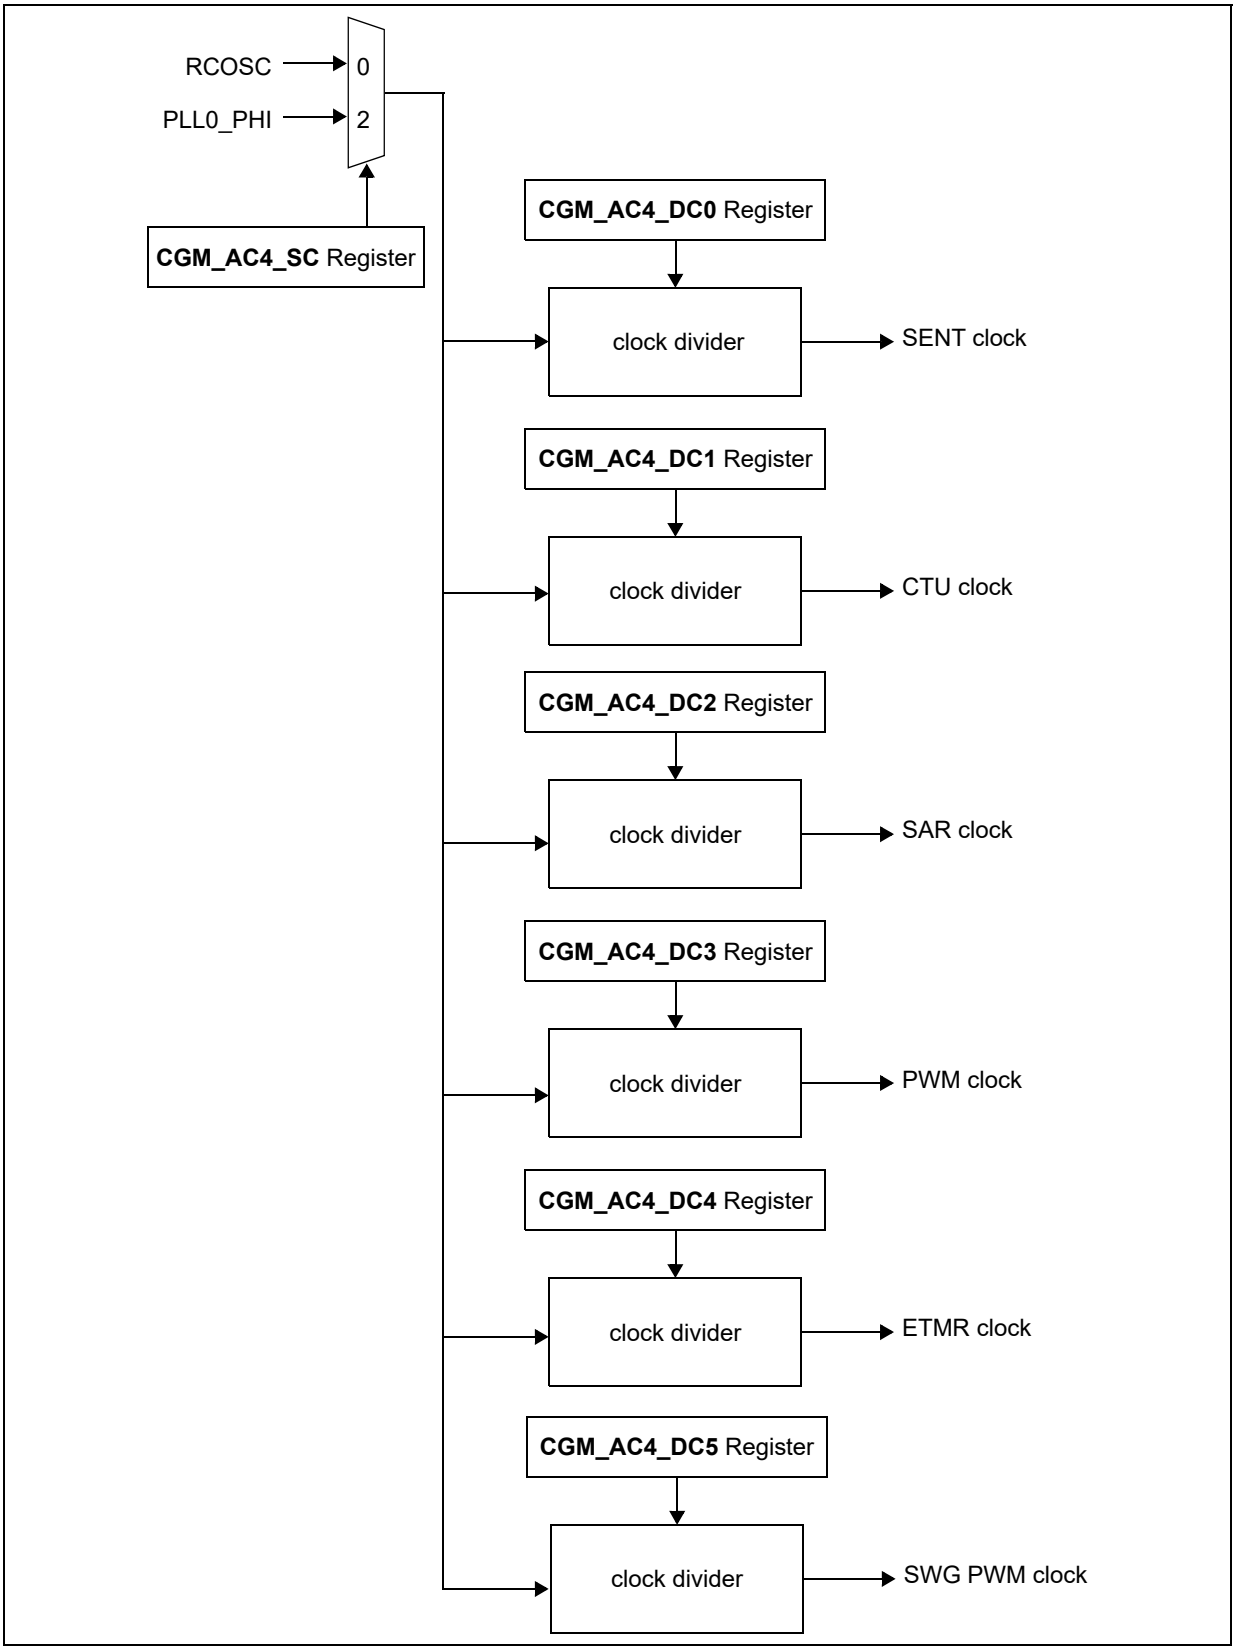

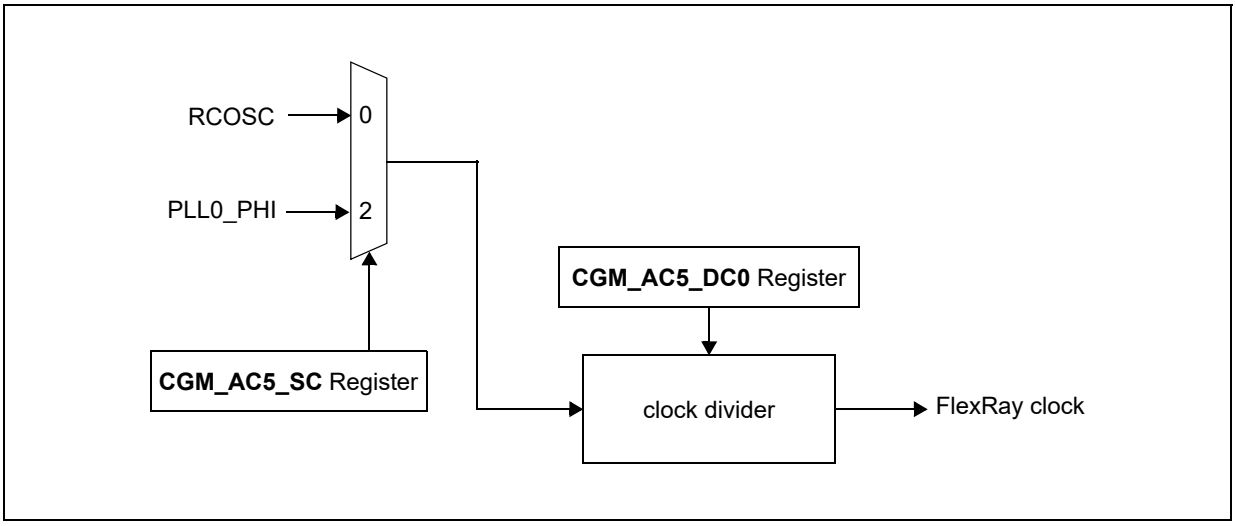

Figure 274. MC_CGM Auxiliary Clock 5 Generation Overview

27.4.2.1 Auxiliary Clock Dividers

The MC_CGM generates clocks the following derived clocks:

- Pit clock – controlled by the CGM_AC0_DC0 register.
- DSPI clock 0 – controlled by the CGM_AC0_DC1 register.
- DSPI clock 1 – controlled by the CGM_AC0_DC1 register.
- DSPI clock 2 – controlled by the CGM_AC0_DC1 register.
- DSPI clock 3 – controlled by the CGM_AC0_DC1 register.
- Linflex clock 0 – controlled by the CGM_AC0_DC2 register.
- Linflex clock 1 – controlled by the CGM_AC0_DC2 register.
- MCAN clock – controlled by the CGM_AC1_DC0 register.
- Sent clock – controlled by the CGM_AC4_DC0 register.
- CTU clock – controlled by the CGM_AC4_DC1 register.
- SAR clock – controlled by the CGM_AC4_DC2 register.
- PWM clock – controlled by the CGM_AC4_DC3 register.
- ETMR clock – controlled by the CGM_AC4_DC4 register.
- SWG PWM clock – controlled by the CGM_AC4_DC5 register.
- FlexRay clock – controlled by the CGM_AC5_DC0 register.

27.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The control registers for the built-in dividers can be referenced in *Section 27.3.1: Register descriptions*.

The reset value of all counters is ‘1’. If the DE bit of a divider in the respective configuration register is set to ‘0’, the divider is disabled and any value in the DIV field is ignored.

28 OSC Digital Interface (XOSC)

28.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provides the register interface for the programmable features. Selection of the XOSC as a source clock is controlled the Clock Generation module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

28.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that can used as an input to PLL(s) and can be selected as the reference clock for many of the peripherals on the device.

Table 368 shows the possible configurations of the XOSC.

Table 368. XOSC configurations

OSC EN	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	No crystal, high-impedance	No crystal, high-impedance	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

28.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<*mode*>_MC[XOSCON] controls the power-down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

28.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the oscillator is enabled at power-up of the device (if the DCF client miscellaneous has been programmed, otherwise the valid configuration is the value present in *Chapter 9: Device Configuration Format (DCF) Records*, *Table 138: DCF client list*). If enabled, the oscillator is started after Phase3 of the

device reset sequence. In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL(s)).

The default value for this field after reset depends on implementation and can be found in the XOSC section of the Device Configuration chapter. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note: It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

28.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

28.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software, and is only cleared by a system reset. In bypass mode, the oscillator is disabled, and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

Note: The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

28.2.4.1 Full Swing Pierce mode

Full Swing Pierce mode (FSP) has the following attributes when compared with LCP:

- Provides a wider frequency range
- Less susceptible to noise
- The crystal amplitude is rail-to-rail
  - Distorted oscilation with several harmonics
  - Increased EMI
- Slower settling time
- Feedback resistor and 300 ohms of current limitation are already integrated.

Note: Consult with crystal supplier to determine the need of extra resistance in XTAL to avoid crystal overdrive.

28.3 Memory map and register definition

Table 369 shows the memory map of the XOSC registers.

Table 369. XOSC memory map

Offset	Register	Location
0x00	XOSC Control Register (XOSC_CTL)	*Section 28.3.1.1*

28.3.1 Register descriptions

Note: Module generates transfer error (ips_xfr_err) only for 32 bytes address space (00 : 1F). If the address space allocated for this module exceed 32 bytes, then transfer error has to be managed at SoC level for the remaining space.

28.3.1.1 XOSC control register (XOSC_CTL)

Figure 275. XOSC_CTL register

Table 370. XOSC_CTL register field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock 1 EXTAL is used as root clock
8:15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked 1 Crystal oscillator clock interrupt is enabled
24 I_OSC	Crystal oscillator clock interrupt This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV × 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred 1 Oscillator clock interrupt pending

29 IRCOSC digital interface

29.1 Introduction

The Internal RC Oscillator digital interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC) , as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage

It also provides access to trimming information used for safety implementations.

29.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see Data Sheet for timing information) which is required for stabilization. The IRCOSC status indication is found in the MC_ME_GS[S_IRC] field (see the “Mode Entry Module MC_ME” chapter).

During a power on reset sequence the following are initialized from TEST flash memory:

- Native trimming bits
- Fine trimming bits
- TSENS code bits

For safety reasons, these bits can be accessed through the IRCOSC Native Trimming register (NT). The main IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

29.3 Memory map and register definition

Table 371 shows the memory map of the IRCOSC registers.

Table 371. IRCOSC memory map

30 Platform RAM controller (PRAM)

30.1 Introduction

This section provides an overview of the Platform RAM Controller. The PRAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The PRAM controller supports two 64-bit AHB and one 64-bit RAM array interfaces. The first AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The second AHB port provides a connection from the flash controller to facilitate calibration overlay access. *Figure 279* is a simplified block diagram depicting the position of the PRAM controller within a typical platform architecture:

Figure 279. Simplified platform block diagram

The following list summarizes the key features of the PRAM controller:

- System bus supports 64-bit data and 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data and 8-bit ECC interface
- Late-write support via 64-bit data and 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than 64-bit data

The address path of the PRAM controller contains a multiplexer that chooses among the addresses presented on the system bus during read/write requests to RAM. These addresses are transferred to RAM array either immediately, for read accesses, or, for write accesses, through a temporary write address buffer or through a late-write address buffer

The temporary write address buffer contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to simultaneously present the address and associated write data, because the write data is not valid until the AHB data phase. The late-write buffer holds write requests which are delayed to facilitate single-cycle responses on the system bus.

The read data is the result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire data path of the PRAM controller, including the late-write buffer, to support end-to-end ECC (e2eECC) coverage.

The write data path contains the multiplexer that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and stored directly in the RAM.

30.2 SRAM controller memory map and register definitions

The PRAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses will generate an IPS error.

Table 376. PRAM controller memory map

Address offset (hex)	Register name	Reset value (hex)	Location
0x00	Platform RAM Configuration Register 1 (PRCR1)	0x0000_0200	*Section 30.2.1*

30.2.1 Platform RAM configuration register 1 (PRCR1)

The Platform RAM configuration register 1 (PRCR1) is used to specify the operation of the PRAM controller.

Note: This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Table 377. PRCR1 field descriptions

Field	Description
22 PRI1	Not used, since port 1 is not used. This bit can be written by software.
23 PRI0	Not used, since port 1 is not used. This bit can be written by software.
24 P1_BO_DIS	Not used, since port 1 is not used. This bit can be written by software.
25 P0_BO_DIS	Port p0 read burst optimization disable 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response(1) when PRCR[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response(1) when PRCR[FT_DIS]=1
31 FT_DIS	Flow through disabled This field defines the AHB read response of the PRAM controller . The state of this field has no impact on the write response latency. This bit is cleared by hardware reset. **Note:** Do not change the FT_DIS bit value while accessing system RAM. Realocate code programming the FT_DIS bit to another area (for example, local core memory). 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

30.3 Functional description

30.3.1 Read/Write introduction

The PRAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The PRAM controller captures read data from the RAM array and drives it onto the AHB along with the associated dataphase termination signals. To facilitate operating at higher frequencies, the PRAM controller can optionally incur a single wait state on the AHB response.

30.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

30.3.1.2 Optional read wait-state

The PRAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCR1[FT_DIS] = 0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock

cycles (3T) to complete if PRCR1[FT_DIS] = 1, and a WRAP4 burst will have an access time of 3-2-2-2

30.3.2 Writes

30.3.2.1 64-bit writes

Aligned **64**-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Instead, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

30.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the PRAM controller performs single-error correction, double-error detection on the read data. The write data is merged into the appropriate byte lanes along with the potentially-corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. For details on the ECC coding scheme, refer to *Section 30.5: Safety considerations*.

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of less than 64 bits require the insertion of one wait state before the data phase can be completed.

30.3.2.3 Unaligned writes

The PRAM controller is compliant with the AMBA-AHB2.v6 extensions specification concerning byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

Note: Unaligned writes always generate read-modify-write operations in the PRAM controller in order to preserve the validity of the ECC codeword.

30.4 Initialization/application information

Prior to reading, the ECC must be initialized by writing a known 64-bit value to each memory address. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Reading from an uninitialized address is likely to generate an uncorrectable ECC event.

The PRAM memory space can be initialized by storing a 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

30.5 Safety considerations

30.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named after M.Y. Hsiao, an IBM researcher who published a paper in the early 1970s about SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns
2. Every column is distinct
3. Every column contains an odd number of ones, and hence is “odd weight”

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in *Table 378*. A ‘*’ in *Table 378* indicates the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 378. PRAM controller basic H-matrix definition

Checkbits [7:0]	Data Bit(1)

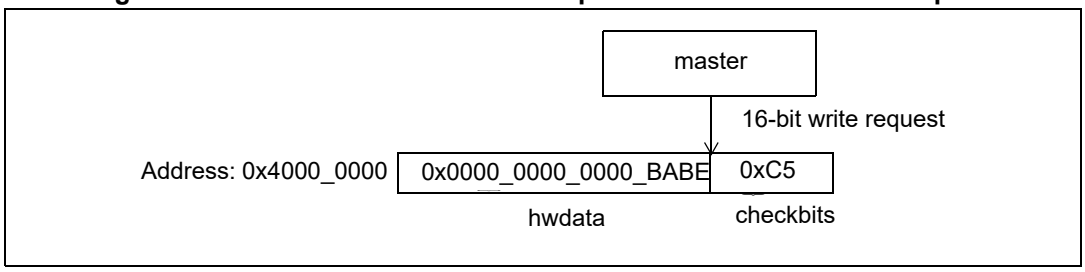
0	*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*			



1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

30.5.1.1 E2EECC considerations on less-than-64-bit write transactions

Recall that writes of less than 64-bits incur a read-modify-write action as a consequence of the ECC coding scheme 64-bits granularity. In the case of a read-modify-write action, the PRAM controller performs SEC/DED on the read data. The PRAM controller uses the following checkbit manipulation technique to ensure that any faults in the PRAM control logic, associated with performing the read-modify-write action, will ultimately be detectable by e2eECC:

- On an 8-bit, 16-bit or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non pertinent byte lanes zeroed out, and the associated checkbit is based on this “zero-padded” write data.
  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

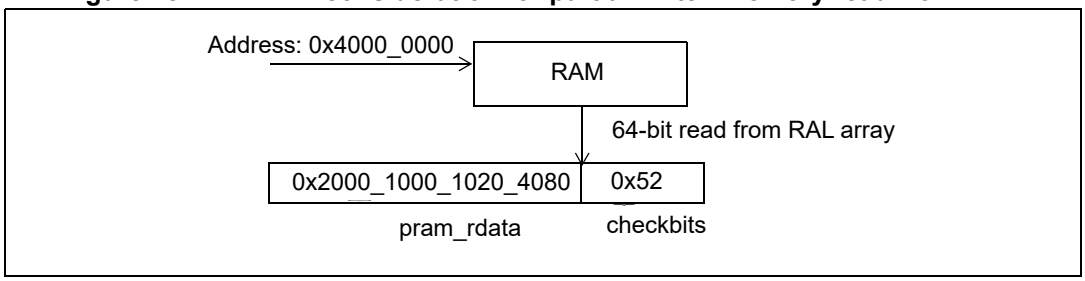


Figure 281. E2EECC consideration for partial write - 16-bit write request

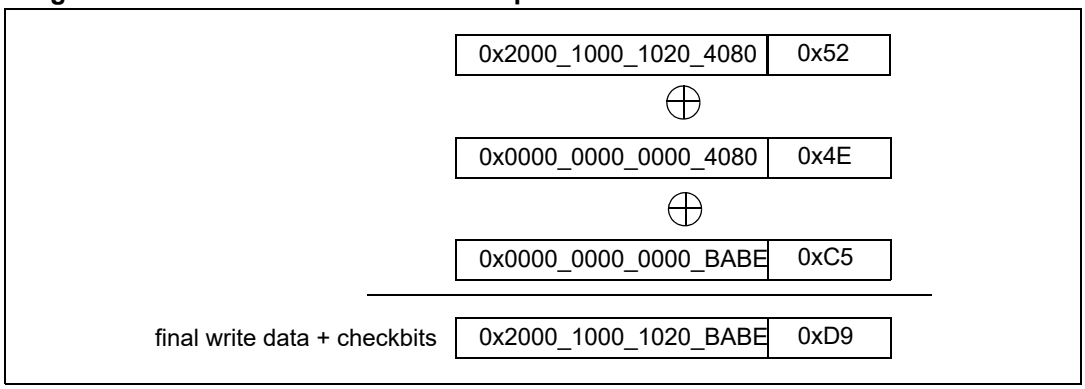
- The PRAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

  If a non correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

Figure 282. E2EECC consideration for partial write - memory read from RAM



- The PRAM controller isolates the pertinent byte lanes of the read data by zero-padding the non pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

Figure 283. E2EECC consideration for partial write - Separation of check-bits of targeted bit-lines

- The PRAM controller merges the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

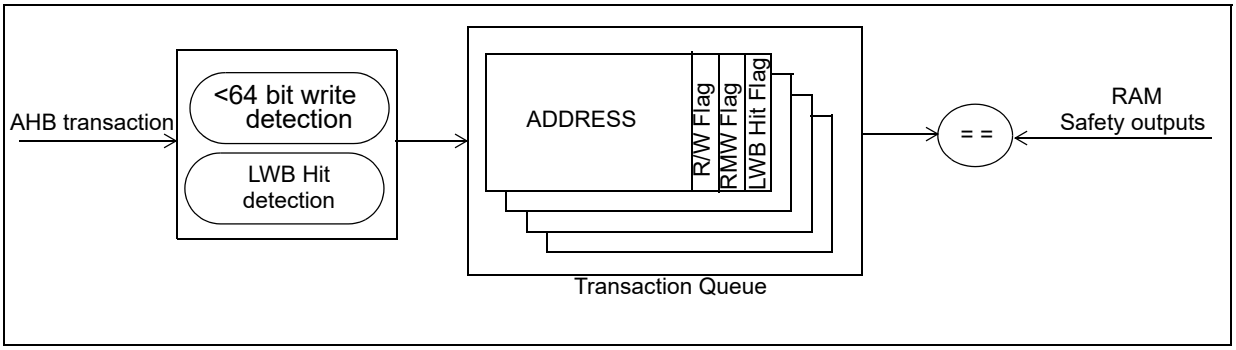
Figure 284. E2EECC consideration for partial write - calculation of final check-bits

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and PRAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The PRAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

30.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by an e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the PRAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions



- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, the safety feature compare outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

Figure 285. RAM controller transaction monitor block diagram

31 Flash memory controller (PFLASH Controller)

31.1 Introduction

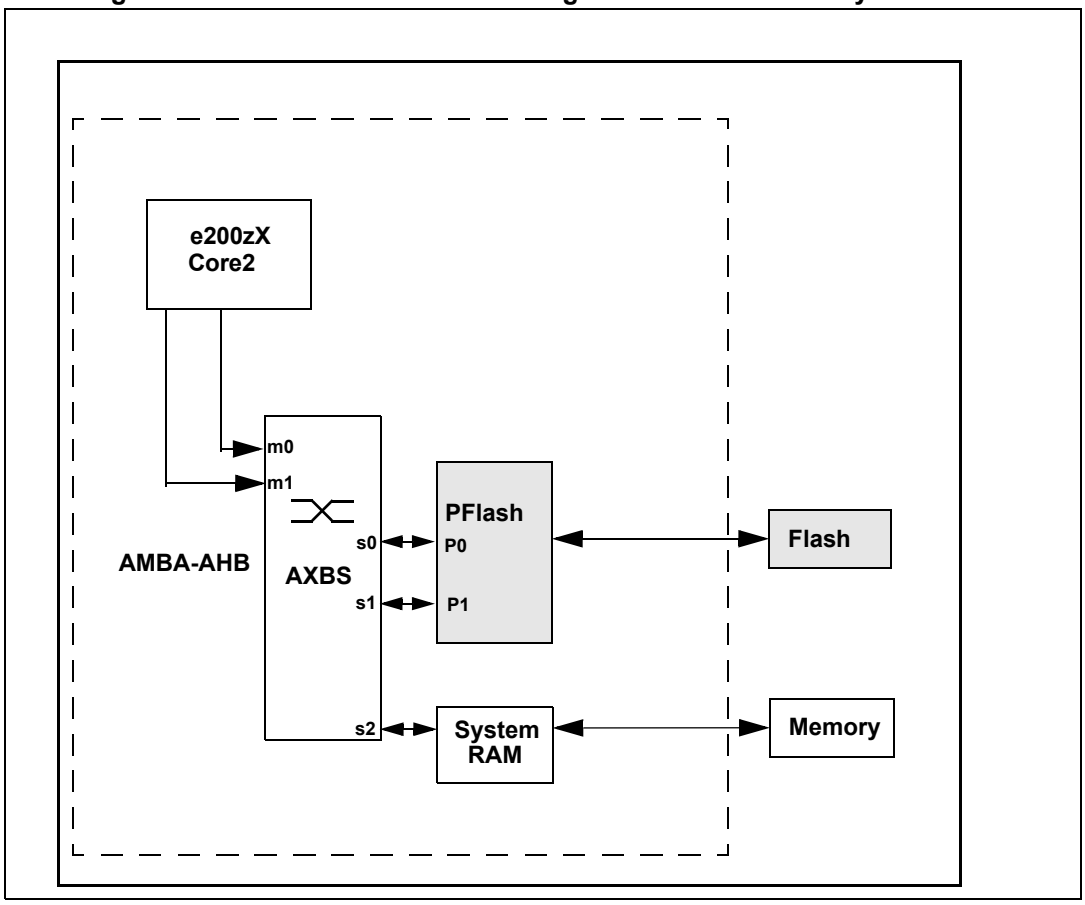
The flash memory controller:

- Acts as an interface between the system bus (AHB-Lite 2.v6) and the flash array.

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface to the flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the code flash array page size and providing 256 bytes of high-speed local storage.

Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC coverage (e2eECC).

31.2 Features



The following list summarizes the key features of the flash memory controller:

- Two 64-bit AHB ports (p0, p1)
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle “buffer hit” read response
- Configurable access control based on read/write and AHB master ID attributes
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary

31.3 Block diagram

Figure 286 provides a block diagram showing the flash memory controller and the attached flash array.

Figure 286. Platform-centric block diagram with flash memory controller

31.4 Memory map and register definitions

31.4.1 Overview

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash access configuration .

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the middle of an operation results in non-deterministic behavior.

Table 379. Flash memory controller memory map

15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
19:23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. The required settings are documented in the SoC specification. Higher operating frequencies require non-zero settings for this field for proper flash operation. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added **Note:** Refer to the device data sheet for wait-states configuration
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access

Table 380. PFCR1 field descriptions (continued)

Field	Description
29:30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

31.4.1.2 Platform Flash Configuration Register 2 (PFCR2)

The PFlash Configuration Register 2 (PFCR2) is used to specify operation Port1 of the flash memory controller.

3 P1_M12PFE	Port1 Master 12 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 12. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P1_M11PFE	Port1 Master 11 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 11. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P1_M10PFE	Port1 Master 10 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 10. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P1_M9PFE	Port1 Master 9 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 9. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P1_M8PFE	Port1 Master 8 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 8. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
8 P1_M7PFE	Port1 Master 7 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 7. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P1_M6PFE	Port1 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P1_M5PFE	Port1 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table 381. PFCR2 field descriptions (continued)

Field	Description
11 P1_M4PFE	Port1 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P1_M3PFE	Port1 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P1_M2PFE	Port1 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P1_M1PFE	Port1 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P1_M0PFE	Port1 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
25 P1_DPFEN	Port1 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P1_IPFEN	Port1 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
29:30 P1_PFLIM	Port1 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 1x The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P1_BFEN	Port1 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

Field	Description
0:1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across all four ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 All four buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 and 1 allocated for instruction fetches and way 2 and 3 for data accesses. 11 Reserved
2:3 P1_WCFG	Port1 Line Buffer Configuration. This field controls the configuration of the line buffers for a given set across all four ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 All four buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffers 0 and 1 allocated for instruction fetches and buffers 2 and 3 for data accesses. 11 Reserved
11	Reserved This is a Read only bit. It can be programmed but it has no functionality.

Table 382. PFCR3 field descriptions (continued)

Field	Description
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash, where the access type is detected by evaluating {p0,p1}_hprot[0]. Once this field is set, attempted instruction access attempts targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.
16:17 ARBM	Arbitration Mode. This 2-bit field controls the arbitration of concurrent flash access requests from the two AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 1x Round-robin arbitration

31.4.1.4 Platform Flash Access Protection Register (PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

31.5 Functional description

As shown in *Figure 286* the flash memory controller interfaces between the dual AHB system bus ports, flash memory array,.

For accesses targeting the flash array, the flash memory controller generates read and write enables, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

31.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

31.5.2 Access protections

31.5.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in *Section 31.4.1.4: Platform Flash Access Protection Register (PFAPR)*. Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

31.5.2.2 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code, which is loaded in a predetermined OTP flash block. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on either Port0 or Port1 are evaluated. If the flash memory controller detects an attempted instruction fetch access to the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

31.5.3 Read cycles - buffer miss

On an incoming AHB read request, a buffer lookup and access checks are performed during the AHB address phase. In the event of a buffer miss the AHB address and attributes are registered and the flash access is initiated the cycle following the AHB address phase (the first AHB data phase cycle).

If the flash access was the direct result of an AHB transaction, the corresponding page buffer is marked as most-recently-used as it is being loaded. If the flash access was the result of a speculative prefetch to the next sequential line, it is first loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

31.5.4 Read cycles – buffer hit

Single cycle read responses to the AHB are possible with the flash memory controller when the requested read access was previously loaded into one of the page buffers. In these “buffer hit” cases, read data is returned to the AHB data phase with a zero wait-state response.

31.5.5 Error termination

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read Access Control or Write Access Control settings do not allow the access, thus causing a protection violation, see *Section 31.4.1.4: Platform Flash Access Protection Register (PFAPR)* for more detail. In this case the flash memory controller does not initiate a flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is

set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed, see *Section 31.4.1.3: Platform Flash Configuration Register 3 (PFCR3)* for more detail. In this case, the flash memory controller does not initiate a flash array access.

- Attempted access by an AHB master to a flash region, where the corresponding censorship control is asserted.
- The flash returns an error response on an attempted flash access (See *Section 31.5.6: Flash error response operation*).

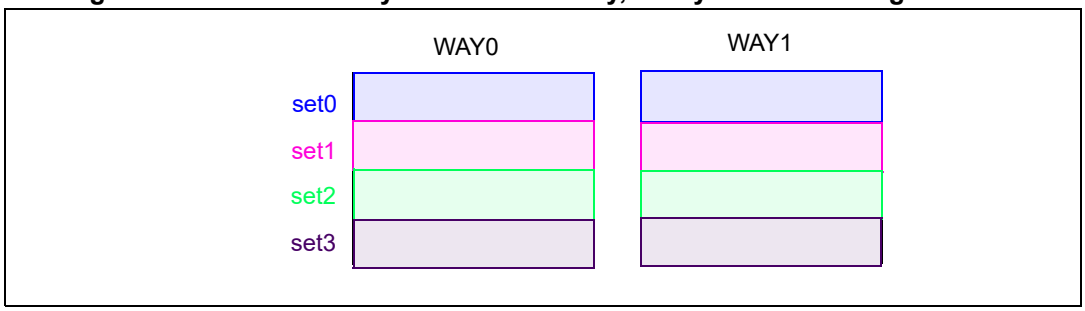
31.5.6 Flash error response operation

The flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations. When an error response is received, the flash memory controller does not update or validate a page read buffer. An error response may be signaled on read operations. For more information on the specifics related to signaling of flash errors including flash ECC events and read-while-write events, refer to the Embedded Flash Memory chapter.

31.5.7 Censorship

The entire flash space is defined by three major regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- UTest flash



Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

31.5.8 Line read buffers and prefetch operation

Each AHB port of the flash memory controller contains a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see *Section 31.4.1.1: Platform Flash Configuration Register 1 (PFCR1)*). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 291. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the just-loaded buffer is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in *Section 31.4.1.1: Platform Flash Configuration Register 1 (PFCR1)*. More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

In order for prefetching to occur, PFCR{1,2}[P{0,1}_BFEN] must be set to '1', PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted. Refer to *Section 31.4.1.1: Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls.

31.5.9 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to *Section 31.4.1.1: Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to *Section 31.4.1.2: Platform Flash Configuration Register 2 (PFCR2)* for a description of these controls. Prefetches are never triggered by write cycles.

31.5.10 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to *Section 31.4.1.1: Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls.

31.5.11 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to *Section 31.4.1.3: Platform*

Flash Configuration Register 3 (PFCR3). The buffers can be organized as a “pool” of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, ways 0 is allocated for instruction fetches and way1 for data accesses.

31.5.12 Safety considerations

31.5.12.1 e2eECC (End-to-End ECC)

31.5.12.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all ones codeword, since it reflects the state of an erased flash location, is treated as a valid, error-free encoding. Second, since an erased flash block generates an all ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation; in particular, it is required that the checkbits associated with the all ones data value and the all zeroes data value are required to be the same with a checkbit value of 0xFF.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR’ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all ones erased state.

On a flash read operation, a similar but “reversed” set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the fault collection module.

31.5.12.1.2 e2eECC and data flash accesses

ECC events detected on accesses to the data flash blocks are suppressed from being reported to the ECC event collection unit.

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode, value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address and the non-correctable error event is suppressed from being reported to the MEMU.

31.5.12.2 Flash address generation check

Functional safety coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Functional safety coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. On a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals which invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup:

- Encoded address as received by flash memory
- Address encoding error provided by flash memory

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the Fault Collection and Control Unit (FCCU) and the corresponding buffer is invalidated. The flash memory controller has a separate MEMU reporting interface associated with AHB port p0 and p1.

31.5.13 Array integrity considerations

During an array integrity sequence, the flash array ignores any incoming read requests. The flash provides an output sideband, which indicates when an array integrity sequence is in progress. When it is asserted, the flash memory controller aborts any incoming flash access requests and terminates the system bus transfer with an error.

32 Embedded Flash Memory

32.1 Introduction

The Flash memory module serves as electrically programmable and erasable nonvolatile memory, for instructions and data storage.

The Flash memory module is a nonvolatile, solid-state silicon memory device consisting of blocks of single transistor storage elements, an electrical means for selectively adding (programming) and removing (erasing) charge from these elements, and a means of selectively sensing (reading) the charge stored in these elements.

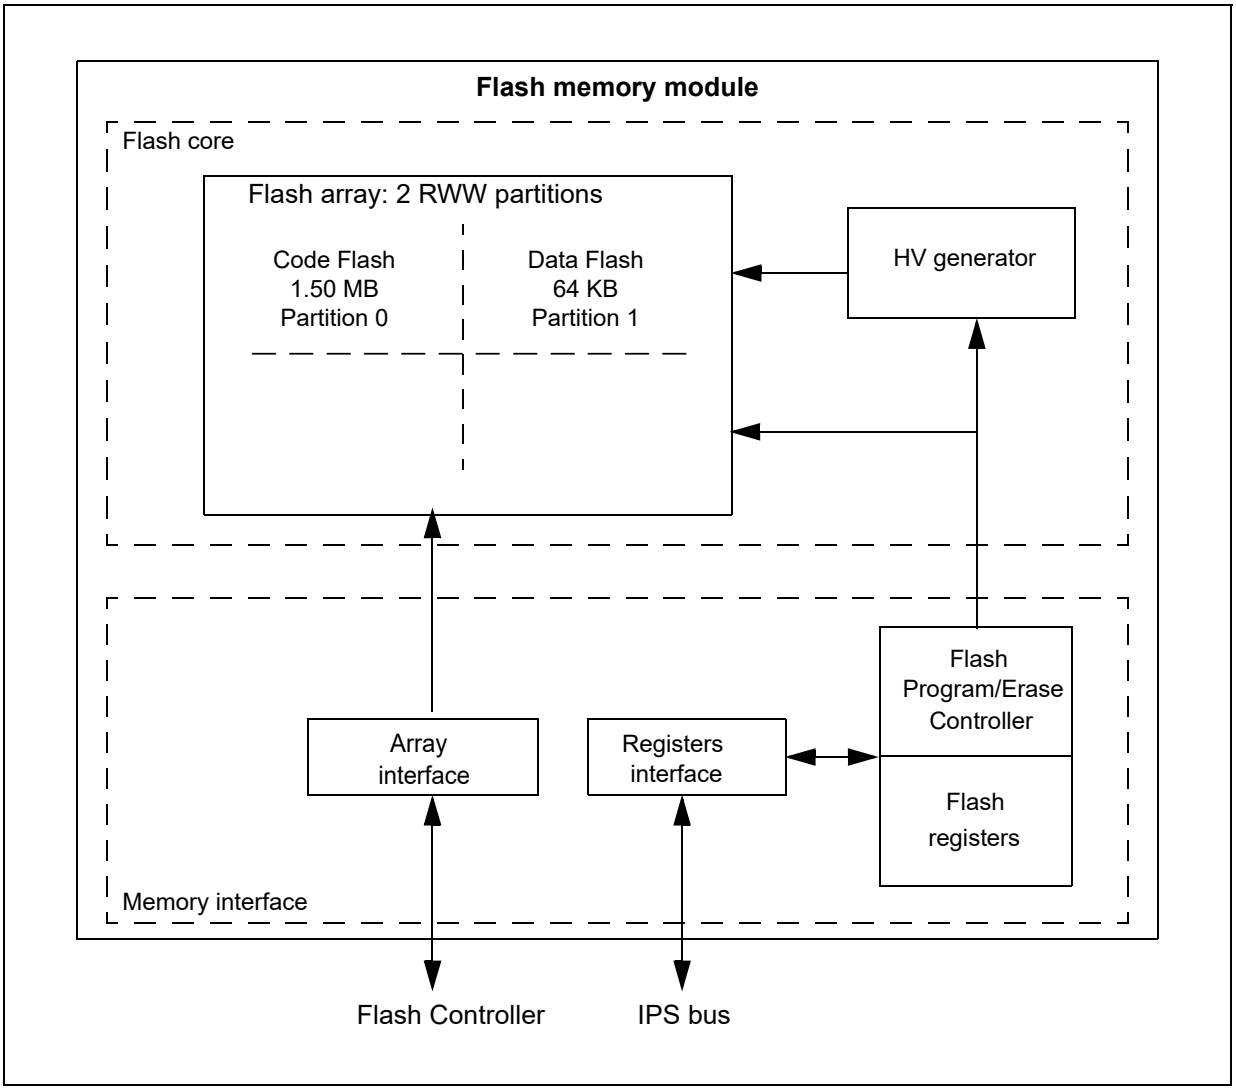
The Flash memory module has two functional units:

- **The Flash core.**
  It is composed of a common high voltage HV block and a Flash array which can contain one or more Flash partitions. Each Flash partition is composed of arrayed nonvolatile storage elements, sense amplifiers, row decoders and column decoders. The arrayed storage elements in the Flash partitions are subdivided into physically separate units referred to as blocks.
- **The Memory interface.**
  It contains the registers and logic which control the operation of the Flash core and comprises two main ports: the Array interface and the Registers Interface. The memory interface is also the interface between the Flash memory module and a Bus Interface Unit (BIU) and contains the ECC and redundancy logic.

A BIU connects the Flash memory module to a system bus, and contains all the system level customization required for the SoC application. The Flash memory module is generic and requires a BIU to configure it for different SoC applications. A BIU is not included.

32.1.1 Overview

The 1632 KB Flash memory module contains two array partitions. Read-While-Write operations are only possible for separate partitions, meaning fetching/reading from one (or more) partition(s) while a Program/Erase operation is active on another partition. Each module counts as an RWW partition.



EEPROM emulation is managed in one block of the module, referred to as Data Flash.

The Modify operations are managed by an embedded Flash Program/Erase Controller (FPEC). Commands to the FPEC are delivered through a User Registers interface.

The read data bus is 256 wide, while the Flash registers are on a separate, 32-bit bus.

The high voltages needed for Program and Erase operations are internally generated and are common for the two partitions.

Figure 292. Flash memory module structure

The Flash memory module is designed for use in embedded MCU/SoC applications which require high density nonvolatile memories with high-speed read access.

The Flash array is addressable:

- For programs: by word (32 bits) or doubleword (64 bits).
- For reading code partitions: by page (256 bits).
- For reading data partitions: by half-page (128 bits).

Multipleword or doubleword Writes to the Flash memory may be performed to fill the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 doubleword Writes) and quad-page programming (1024 bits, requiring 16 doubleword Writes). Code Flash memory Reads always return 256 bits, although read buffering may be performed by the Bus Interface Unit (BIU). The address for each word retrieved within a page differs from the other addresses in the page by address bits (3:2).

Data Flash memory Reads always return 128 bits, or two consecutive doublewords of information. The address for each word retrieved within a doubleword differs from the other addresses by address bits (3:2).

The Flash memory module supports fault tolerance through Error Correction Code (ECC) and error detection. The ECC implemented within the Flash memory module corrects single bit failures and detects double bit failures.

The Flash memory module uses an embedded hardware algorithm implemented in the Flash Program/Erase Controller to program and erase the Flash partitions.

Control logic that works with the software block-enables and software lock mechanisms are included in the embedded hardware algorithm to guard against accidental program/erase. The hardware algorithm performs the necessary steps to ensure that the storage elements are programmed and erased with sufficient margin to guarantee data integrity and reliability.

A programmed bit in the Flash array reads as logic level ‘0’ (or low). An erased bit in the Flash array reads as logic level ‘1’ (or high).

Programming and erasing of the Flash array requires multiple system clock cycles to complete.

The Program and Erase sequences may be suspended or aborted.

32.1.2 Features

- 30 ns code/data array access time
- Code Partition High Read parallelism: 256 bits
- Data Partition Read parallelism: 128 bits
- Error Correction Code (SEC-DED) to enhance data integrity
- Doubleword program granularity: 64 bits
- Erase with fast erase time at factory
- Blocks one time programmable (OTP) marking
- Read-While-Modify capability when the accesses are to different partitions
- Erase/Program Suspend
- Programming during Erase Suspend
- Software programmable program/erase protection to avoid unwanted writings
- Temperature range (-40 °C to 150 junction)
- UTEST mode (user-accessible Test modes)
- Critical flops, which may affect Flash content, are triple-voted for safety application.

32.1.3 Modes of operation

The Flash memory module supports the following modes of operation:

- Reset: the Flash memory module initializes when the reset is deasserted.
- Power-down (Disable mode): the Flash memory module removes all static consumption. The embedded Flash memory (array and registers) is not accessible to Read, Program or Erase once disabled. The wake-up time from Disable mode is longer than the wake-up time from Sleep mode.
- Low-power mode (Sleep mode): the Flash memory module removes most of the static consumption. It is not accessible to Read, Program or Erase once disabled, however it does maintain a faster exit to Read mode with respect to power-down.
- Read mode: the Flash memory module accepts Read accesses to the array.

- Modify mode: it is possible to read and write registers, interlock write the memory array, program the memory array, and erase the memory array. Program and Erase operations are initiated by performing array and register writes, and controlled by an internal state machine. Program/Erase operations or User Test modes (Margin Read or Array Integrity Check) are considered Modify modes.
- Read-While-Write: The Flash memory module accepts Read accesses to array partitions that are not in Modify mode.

Such modes of operation are described in detail in *Section 32.4: Functional description*.

32.2 Flash memory map and description

The Flash memory module general architecture supports total memory sizes ranging from 32 KB to 8 MB of user memory, plus up to 48 KB of Test memory (a portion of which is One Time Programmable by the user).

Optionally, an extra memory space ranging from 32 KB to 512 KB can be used as data space for EEPROM emulation, and can be organized in different RWW partitions (in addition to the main user memory partition).

There are four User Address Spaces: Low, Mid, High and 256K Address Space:

- Low Address Space
  it must always be present and be up to 256 KB in size and may be organized in a maximum of 14 blocks (16 KB[k], 32 KB and 64 KB blocks).
- Mid Address Space
  it can be present and be up to 512 KB in size and may be organized in a maximum of 16 blocks (16 KB, 32 KB and 64 KB blocks).
- High Address Space
  it can be present and be up to 512 KB may be organized in a maximum of 16 small blocks (8 KB[k], 16 KB, 32 KB and 64 KB blocks).
- 256K Address Space
  it can be present and be up to 7.5 MB in size and may be organized in a maximum of 31 blocks (256 KB).

Note: There is also a special Test Address space which must always be present and be up to 48 KB in size. Test Address space is part of Flash Partition 0.

The Flash memory module can be divided into a minimum of one to a maximum of eight Flash partitions.

The total size of each Code Flash partition cannot be greater than 2 MB and the maximum number of blocks cannot exceed 16, including TestFlash. The total size of each Data Flash partition cannot be greater than 256 KB and the maximum number of blocks cannot exceed eight.

There are up to six sizes of blocks available for user Flash partitions: 256 KB, 128 KB, 64 KB, 32 KB, 16 KB and 8 KB.
The 64 KB, 32 KB and 16 KB blocks can be mapped anywhere in the Low, Mid and High address spaces.

k. If the BAF is 8 KB in size, it is integrated with the 8 KB UTEST area to form a single 16 KB block in Low Address Space.

The 256 KB blocks can be mapped in the 256K address space. 8 KB[(k)] blocks may only be mapped in the High address space.

The Flash memory module block subdivision also facilitates independent Erase and Program protection. A software mechanism is provided to independently lock and unlock each block in Low, Mid, High and Data address spaces against program and erase.

32.2.1 Flash array memory map

32.2.1.1 Code Flash

Partition 0 accounts for 1.50 MB of the total Flash memory and is divided into 13 user blocks for code storage. The first 256 KB block is organized as 4 × 16 KB, 2 × 32 KB and 2 × 64 KB. Remaining blocks are 256 KB.

Partition 0 also contains a reserved block named TestFlash in which some One Time Programmable (OTP) user data is stored.

The sectorization of partition 0 of the 1632 KB Flash memory module is shown in *Table 384*.

Table 384. Flash memory partition 0 memory map

Block	Absolute addresses	Size	Address space	LOCK	SEL
B0BF	0x0040_4000 to 0x0040_7FFF	16 KB	Low	LOWLOCK[0]	—
B0F1	0x00FC_0000 to 0x00FC_3FFF	16 KB	Low	LOWLOCK[1]	LOWSEL[1]
B0F2	0x00FC_4000 to 0x00FC_7FFF	16 KB	Low	LOWLOCK[2]	LOWSEL[2]
B0F3	0x00FC_8000 to 0x00FC_BFFF	16 KB	Low	LOWLOCK[3]	LOWSEL[3]
B0F4	0x00FC_C000 to 0x00FC_FFFF	16 KB	Low	LOWLOCK[4]	LOWSEL[4]
B0F5	0x00FD_0000 to 0x00FD_7FFF	32 KB	Low	LOWLOCK[5]	LOWSEL[5]
B0F6	0x00FD_8000 to 0x00FD_FFFF	32 KB	Low	LOWLOCK[6]	LOWSEL[6]
B0F7	0x00FE_0000 to 0x00FE_FFFF	64 KB	Low	LOWLOCK[7]	LOWSEL[7]
B0F8	0x00FF_0000 to 0x00FF_FFFF	64 KB	Low	LOWLOCK[8]	LOWSEL[8]
B0F9	0x0100_0000 to 0x0103_FFFF	256 KB	256 K	A256KLOCK[0]	A256KSEL[0]
B0F10	0x0104_0000 to 0x0107_FFFF	256 KB	256 K	A256KLOCK[1]	A256KSEL[1]
B0F11	0x0108_0000 to 0x010B_FFFF	256 KB	256 K	A256KLOCK[2]	A256KSEL[2]
B0F12	0x010C_0000 to 0x010F_FFFF	256 KB	256 K	A256KLOCK[3]	A256KSEL[3]
B0F13	0x0110_0000 to 0x0113_FFFF	256 KB	256 K	A256KLOCK[4]	A256KSEL[4]
B0UT	0x0040_0000 to 0x0040_3FFF	16 KB	Low	TSLOCK	—
B0TF	0x0040_8000 to 0x0040_BFFF	16 KB	Reserved	—	—

32.2.1.2 Data Flash

Data Flash is allocated in partition one of the Flash memory module in 4 × 16 blocks destined for data storage.

The Data Flash sectorization of the Flash memory module is listed below.

Table 385. Flash memory Partition 1 memory map

Block	Absolute addresses	Size	Address Space	LOCK	SEL
B1F0	0x0080_0000 to 0x0080_3FFF	16 KB	High	HIGHLOCK[0]	HIGHSEL[0]
B1F1	0x0080_4000 to 0x0080_7FFF	16 KB	High	HIGHLOCK[1]	HIGHSEL[1]
B1F2	0x0080_8000 to 0x0080_BFFF	16 KB	High	HIGHLOCK[2]	HIGHSEL[2]
B1F3	0x0080_C000 to 0x0080_FFFF	16 KB	High	HIGHLOCK[3]	HIGHSEL[3]
—	—	—	—	—	—

32.2.1.3 TestFlash block memory map

The TestFlash block exists outside the normal address space and is programmed, erased and read independently of the other blocks. The independent TestFlash block is also included to support systems which require nonvolatile memory for security and to store system initialization information.

A section of the TestFlash is reserved for storing the nonvolatile information related to Redundancy, Configuration and Protection. The usage of reserved TestFlash block is detailed in *Table 386*.

Table 386. TestFlash block memory map

Address Offset	Description	Size	Access
UTEST (Base Address 0x0040_0000 to 0x0040_3FFF)			
0x0000	OTP area for Device Serial Number	8 bytes	R/P
0x0008	Reserved	4 bytes	R/P
0x000C	Test Mode Disable Seal	4 bytes	R/P
0x0010	Test Mode Disable Block Select 0	16 bytes	R/P
0x0020	Factory Erase Diary Location	16 bytes	R/P
0x0030	Test Mode Disable Block Select 1	16 bytes	R/P
0x0040	Customer Single Bit Correction area	32 bytes	R
0x0060	Customer Double Bit Detection area	32 bytes	R
0x0080	Customer Programmable Detection area	32 bytes	R/P
0x00A0	Reserved	96 bytes	R/P
0x00B4	Flash Firmware — Minor identifier (f)	1 byte	R
0x00B5	Flash Firmware — Major identifier (F)	1 byte	R
0x00B6	Flash parameters identifiers (P)	1 byte	R
0x00B7	Flash Firmware and parameters — unused	1 byte	R
0x0100	Test Mode Disable Override Passcode0	4 bytes	R/P
0x0104	Reserved	252 bytes	R/P
0x0200	Reserved	3584 bytes	R/P
0x1000	Customer OTP data	12288 bytes	R/P

Table 386. TestFlash block memory map (continued)

Address Offset	Description	Size	Access
BAF (Base Address 0x0040_4000 to 0x0040_7FFF)			
0x0000	User OTP – BAF Area	16 KB	R/P

The TestFlash block can be enabled by the BIU. When the Test space is enabled, all the operations are mapped to the Test block. The TestFlash supports RWW, and is grouped with the Code Flash in partition 0.

Erase of the TestFlash block is always locked in User mode.

Programming of any section of the TestFlash block is subject to similar restrictions as the array in terms of how ECC is calculated. Only one program is allowed per 64-bit ECC segment.

The TestFlash block contains two different user sections: UTEST (16 KB) and BAF (16 KB).

The UTEST nonvolatile memory section is OTP and erase is not allowed. User mode programming of the UTEST section is enabled only when MCR.PEAS is high. The UTEST section is divided into a *Flexible* area where content is managed at SoC level, and a *Reserved* area where addresses are pre-allocated for storing certain content. The UTEST section may be locked and unlocked against programming via LOCK0.TSLOCK in conjunction with the relative sideband (SoC specific). For locking purposes, UTEST is treated as a standalone block even though it resides in the TestFlash block. UTEST access (both Read and Modify) is disabled in Test mode once the test mode disable seal password is written. As UTEST is part of the TestFlash physical block, it is also protected.

The UTEST section is also set as OPP once the test mode disable seal password is written, thus programming is only allowed on virgin 64-bit locations.

The other area of the TestFlash block is BAF and may be used for defined functions (possibly to store boot code, other configuration words or factory process codes). This nonvolatile memory area is OTP and cannot be erased once programmed.

Although the BAF (like UTEST) is part of the TestFlash block, OPP functionality is managed through sideband (SoC specific). Program protection is also managed through sideband (SoC specific), in conjunction with LOCK0.LOWLOCK. For locking and OPP purposes, BAF is treated as a standalone block.

When the UTEST section (via the entire TestFlash block) is protected via test mode disable seal, the BAF is also protected from any high voltage operation which may alter the content. Access to BAF is read only for FPEC in the event that the test interface is open (Failure Analysis scenario).

32.3 Register memory maps and descriptions

In this section some nonvolatile registers are described as well as the usual volatile registers. Note that such entities are not Flip-Flops, but TestFlash block locations with a specific purpose.

During the Flash initialization phase, the FPEC reads these nonvolatile registers and updates their corresponding volatile registers. When the FPEC detects ECC double errors in these special locations, it behaves in the following way:

- In the case of failing system locations (configurations, redundancy, EmbAlgo firmware), the initialization phase is interrupted and a Fatal Error is flagged.
- In the case of failing user locations (protections, censorship, BIU, etc.), the volatile registers are filled with ‘1’s and the Flash Initialization ends setting MCR.PEG to low.

32.3.1 Register memory maps

This section presents the memory mapping of all the Flash memory registers.

32.3.1.1 User Register memory maps

The Flash user registers represent the communication interface between the host CPU and the FPEC.

Some register bits (command bits) are Read/Write for the CPU and read only for the FPEC. Other register bits (status bits) are Read/Write for the FPEC and read only for the CPU.

The Flash user registers mapping is shown in *Table 387*.

Table 387. Flash user registers memory map

Offset address	Description	Access(1)	Reset value(2)	Location

0x008C	Reserved	—	—	—
0x0090	Test Mode Disable Password Check (TMD)	W	—	*Figure 316*

1. Note that R/W registers may contain some read only or write only bits.
2. Reset value comes from UTEST are within TestFlash, and this assumes the location is erased and all possible blocks are available.
3. Note that R/W register may contain some read or write only bits.

32.3.2 User register descriptions

This section consists of user register descriptions in address order.

32.3.2.1 Module Configuration Register (MCR)

The Module Configuration Register is used to enable and monitor all the Modify operations of the Flash memory module.

Address: 0x0000 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 293. Module Configuration Register (MCR)

Table 388. MCR field descriptions

Field	Description
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the analog Read references. If the current and voltage Read references are out of range, this bit is set to signify that previous reads requested may have been corrupted. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally 1 A Read Reference Error occurred during a previous Read
2 AEE	Address Encode Error On every Read request to the Flash, the incoming address is compared to an encoded address (row, column, and block) from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error is recorded. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally 1 An Address Encode Error occurred during a previous Read.
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every Read request to the Flash, ECC parity is recomputed (encoding) just after ECC decoding, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error is reported. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally 1 A previous Read may have been corrupted.
4:7 DWEE	Double Word Uncorrectable Ecc Error DWEE provides indication about which Double Word has been involved in Ecc Uncorrectable Event Error. DWEE is a read only. Flags bits get cleared when EER is cleared.

Table 388. MCR field descriptions (continued)

Field	Description
16 EER	ECC Event Error EER provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. EER may not be set to ‘1’ by the user. EER is not set for a ECC Single Error detection and correction event. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An ECC Double Error occurred during a previous Read.
17 RWE	Read-While-Write event Error RWE provides information on previous Reads during a Modify operation. Read-While-Write Error means that a Read access to the Flash Array partition has occurred while the FPEC was performing a Program or Erase operation or an Array Integrity Check on the same partition. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A RWW Error occurred during a previous Read.
18 SBC	Single Bit Correction SBC provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Double Error detection, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE). 0 Reads are occurring normally. 1 An ECC Single Error occurred and was corrected during a previous Read.
20 PEAS	Program/Erase Access Space PEAS is used to indicate which space is valid for Program and Erase operations: main array space or UTEST section within Test Flash block. – PEAS is captured and held with the first Interlock Write done for Modify operations. – PEAS is retained between sampling events (such as subsequent to first Interlock Writes). – PEAS is changed during erase-suspended program (when program is in UTEST) and reverts back to its original state (related to erase-suspended operation) once the erase-suspended program is completed (at MCR.PGM 1-0 transition). 0 UTEST address space is disabled for program and main address space enabled. 1 UTEST address space is enabled for program and main address space disabled.

Table 388. MCR field descriptions (continued)

Field	Description
21 DONE	Modify operation DONE DONE indicates if the Flash memory module is performing a high voltage operation. DONE is set to ‘1’: – On termination of the Flash memory module reset. – At the end of program and Erase high voltage sequences. – After 1-0 transition of EHV, which aborts a high voltage Program/Erase operation (within t_{PABT} or t_{EABT}, equal to the P/E Abort Latency). – After 0-1 transition of ESUS/PSUS which suspends an Erase/Program operation (within t_{ESUS}/t_{PSUS} time equal to the Erase/Program Suspend Latency). – DONE is cleared to ‘0’: – just after 0-1 transition of EHV, which initiates a high voltage operation, or after resuming a suspended operation. 0 Flash is executing a high voltage operation. 1 Flash is not executing a high voltage operation.
22 PEG	Program/Erase Good PEG is automatically updated to show the completion status of the last Flash Program or Erase sequence involving high voltage operations. PEG is evaluated on the completion status of only the interlocked doubleword during page program or quad-page programming where some doubleword addresses are not interlocked (already programmed or intended to remain virgin). PEG is set to ‘0’ after Aborting a Program/Erase high voltage operation, indicating sequence failure. PEG is set to ‘1’ when the Flash memory module is reset, unless a Flash Initialization error has been detected. **Note:** PEG is valid only when PGM=1 and/or ERS=1 and after DONE 0-1 transitions due to an Abort or the completion of a Program/Erase operation. PEG remains valid until PGM/ERS 1-0 transitions or EHV 0-1 transitions. PEG is not valid after DONE 0-1 transitions when ESUS/PSUS is set to logic ‘1’. If Program or Erase is attempted on blocks that are locked, PEG=1 indicating that the operation was successful and the content of the block were properly protected from the Program or Erase operation. Blocks can be locked through LOCK0/1/2 registers OR with f90_plock0/1/2 sideband signals. If a Program operation tries to write ‘1’ to bits that are ‘0’, the program operation is correctly executed on the new bits to be programmed at ‘0’, but PEG is cleared indicating that the requested operation has failed. If programming during an Erase Suspend a location that was under suspended erase, program is not executed and PEG is set to ‘0’. With end2end ECC scheme, during an Interlock Write also ECC parity bits are input. After setting EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, in the page program or in the quad-page program, contains an inconsistency between data and parity, the whole operation is rejected and a PEG=0 is set. PEG behavior with blocks marked as OPP (though f90_otpen0/1/2 sideband signals) is the following: PEG=0 if the location to be programmed is not virgin, and thus would not be over programmed. In Array Integrity Check or Margin Read PEG is not altered when the operation is completed, regardless of the occurrence of any error, abort, break point or suspend. The presence of errors can only be detected by comparing the checksum value stored in UM0-9 and by checking the MCR flags. 0 Program, Erase operation failed or Program, Erase aborted. 1 Program or Erase operation successful.

Table 388. MCR field descriptions (continued)

Field	Description
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag. 0 An interrupt request is not generated when the DONE flag is set. 1 An interrupt request is generated when the DONE flag is set.
24 FERS	Factory Erase FERS is used for Erase and Program operations to enable a faster operation. Factory Erase must adhere to *Initial maximum (All Temperatures)* conditions, with respect to voltage conditions and Write/Erase cycling. The temperature can range from -40 °C to 150 °C. Factory erase does not support Read and RWW operations. – FERS may be set to enable a Factory Erase or Program after setting ERS or PGM but prior to setting EHV. – FERS can be cleared only when EHV is low and DONE is high. – FERS is cleared on reset **Note:** Factory Erase may also be disabled by writing a location in the UTEST nonvolatile memory space. Address 0x800020 in the UTEST nonvolatile memory space is checked at reset, and if programmed with data that contains at least one zero, a Factory Erase is not allowed, and FERS is locked. Writes attempted that violate the above cases result in FERS remaining cleared. 0 Factor Erase is disabled. 1 Factory Erase is enabled.
27 PGM	Program PGM is used to setup the Flash memory module for a Program operation. – 0-1 transition of PGM initiates a program sequence. – 1-0 transition of PGM ends the program sequence. PGM can only be set in the following conditions: – User Mode Read (ERS is low and UT0.UTE is low); – Erase Suspend (ERS and ESUS high) with EHV low. PGM can only be cleared by the user when PSUS and EHV are low and DONE is high. PGM is cleared on reset. **Note:** In an erase-suspended program, programming Flash memory locations in blocks which were being operated on in the Erase is forbidden. Command is not accepted and PEG is set to ‘0’ 0 Flash is not executing a program sequence. 1 Flash is executing a program sequence.

Table 388. MCR field descriptions (continued)

Field	Description
28 PSUS	Program Suspend PSUS is used to indicate that the Flash memory module is in Program Suspend or in the process of entering a Suspend state. The Flash memory module is in Program Suspend when PSUS=1 and DONE=1. – PSUS can be set high only when PGM and EHV are high. – 0-1 transition of PSUS starts the sequence which sets DONE and places the Flash in Program Suspend. The Flash memory module enters Suspend within t_{PSUS} of this transition. – PSUS can be cleared only when DONE and EHV are high. – 1-0 transition of PSUS with EHV=1 starts the sequence which clears DONE and returns the module to Program. The Flash memory module cannot exit Program Suspend and clear DONE while EHV is low. In the case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), PSUS has to be cleared first in order to resume currently higher level suspended operation that is program. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERS	Erase ERS is used to setup the Flash memory module for an Erase operation. – 0-1 transition of ERS initiates an Erase sequence. – 1-0 transition of ERS ends the Erase sequence. ERS can be set only under User Mode Read (PGM is low and UT0.UTE is low). ERS can be cleared by the user only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash is not executing an Erase sequence. 1 Flash is executing an Erase sequence.

Table 388. MCR field descriptions (continued)

Field	Description
30 ESUS	Erase Suspend ESUS is used to indicate that the Flash memory module is in Erase Suspend or in the process of entering a Suspend state. The Flash memory module is in Erase Suspend when ESUS = 1 and DONE=1. – ESUS can be set high only when ERS and EHV are high and PGM is low. – 0-1 transition of ESUS starts the sequence which sets DONE and places the Flash in Erase Suspend. The Flash memory module enters Suspend within t_{ESUS} of this transition. – ESUS can be cleared only when DONE and EHV are high and PGM is low. – 1-0 transition of ESUS with EHV=1 starts the sequence which clears DONE and returns the module to Erase. The Flash memory module cannot exit Erase Suspend and clear DONE while EHV is low. In case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), ESUS cannot be cleared first. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the Flash memory module for a high voltage Program/Erase operation. EHV is cleared on reset. EHV must be set after an Interlock Write to start a Program/Erase sequence. EHV may be set under one of the following conditions: – Erase (ERS=1, ESUS=0, UT0.AIE=0) – Program (ERS=0, ESUS=0, PGM=1, UT0.AIE=0) – Erase-suspended program (ERS=1, ESUS=1, PGM=1, PSUS=0, UT0.AIE=0). For a program operation to initiate while an Erase is suspended, EHV must be cleared while in Erase Suspend (after DONE transitions to 1) before setting PGM. In normal operation, a 1-0 transition of EHV with DONE high, PSUS low and ESUS low terminates the current Program/Erase high voltage operation. In an erase-suspended program operation, a 1-0 transition of EHV with DONE, ESUS, PGM and ERS high and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1-0 transition of EHV with DONE low and the eventual Suspend bit for the current Program/Erase operation low. An Abort causes the value of PEG to be cleared, indicating failed Program/Erase. Address locations being operated on by the aborted operation contain indeterminate data after an Abort. EHV cannot be set to ‘1’ after an Abort request (EHV being cleared) until the Abort sequence is completed (DONE transitions to 1). Once the Abort sequence is completed (DONE=1) a new operation of the kind aborted can start provided that a new interlock is given and then EHV is set to ‘1’ again. A suspended operation cannot be aborted. Aborting a high voltage operation leaves the Flash memory module addresses in an indeterminate data state. This may be recovered by executing an Erase on the affected blocks. EHV may be written during Suspend. EHV must be high to exit Suspend, resuming previously suspended command. EHV cannot not be written during transition into Suspend state (after Suspend bit (ESUS or PSUS) is set high) until DONE transitions to ‘1’. EHV may not be written after ESUS is set and before DONE transitions high. EHV may not be cleared after ESUS is cleared and before DONE transitions low. 0 Flash is not enabled to perform a high voltage operation. 1 Flash is enabled to perform a high voltage operation.

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

The Flash memory module does not allow the user to write bits simultaneously (which puts the device into an illegal state). This is implemented through a priority mechanism among the bits shown in *Table 389*.

Table 389. MCR bits Set/Clear priority levels

Priority level	MCR bits
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If the user attempts to write two or more MCR bits simultaneously then only the bit with the lowest priority level is written.

32.3.2.2 Extended Module Configuration Register (MCRE)

The Extended Module Configuration Register value is based on the size, blocks and address space configuration of the Flash memory module.

32.3.2.3 Lock 0 register (LOCK0)

The LOCK0 (Low/Mid Address Space Block Locking) register provides a means of protecting blocks from being modified. LOWLOCK and MIDLOCK bits corresponding to non existent blocks are read as ‘1’.

To determine the effective status of the Low/Mid Address Space, combine (Or) LOCK0 with sidebands:

- f90_plock0 – in order to evaluate protection against programming.
- f90_elock0 – in order to evaluate protection against erase.

The effect of programming or erasing a block protected with LOCK0 is that no modification occurs and PEG is set to ‘1’.

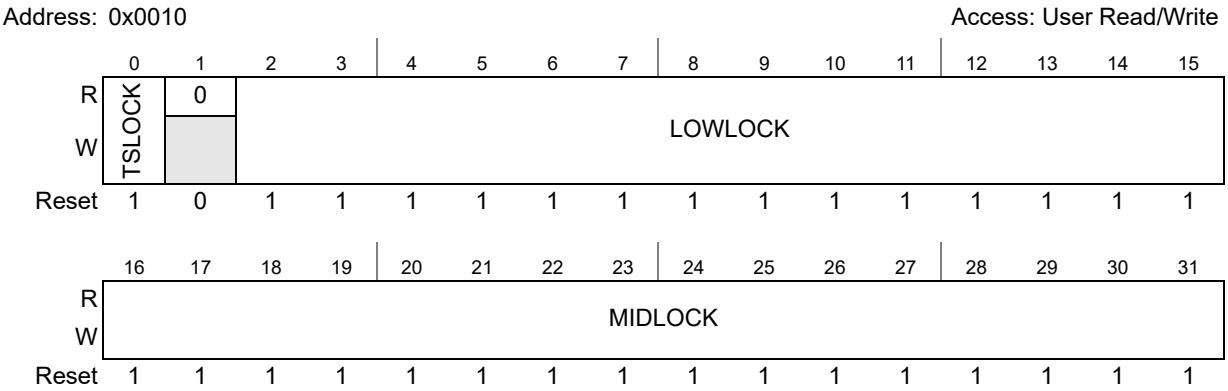

Figure 295. Lock 0 register (LOCK0)

Table 391. LOCK0 field descriptions

Field	Description
0 TSLOCK	UTEST NVM block lock This bit is used to lock the UTEST NVM from programming (UTEST NVM is not erasable). The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set. – If a high voltage operation is suspended. The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0.TSLOCK with sidebands *f90_plock0.31* in order to evaluate protection against program. 0 Test Address Space Block is unlocked and can be modified. 1 Test Address Space Block is locked and cannot be modified.
2:15 LOWLOCK	Low address space block lock 13-0 These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set. – If a high voltage operation is suspended. The default value of the LOWLOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOWLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Low Address Space Block is unlocked and can be modified. 1 Low Address Space Block is locked and cannot be modified.
16:31 MIDLOCK	Mid address space block lock 15-0 These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set. – If a high voltage operation is suspended. The default value of the MIDLOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the MIDLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Mid Address Space Block is unlocked and can be modified. 1 Mid Address Space Block is locked and cannot be modified.

32.3.2.4 Lock 1 register (LOCK1)

The LOCK1 (High/Data Address Space Block Locking) register provides a means of protecting blocks from being modified. HIGHLOCK bits corresponding to nonexistent blocks on are read as ‘1’.

- To determine the effective status of the High Address Space, combine (Or) LOCK1 with sidebandsf90_plock1 – in order to evaluate protection against program
- f90_elock1 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK1 is that no modification occurs and PEG is set to ‘1’.

Table 392. LOCK1 field descriptions

Field	Description
16:31 HIGHLOCK	High address space block lock 15-0 These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set. – If a high voltage operation is suspended. The default value of the HIGHLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

32.3.2.5 Lock 2 Register (LOCK2)

The LOCK2 (256K Address Space Block Locking) register provides a means of protecting blocks from being modified. The A256KLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the A256KLOCK Address Space, combine (Or) LOCK2 with sidebands:

- f90_plock2 – in order to evaluate protection against program
- f90_elock2 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK2 is that no modification occurs and PEG is set to ‘1’.

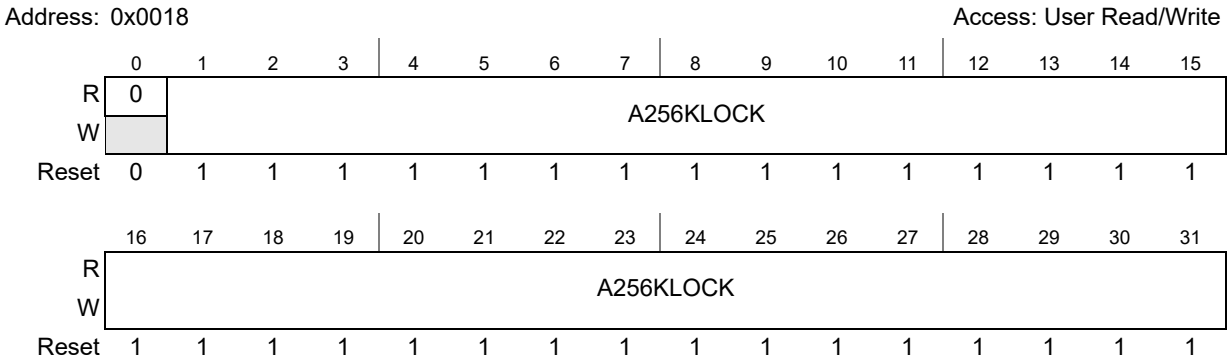

Figure 297. Lock 2 Register (LOCK2)

Table 393. LOCK2 field descriptions

Field	Description
1:31 A256KLOCK	256K address space block lock 30-0 These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the 256 KB blocks starts with A256KLOCK[0] and continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set. – If a high voltage operation is suspended. The default value of the A256KLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the A256KLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 A256K Address Space Block is unlocked and can be modified. 1 A256K Address Space Block is locked and cannot be modified.

32.3.2.6 Select 0 register (SEL0)

The SEL0 (Low/Mid Address Space Block Select 0) register provides a means to select blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL0 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 32.4.5.5: Erase*) until the completion of the erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL0 at the start of the erase operation) while writing has no effect.

Address: 0x0038 Access: User Read/Write

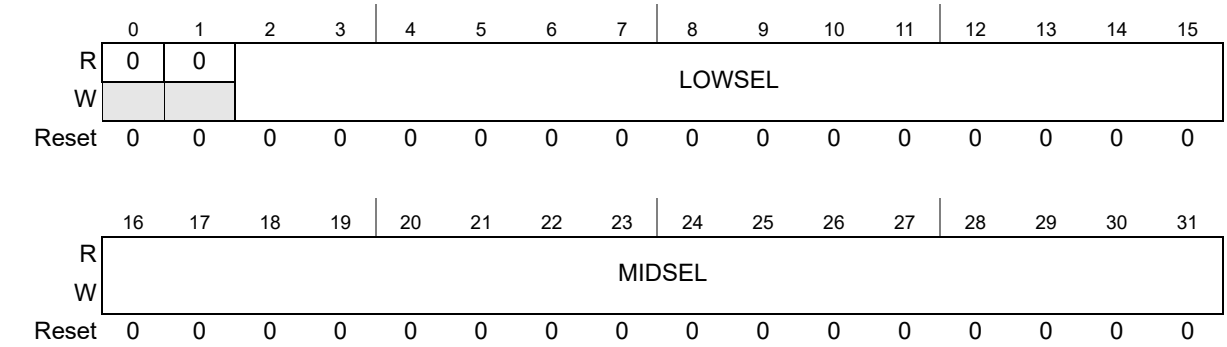

Figure 298. Select 0 register (SEL0)

Table 394. SEL0 field descriptions

Field	Description
2:15 LOWSEL	Low address space block Select 13-0 The block numbering for the Low Blocks starts at LOWSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding LOWSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 Low Address Space Block is unselected for Erase. 1 Low Address Space Block is selected for Erase.
16:31 MIDSEL	Mid address space block Select 15-0 The block numbering for the Mid Blocks starts at MIDLSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size), the corresponding MIDSEL bits default to unselected and are not writable.The reset value is always ‘0’, and register writes have no effect. 0 Mid Address Space Block is unselected for Erase. 1 Mid Address Space Block is selected for Erase.

32.3.2.7 Select 1 register (SEL1)

The SEL1 (High Address Space Block Select Register 1) provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL1 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 32.4.5.5: Erase*) until the completion of the erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL1 at the start of the erase operation) while writing has no effect.

16:31 HIGHSEL	High/Data address space block Select 1 15-0 AThe block numbering for the High Blocks starts at HIGHSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding HIGHSEL bits default to unselected and are not writable. The reset value is always ‘0’ and register writes have no effect. 0 High Address Space Block is unselected for Erase. 1 High Address Space Block is selected for Erase.

32.3.2.8 Select 2 register (SEL2)

The SEL2 (256K Address Space Block Select 2) register provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL2 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 32.4.5.5: Erase*) until the completion of the erase high voltage operation (1–0 transition of MCR.EHV

with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL2 at the start of the erase operation) while writing has no effect.

Field	Description
1:31 A256KSEL	256K address space block select 30-0 The block numbering for the 256 KB blocks starts with A256KSEL[0] and continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding A256KSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 A256K Address Space Block is unselected for Erase. 1 A256K Address Space Block is selected for Erase.

32.3.2.9 Address register (ADR)

The address register provides the first failing address in the event of module failures (ECC, RWW or FPEC) or the first address at which ECC single error correction occurs. ADR captures the first failing address for the modes listed in *Table 397* according to the priority rules in *Table 398*.

Table 397. ADR update mode list

Mode	Update on error	Note
Read	ECC Double Error, ECC Single Error (if UT0.SBCE=1)	—
Modify	FPEC error	—

Table 397. ADR update mode list

Mode	Update on error	Note
RWW	ECC Double Error, RWW error, FPEC error, ECC Single Error (if UT0.SBCE=1)	—
User Test	ECC Double Error, ECC Single Error (if UT0.SBCE=1)	With Break Point enabled (UT0.AIBPE=1), ADR requires MCR.ERR and MCR.SBC to be cleared

In case of Array Integrity Check or Margin Read with Break Point enabled (UT0.AIBPE=1), the ADR value matches the address where the Break Point was triggered only when the current run (first start or re-start after a breakpoint (NAIBP cleared)) starts with MCR.ERR and MCR.SBC flags cleared, otherwise the ADR priority rule overrides Break Point.

Table 398. ADR content: priority list

Priority level	Error flag	ADR content
1	MCR.EER = 1	Address of first ECC Double Error
2	MCR.RWE = 1	Address of first RWW Error
3	MCR.PEG = 0	Address of first FPEC Error
4	MCR.SBC = 1	Address of first ECC Single Error Correction

Figure 301. Address register (ADR)

Table 399. ADR field descriptions

Field	Description
0 SAD	Test Address When this bit is high, the address indicated by ADDR[23:3] belongs to the Test Block.
8:28 ADDR	Address 23-3 The Address Register provides the first failing address in the event of ECC error (MCR.EER set) or the first failing address in the event of RWW error (MCR.RWE set), or the address of a failure that may have occurred in a FPEC operation (MCR.PEG cleared). The Address Register also provides the first address at which a ECC single error correction occurs (MCR.EDC set) if the SoC is configured to show this feature through UT0.SBCE. The ECC double error detection takes the highest priority, followed by the RWW error, the FPEC error and the ECC single error correction. When accessed, ADR provides the address related to the first event occurred with the highest priority. This address is always a doubleword address that selects 64 bits. In case of a simultaneous ECC Double Error Detection on more than one doubleword of the same page, bits ADDR[4] and ADDR[3] output '0'. The same is valid for a simultaneous ECC Single Error Correction on more than one doubleword of the same page. In User mode the Address Register is read only. Address given is in Flash format and has to be intended as in the Flash memory Map: offset respect to absolute address (See *Table 400: Flash memory partition 0 addresses mapping*, *Table 401: Flash memory Partition 1 addresses mapping*).

Table 400. Flash memory partition 0 addresses mapping

32.3.2.10 User Test 0 register (UT0)

The User Test 0 register feature gives the user of the Flash memory module the ability to perform test features on the Flash.

The User Test 0 register allows control of the way the Flash content check is performed. Bits MRE, MRV and AIS of the User Test 0 register are not accessible when MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

Address: 0x0054 Access: User Read/Write

Figure 302. User Test 0 register (UT0)

Table 402. UT0 field descriptions

Field	Description
0 UTE	User Test Enable This status bit gives indication when User Test is enabled. All bits in UT0 and UM0–UM9 are locked when this bit is ‘0’. This bit is not writable to a ‘1’, but may be cleared. The reset value is ‘0’. To set UTE, write the password 0xF9F99999 to the UT0 register. The UTE password is only accepted if PGM=0 and ERS=0 (Program and Erase are not being requested). UTE can only be cleared if AID=1, MRE=0 and AIE=0. While clearing UTE, writes to set AIE or MRE are ignored.
1 SBCE	Single Bit Correction Enable This bit, when high, enables to flag the information about any eventual ECC Single Bit Correction in the Flash array (MCR.SBC and ADR). This is true in read mode and in Array Integrity Check. SBCE is also used as an Enable for interrupt signals created by the embedded Flash memory. ECC corrections that occur when SBCE is cleared are not logged.
13 CPR	Customer Programmable Read Voltage and Reference Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set and the Customer Programmable Detection location in UTEST is read, a Read Voltage and Reference Error detection is set. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled.
14 CPA	Customer Programmable Address Encode Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read an Address Encode Error detection is set. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read a EDC after ECC Error detection is set. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
22 NAIBP	Next Array Integrity Break Point If AIBPE is set, NAIBP is set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to ‘1’ but may be cleared to ‘0’. Clearing NAIBP to ‘0’ enables the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID is set with NAIBP remaining ‘0’. 0 Array Integrity is not currently at a break point. 1 Array Integrity is at a break point.
23 AIBPE	Array Integrity Break Point Enable. To enable breakpoints during an Array Integrity test, AIBPE may be set. When breakpoints are enabled, if the run has been started with MCR.ERR (and MCR.SBC when UT0.SBCE=1) flag cleared, on the eventual occurrence of a breakpoint condition, MCR flags and ADR value may be updated. See NAIBP description for more information about Array Integrity breakpoints. 0 Array Integrity breakpoints are not enabled. 1 Array Integrity breakpoints are enabled during Array Integrity Checks.

Table 402. UT0 field descriptions (continued)

Field	Description
25 AISUS	Array Integrity Suspend. AISUS toggles Suspend of an Array Integrity - Margin Read operation. AISUS can be written to ‘1’ only when AID is low AISUS can be written to ‘0’ only when AID is high. Attempting to Write AISUS and AIE on the same clock cycle results in only AIE being written. 0 Array Integrity sequence not suspended. 1 Array Integrity sequence is suspended.
26 MRE	Margin Read Enable MRE enables Margin Reads to be done. MRE combined with MRV enables User Margin Reads to be done. Margin Reads run on a block-by-block basis in linear address sequence selected by SEL0, SEL1 and SEL2. This bit is not accessible when MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Margin Read is not enabled. 1 Margin Read is enabled.
27 MRV	Margin Read Value If MRE is high, MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). This bit is not accessible whenever MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Zero’s (programmed) Margin Reads are requested (if MRE=1). 1 One’s (erased) Margin Reads are requested (if MRE=1).
29 AIS	Array Integrity Sequence AIS determines the address sequence to be used during Array Integrity checks. The default AIS=0 checks the read propagation paths along proprietary sequences followed by user code. The sequential run sequence time is significantly shorter than the proprietary sequence. AIS is not writable if AIE is high. This bit is not accessible whenever MCR.DONE or UT0.AID are low: reading returns indeterminate data while writing has no effect. 0 Array Integrity sequence is proprietary sequence. 1 Array Integrity sequence is sequential.

Table 402. UT0 field descriptions (continued)

Field	Description
30 AIE	Array Integrity Enable Setting AIE to ‘1’ starts the Array Integrity Check and the Margin Read on all selected blocks. The sequence is selected by AIS and the MISR (UM0–UM9) is checked on completion to determine if a correct signature is obtained. AIE can be set only if MCR.ERS, MCR.PGM and MCR.EHV are all low. AIE is not simultaneously writable to ‘1’ while UTE is being cleared to ‘0’. Clearing AIE terminates the check when an Array Integrity operation finishes (AID=1) and aborts the check when and Array Integrity operation is ongoing (AID=0). AIE remains ‘1’ when the Array Integrity Check - Margin Read are suspended or are in breakpoint and cannot be cleared. (AIE can be cleared if NAIBP=0 and AISU=0) 0 Array Integrity Check and Margin Read are not enabled. 1 Array Integrity Check and Margin Read are enabled.
31 AID	Array Integrity Done AID is set to indicate that the Array Integrity Check - Margin Read is complete and the MISR (UM0–9) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set) and the breakpoint condition is met. AID may also assert if Suspend is set (AISUS 0–1). AID can not be written, and is status only. 0 Array Integrity Check is ongoing. 1 Array Integrity Check is done.

32.3.2.11 User Multiple Input Signature registers

The Multiple Input Signature registers allow evaluation of the Array Integrity or Margin Read run on a block-by-block basis by accumulating signatures from data bit fields.

These registers are not accessible whenever MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

The registers can be written in order to seed signatures before starting an AIC or MR operation.

Note: Do not write to the MISR registers during an Array Integrity operation (including Suspend or Breakpoint) as it may alter the final signature in an unpredictable way.

If reads extend into an invalid address location during address sequencing (such as greater than the maximum address for a given array size), reads are still executed to the array but the results are not deterministic: MISR registers are not recalculated and the previous value is retained.

32.3.2.11.1 User Multiple Input Signature 0 register (UM0)

UM0 represents bits 31–0 of the whole 288-bit word (4 doublewords including ECC).

Address: 0x0058 Access: User Read/Write

Figure 316. Test Mode Disable Password Check register (TMD)

Table 416. TDM field descriptions

Field	Description
0:31 PWD	The Test Mode Disable Check register is used as a location to provide a password challenge to unlock blocks selected to be sealed as part of the Test Mode Disable seal mechanism. Please see *Section 32.4.6.2: Test mode disable* for more information. Writes to the register have no effect except for a password challenge. Reads to this register will always return 0. The register's reset value is 0. **Note:** PWD bitfield is byte-reversed compared to UTEST TMD password : for instance, if UTEST TMD password is written 0x01020304, the PWD bitfield must be written 0x04030201

32.4 Functional description

This chapter describes the details of all the modes of operation available to the Flash memory module.

32.4.1 Reset

A reset is the highest priority operation for the Flash memory module and terminates all other operations.

The Flash memory module uses reset to initialize register and status bits to their default reset values. If the Flash memory module is executing a Program or Erase operation (MCR.PGM=1 or MCR.ERS=1) and a reset is issued, the operation is immediately terminated and the module disables the high voltage logic without damage to the high voltage circuits. Reset terminates all operations and forces the Flash memory module into Read mode ready to receive Read/Write accesses.

Reset and power-off must not be used as a systematic way to terminate a Program or Erase operation.

After reset is negated read register access may be performed, although registers that require updating from shadow information or other inputs may not read updated values until MCR.DONE transforms. MCR.DONE may be polled to determine if the Flash memory module has transitioned out of reset. Note that the registers cannot be written until MCR.DONE is high.

32.4.2 Power-down mode (Disable mode)

The power-down (or Disable) mode allows the turning-off of all Flash DC current sources. All power dissipation in this mode is due solely to leakage.

In power-down mode no Read from or Write to the Flash array is possible. Every Flash array Read access executed when the power-down mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the power-down mode is exited. On the contrary, write access is locked on all the registers in power-down mode.

When enabled the Flash memory module returns to its pre-disable state in all cases unless in the process of executing an Erase or a Program high voltage operation at the time of disable. If the Flash memory module is disabled during an Erase operation, the operation is

suspended and MCR.ESUS bits are set to ‘1’. The user may resume the Erase operation at the time the module is enabled by clearing MCR.ESUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash memory module is disabled during a Program operation, the operation is suspended and MCR.PSUS bit is set to ‘1’. The user may resume the Program operation at the time the module is enabled by clearing MCR.PSUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash memory module is disabled during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled PSUS must be cleared first to resume the program. Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

If the Flash memory module is put in power-down mode and the vector table remains mapped in the Flash address space, the user must be mindful that the Flash memory module significantly increases the interrupt response time by adding several Wait states.

Note: Do not enter low-power mode when the power-down mode is active.

32.4.3 Low-power mode (Sleep mode)

The low-power (or Sleep) mode turns off most of the DC current sources within the Flash memory module. Wake-up time from low-power mode is faster than wake-up time from power-down mode.

In low-power mode no Read from or Write to the Flash array is possible. Every Read access executed when the low-power mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the low-power mode is exited. Write access is locked on all the registers in low-power mode.

When exiting from low-power mode the Flash memory module returns to its pre-sleep state in all cases unless in the process of executing an Erase high voltage operation at the time of entering sleep mode. If the Flash memory module is put in sleep mode during an Erase operation, MCR.ESUS is set to ‘1’. The user may resume the Erase operation at the time the module exits from sleep by clearing MCR.ESUS. MCR.EHV must be high to resume the Erase operation.

If the Flash memory module is put in low-power mode during a Program operation, the operation is suspended and MCR.PSUS is set to ‘1’. The user may resume the Program operation at the time the module is enabled by clearing MCR.PSUS. MCR.EHV must be high to resume the Erase operation.

If the Flash memory module is put in low-power mode during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled, PSUS must first be cleared for the program to resume. The Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

Note: Do not enter power-down mode when the low-power mode is active.

32.4.4 Read mode

Read mode is the active mode of operation of the Flash memory module in which the Flash array can be read or ‘written’ (the so-called Interlock Write), or the Flash registers can be read or written.

The Flash memory module enters Read mode when exiting from reset. The default state of the Flash memory module is Read mode.

The main spaces (Low, Mid, High, and 256K) and Test address space of Flash array can only be read in Read mode.

Flash registers can even be read when the module is in power-down or low-power mode (except a few documented registers) as well as in Read mode. However, Flash registers can only be written while in Read mode.

Flash memory module is in Read mode, granting the same access time, under the following conditions:

- The Read state is active when the module is enabled (user mode Read)
- The Read state is active when MCR.ERS and MCR.ESUS are high and MCR.PGM is low (Erase Suspend)
- The Read state is active when MCR.PGM and MCR.PSUS are high (Program Suspend)
- The Read state is active when MCR.PGM or MCR.ERS are high and high voltage operation is ongoing on one partition, thus MCR.EHV is high (condition referred as Read-While-Write). In this case Reads done on the other partitions are allowed, while Reads done to the partition being operated on (either Erase or Program) result in an error with MCR.RWE set and the data read back possibly being random including the possibility of ECC errors.

Code Flash partitions Reads return 256 (1 page = 4 doublewords).
Data Flash partition Reads return 128 bits.
Register Reads return 32 bits (1 word).

Flash array Reads are performed through the Bus Interface Unit. In many cases the BIU applies “Read Page Buffering” to allow sequential reads to be executed with higher performance. This can provide data coherency issues that must be handled by software. Data coherency may be an issue after a Program or an Erase operation, as well as Test block operations.

Flash array Reads to invalid locations result in indeterminate data. Invalid locations occur when addressing points to blocks that are not included in the Flash memory map of any partition. Interlock Writes to invalid locations result in an interlock occurring, but attempts to program these blocks do not eventuate since they are forced into a locked state. Erase occurs to selected and unlocked blocks even if the Interlock Write is to an invalid location.

Register Reads to unmapped register address spaces return all 0’s. Registers Writes to unmapped register address spaces have no effect.

Simultaneous Read cycles on the Flash array and Read/Write cycles on the registers are possible, but not simultaneous register Read/Write accesses with Flash Array Interlock Writes are forbidden.

32.4.4.1 Error correction code

The Flash memory module implements a strategy for improving the reliability of the data stored in Flash via the use of Error Correction Code. The word size is fixed to 64 bits.

For each doubleword of 64 bits, 8 ECC bits are associated and programmed in such a way as to guarantee Single Error Correction and Double Error Detection (SEC-DED). ECC coding has all 0's (intended as data and parity) as an invalid word and all 1's as a valid word.

In addition to providing the requested Read data, the Flash also provides output sidebands reflecting the status of the single bit corrections and double bit detections performed at the end of each Read.

For functional safety coverage, Flash performs an EDC post ECC operation at every Read to detect mismatches in the ECC logic detection and correction. The result is output as sideband. Also active is a monitor circuit that checks the reference current in the sense amplifiers, including control of the internally regulated Read voltage, to prevent anomalous Read operation.

ECC circuitry provides single-bit fault correction used to achieve automotive reliability targets. Some units experience single-bit corrections throughout the life of the product with no impact on product reliability.

32.4.4.1.1 EEPROM emulation

The chosen ECC algorithm allows some bit manipulation so that a doubleword can be rewritten several times without needing an erase of the block. This allows the use of a doubleword to store flags useful for the EEPROM emulation.

As an example, the chosen ECC algorithm allows starting from an all 1's doubleword value and rewriting whichever of its four 16-bit halfwords to all 0's content by keeping the same ECC value.

Table 417 shows a set of doublewords sharing the same ECC value:

Table 417. Bits Manipulation: doublewords with the same ECC value

Doubleword	ECC parity bits
0xFFFF_FFFF_FFFF_FFFF	0xFF
0xFFFF_FFFF_FFFF_0000	0xFF
0xFFFF_FFFF_0000_FFFF	0xFF
0xFFFF_0000_FFFF_FFFF	0xFF
0x0000_FFFF_FFFF_FFFF	0xFF
0xFFFF_FFFF_0000_0000	0xFF
0xFFFF_0000_FFFF_0000	0xFF
0x0000_FFFF_FFFF_0000	0xFF
0xFFFF_0000_0000_FFFF	0xFF
0x0000_FFFF_0000_FFFF	0xFF
0x0000_0000_FFFF_FFFF	0xFF

Table 417. Bits Manipulation: doublewords with the same ECC value (continued)

Doubleword	ECC parity bits
0xFFFF_0000_0000_0000	0xFF
0x0000_FFFF_0000_0000	0xFF
0x0000_0000_0000_0000	0xFF

Note: When some Flash blocks are used for EEPROM emulation, reserve at least three blocks for this purpose.

32.4.4.2 Flash address generation check

For functional safety coverage, Flash provides output sidebands reflecting the re-encoded address used to perform the actual Read operation. In the re-encoding process both wordline and column within the selected block are evaluated. For the completion of the re-encoding operation, the addresses related to block selections are also computed. Re-encoding circuitry is able to detect both no-selection as well as multi-selection. Flash provides a self-check of address consistency comparing at each Read the sampling of the current Read address with the re-encoded one, and in case of mismatch an error sideband is set.

32.4.5 Modify mode

All the Modify operations of the Flash memory module are managed through the Flash User Registers interface.

When a Modify operation is active on some blocks, no Read access is possible on any other block of the same Flash partition. The Read-While-Modify is supported only among different Flash partitions.

During a Flash Modify operation any attempt to read any Flash location in the same Flash partition outputs invalid data and MCR.RWE is automatically set.

If a reset occurs during a Modify operation, the operation is immediately terminated and the module is reset to Read mode. The data integrity of the Flash section where the Modify operation was terminated is not guaranteed: the interrupted Flash Modify operation must be repeated.

In general each Modify operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in MCR.PGM or MCR.ERS or UT0.MRE.
2. The second step is the definition of the operands: the address and the data for programming, or the blocks for Array Integrity Check or Margin Read.
3. The third instruction is used to start the Modify operation by setting MCR.EHV or UT0.AIE.

Once selected, but not yet initiated, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Modify operations are shown in *Table 418*.

Table 418. Flash Modify operations

Operation	Select bit	Operands	Start bit
Doubleword Program	MCR.PGM	Address and Data by Interlock Writes	MCR.EHV
Block Erase	MCR.ERS	SEL0, SEL1 and SEL2	MCR.EHV
Array Integrity Check	None	SEL0, SEL1 and SEL2	UT0.AIE
Margin Read	UT0.MRE	UT0.MRV + SEL0, SEL1 and SEL2	UT0.AIE

Once MCR.EHV (or UT0.AIE) is set, all the operands can no longer be modified until MCR.DONE (or UT0.AID) is high.

In general each Modify operation is completed through a sequence of 4 steps:

1. Wait for operation completion: wait for MCR.DONE (or UT0.AID) to go high.
2. Check operation result: check bit MCR.PEG (or compare UM0–UM9 with expected value).
3. Switch-off FPEC by resetting MCR.EHV (or UT0.AIE).
4. Deselect current operation by clearing MCR.PGM/ERS (or UT0.MRE).

Note: Do not initiate a Modify operation on a Flash memory module while another Modify operation is in progress on a separate module.

In the following sections, all the possible Modify operations are described with accompanying examples of the sequences needed to activate them.

32.4.5.1 Program

A Flash Program sequence operates on any doubleword within the Flash core. Up to two words within the doubleword may be altered in a single doubleword Program operation. A single Program operation can also alter one page (4 doublewords, 32 bytes), or 4 pages max (128 bytes in total). It is possible to program only certain doublewords in the page or the quad-page, leaving the others with their original content. Whenever the array is programmed, the ECC bits are also programmed.

ECC is handled on a 64-bit boundary. Whenever you program, ECC bits are also programmed. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. All programming operations should be from 64 bits to 1024 bits, and should be 64-bit aligned. The programming operation should completely fill selected ECC segments within the doubleword. Over programming of a 64-bit ECC segment may be done only in case of EEPROM emulation byte zeroing.

Due to the fact that Flash is supposed to function in an SoC with an end2end ECC scheme, ECC parity bit are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, the page program or the quad-page program contains an inconsistency between data and parity, the whole operation is rejected and a MCR.PEG=0 is set. The doublewords without data and with parity inconsistency are thus not programmed.

Programming changes the value stored in an array bit from logic ‘1’ to logic ‘0’ only. Programming cannot change a stored logic ‘0’ to a logic ‘1’. If a logic ‘0’ is attempted to be

over programmed by a logic ‘1’, the resulting operation fails (MCR.PEG=0), and the 0s that are interlocked are merged (ORed) with 0s that are already present in the 64-bit ECC segment. Extreme care has to be taken when doing such an operation due to the high risk of producing ECC errors.

Addresses in locked blocks cannot be programmed. Register locked blocks cannot be programmed. Hardware locking is also available which only affects the Program operation. Hardware locking is enabled by sideband signals, and if enabled, programs are prevented from accessing hardware locked blocks in the same way as program software locking.

The user may program the values in any or all of eight the words in a page with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. Only certain doublewords may be programmed within the page or the quad-page, without altering the content of the ones unselected via interlock.

The Program operation consists of the following sequence of events:

1. Change the value of MCR.PGM from ‘0’ to ‘1’.
2. Ensure the block that contains the address to be programmed is unlocked. Write the first address to be programmed with the program data. The Flash memory module latches address bits (23:7) at this time, as well as written data. This Write is referred to as a Program Data Interlock Write. An Interlock Write may be as large as 64 bits, and as small as 32 bits (depending on the CPU bus).
3. If more than 1 word is to be programmed, write the additional address in the doubleword with data to be programmed. This is referred to as a Program Data Write. The Flash memory modules ignore address bits (23:7) for Program Data Writes. The eventual unwritten data word defaults to 0xFFFFFFFF.
4. Write a logic ‘1’ to the MCR.EHV to start the internal program sequence or terminate via step 9.
5. Wait until the MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to the MCR.EHV.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic ‘0’ to the MCR.PGM to terminate the Program operation.

Programs may be initiated with the 0–1 transition of MCR.PGM or by clearing MCR.EHV at the end of a previous program. The first Write after a program is initiated determines the page address to be programmed. This first Write is referred to as an Interlock Write. The Interlock Write determines if the UTEST or normal array space will be programmed via MCR.PEAS.

In the case of an erase-suspended program, the values in MCR.PEAS may be modified via the Program Interlock Write, enabling erase-suspended programs to UTEST nonvolatile memory space and revert back to their original state (related to erase-suspended operation) once the erase-suspended program is completed.

An Interlock Write must be performed before setting MCR.EHV. An Interlock Write performed after setting MCR.EHV is forbidden and data and address passed through interlock is lost.The user may terminate a program sequence by clearing MCR.PGM prior to setting MCR.EHV.

After the Interlock Write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024 bit

segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are performed on the same location, the data for the last Write is used in programming.

While MCR.DONE is low and MCR.EHV is high, the user may clear EHV, resulting in a Program Abort.

A Program Abort forces the module to step 8 of the program sequence.

An aborted program results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The data space being operated on before the Abort contains indeterminate data. This may be recovered by repeating the same program instruction or executing an Erase of the affected blocks.

The user may not abort a program sequence while in Program Suspend.

Figure 317. Doubleword program of data 0x55AA_55AA at address 0x00_AAA8 and data 0xAA55_AA55 at address 0x00_AAAC

```
MCR = 0x0000_0010;           /* Set PGM in MCR: Select Operation */
(0x00_AAA8) = 0x55AA_55AA;   /* Latch Address and 32 LSB data */
(0x00_AAAC) = 0xAA55_AA55;   /* Latch 32 MSB data */
MCR = 0x0000_0011;           /* Set EHV in MCR: Operation Start */
do                           /* Loop to wait for DONE=1 */
{ tmp = MCR;                 /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;  /* Check PEG flag */
MCR = 0x0000_0010;           /* Reset EHV in MCR: Operation End */
MCR = 0x0000_0000;           /* Reset PGM: Deselect Operation */
```

32.4.5.2 Program Suspend/Resume

The program sequence may be suspended to allow Read access to the Flash array. It is not possible to program or to erase during a Program Suspend. Read-While-Write operations may also be used to read the array during a program sequence providing the Read is to a different partition.

During Program Suspend, all reads to the doubleword targeted for program return indeterminate data.

A Program Suspend can be initiated by changing the value of MCR.PSUS from ‘0’ to ‘1’. MCR.PSUS can be set to ‘1’ at any time when MCR.PGM and MCR.EHV are high and MCR.ERS is low. 0–1 transition of MCR.PSUS causes the module to start the sequence which places it in Program Suspend.

It is possible to suspend a program performed during an Erase Suspend. The user must wait until MCR.DONE=1 before the module is suspended and further actions are attempted. MCR.DONE takes no more time than t_{PSUS} to go high after MCR.PSUS is set to ‘1’.

Once suspended, the array may be read. Flash memory reads while MCR.PSUS=1 from the doubleword being programmed return indeterminate data.

Figure 318. Doubleword Program Suspend

```
MCR = 0x0000_0019; /* Set PSUS in MCR: Program Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.PGM in order to perform reads during Program Suspend.

The program sequence is resumed by writing a logic ‘0’ to MCR.PSUS.

MCR.EHV must be set to ‘1’ before MCR.PSUS can be cleared to resume the operation.

The module continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

Figure 319. Doubleword Program Resume

```
MCR = 0x0000_0011;/* Reset PSUS in MCR: Program Resume */
```

Repeated Suspends at a high frequency may result in the operation timing out, and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Program Suspends to ensure this does not occur is t_{PSRT}.

32.4.5.3 Over programming protection (OPP) enable

Over programming protection can be enabled on a block-by-block basis. In an OPP enabled block, any doubleword which has already been programmed cannot be programmed again. The OPP enable does not affect the Erase operation. It is possible to independently set OPP and (hardware) erase protection in order to avoid any kind of overwrite. Using these protection mechanisms in conjunction with the Test mode disable feature gives even greater overwrite protection. Attempts to over-program result in MCR.PEG being cleared.

OPP can be enabled for 16 KB, 32 KB, 64 KB and 256 KB blocks.

OPP is enabled by sideband signals and, if enabled, the Program operation is modified to check for programmed bits prior to undertaking a high voltage program event.

32.4.5.4 Successful program address

To enable the SoC to create logic to authenticate operations with a program (like in a diary operation), the Flash memory module provides the last successful address programmed as a sideband signal. This value is held until the next successful program. A successful program is defined as a program operation of data that is not all 1s, to an unlocked block and the operation results in MCR.PEG returning a ‘1’. An all 1’s value is the default (and invalid) address after reset.

In case of page programming, the last successful address returned is the beginning of the page itself regardless of whether that specific address has not been passed through interlock. In case of quad-page programming, the last successful address returned is the beginning of the quad-page itself regardless of whether that specific address has not been passed through interlock.

32.4.5.5 Erase

Erase changes the value stored in all bits of the selected block(s) to logic ‘1’. An Erase sequence operates on any combination of blocks in the low, mid, high or 256K address space. The Test block cannot be erased.

The Erase sequence is fully automated within the Flash. The user only needs to select the blocks to be erased and initiate the Erase sequence.

Register locked blocks cannot be erased. Hardware locking, which only affects the Erase operation is also available. Hardware locking is enabled by sideband signals and, if enabled, erases are prohibited on hardware locked blocks in the same way as erase software locking. If multiple blocks are selected for erase during an Erase sequence, no specific operation order can be assumed.

The Erase operation consists of the following sequence of events:

1. Change the value in the MCR.ERS bit from ‘0’ to ‘1’.
2. Select the block(s) to be erased by writing 1’s to the appropriate register(s) in SEL0, SEL1 and SEL2 registers. Note that Lock and Select are independent. If a block is selected and locked, no erase occurs.
3. Write to any address in Flash. This is referred to as an Erase Interlock Write.
4. Write a logic ‘1’ to MCR.EHV to start the internal Erase sequence or skip to step 9 to terminate.
5. Wait until MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to MCR.EHV.
8. If more blocks are to be erased, return to step 2.
9. Write a logic ‘0’ to the MCR.ERS bit to terminate the Erase operation.

After setting MCR.ERS, one Write (referred to as an Interlock Write) must be performed before MCR.EHV can be set to ‘1’.

Data words written during Erase sequence Interlock Writes are ignored. As Flash is supposed to function in an SoC with an end2end ECC scheme, ECC parity bits are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC even if the value of the data is not meaningful for the Erase operation. If an inconsistency between data and parity is found, the whole operation is rejected and MCR.PEG=0 is set.

The user may terminate the Erase sequence by clearing ERS before setting EHV.

An Erase operation may be aborted by clearing MCR.EHV assuming MCR.DONE is low, MCR.EHV is high and MCR.ESUS is low. An Erase Abort forces the module to step 8 of the Erase sequence. An aborted Erase results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The block(s) being operated on before the Abort contain indeterminate data. This may be recovered by executing an Erase on the affected blocks. The user may not abort an Erase sequence while in Erase Suspend.

Figure 320. Erase of blocks B0F1 and B0F2

```
MCR = 0x0000_0004;            /* Set ERS in MCR: Select Operation */
SEL0 = 0x0006_0000;           /* Set LSL2-1 in SEL0: Select Blocks */
(0x00_0000) = 0xFFFF_FFFF;    /* Latch a Flash Address */
MCR = 0x0000_0005;            /* Set EHV in MCR: Operation Start */
do                            /* Loop to wait for DONE=1 */
{ tmp = MCR;                  /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;   /* Check PEG flag */
MCR = 0x0000_0004;            /* Reset EHV in MCR: Operation End */
MCR = 0x0000_0000;            /* Reset ERS: Deselect Operation */
```

32.4.5.5.1 Erase Suspend/Resume

The Erase sequence may be suspended to allow Read access to the Flash array. It is possible to program another block in any Flash memory module during Erase Suspend. Programming a location subject to suspended Erase results in the program not being executed and PEG being set to 0.

It is not possible to erase any block during an Erase Suspend.

During Erase Suspend, all Reads to blocks targeted for erase return indeterminate data.

An Erase Suspend can be initiated by changing the value of MCR.ESUS from ‘0’ to ‘1’. MCR.ESUS can be set to 1 at any time when MCR.ERS and MCR.EHV are high and MCR.PGM is low. A 0–1 transition of MCR.ESUS causes the module to start the sequence which places it in Erase Suspend. The user must wait until MCR.DONE=1 before the module is suspended and further actions are attempted.

MCR.DONE takes no longer than t_{ESUS} to go high after MCR.ESUS is set to ‘1’.

Once suspended, it is not possible to alter the content of SEL0, SEL1 and SEL2 registers. Once suspended, the array may be read. Flash memory Reads while MCR.ESUS=1 from the block(s) being erased return indeterminate data.

Figure 321. Block Erase Suspend

```
MCR = 0x0000_0007; /* Set ESUS in MCR: Erase Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.ERS in order to perform Reads during Erase Suspend.

The Erase sequence is resumed by writing a logic ‘0’ to MCR.ESUS.

MCR.EHV must be set to ‘1’ before MCR.ESUS can be cleared to resume the operation. The module continues the Erase sequence from one of a set of predefined points and this may extend the time required for the Erase operation.

Figure 322. Block Erase Resume

```
MCR= 0x0000_0005;/* Reset ESUS in MCR: Erase Resume */
```

Repeated Suspends at a high frequency may result in the operation timing out and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Erase Suspends to ensure this does not occur is t_{ESRT}.

32.4.5.5.2 Factory Erase

The Factory Erase feature can be used only once through a diary location mechanism. If location UTEST at offset +0x0020 was virgin at the moment of the reset, MCR.FERS can be set, after rising MCR.ERS and before MCR.EHV. After setting MCR.EHV the FPEC recognizes the value of FERS and checks if the diary location has been programmed by the user (having changed from being virgin at reset). Under those conditions a Factory Erase can commence and no Read-While-Write is allowed (all the f90_busy sideband signals are set high).

32.4.5.6 User Test mode

Customers can put the Flash memory module in User Test mode to perform specific tests for the integrity of the Flash array.

Two kinds of test can be performed:

- Array Integrity Self Check
- Margin Read

User Test mode is an exclusive operation: it cannot be run in conjunction with any other Flash mode (Read, Write, low-power and power-down), and Read-While-Write functionality is inapplicable. Read accesses attempted by the user during User Test mode generates a Read-While-Write error (RWE of MCR set).

It is not permitted to perform User Test operations on the Test blocks (including the UTEST section).

32.4.5.6.1 Array Integrity Self Check

Array Integrity is checked using a predefined address sequence (proprietary), and this operation is executed on selected (SEL0, SEL1 and SEL2) blocks. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Any random or non-random code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value (stored in UM0–UM9), to determine if an incorrect Read, or ECC detection was noted. Array Integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the frequency being used.

The internal MISR calculator is a 64 + 8 + 1-bit register.

The 256-bit data, the respective ECC parity data, and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location.

The whole check is done through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction and the double error flag is set after any ECC detection. Single-bit correction is always active and logging may be enabled (UT0.SBCE), resulting in the MCR.SBC flag and related address to be captured in ADR register, but this does not change the final signature in the UM0–UM9.

Only data from existing locations are captured by the MISR. The MISR can be seeded to any value by writing the UM0–UM9 registers.

The Array Integrity Self Check consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1 and/or SEL2 registers. Blocks selected for Array Integrity Check do not need to be unlocked. It is not possible to perform Array Integrity operations on the UTEST nonvolatile memory block.
3. If desired, UT0.AIS can be set for sequential addressing only.
4. Seed the MISR UM0–UM9 with desired values.
5. If breakpoints are desired, set UT0.AIBPE to '1', and ensure that MCR.EER and MCR.SBC are cleared. If breaking on single-bit correction is required, ensure that UT0.SBCE is set.
6. Write a logic '1' to UT0.AIE to start the Array Integrity Check. Array Integrity operations may be aborted prior to UT0.AID going high. This may be done by clearing UT0.AIE. It should be noted that in the event of an aborted Array Integrity check, the MISR registers contain a signature for the portion of the operation that was completed prior to the Abort, and is not definitive. Prior to performing further Array Integrity operations, the UM0–UM9 registers may require initialization to the desired seed value by performing register writes. Array Integrity operations may be suspended while UT0.AID is low. UT0.AISUS may be set to request an Array Integrity Suspend. Once UT0.AID has been set high, UT0.AISUS may be cleared to resume the Array Integrity sequence.
7. Wait until UT0.AID goes high.
8. Check that UT0.NAIBP is set to '1' if breakpoints were previously enabled so that the MCR.EER, MCR.SBC and ADR registers may be checked to determine the cause and address of the break. Prior to resuming the operation, it necessary to clear MCR.SBC or MCR.EER in order to preserve coherency of MCR.SBC, MCR.EER and ADR updates with respect to any subsequent breakpoints. Operation may then be resumed by clearing UT0.NAIBP. Continue waiting until the UT0.AID bit goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
9. Compare UM0–UM9 content with the expected result.
10. Write a logic '0' to the UT0.AIE bit.

Use sequential addressing for normal integrity checks of the Flash memory. If a more detailed check of the Read path is required (in diagnostic mode), leave UT0.AIS at '0' and use the proprietary address sequence that checks the Read path more completely, however this sequence takes more time.

Caution: Do not modify the content of Block Select (SEL0, SEL1 and SEL2) and Lock (LOCK0, LOCK1 and LOCK2) registers during execution of the Array Integrity Check operation or the MISR value may vary unpredictably.

User mode array Reads requested during the Array Integrity test are ignored to ensure that the Array Integrity operation is not corrupted. The memory array does not respond to array

Read requests during this time. User mode array Reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may clear AIE, resulting in an Array Integrity Check Abort. UT0.AID must be checked to know when the aborting command has completed.

Array Integrity Check can be suspended by setting UT0.AISUS while Array Integrity Check is running (UT0.AID=0). Once suspended (UT0.AID=1) Array Integrity Check cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 323. Array Integrity Check of blocks B0F1 and B0F2

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set LSL2-1 in SEL0: Select Blocks */
SEL2 = 0x0000_0006;  /* Set A256KSL2-1 in SEL2: Select Blocks */
UT0 = 0x8000_0002;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9 = UM0/9;     /* Read UM0/9 content*/
UT0 = 0x0000_0000;   /* Reset UTE, AIE: Operation End */
```

32.4.5.6.2 Margin Read

User Margin Read may be achieved using the Array Integrity interface and has all the associated features of the Array Integrity interface (MISR calculation, suspend capability and Breakpoints).

Margin Read procedure (either Margin 0 or Margin 1) can be run on selected blocks in order to unbalance the Sense Amplifiers with respect to standard Read conditions, so that all the Read accesses reduce the margin vs ‘0’ (UT0.MRV=0) or vs ‘1’ (UT0.MRV=1).

User Margin Read is a self timed event and is independent of system clocks or wait states selected. Margin Read can be run on selected (SEL0, SEL1 and SEL2) blocks, generating checksum calculations on MISR and ECC flagging. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Once the operations are completed, the results of the Margin Reads can be checked, comparing checksum values in UM0–UM9 and reading MCR.EER and MCR.SBC to determine if zero, one or two bits are being detected by the Margin Read.

The MISR can be seeded to any value by writing the UM0–UM9 registers.

As with Array Integrity Check, the internal MISR calculator is a 64 + 8 + 1-bit register. The 256-bit data, the corresponding ECC parity data and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location. The whole check is accomplished through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction, and the double error flags are set after any ECC detection. Single-bit logging is always enabled regardless of the value of UT0.SBCE, resulting in the MCR.SBC flag and related address to be captured in ADR register, but this does not alter the final signature in the UM0–UM9.

In any case, the charge losses detected through the Margin Read cannot be considered device failures and no Failure Analysis is initiated on them.

The Margin Read setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1 and SEL2 registers. Blocks selected for Margin Read do not need to be unlocked. It is not possible to do Margin Read operations on the UTEST nonvolatile memory block.
3. Seed the MISR UM0–UM9 with desired values.
4. Ensure that MCR.EER and MCR.SBC are cleared.
5. Set UT0.SBCE to '1' to detect single bits during Margin Read.
6. Change the value of UT0.MRE from '0' to '1'.
7. Select the Margin level: UT0.MRV=0 for 0's margin, UT0.MRV=1 for 1's margin.
8. Write a logic '1' to UT0.AIE to start the Margin Read.
9. Wait until UT0.AID goes high.
10. Check that UT0.NAIBP is set to '1' if breakpoints were previously enabled so that MCR.EER, MCR.SBC and ADR.ADDR may be checked to determine the cause and address of the break. Prior to resuming operation, clear MCR.SBC or MCR.EER. Operation may then be resumed by clearing UT0.NAIBP. Continue to wait until UT0.AID goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
11. Compare UM0–UM9 content with the expected results.
12. Check MCR.EER and MCR.SBC.
13. Write a logic '0' to UT0.AIE, UT0.MRE and UT0.MRV.
14. If more blocks are to be checked, return to step 2.

The linear address sequence is used regardless of the value of UT0.AIS.

Caution: Do not modify the content of Block Select (SEL0, SEL1 and SEL2) and Lock (LOCK0, LOCK1 and LOCK2) registers during execution of the Margin Read operation, otherwise the MISR value may vary unpredictably.

User mode array Reads requested during the Margin Read are ignored to ensure that the Margin Read operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array Reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may abort Margin Read by clearing AIE. UT0.AID must be checked to know when the aborting command has completed. Margin Read can be suspended by setting UT0.AISUS while Margin Read is running (UT0.AID=0). Once suspended (UT0.AID=1), Margin Read cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 324. Margin Read Check versus 1's

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set LSL2-1 in SEL0: Select Blocks */
UT0 = 0x8000_0020;   /* Set MRE in UT0: Select Operation */
UT0 = 0x8000_0030;   /* Set MRV: Select Margin versus 1's */
UT0 = 0x8000_0032;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9 = UM0/9;     /* Read UM0/9 content*/
UT0 = 0x8000_0030;   /* Reset AIE in UT0: Operation End */
UT0 = 0x0000_0000;   /* Reset UTE, MRE, MRV, AIS in UT0:
                        Deselect Operation */
```

32.4.6 Protection strategy

Two kinds of protection are available: Modify Protection to avoid unwanted program/erase in Flash blocks and Test Mode Disable to avoid piracy.

32.4.6.1 Modify Protection

The Flash Modify Protection information is stored in nonvolatile Flash cells located in the UTEST region. This information is read once during the Flash Initialization phase following exit from reset and is stored in volatile registers that act as actuators at SoC level. The information is passed to the Flash memory module through erase_lock and program_lock sidebands, and allows independent protection of each block of Low, Mid, High and 256K Address Space Block.

There are also Address Space Block Locking registers provided to independently lock/unlock each block of Low, Mid, High and 256K Address Space Block against program and erase. Locking is done through the LOCK0, LOCK1 and LOCK2 registers. These registers do not have a nonvolatile image stored in the UTEST area of TestFlash, so the locking information is kept on reset: volatile content is all 1's, meaning all blocks are locked.

All the volatile registers can be written to '0' or '1' at any time, therefore the user application can lock and unlock blocks when desired. Note, however, that overall protection is achieved by the combination of sidebands with Low, Mid, High and 256K Address Space Block Locking registers in such a way that a block can be programmed/erased only if both (sidebands and Locking registers) indicate an unlocked state. Sidebands independently control program protection, erase protection and over programming protection (OPP) on a block-by-block basis.

As UTEST and BAF (each one with its own lock bit, LOCK0.TSLOCK and LOCK0.LOWLOCK respectively) are two sections of the same physical block (TestFlash), effective locking is achieved via the 'AND' operand of the lock bits. For effective locking, overall protection is obtained in conjunction with sidebands: UTEST and BAF have dedicated program protection sidebands (SoC specific).

32.4.6.2 Test mode disable

In the TestFlash area a mechanism is also available to disable entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected for protection in this way cannot be analyzed for possible failures by manufacture failure analysts.

Protection of this sort prevents all high voltage operations to the Flash executed by the internal FPEC as well as reads from FPEC, including Array Integrity Check or Margin Read, when using Test mode interfaces. Protection through other interfaces is managed through normal User mode protection mechanisms, that are SoC specific.

To disable manufacturer entry into Test mode, first program the Test Mode Disable Seal location to 0x5A4B_3C2D and once the next reset is asserted, Test mode is disabled.

It is possible to create a password to enable manufacturer entry into Test mode. This can be programmed into the Test Mode Disable Override Passcode. It is safest to do this prior to censoring the part to avoid unintended lockout. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and are not accepted for override. If the customer desires that override never be possible, one of the three invalid passcodes should be put into this location. Passcodes may be entered to authenticate entry (if enabled) by performing a register Write to address 0x90.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus is it possible for customers to select blocks for this type of protection, and render them ineligible for manufacturer failure analysis. Bits programmed to ‘0’ in the Test Mode Disable Block Select field designate blocks that are controlled by Test Mode Disable feature. The TestFlash block, and thus the UTEST and BAF sections, is always protected once the Test Mode Disable Seal password is written. In order to permit two opportunities to select blocks for Test Mode disable, two regions are available: one at address 0x804010, and the other at address 0x804030; both 128-bit sized (only 80 may be effective, depending on actual sectorization). The bits of these two regions are logically ANDed in order to define which blocks are effectively selected for the Test Mode Disable feature.

The 80-bit Block Select field is organized as follows, and aligned in the way blocks are defined in the LOCK registers:

Table 419. Test Mode Disable block select

Block	Block selection bits
Blocks in Mid space	Data[15:0]
Blocks in Low space	Data[29:16]
Blocks in High space	Data[47:32]
Blocks in 256K space	Data[78:48]

33 Decorated Storage Memory Controller (DSMC)

33.1 Introduction

This section details hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called “*decorated storage*”. It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A “decoration” is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rA,rB` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rA,rB` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `“x”` mnemonic suffix, signaling an “indexed” addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in *Figure 325*.

Figure 325. Power Architecture Decorated Load and Store Instruction Formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

sthdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	1	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	1	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit “decoration”. The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and operand data for the command or both.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

33.2 Decorated Stores: st[b,h,w]d{cb}x rS,rB,rA

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a <command>.<size> syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

33.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container

Figure 326. Decoration Format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory “container” defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read

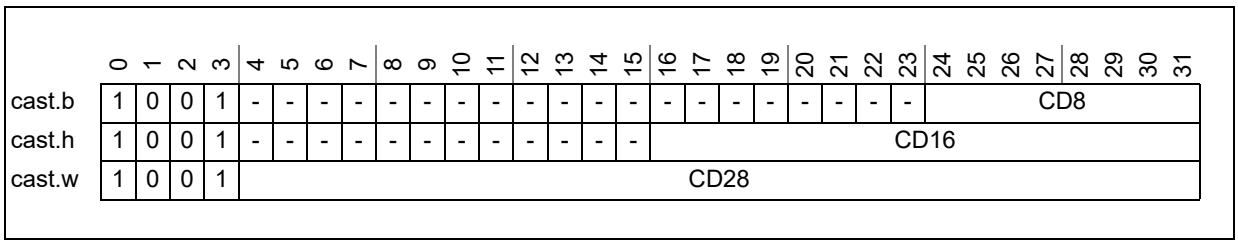
if bfw == 0
   then bfw = container

if ((srtbit + bfw) <= container)// generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp   & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp// memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.



To illustrate, consider the following example of the insertion of the 3-bit field “xyz” into an 8-bit memory container, initially set to “abcd_efgh”. For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is “xyzd_efgh”
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is “axyz_efgh”
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is “abxy_zfgh”
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is “abcx_yzgh”
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is “abcd_xyzh”
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is “abcd_exyz”
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is “abcd_efxy”
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is “abcd_efgx”
```

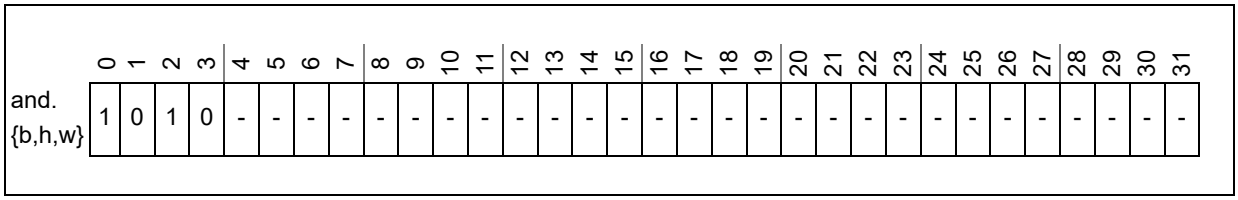
If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

33.2.2 Compare-and-Store (CAST)

Figure 327. Decoration Format: CAST

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read



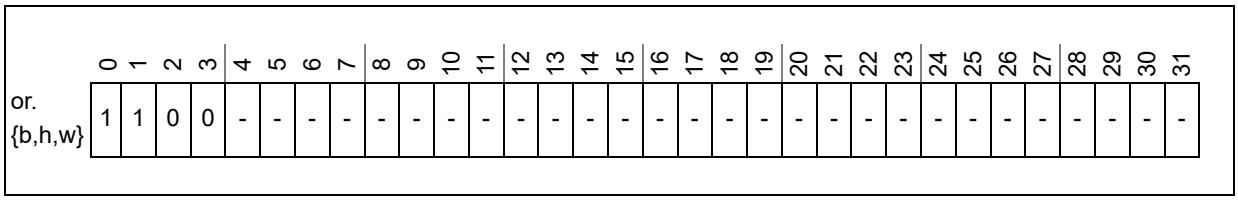
if (size == 8)// define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand)// compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

33.2.3 Logical AND (AND)

Figure 328. Decoration Format: AND

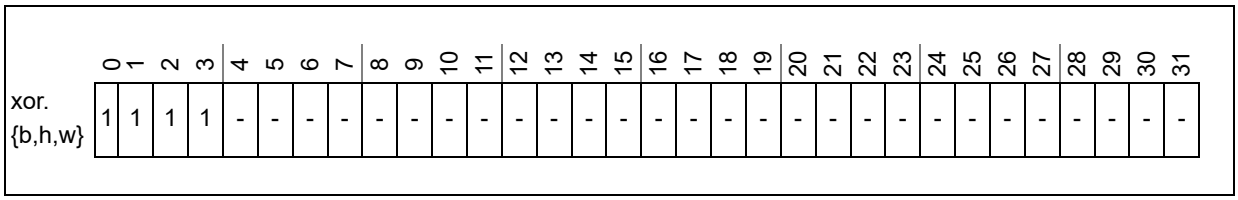


This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata// modify
mem[accessAddress, size] = tmp// memory write
```

33.2.4 Logical OR (OR)

Figure 329. Decoration Format: OR



This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata// modify
mem[accessAddress, size] = tmp// memory write
```

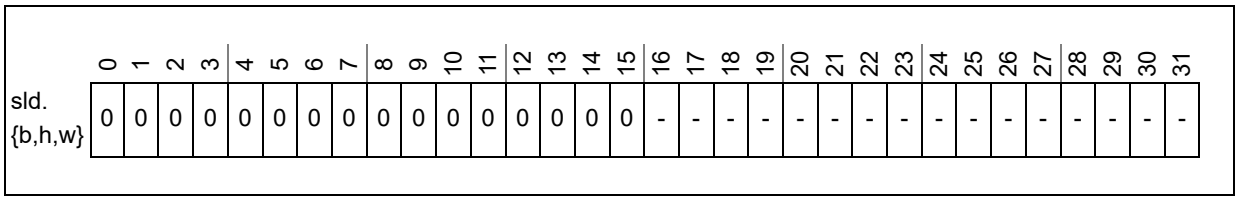
33.2.5 Logical Exclusive-OR (XOR)

Figure 330. Decoration Format: XOR

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata// modify
mem[accessAddress, size] = tmp// memory write
```

33.3 Decorated Loads: `l[b,h,w]d{cb}x rT,rB,rA`



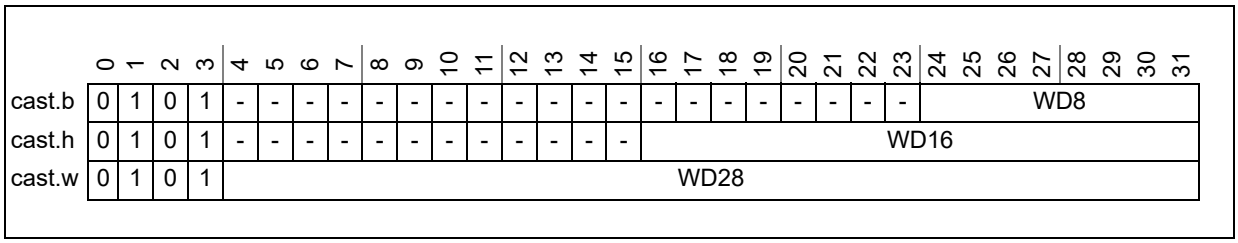
The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an “extract”) operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

33.3.1 Simple Load (SLD)

Figure 331. Decoration Format: SLD



This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

33.3.2 Registers-and-Memory Exchange (SWAP)

Figure 332. Decoration Format: SWAP

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)// store_operand - "modify"
    store_operand = WD8
else if (size == 16)
          store_operand = WD16
     else store_operand = {0x0, WD28}// zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

33.3.3 Load-and-Set-1(Bit) (LAS1)

Figure 333. Decoration Format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp
mask  = 1 << (container - bit - 1)// generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

33.4 DSMC Instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the data port of the cores and the master ports of the crossbar.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the targeted slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

34 Successive Approximation Register Analog-to-Digital Converter (SARADC)

34.1 Introduction

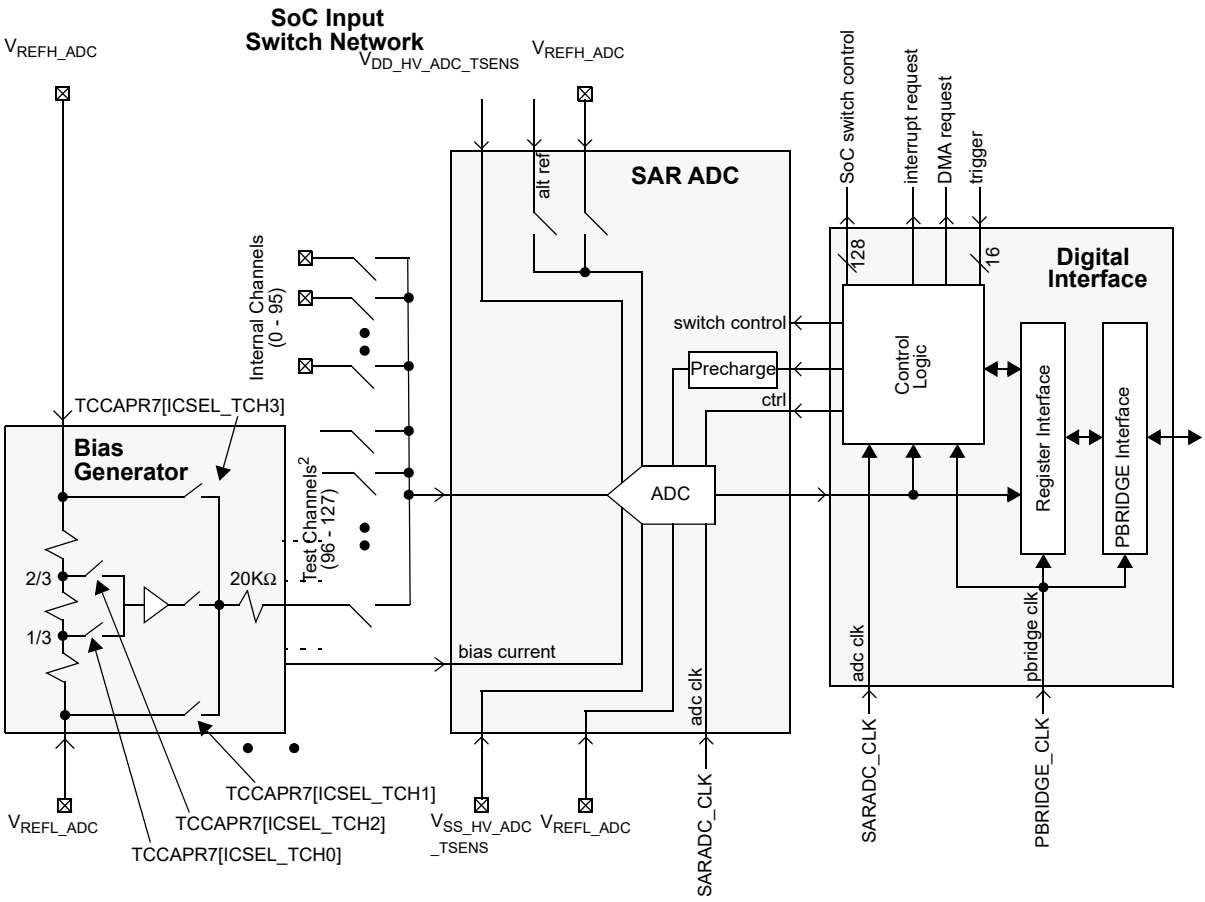
The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for the application. It provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has its corresponding digital interface implemented at the chip level.

34.2 Overview

The SARADC digital interface contains advanced features for normal or injected conversion modes of operation. The conversion can be triggered by software or hardware. For advanced cross triggering functions, it provides interface with an on-chip Crosstriggering Unit (CTU) which can support two different CTU Modes: CTU trigger mode and CTU Control Mode (see details in *Section 34.4.5: CrossTriggering Unit (CTU) interface*).

The digital interface can be configured to control up to 256 multiplexed analog input channels. There are three types of input channels:

- Internal channels, mapped to index ranging from 0 to 95.
- Test channels, mapped to index ranging from 96 to 127.



Note: The number of input channels and their mapping depends on the device configuration. See the device-specific Analog-to-Digital Converters (ADC) Configuration section (analog input pin multiplexing and SAR ADC channel assignment) for a channel mapping table.

The mask registers present within the digital interface can be properly programmed to configure which channel has to be converted.

Four conversion timing registers allow configuration of different precharging and sampling durations, one of which can then be assigned to each channel. For each channel, it is possible to choose the voltage reference through software. Analog Watchdogs allow continuous hardware monitoring of analog input channels. The digital interface also provides for interrupt/DMA support for various conditions related to end of channel conversions.

Figure 334 shows the SARADC block diagram.

Figure 334. SARADC block diagram

Note: Test channels are mapped to internal analog channels via the SARADCB_TCCAPRx registers.

34.3 Feature description

34.3.1 Main features

- Selectable 10-bit or 12-bit data resolution output for 12-bit SARADC.
- Selectable 8-bit or 10-bit data resolution output for 10-bit SARADC.
- Up to 96 internal channels, 32 test channels; variable number of analog channels of each type controlled by parameters
- 4 different conversion timing registers selectable for any channel
- Mapping of external channel to any internal channel through static programming by software
- Shorting of test channel with internal channel through static programming by software
- Normal conversion with One Shot/Scan modes
- Injected conversion with One Shot mode
- 2 different abort features that allow to abort either a single channel conversion or chain conversion
- Reference selection for each channel
- Power Down Mode
- Dedicated data register for each channel, containing the following information:
  - Conversion result in one half-word:
    10-bit or 12-bit for 12-bit SARADC.
    8-bit or 10-bit for 10-bit SARADC.
  - Status byte which provides some conversion information such as mode of operation (Normal, Injected, or CTU), data valid, data overwritten status
  - Control byte for reference selection, conversion timing parameter selection
- Configurable number of analog watchdogs.
- 2 different CTU modes (CTU Control mode and CTU Trigger mode) available when CTU feature is present in SARADC instance.
- Interrupt/DMA support for the following conditions
  - End of conversion of single channel for both normal, injected conversions
  - End of conversion chain for both normal, injected conversions
  - End of CTU conversion
  - Watchdog thresholds crossover

34.4 Functional description

Two main conversion types are available within the SARADC digital interface:

- Normal conversion
- Injected conversion

Note: "precharge" option on this device means "de-charge" to Reference ground VSS_HV_ADR_S .

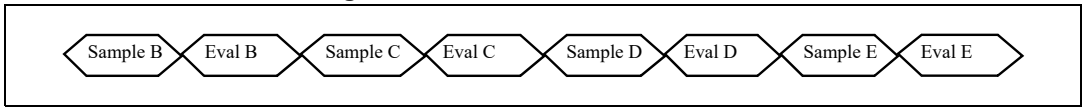
34.4.1 Normal channel conversion

This is the normal conversion that the user programs by configuring the normal conversion mask registers (ICNCMR0–2, TCNCMR). Each channel can be individually enabled by setting '1' in the corresponding field of these registers. Mask registers must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends (MSR[NSTART] bit is reset).

34.4.1.1 Start of normal conversion

The normal conversion can be started as follows:

- By software
  - The normal conversion chain starts when the MCR[NSTART] bit is set. It is recommended that the normal trigger enable MCR[NTRGEN] bit is reset during conversions started by software. Once normal conversion has started, any further write operation of MCR[NSTART] bit has no effect during ongoing conversion, but the conversion is enqueued after completion of current conversion in oneshot mode.



34.4.1.2 Normal conversion operating modes

Two operating modes are available for the normal conversion:

- One Shot Mode
- Scan Mode

To enter one of these modes, it is necessary to program the MCR[MODE] bit. The first phase of the conversion process involves sampling the analog channel and the next phase involves the conversion phase when the sampled analog value is converted to digital as shown in *Figure 335*.

Figure 335. Normal conversion flow

In **One Shot Mode** (MODE = 0), a sequential conversion specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored into the corresponding data register.

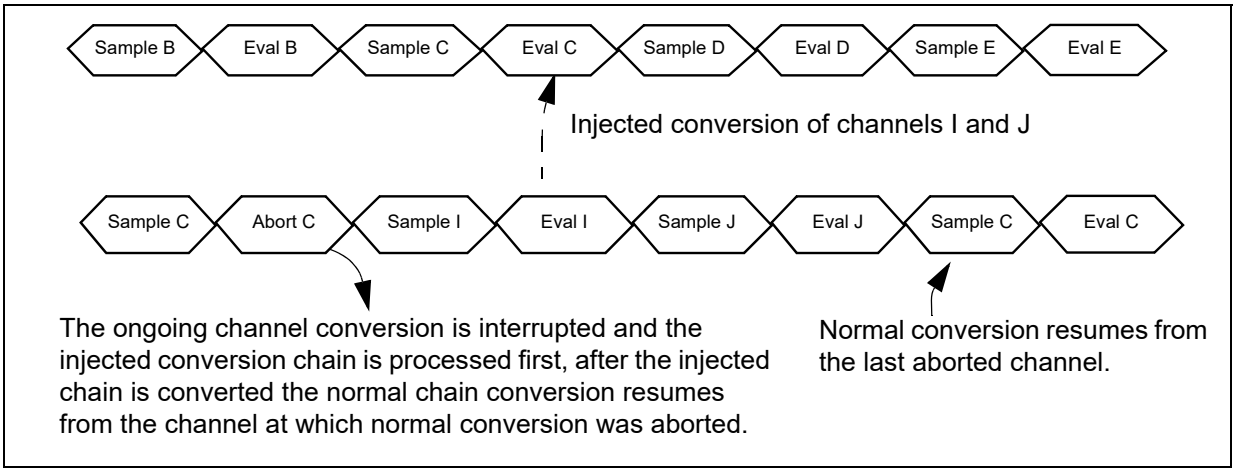
For Example, channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the One Shot Mode. MODE = 0 is set for One Shot mode. Conversion starts from the channel B followed by conversion of channels D-E. At the end of conversion of channel E, the scanning of channels stops.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time MCR[NSTART] bit is reset if the conversion is started by software.

Once the normal conversion operation starts in oneshot mode and another software conversion request is made writing the MCR[NSTART] bit and before MSR[NSTART] is cleared, one additional conversion is initiated with the same channel mask register settings after the current conversion is finished. This is called **enqueuing**. Enqueuing can help in removing the delay between two consecutive one shot chains and uncertainty caused by metastability between MCR[NSTART] bit written at system clock and generation of start pulse on ADC clock before every chain execution.

In **Scan Mode** (MODE = 1), a sequential conversion of N channels specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 registers is continuously performed. As in the previous case, at the end of each conversion the digital result of the conversion is stored into the corresponding data register.

In this mode, the software can start conversion by writing '1' to MCR[NSTART] bit or a valid normal trigger edge is detected which also sets MCR[NSTART] bit. The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One Shot Mode, the MCR[NSTART] bit is not reset. It can be reset by software when the user needs to stop scan mode. In this case, the current scan conversion is completed and MSR[NSTART] bit is also reset after the last conversion of the chain.



For Example, channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *Scan Mode*. MODE = 1 is set for Scan Mode. Conversion starts from the channel B followed by conversion of the channels D-E. At the end of conversion of channel E the scanning of channel B starts followed by conversion of the channels D-E. This sequence repeats itself until the MCR[NSTART] bit is reset by software.

In both modes, at the end of each channel conversion an End Of Conversion interrupt is issued (if enabled by the corresponding mask bit), and at the end of the conversion sequence an End Of Chain interrupt is issued (if enabled by the corresponding mask bit). The End Of Chain interrupt is issued for each pass of scan mode.

34.4.2 Injected channel conversion

A conversion chain can be injected into the current normal conversion by configuring the injected mask registers (ICJCMR0–2, TCJCMR). As in normal conversion, each internal, test channel can be individually selected. This injected conversion can only be in one shot mode and interrupts the normal conversion. When an injected conversion is inserted, ongoing channel conversion is aborted and the injected channel request is processed. After the last channel in the injected chain is converted, normal conversion resumes from the channel at which the normal conversion was stopped, as shown in *Figure 336*.

Figure 336. Injected sample/conversion sequence

The injected conversion can be started as follows:

- By software
  - The injected conversion chain starts when the MCR[JSTART] bit is set. The current conversion is suspended and the injected chain is converted. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed. It is recommended that the injection trigger enable MCR[JTRGEN] bit is reset during conversions started by software. Once injected conversion has started, any further write operation of MCR[JSTART] bit will not have any effect during ongoing conversion and the new request will get enqueued and executed after current injected chain finishes.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time MSR[JSTART] is reset if the conversion is started by software.

At the end of each injected conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit) and at the end of the sequence an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit).

34.4.3 Abort conversion

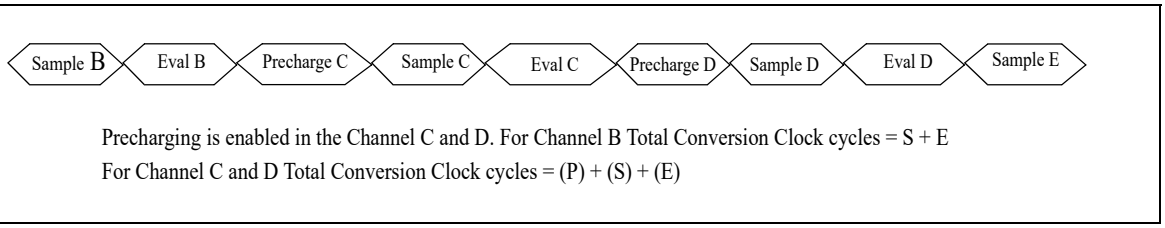
Two different abort functions are provided:

- The user can abort the ongoing conversion by setting the ABORT bit in the MCR. The current conversion is aborted and the conversion of the next channel of the chain is immediately started (generating a new start pulse to the SARADC). In the case of an abort operation, the NSTART/JSTART bit remains set and the ABORT bit is reset after the conversion of the next channel starts. The EOC corresponding to the aborted channel is not generated. This behavior is true for normal or triggered/Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported generating an ECH interrupt. ABORT function should not be used when only single channel is selected in a conversion chain, instead ABORTCHAIN can be used.
- It is also possible to abort the current chain conversion by setting the ABORTCHAIN bit in the MCR. In that case the behavior of the ADC depends on the MODE bit. In fact, if scan mode is disabled, the NSTART bit is automatically reset together with the ABORTCHAIN bit. Otherwise, if the MODE bit is set to ‘1’, a new chain conversion is started. The EOC of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

  When a chain conversion abort is requested (ABORTCHAIN bit is set) while an injected conversion is running over a suspended Normal conversion, there are 2 cases. If One Shot Mode is enabled (MODE=0 in MCR register) then both injected chain and Normal conversion chain are aborted (both the NSTART and JSTART bits are also reset). If the Scan Mode is enabled (MODE=1 in MCR register) theninjected conversion is stopped and the suspended Normal conversion is restarting. (only JSTART bit is reset).

Note: ABORT/ABORTCHAIN functions are not supported during CTU initiated conversions.

34.4.4 Analog conversion timings



34.4.4.1 Conversion timings

In order to support different loadings and switching times (in particular for the external channel types) four different Conversion Timing registers are present (CTR0–3). Each conversion timing register contains PRECHG, INPSAMP bitfields to program the required

duration for precharging and sampling phases. The selection of these registers for each channel is done by the SAMPSEL bitfield of corresponding channel data register.

Precharging phase allows to precharge or discharge the internal capacitor to a fixed internal voltage for duration determined by PRECHG bitfield prior to actual analog channel sampling start. This is useful for resetting information regarding the last converted data. Precharging feature can be enabled or disabled for each channel by programming the PCE bit of corresponding channel data register. If precharging is enabled for a given channel, the normal sequence of operation is precharging, then sampling, then evaluation, as shown in *Figure 337*. Please refer to device datasheet for the minimum precharge and sample durations required.

Figure 337. Analog conversion sequence

Bitfields PRECHG, INPSAMP are used to define the total conversion duration (t_{conv}) and in particular the partition among precharge duration (t_{prechg}), sampling phase duration (t_{sample}) and evaluation phase duration (t_{eval}).

The precharging phase duration is given by

$$t_{prechg} = PRECHG * t_{ck}$$

where PRECHG must be greater than or equal to 2 (hardware requirement) and PCE bit of channel data register is ‘1’. In case the value of PRECHG is found to be less than 2, it is automatically set to 2 inside SARADC. If the PCE bit is ‘0’, the precharging phase is skipped and conversion starts with sampling phase directly.

The sampling phase duration is given by the following equation:

$$t_{sample} = INPSAMP * t_{ck}$$

where INPSAMP must be greater than or equal to 5 (hardware requirement). In case the value of INPSAMP is found to be less than 5, it is automatically set to 5 inside SARADC. The total evaluation phase duration is given by the following equations:

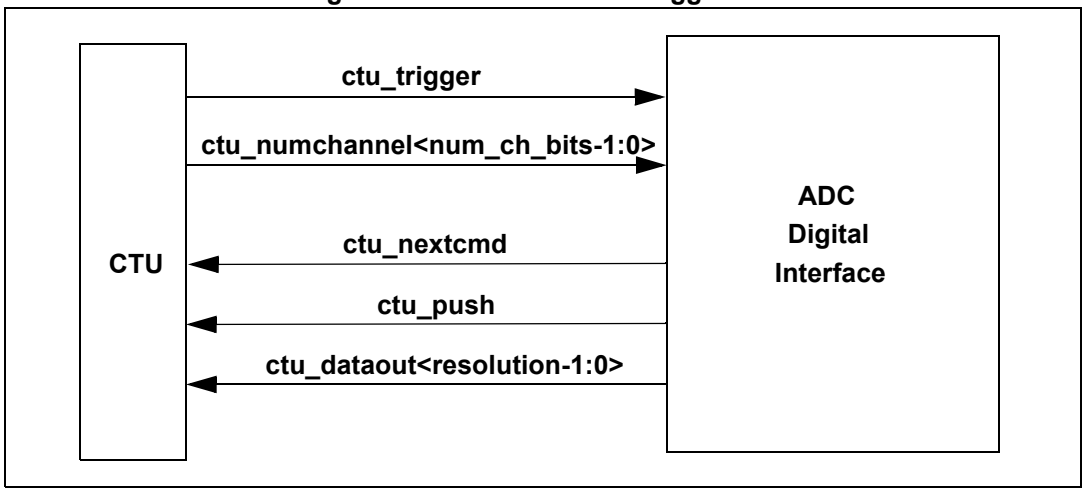
$$t_{eval} = EVAL * t_{ck}$$

In this phase, the internal sampling capacitor is disconnected from the analog channel and ADC estimates the digitized value of the sampled input using successive approximation algorithm. In the evaluation phase, all the bits are estimated sequentially to provide the conversion result.

The total conversion duration is (not including external multiplexing) is given by the following:

$$t_{conv} = t_{prechg} + t_{sample} + t_{eval}$$

The timings refer to the unit t_{ck} which is the inverse of f_{ck}, where f_{ck} = SARADC peripheral clock. Refer to the device data sheet for the total conversion time.



Note: The current implementation of ADCDIG does not support hardware restriction over values of PRECHG and INPSAMP fields. As minimum values for these fields are product specific and need to be managed through software.

34.4.5 CrossTriggering Unit (CTU) interface

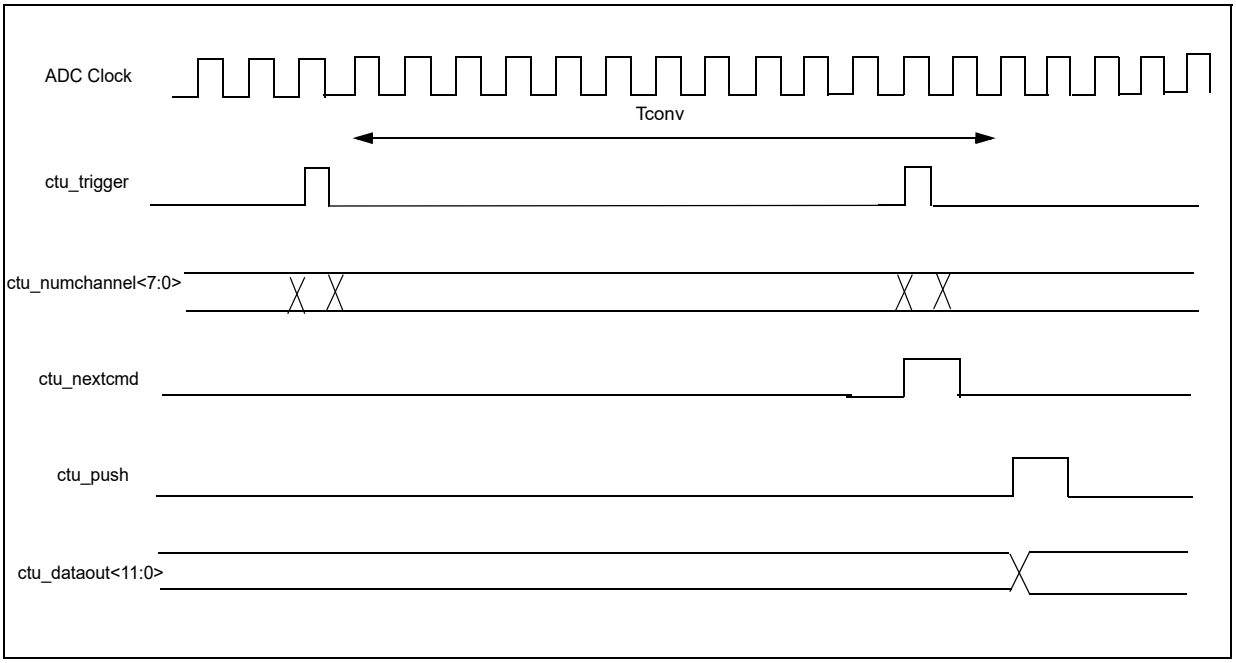
The Cross Triggering Unit (CTU) is added to enhance the injected conversion capability of the SARADC. The CTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. In *Figure 338* the CTU/ADC interface is shown.The CTU generates a trigger output pulse of one clock cycle and outputs onto a data bus which channel has to be converted. A single channel is converted for each request. After performing the conversion, the digital interface returns the conversion result to CTU. The conversion result is also saved in the corresponding channel data register and it is compared with watchdog thresholds if requested. Together with the converted data, it also sends a request for next command and a control which can be used to push the conversion result into CTU data storage registers/fifo.

These two pulses named *ctu_nextcmd* and *ctu_push* spaced of one or two clock cycle (of analog ADC clock). The ctu_nextcmd is set to '1' during the last clock cycle or last but one of ADC evaluation phase (depending on ADC type used). The ctu_push is asserted when the conversion is finished meaning that the ctu_dataout is valid.

Figure 338. SARADC crosstrigger unit

Different CTU modes can be selected programming the CTUEN and CTU_MODE fields of the MCR with respect of CTSEN SARADC parameter as described in the following table.

Table 420. CTU modes



CTSEN(1)	CTUEN	CTU_MODE	CTU mode
—	0	—	CTU is disabled
0	1	—	CTU Trigger Mode is enabled
1	1	—	CTU Control Mode is enabled
2	1	1	CTU Trigger Mode is selected
2	1	0	CTU Control Mode is selected

1. Refer to SAR ADC triggering section of chapter Analog-to-Digital Converters (ADC) Configuration for CTSEN value applicable on each SAR_ADC instance.

The CTU, SARADC analog block and digital Interface are synchronous to each other, the CTU clock and ADC clock post division should be synchronous and phase aligned to ensure

jitter free start pulses to ADC analog. Timings of CTU Interface signals are described in *Figure 339*.

Figure 339. CTU interface timings

34.4.5.1 CTU trigger mode

In CTU trigger mode, normal and injected conversions triggered by the CPU are still enabled. When a trigger pulse and the injected channel are received internally by the ADCDig, the conversion starts. The CTUSTART bit in the MSR is set automatically at this point and it is also automatically reset when the triggered injected conversion is completed.

If an injected conversion (programmed by the user by setting the JSTART bit) is ongoing and a pulse is received on the CTU trigger input line, then the injected channel conversion chain is aborted and only the triggered CTU injected conversion proceeds. Aborting the injected conversion, the JSTART bit in the MSR is reset to ‘0’. That abort is signalled through the status bit JABORTCHAIN in the MSR.

If normal conversion is ongoing and a pulse is received on the CTU trigger input line, then ongoing channel conversion is aborted and the triggered injected conversion is processed. When it is finished, normal conversion resumes from the channel at which the normal conversion was aborted.

If another CTU trigger pulse is received before the end of conversion, that request is discarded and this error condition is reported by CTUTRGERR bit in ISR.

When a normal conversion is requested during CTU conversion (CTUSTART bit = ‘1’), the normal conversion starts when CTU conversion is completed (CTUSTART reset). Otherwise, when an Injected conversion is requested during CTU conversion, that conversion is discarded and the JSTART bit in the MCR is immediately reset.

CTU trigger mode can be entered by setting CTUMODE=’1’ during powerdown and CTUEN=’1’ any time after the powerdown is exited. CTU trigger mode can be exited by clearing the CTUEN bit, But care must be taken not to exit the CTU mode when some CTU

initiated conversion is ongoing. Also power down request (by setting MCR[PWDN] bit) should not be made while CTU transactions are ongoing.

34.4.5.2 CTU control mode

When CTU Control mode is enabled, the CPU is able to write in the ADC registers but it cannot start any conversion. Conversion requests can be generated only by the CTU trigger pulse. If a normal or injected conversion is requested, it is automatically discarded.

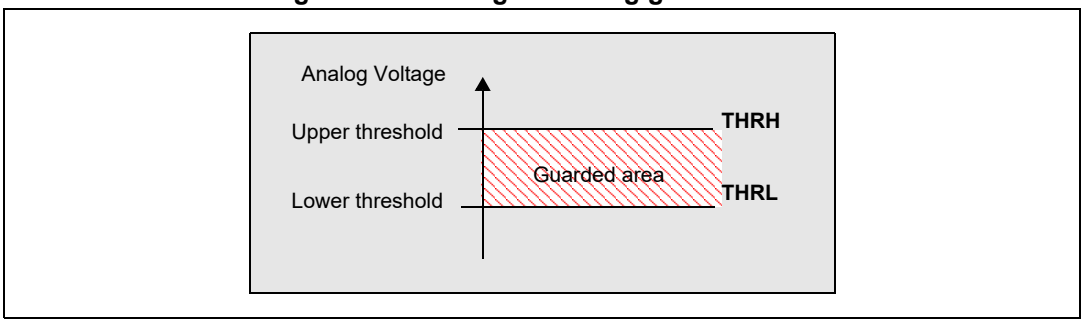
When a CTU sends trigger pulse and channel number to be converted to SARADC digital interface, triggered injected conversion starts. The MSR[CTUSTART] bit is set automatically on the first received trigger pulse and it can be reset only when CTU is disabled (CTUEN bit to ‘0’).

CTU control mode can be entered by setting CTUMODE=’0’ during powerdown and CTUEN=’1’ any time after the powerdown is exited. CTU control mode can be exited by clearing the CTUEN bit, But care should be taken not to enter or exit the CTU mode when some conversion is ongoing. Also power down request (by setting MCR[PWDN] bit) should not be made while CTU transactions are ongoing.

34.4.6 Test channel connection with internal analog channel

The test channels are meant for monitoring various on-chip analog signals coming from temperature sensor, bandgap, voltage regulator and different voltage levels available on the chip. These analog signals can be interfaced to SARADC through test channels for testing purpose. Test channels are mapped from 96 to 127. Each test channel is controlled in the same way as normal internal channel.

SAR ADC self-testing method: the test channel[127:124] is also mapped to various V_ref voltages (4 voltages) selection switches in the ADCBIAS block. The decoding of these channels to switch on and select a particular V_ref voltage is done in SoC level muxing logic.



It is also possible to perform test channel conversions with and without shorting the normal analog channel pin with the internal test voltage.

After the conversion is performed on a test channel the converted data is stored at two CDR locations at the end of conversion, first location is the CDR belonging to the test channel on which conversion is performed and second location is the CDR belonging to internal channel on which test channel is mapped.

34.4.7 Programmable analog watchdog

Analog watchdogs are used for determining whether the result of the conversion of a channel lies within a given guard area (as shown in the *Figure 340*) bounded by upper and a lower threshold values named THRH and THRL respectively.

Figure 340. Analog watchdog guarded area

Following conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside that guard area, then corresponding threshold violation interrupts are generated. The comparison result is stored as WDGxH and WDGxL bits in the WTISR as explained in *Table 421*. Depending on the MSKWDGxL and MSKWDGxH mask bits in the WTIMR, an interrupt is generated on threshold violation.

Table 421. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

The lower and higher threshold values for the analog watchdog are programmed using THRHLR0–15 registers. Analog watchdog functionality for each channel can be enabled independently from ICWENR0–2, TCWENR, ECWEN0–3 registers and can select the watchdog threshold registers (THRHLR0–15) to be used by programming ICWSELR0–11, TCWSELR0–3, ECWSELR0–15 registers. The threshold registers selected by WSEL_CHx field of watchdog threshold selection registers will provide the threshold values.

For example, if channel 30 is to be monitored with the threshold values in register THRHLR12, then WSEL_CH30 is programmed to select THRHLR12 register to provide threshold values. Enabling is done by setting the bit corresponding to channel 30 in ICWENR0 register.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in ICAWORR0–2, TCAWORR, ECAWORR0–3 registers. In this case, a set of threshold registers (THRHLR0–15) can be linked to several analog channels. The threshold values to be selected for a channel needs be programmed only once in ICWSELR, TCWSELR, ECWSELR registers.

Note: If the higher threshold for the analog watchdog is programmed lower than the lower threshold and the converted value is less than the lower threshold, then the WDGxL interrupt for the low threshold violation is set, else if the converted value is greater than the lower threshold (consequently also greater than the higher threshold) then the interrupt WDGxH for high threshold violation is set. The user should therefore take care to avoid this situation as it could lead to misinterpretation of the watchdog interrupts.

34.4.8 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel by setting the respective masking bit in ICDSR0–2, TCDSR and ECDSR0–3 registers. The DMA masking registers must be programmed before starting any conversion. The DMA transfers can be enabled using the DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

34.4.9 Interrupts

The SARADC digital interface generates the following maskable interrupt signals:

- End Of Conversion interrupts
  - NEOC (end of normal conversion of each channel)
  - NECH (end of normal chain)
  - JEOC (end of injected conversion of each channel)
  - JECH (end of injected chain)
  - EOCTU (End of CTU Conversion)

The EOC_CH[x] bit of interrupt pending registers (ICIPR0–2, TCIPR) is set when channel x completes the conversion (normal or injection). This pending status is qualified when the corresponding mask bit IM_CH[x] is also set in the interrupt mask registers (ICIMR0–2, TCIMR).

The NEOC interrupt is generated only if the following conditions are met

- ISR[NEOC] bit is set after the normal conversion completion for any channel x.
- IMR[MSKNEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The JEOC interrupt is generated only if the following conditions are met

- ISR[JEOC] bit is set after the injected conversion completion for any channel x.
- IMR[MSKJEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The EOCTU interrupt is generated only if the following conditions are met

- ISR[EOCTU] bit is set after the CTU triggered conversion completion for any channel x.
- IMR[MSKEOCTU] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

It is recommended to clear the NEOC/JEOC/EOCTU bits of ISR and all the individual channel pending bits which are not masked while servicing the interrupt.

The ISR[NECH] bit is set when a normal channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

The ISR[JECH] bit is set when an injected channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

- WDGxL and WDGxH (Watchdog threshold) interrupt requests

The interrupts generated due to the analog watchdog are handled by registers WTISR and WTIMR in order to check and enable the interrupt requests to external interrupt controller module. The watchdog interrupt source sets two pending bits WDGxH and WDGxL for each

channel being monitored in the WTISR. The interrupt request is generated if at least one of the following conditions are met:

- WTISR[WDGxL] bit is set and the corresponding mask bit MSKWDGxL is also set in WTIMR for at least one channel.
- WTISR[WDGxH] bit is set and the corresponding mask bit MSKWDGxH is also set in WTIMR for at least one channel.

The ISR and WTISR contain the interrupt pending request status flags. In case the user wants to clear a particular interrupt event status, writing a '1' to the corresponding status bit clears the pending interrupt flag. (At this write operation, all other bits of the ISR must be maintained at '0'.)

The ADC module provides dedicated interrupt outputs for all interrupt sources. Also, all interrupt lines are OR-ed together to provide a single output to the external interrupt controller if a combined interrupt is required.

34.4.10 Power down mode

The SARADC analog block can be put in low current consumption mode by setting the PWDN bit in MCR. This is the default mode after exiting from reset. This state must be exited before starting any operation by resetting the PWDN bit in the MCR. When in powerdown mode, no conversion should be started. Bit ADCSTATUS[0] in the MSR is set only when ADC enters Powerdown mode.

The power-down mode can be requested by setting the PWDN bit in the MCR. If a one-shot conversion is ongoing, the SARADC cannot immediately enter the power-down mode. In fact, the SARADC enters power-down mode only after completing the ongoing conversion. If a scan conversion is ongoing, the ongoing operation shall be first aborted manually by resetting the NSTART bit and using the ABORTCHAIN bit. A power Down request while scan mode conversion is ongoing is ignored.

After the power down phase is completed, the process ongoing before the power down phase must be restarted manually (by setting the appropriate START bit). Resetting PWDN bit and setting NSTART or JSTART bit during the same cycle is forbidden.

CTU triggered conversion should not be initiated during power down mode. In both CTU modes, to request power down mode the application has to wait for the end of the current CTU conversion (CTUSTART bit automatically reset when conversion finishes). Additionally, when SARADC is in CTU control mode the application needs to exit the CTU control mode (by resetting the CTUEN bit) before requesting the power down mode.

34.4.11 Stop Mode

The SARADC can be request to enter this low power mode anytime during the operation. If stop mode is requested while some Normal/Injected mode chained conversion are ongoing, the current channel conversion will be completed and upon stop mode exit the conversion will be resumed from next channel. However, stop mode should not be requested while CTU triggered conversions are ongoing.

34.5 Memory map and registers

This section provides memory map for the SARADC digital interface.

Note:

Figure 341. Main Configuration Register (MCR)

Table 423. MCR field descriptions

Field	Description
0 OWREN	Overwrite enable This bit enables or disables the functionality to overwrite unread converted data in ICDR, TCDR, ECDR registers. 0 Prevents overwrite of unread converted data, new result is discarded. 1 Enables converted data to be overwritten by a new conversion.
1 WLSIDE	Write left/right-aligned 0 The conversion data in ICDR, TCDR, ECDR registers is written right-aligned. 1 Conversion data is left-aligned (from 15 to (15 – resolution + 1))
2 MODE	One Shot/Scan 0 One Shot Mode: Configures the normal conversion of one chain. 1 Scan Mode: Configures continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately
4 NSTART	Normal Start conversion Setting this bit starts the chain or scan conversion. Resetting this bit during scan mode causes the current chain conversion to finish, then stops the operation. 0 Causes the current chain conversion to finish and stops the operation. 1 Starts the chain or scan conversion

Table 423. MCR field descriptions (continued)

Field	Description
8 JSTART	Injected Start conversion Setting this bit will start the configured injected analog channels to be converted by software. Resetting this bit has no effect, as the injected chain conversion cannot be interrupted. 0 Writing '0' has no effect 1 Starts the injected chain conversion
14 CTUEN	Cross Trigger Unit Enable 0 The cross triggering unit is disabled and the triggered injected conversion cannot take place 1 The cross triggering unit is enabled and the triggered injected conversion can take place **Note:** Can be set or cleared anytime with some restriction mentioned in CTU trigger/control mode section.
15 CTU_MODE	Cross Trigger Unit Mode This bit is present only if generic parameter CTSEN = 2, otherwise this bit is a reserved bit and always read as 0. This should be set only when ADC Digital is in powerdown mode. 0 CTU control mode is selected 1 CTU trigger mode is selected
24 ABORTCHAIN	Abort Chain When this bit is set, the ongoing Chain Conversion is aborted. This bit is reset by hardware as soon as a new conversion is requested. 0 Conversion is not affected 1 Aborts the ongoing chain conversion **Note:** Behavior of this request during CTU mode is mentioned in CTU trigger/control mode section.
25 ABORT	Abort Conversion When this bit is set, the ongoing conversion is aborted and a new conversion is invoked. This bit is reset by hardware as soon as a new conversion is invoked. 0 Conversion is not affected 1 Aborts the ongoing conversion **Note:** Behavior of this request during CTU mode is mentioned in CTU trigger/control mode section.

Table 423. MCR field descriptions (continued)

Field	Description
27 FRZ	Freeze This bit enables to stop the SARADC conversions at the end of current channel conversion when SoC enters debug mode. 0 Conversions are not stopped 1 When SoC enters debug mode, further conversions by SARADC analog block will be stopped. The ongoing channel conversion will be completed and the converted data is stored. When the SoC exits debug mode, SARADC resumes the job that was left before halting the conversions. Changing configuration registers during halted condition may cause a pending operation to fail when normal operation is resumed
31 PWDN	Power-down enable When this bit is set, the analog module is requested to enter Power Down mode. When SARADC status is PWDN, resetting this bit starts SARADC transition to IDLE mode. 0 SARADC is in normal mode 1 SARADC has been requested to power down

Figure 342. Main Status Register (MSR)

Table 424. MSR field descriptions

Field	Description
4 NSTART	This status bit is used to signal that a normal conversion is ongoing. 0 Normal conversion is not taking place. 1 Normal conversion is ongoing or the normal conversion is pending due to injected conversion or CTU triggered injected conversion.
8 JSTART	This status bit is used to signal that an injected conversion is ongoing. 0 Injected conversion is not taking place. 1 Injected conversion is ongoing.
13 JABORTCHAIN	This status bit is used to signal that an Injected conversion chain has been aborted. This bit is reset when a new conversion starts. 0 Last injected conversion chain has not been aborted. 1 Last injected conversion chain has been aborted.
15 CTUSTART	This status bit is used to signal that a CTU conversion is ongoing. This bit is set when a CTU trigger pulse is received and the CTU conversion starts. When CTU trigger mode is enabled this bit is automatically reset when the conversion is completed. Otherwise, if Control Mode is enabled this bit can be reset only when the CTU is disabled (CTUEN set to ‘0’). 0 CTU triggered injected conversion is not taking place. 1 CTU triggered injected conversion is ongoing.
16:23 CHADDR	Channel under measure address This status bit is used to signal which channel is under measure.
29:31 ADCSTATUS	The value of this parameter depends on ADC status. While requesting an external channel conversion, SARADC digital interface needs to wait for a fixed time determined by DSD bitfield of DSDR before proceeding to actual sampling phase. This is known as wait state. 000 IDLE 001 Power-down 010 Wait state 011 — 100 Sample 101 — 110 Conversion 111 —

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Only available with cross-triggering unit (CTU) feature.

Figure 343. Interrupt Status Register (ISR)

Table 425. ISR field descriptions

Field	Description
26 CTUTRGERR	CTU Trigger Error Flag This Error Flag indicates that the next CTU trigger has been discarded as it overlapped during execution of current CTU conversion. This indicated that CTU sampling duration is less than programmed conversion time of ADC. 0 No CTU trigger overlap error condition since last CTU conversion. 1 CTU trigger overlap error has occurred.
27 EOCTU	End of CTU channel conversion interrupt flag This bit indicates the end of conversion for a CTU injected channel. 0 End of conversion of CTU triggered channel has not occurred since the last time the flag is cleared. 1 End of conversion of CTU triggered channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
28 JEOC	End of injected channel conversion interrupt flag This bit indicates the end of conversion for an injected channel. 0 End of conversion of injected channel has not occurred since the last time the flag is cleared. 1 End of conversion of injected channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
29 JECH	End of injected chain conversion interrupt flag This bit indicates the end of conversion for an injected chain. 0 End of conversion of injected chain has not occurred since the last time the flag is cleared. 1 End of conversion of injected chain has occurred or the flag has not been cleared since the last end of conversion occurrence.

Table 425. ISR field descriptions (continued)

Field	Description
30 NEOC	End of normal channel conversion interrupt flag This bit indicates the end of conversion for a normal channel. 0 End of conversion of normal channel has not occurred since the last time the flag is cleared. 1 End of conversion of normal channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
31 NECH	End of normal chain conversion interrupt flag This bit indicates the end of conversion for an normal chain. 0 End of conversion of normal chain has not occurred since the last time the flag is cleared. 1 End of conversion of normal chain has occurred or the flag has not been cleared since the last end of conversion occurrence.

34.5.1.4 Internal Channel Interrupt Pending Register *n* (ICIPR*n*)

The interrupt channel register to channel association is described in *Table 427*.

Offset: 0x014 + *n**0x4 (*n* = 0 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EOC_CH[x]															
W	w1c

Field	Description
0:31 DS_CH[x]	DMA select for channel x 0 CH[x] is disabled to transfer data in DMA mode. 1 CH[x] is enabled to transfer data in DMA mode.

Table 435. Internal Channel DMA Select Registers to Channel Association

Register	Register bits 0:31
ICDSR0	DS_CH[31:0]
ICDSR1	DS_CH[63:32]
ICDSR2	DS_CH[95:64]

Note: If channel CH[x] is not existing then the corresponding bit field DS_CH[x] is reserved and returns 0.

If all channels CH[x] are not existing, the full register is not existing and any attempt to access this space generates a transfer error.

34.5.1.11 Watchdog Threshold Register *n* (WTHRHLR*n*)

Note: The number of WTHRHLR registers corresponds to the number of analogs watchdogs implemented in the ADC module.

The length of the threshold field depends on the SARADC resolution. For 10-bit SARADC, the bits 4, 5, 20 and 21 are reserved.

Note: The reset value of the bits 4 and 5 is 0 instead of 1 in case SARADC resolution is 10-bit.

Offset: 0x060 + *n**0x4 (*n* = 0 to 3) Access: User Read/Write

Figure 355. Power Down Exit Delay Register (PDEDR)

Table 442. PDEDR field descriptions

Field	Description
24:31 PDED	Power down exit delay duration Defines the delay between the power-down bit reset and the starting of conversion. The power-down delay is calculated as [PDED × 1/(SARADC clock frequency)].

34.5.1.16 Internal Channel Data Register n (ICDR*n*)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid, timing parameter selection for each channel.

This register should be accessed via 32-bit R/W.

Offset: 0x100 + *n**0x4 (*n* = 0 to 95) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 356. Internal Channel Data Register *n* (ICDR*n*)

Table 443. ICDR*n* field descriptions

Field	Description
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled. 1 Precharge phase is enabled.
6:7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected. 01 CTR1 is selected. 10 CTR2 is selected. 11 CTR3 is selected.
11	Reserved
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten. 1 Previous converted data has been overwritten before having been read.
14:15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode. 01 Data is a result of Injected conversion mode. 10 Data is a result of CTU conversion mode. 11 Reserved
16:31 CDATA	Channel converted data **Note:** If MCR[WLSIDE] is set to ‘0’ than the converted data is read right aligned with lower 12/10 bits representing the actual converted data(width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining upper 4/6 bits are read as zeros. Whereas if the MCR[WLSIDE] is set as ‘1’ than the converted data is read left aligned with upper 12/10 bits representing the actual converted data(width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining lower 4/6 bits are read as zeros.

34.5.1.17 Internal Channel Watchdog Select Register *n* (ICWSELR*n*)

These registers contain WSEL_CHx[0:3] bitfields to select the threshold register which provides the values to be used for upper and lower bounds for channel x.

The Watchdog select registers to channel association is described in *Table 445*.

Offset: 0x2B0 + n*0x4 (*n* = 0 to 11) Access: User Read/Write

Table 445. Internal Channel Watchdog Enable Registers to Channel Association

Register	Register bits 0:31
ICWSELRn (n = 0 to 11)	WSEL_CH[(8*n)+7] … WSEL_CH[8*n]

The number of bits implemented for each WSEL_CHx depends on Watchdog number:

- If Watchdog number > 8, the number of bits implemented is 4 (WSEL_CHx[3:0])
- If 4 < Watchdog number <= 8, the number of bits implemented is 3 (WSEL_CHx[3] is reserved).
- If 1 < Watchdog number <= 4, the number of bits implemented is 2 (WSEL_CHx[3:2] is reserved).
- If Watchdog number = 1, only 1 bit is present.

Each such nibble (WSEL_CHx) has positional correspondence to Internal Channel number (each channel has a 1:1 nibble correspondence), so each word ICWSELRx corresponds to eight internal Channels for a total of twelve 32-bit registers to covering all 96 test channels.

If an Internal channel is not defined, the corresponding WSEL_CHx nibble is not implemented. For the implemented nibbles, width of WSEL_CHx field within the nibble is dependent on the Watchdog number. For example, if Watchdog number is 4 than only two LSBs of each WSEL_CHx are implemented and remaining two will remain unimplemented. If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

34.5.1.18 Internal Channel Watchdog Enable Register *n* (ICWENR*n*)

The Watchdog enable registers to channel association is described in *Table 447*.

Offset: 0x2E0 + *n**0x4 (*n* = 0 to 2) Access: User Read/Write

Table 460. TCWSELR*n* field descriptions (continued)

Field	Description
24:27 WSEL_CH[(8*n)+97]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
28:31 WSEL_CH[(8*n)+96]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.

Table 461. Test Channel Watchdog Select Registers to Channel Association

Register	Register bits 0:31
TCWSELR0	WSEL_CH[103] … WSEL_CH[96]
TCWSELR1	WSEL_CH[111] … WSEL_CH[104]
TCWSELR2	WSEL_CH[119] … WSEL_CH[112]
TCWSELR3	WSEL_CH[127] … WSEL_CH[120]

The number of bits implemented for each WSEL_CHx depends on Watchdog number:

- If Watchdog number > 8, the number of bits implemented is 4 (WSEL_CHx[3:0])
- If 4 < Watchdog number <= 8, the number of bits implemented is 3 (WSEL_CHx[3] is reserved).
- If 1 < Watchdog number <= 4, the number of bits implemented is 2 (WSEL_CHx[3:2] is reserved).
- If Watchdog number = 1, only 1 bit is present.

Each such nibble (WSEL_CHx) has positional correspondence to Test Channel number (each channel has a 1:1 nibble correspondence), so each word TCWSELRx corresponds to eight test Channels, thus requiring total four 32-bit registers to cover all 32 test channels.

If a Test channel is not defined, the corresponding WSEL_CHx nibble is not implemented. For the implemented nibbles, width of WSEL_CHx field within the nibble is dependent on the Watchdog number. For example, if Watchdog number is 4 than only two LSBs of each WSEL_CHx are implemented and remaining two will remain unimplemented. If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

34.5.1.26 Test Channel Watchdog Enable Register (TCWENR)

The Watchdog enable registers to channel association is described in *Table 463*.

34.5.1.29 Test Channel Data Register *n* (TCDR*n*)

The conversion results for each channel is loaded into data registers. Each data register contains:

- The conversion result
- Status information related to ADC mode,
- Data valid
- Control information to select the required reference voltage
- Timing parameter selection for each channel.

These registers are accessed 32-bit R/W.

Offset: 0x2D0 + *n**0x4 (*n* = 96 to 127) Access: User Read/Write

Figure 369. Test Channel Data Register *n* (TCDR*n*)

Table 468. TCDR*n* field descriptions

Field	Description
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled 1 Precharge phase is enabled
6:7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
11 FCERR	Fast Comparator Error Flag This bit is used to notify error condition on current fast comparator operation inside ADC analog block. It is automatically cleared when data is read. 0 Cleared by reading the Converted by software 1 Fast Comparator Error Condition has occured in current conversion

Table 468. TCDR*n* field descriptions (continued)

Field	Description
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software 1 Converted data is valid and has not been read yet
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14:15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16:31 CDATA	Channel converted data **Note:** If MCR[WLSIDE] is set to ‘0’ than the converted data is read right aligned with lower 12/10 bits representing the actual converted data(width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining upper 4/6 bits are read as zeros. Whereas if the MCR[WLSIDE] is set as ‘1’ than the converted data is read left aligned with upper 12/10 bits representing the actual converted data(width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining lower 4/6 bits are read as zeros.

34.6 Start of conversion pulse delay

The following table lists the delays between various trigger points (initiation request for conversion as registered at system clock) and the actual issue of start pulse (adc_start[l]) to the ADC hard-macrocell. Here, each possible trigger source is described with the number of clock cycles required for different operations until the trigger of adc_start. This table does not take into account any software delay involved in programming or polling of any bit in order to measure conversion timing.

l. adc_start is the start of conversion indication to ADC hard-macrocell to start the conversion.

Table 469. Start of conversion pulse delay table

Trigger source	Register control (PBRIDGE_ CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_ CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Normal conversion triggered by software (setting of NSTART of MCR)	1	—	2	1-2[3]	Cumulative delay from wen(byte_en) assertion to actual issue of adc_start pulse = 3-4 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Normal conversion triggered by external trigger (HW trigger through)	—	—	2	1–2[3]	Cumulative delay from the triggering edge (rising or falling) to the actual issue of adc_start pulse = 3–4 SARADC_CLK cycles.
Normal conversion within a chain	—	—	0 (from EOC[1] of previous conversion)	—	Delay from the EOC[1] of last conversion, The start of next conversion is issued exactly on the same cycle when EOC[1] is expected for previous conversion.
Injected conversion triggered by software (setting of JSTART bit of MCR)	1	—	3	1–2[3]	Cumulative delay from wen(byte_en) assertion. Here delay for first start pulse of the injected chain execution when FSM was originally in IDLE state is considered = 4–5 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Injected conversion triggered by external Trigger (HW trigger)	—	—	3	1–2[3]	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Injected conversion within a chain (delay between consecutive conversion of injected chain)	—	—	0 (from EOC[1] of previous conversion)	—	Delay from EOC[1] of last injected channel and adc_start pulse of next injected channel. The start of next conversion is issued exactly on the same cycle when EOC[1] is expected for previous conversion

Table 469. Start of conversion pulse delay table (continued)

Trigger source	Register control (PBRIDGE_CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Injected conversion over normal conversion (software injected conversion chain)	1	1–2(3)	3–5(2)	1–2(3)	Cumulative delay from wen(byte_en) assertion to actual trigger of first injected channel, when the FSM was in conversion cycle of previous normal conversion = 4–7 SARADC_CLK cycles + 2-3 PBRIDGE_CLK cycles.
Injection of conversion over normal conversion in JTRGSEQ mode	—	—	3	1–2(3)	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Abort of a Normal/Injected Channel conversion during Normal Chain/Injected Chain execution (setting of MCR[ABORT] bit)	1	1–2(3)	3–5(2)	1–2(3)	Delay from writing of ABORT bit (wen/byte_en assertion) to actual issue of adc_start pulse for the next channel conversion = 4–7 SARADC_CLK cycles + 2–3 PBRIDGE_CLK cycles.

1. EOC is the end of conversion from ADC hard macrocell
2. The above delay values are calculated over a range of system and ADC clock frequencies. With PBRIDGE_CLK(max) = 50 MHz to PBRIDGE_CLK(min) = 40 MHz and SARADC_CLK(max) = 16 MHz to SARADC_CLK(min) = 14 MHz. L.H.S value corresponds to max frequencies and RHS corresponds to min frequencies.
3. The above variation is owing to inter domain synchronization.

34.7 Initialization Information

To initialize the SARADC registers for data conversion, the following programming sequence is required:-

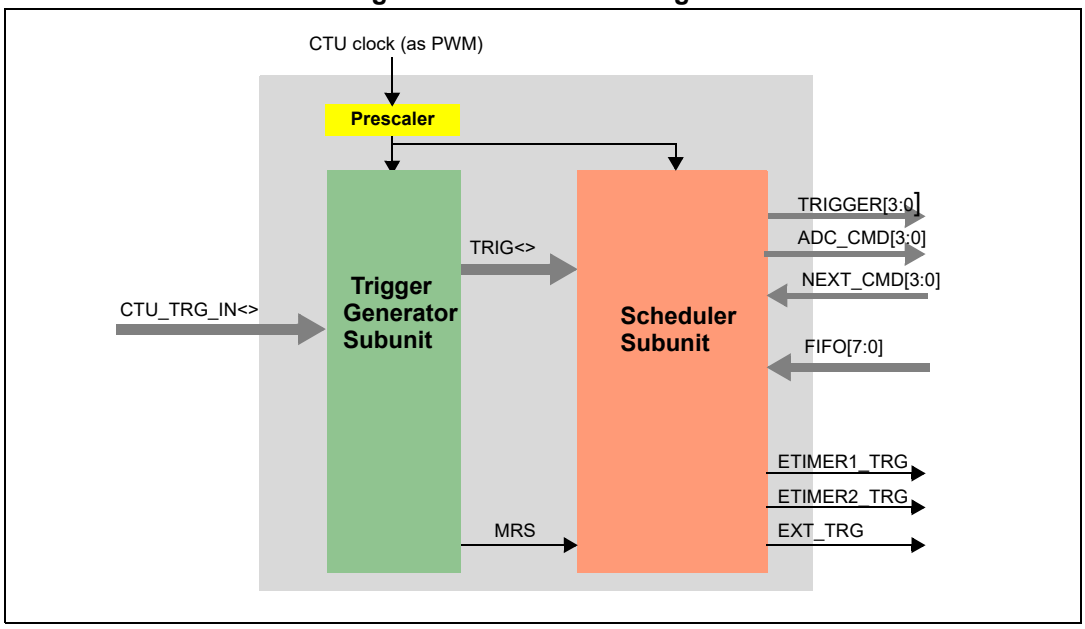
1. Program the PDEDR register with appropriate power down exit delay value and required CTU mode (MCR[CTU_MODE]) in case CTU mode has to be entered later on by setting CTUEN bit.
2. Exit the power down mode by clearing the MCR[PWDN] bit. After the power down mode is exited the SARADC enters the IDLE state, this can be checked by polling for MSR[ADCSTATUS] bits. Note that steps 3-7 can also be executed before step 2.
3. Program the required conversion mode and control options for example one-shot mode or scan mode, hardware trigger enable and selection for normal or injected conversions, hardware trigger edge select, owerwrite enable e.t.c. in MCR register.
4. Program the conversion mask registers({I,T}C{N,J}CMR) for channels to be converted. If required, enable and select watchdog monitors({I,T}CWENR, {I,T}CWSELR) as applicable for each channel, program the watchdog threshold values(WTHRHLR) for each watchdog monitor.
5. If required, Enable and select the , Test to internal channel mapping by programming the TCCAPR registers.
6. Program the required Interrupt/DMA mask registers(DMAE, {I,T}CDSR, IMR, {I,T}C{N,J}MR, WTIMR) for each of the selected channels.
7. Program the Conversion timing registers(CTR0-3) for the required conversion durations. Enable the Precharge phase, reference selection, CTR selection per channel basis by programming the {I,T}CDR registers.
8. To initiate CTU mode conversion enter the selected CTU mode by setting the MCR[CTUEN] bit and program the CTU module accordingly to start the conversions. To initiate Normal/Injected mode conversions by software set the MCR[NSTART/JSTART] bit. To initiate hardware triggered Normal/Injected conversions program the external trigger module to provide the required triggers.
9. Read the conversion data and status in {I,T}CDR registers.

35 Enhanced Cross Trigger Unit (ECTU)

35.1 Introduction

The ECTU (enhanced cross trigger unit) is used to provide commands to the ADCs, start/stop trigger signals to other IPs and external trigger to the pad. This IP, if correctly programmed, provide new commands to the ADC also if the CPU is involved in other operations. It contains a number of FIFOs inside that are used to store converted ADC data and guarantee that no data will be lost.

35.2 Main features



- Receives up to 8 input trigger events from other IPs such as PWM, Timers, external pins . For mapping details, refer to *Figure 33: Module to module connections* and *Table 13: Peripheral multiplexing table description*
- Generates up to 8 internal events to trigger ADC sequences
- Support of 4 ADCs
- Each internal trigger event can generate ADC commands to start conversion
- Support of single-mode conversion and multi-mode conversion
- 8 FIFOs to store converted ADC data
- Up to 64 ADC command registers to support various conversion sequences
- Motor function iMonitor using 32-bit CRC

35.3 Block diagram

The block diagram is composed of the following:

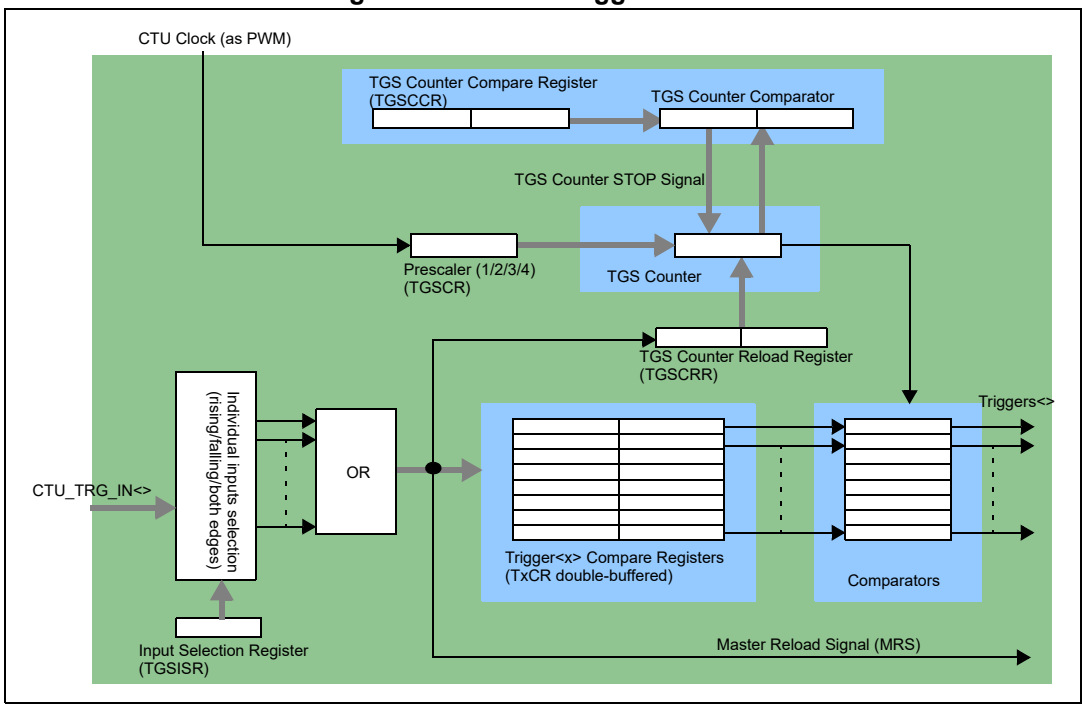
1. TGS (trigger generator subunit)
2. SU (scheduler subunit)

Figure 370. CTU block diagram

Input signal are latched inside TGS to generate up to 8 trigger events. These event go into SU and after a decode phase, generate the corresponding outputs for ADCs/external triggers.

35.4 Functional description

35.4.1 Trigger generator subunit (TGS)



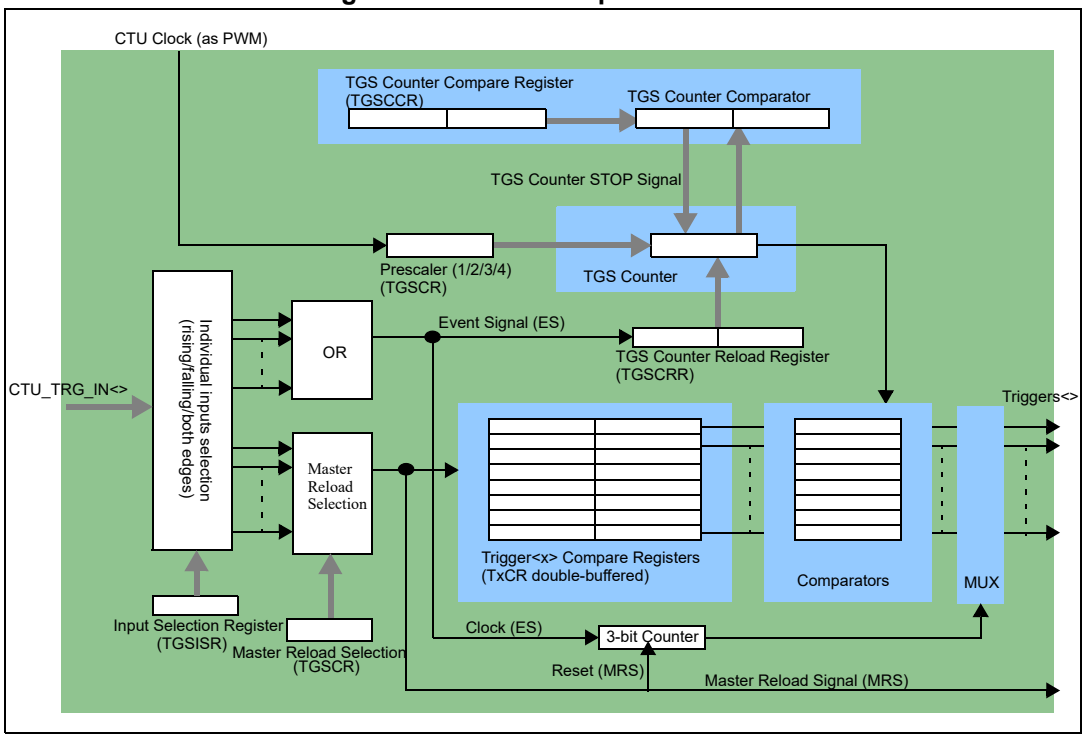
This part of the IP is used to generate up to 8 trigger events from a combination of input signals. The output could be generated in two different modes:

1. Triggered mode: each programmed event generated from the incoming signal can generate up to 8 trigger events.
2. Sequential mode: each trigger is generated from an incoming event. Each new event selects the respective TxCR register for the comparison.

35.4.1.1 TGS in triggered mode

The TGS mode is selected using TGSCR bit in the TGS control register.

Figure 371. TGS in triggered mode



Each input signal is selected from the Input selection register (TGSISR) and is OR-ed with the others selected in order to generate the master reload signal (MRS). This signal is then phase-aligned with the ADC clock to ensure triggers to ADCs are generated always in the same manner. This signal is used to reload the triggers list registers and the TGS counter reload register (TGSCRR). In this way the values written in the trigger list registers are used only when a MRS occurs.

The TGS counter register is used to compare the counter value with the current value of trigger list register, and when the two value are the same an event is generated. A TGS counter STOP signal stops the counter if the value of TGS counter is equal to TGS counter comparator.

The master reload signal can also be set to ‘1’ by software setting the MRS_SG bit in the CTU control register.

A prescaler is used to divide the MC clock in order to increase the time before TGS counter STOP signal goes to one.

Figure 372. TGS in sequential mode

This mode of operation is different from the previous one because the output triggers are generated one at a time in a sequential mode addressed from the 3-bit counter.

The combination of the inputs is used to generate the event signal (ES). The ES signal reloads the TGS counter reload register (TGSCRR) and is used to increase the counter value of the 3-bit counter. The MRS signal otherwise is generated from a single active signal addressed from the Master reload selection (MRS_SM), resets the 3-bit counter and reloads the triggers list registers.

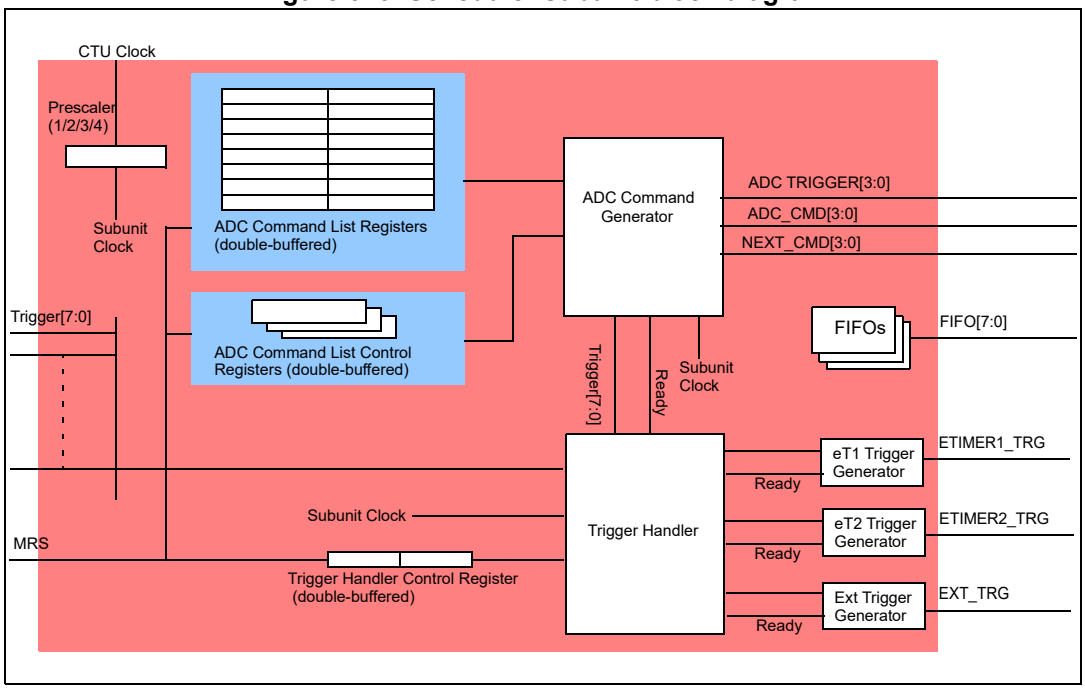
A signal is activated from the Input selection register, for this reason in sequential mode a MRS is a particular EV signal.

The meaning of the other registers are the same as in the previous mode.

35.4.2 Digital filter

External signals which can generate CTU triggers can be asynchronous with motor control clock. For this reason two flip-flops are provided to synchronize the signals. Additionally there is a digital filter that is programmable using the CTU_FILTER register. The external signal is considered at ‘1’ if it is latched <CTU_FILTER.Filter_value>+1 times as ‘1’ and is considered at ‘0’ if it is latched <CTU_FILTER.Filter_value>+1 times as ‘0’.

Due to the uncertainty of synchronizers, all pulses less than <CTU_FILTER.Filter_value> cycles of MT_clk will always be filtered, and all pulses higher than <CTU_FILTER.Filter_value> cycles of MT_clk will always be latched. The pulses in between remain in an uncertain domain that is they might or might not be filtered.



The register is correctly synchronized when the **Filter_en** bit in the control register is set. CTU_FILTER register must always be programmed before setting **Filter_en** bit.

The filter is present for all CTU_TRG_IN[15:0] and is controlled using a static design parameter CTU_TRG_FILTER_EN. For this module, the value of CTU_TRG_FILTER_EN[15:0] is 16'b1000_0000_0000_0000. Filters to all trigger inputs are enabled with a common control bit CTU_CR.Filter_en.

35.4.3 Scheduler subunit (SU)

The SU has the same functionality when TGS is in trigger or in sequential mode.

Figure 373. Scheduler subunit block diagram

Each input trigger event can be linked to any of 8 trigger event by the Trigger handler subunit. The outputs generated are:

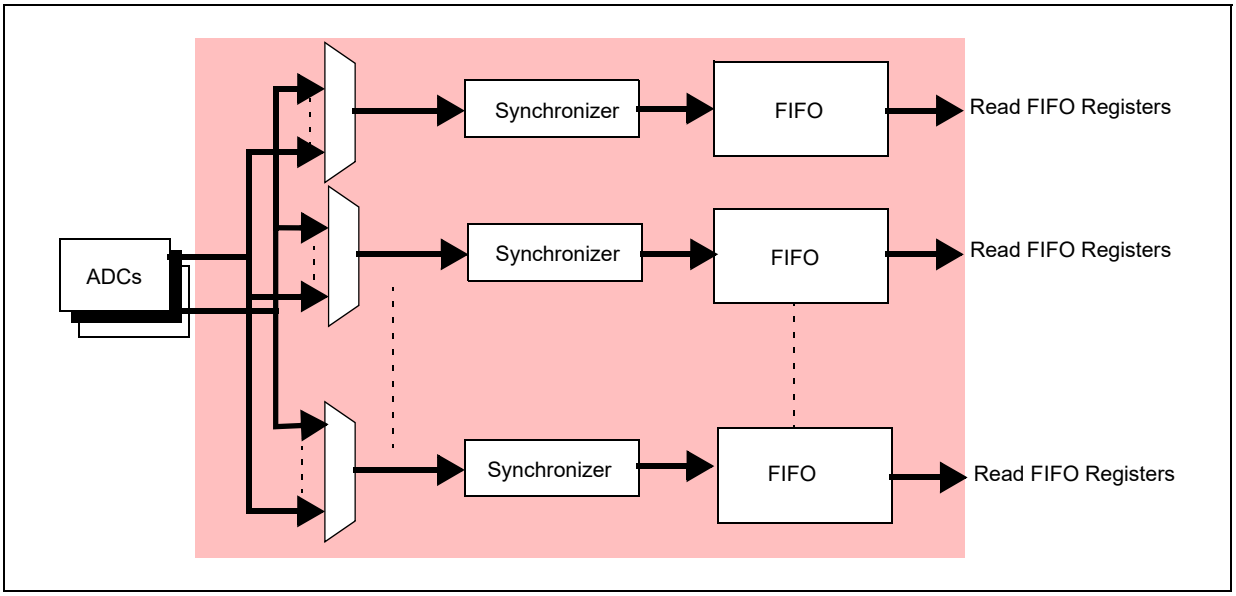
1. ADC command
2. eTimer1
3. eTimer2
4. External trigger

The linking is programmed using THCRx registers in the Trigger handler control and it is possible to disable the output using the respective THCRx register bit.

If two events at the same time are linked to the same output only one output is generated and an error (TGS_OE) is provided. The output is generated using the trigger with the lowest index. For example if trigger 0 and trigger 1 both are linked to the ADC output and they occur together, an error is generated and the output linked with the trigger 0 is generated.

In case a trigger is linked to a timer or to the external trigger, a pulse with active rising edge is generated. Additional feature for external trigger is available: the external trigger output has the Pulse mode and the Toggle mode (1 bit for each trigger event in the TGSCR). In toggle mode, on each trigger event linked to the external trigger, the external trigger pin toggles.

The ON-Time of the triggers is defined from a COTR register (on time register). A guard time is also defined from the same register at the same value of the ON-Time. A new trigger will be generated only if the ON time + Guard time is past. The ON-Time and Guard time are used only for external trigger.



Each trigger index is mapped to ADC Commands (Command list register CLRx) using Command list control registers CLCRx. If a field of CLCRx contains the integer “n” the correspondent command register is the CLR(n+1).

The first time that an event linked to the ADC command is activated, the first command is generated according to the CLCRx register (*Figure 375*).

35.4.4 CTU FIFO

Below are the details about the FIFOs present in the CTU.

Figure 374. FIFO block diagram

FIFOs in the CTU receive data from ADCs at the end of conversion and put it into the right FIFO. The target FIFO information is embedded in the ADC command register. A FIFO bus select signal coming from the CTU command generator logic selects the right FIFO for the write operations. The same protocol is implemented for all ADCs. It is possible that more than one ADC command selects the same FIFO for storing converted data. In this case if ADC data are simultaneouly available then the writing order is selected with the lower indexed ADC command, that is the data of command<n> ADC will be written first then the data of command<n+1> and so on. As the ADC unit number is also stored in FIFOs along with data, the sequence of storing does not matter.

The data from ADC needs to be synchronized as FIFO read occurs at ipg_clk and ADC operates at MT_clk. The time for a correct synchronization is equal to 4 ipg_clk + 4 Motor control clock. If another data from the same ADC arrives into this time slices it is filtered. For this reason if for example the ipg_clk is at 64MHz the motor control clock cannot be less than about 8 Mhz. Otherwise another push that come before 650ns will be filtered.

When a read operation is started, from the CPU or from the DMA, the two fields of data are stored on the bus in a different format as per the description of registers FRx or FLx. Setting

the corresponding bits on the control register is possible to enable interrupt or enable the DMA interface. Three signals (DMA_ACK, DMA_REQ, DMA_DONE) define the DMA interface protocol. A DMA_REQ is activated if the number of elements in the FIFO is bigger than the threshold (overflow condition). When the request is accepted from the DMA (DMA_ACK = 1) the DMA_REQ signal is set to zero. A new request can be performed only after the DMA_done signal is set. Read operations are synchronous to the system clock, write operations instead are synchronous with the CTU clock.

Following flags report the status of the FIFOx

1. **Empty**. This bit is 1 if the FIFO is empty and is 0 if the FIFO is not empty.
2. **Full**. This bit is 1 if the FIFO is full and 0 if it is not full.
3. **Overflow**. This bit is 1 if the number of elements in the FIFO is bigger than the threshold.
4. **Overrun**. This is the only error bit and is 1 if a write in a FIFO occurred when FIFO is FULL after the last clear. It is 0 if, since last clear of this bit, never happens that a overrun condition occurred.

CTU IP contains 8 FIFOs. The depth of the FIFOs are as below:

Table 470. CTU FIFO depths

FIFO #	Depth (number of words)
0	8
1	8
2	8
3	8
4	8
5	8
6	8
7	8

35.5 CTU interrupt and DMA requests

35.5.1 DMA support

The DMA can be used to configure the CTU registers. One DMA channel is reserved for performing a block transfer and the MRS can be used as an optional DMA request signal (MRS_DMAE bit in the CTU Interrupt/DMA Register). Moreover, this CTU implementation requires DMA support for reading the data from the FIFOs. One DMA channel is available for each FIFO.

Each MRS, if MRS_DMAE bit is enabled, generates a DMA request. This request will be set to zero only if DMA acknowledge (ipd_ack) signal is one. An error is generated if the DMA is writing when another MRS occurs. To guarantee that the data will be stable the DMA must set GRE to ‘1’ (if a write operation occurred) and TGSISR_RE (only if TGSISR is changed) bit at the end of operations. A ipg_dma_done will be used like a set operation in the GRE bit if the DMA_DE bit in the CTUIR register is set. Like for any other access when the GRE is at one any other access generates an error (MRS_RE). A new access can be performed only

when a master reload occurs and reset the GRE bit. If an error occurs no DMA request will be provided.

35.5.2 CTU faults and errors

In this paragraph we talk about possible error and interrupt that can happen during the programming.

1. If a MRS occurs while user is updating the double-buffered registers the MRS_RE is set.
2. In sequential mode a 3-bit counter selects the right trigger event. Every time that ES has positive edge the counter is incremented by one. The MRS reloads this counter. If the number of positive edge of ES is bigger than eight an error occurs and SM_TO is set to ‘1’.
3. The ADC command is composed of six fields (ADC number, Channel number, FIFO number, Last command of sequence, Last command, Command interrupt request). If these fields are not correct for the ADC an error occurs and ICE flag is set to ‘1’. ICE flag is also set in following cases:
   a) When same ADC is used more than once in a concurrent command sequence. For example both CLR1 and CLR2 are programmed for ADC_0 conversion and only CLR2.EC bit is set. In such cases conversion takes place as according to lowest index of CLRx registers for example CLR1 will be used to select FIFO/CH_NUM etc for ADC_0.
   b) When LC bit is set but EC bit is not set (this situation can also result in MAX_CON interrupt). In this case conversion does not take place and this is considered as the last command.
4. If the EC bit is not found to be set within the maximum possible 4 commands then MAX_CON flag is set. This signifies that maximum concurrent conversion limit is not followed. When this error happens, no conversion takes place and this condition is considered as the last command. ECTU then waits for next trigger source.
5. If the time window defined from two consecutive MRS is not enough for the number of programmed events in the THCR registers, an error occurs and MRS_O flag is set.
6. TGS Overrun in Sequential Mode: new incoming EV occurs before that the trigger event selected by the previous EV occurs. The error is generated only if the trigger from the TGS is linked to some output of the SU.
7. A trigger event occurs during the time when the actions of the previous trigger event are not completed (user ensures no trigger event occurs during another one is processed, but if user mistakes and a trigger event occurs during another one is processed, the incoming trigger event will be lost and an error occurs). Another overrun error is possible if two trigger event coming from the TGS are linked to the same output trigger in the same time. In this case an overrun error is generated and the output related with the lowest trigger is generated. There are 4 overrun flags (T1_OE, T2_OE, ET_OE, ADC_OE). The Trigger Handler, when a trigger event occurs and the corresponding Ready signal is high, presents the respective trigger signal (one cycle high time + one cycle low time) to the respective generator sub-block (ADC Command Generator, or Ext. Trigger Generator). This generator sub-block then generates the requested signal. Until this real signal is generated (including guard time) the Ready signal is kept low. In case of ADC Command Generator, the Ready signal shall be kept low until last conversion in the batch is finished. The respective overrun flag is set at the following conditions: (a) Ready signal is low and (b) the rising edge of the respective trigger signal (from Trigger Handler to generator sub-block) occurs. This

architecture allows user to pre-set, for example, a trigger to the eTimer1 in the middle of an ADC conversion, that is the SU will be considered busy only if a request to perform the same action that the SU is already performing occurs.

8. The ADC commands has a bit for interrupt request. If this bit is set to 1 each new ADC command set the ADC_i flag at the start of the conversion. This flag is set only if CIR bit of the last command register is set for any concurrent conversion that is the EC bit must be 1 in that register.
9. If the internal counter (TGS counter) reaches the value inside the TGSCCR an error is generated (Error counter).
10. If the conversion time is not in the specified range an error is generated (SAF_ERRx bits in CTUEFR).
11. An interrupt could be generated also if MRS or a trigger occurs and the correspondent enable bit is set.
12. If the programmed CRC is not matching with the computed CRC at the MRS event, an error is generated (CRC_ERR bit in CTUEFR).
13. Others interrupt are due to the FIFO.

Table 471. CTU interrupt flags

Interrupt	Interrupt function
MRS_RE	Master Reload Signal Reload Error
SM_TO	Trigger Overrun (more than 8 EV) in TGS Sequential Mode
CRC_ERR	CRC comparison Error
ICE	Invalid Command Error
MAX_CON	Maximum concurrent command Error
MRS_O	Master Reload Signal Overrun
TGS_OSM	TGS Overrun in Sequential Mode
ADC_OE	ADC command generation Overrun Error
T1_OE	Timer 1 trigger generation Overrun Error
T2_OE	Timer 2 trigger generation Overrun Error
ET_OE	External Trigger generation Overrun Error
ADC_I	ADC command interrupt flag
MRS_I	MRS Interrupt flag
T0_I	Trigger 0 interrupt flag
T1_I	Trigger 1 interrupt flag
T2_I	Trigger 2 interrupt flag
T3_I	Trigger 3 interrupt flag
T4_I	Trigger 4 interrupt flag
T5_I	Trigger 5 interrupt flag
T6_I	Trigger 6 interrupt flag
T7_I	Trigger 7 interrupt flag
SAF_ERR4	Conversion time error flag for 4th concurrent conversion

Table 471. CTU interrupt flags (continued)

Interrupt	Interrupt function
SAF_ERR3	Conversion time error flag for 3th concurrent conversion
SAF_ERR2	Conversion time error flag for 2nd concurrent conversion
SAF_ERR1	Conversion time error flag for 1st concurrent conversion
FIFO interrupt flags (i = 1 to 8)	
FIFO_FULL[i]	This bit is set to 1 if the FIFO i is full
FIFO_EMPTY[i]	This bit is set to 1 if the FIFO i is empty
FIFO_OVERFLOW[i]	This bit is set to 1 if the number of words became higher than the value set in the threshold i
FIFO_OVERRUN[i]	This bit is set to 1 if a write operation occurs when corresponding FIFO_FULL[i] flag is set

In order to reduce the number of interrupt lines, some interrupts are combined together to generate single interrupt.

- IEE interrupt line is ORed of MRS_RE, SM_TO, ICE, MRS_O, TGS_OSM, ADC_OE, T1_OE, T2_OE, Error_compare, MAX_CON, SAF_ERRx and ET_OE.
- FIFOx_I interrupt line is ORed of FIFO_FULL[i], FIFO_EMPTY[i], FIFO_OVERFLOW[i] and FIFO_OVERRUN[i].

35.6 ADC commands list

The SU uses a commands list in order to select the command to send to the ADCs when a trigger event occurs. The commands list can hold 64 32-bits commands (see ADC Commands list format CLRx) and it is double-buffered, that is the commands list can be updated in any time between two consecutive MRS but the changes become visible only after that the next MRS occurs.

In order to manage the Commands List, $\log_2(64)$ bits for the position of the first command in the list of commands for each trigger event are necessary and are present in CLCRx registers. The number of commands piloted by the same trigger event is defined directly in the commands list (for each command there is a bit to say if it is the last command).

35.6.1 ADC commands list format

Each command list register (CLRx) contains command for a single ADC. The various fields of this register is as below:

Table 472. CLRx bit fields

Field	Description
CIR	Command Interrupt Request. If set, it generates an interrupt at the start of command execution. It must be set in the same command register which has EC bit set (end of concurrent command) else ADC_I flag will not be set.
LC	Last command sequence for the trigger.

Table 472. CLRx bit fields (continued)

Field	Description
EC	End of the concurrent command.
FIFO_CH	FIFO number for the conversion. This is to select the FIFO in which the converted ADC data would be stored. CTU can support max 8 FIFOs.
ADC_CH	ADC Channel number. To select the channel number of selected ADC. CTU can support maximum 2^7channels.
ADC_UNIT	ADC unit number. To select the external ADC. CTU can support maximum 4 ADCs.

CTU supports Single Conversion Mode and the Multiple Conversion Mode.

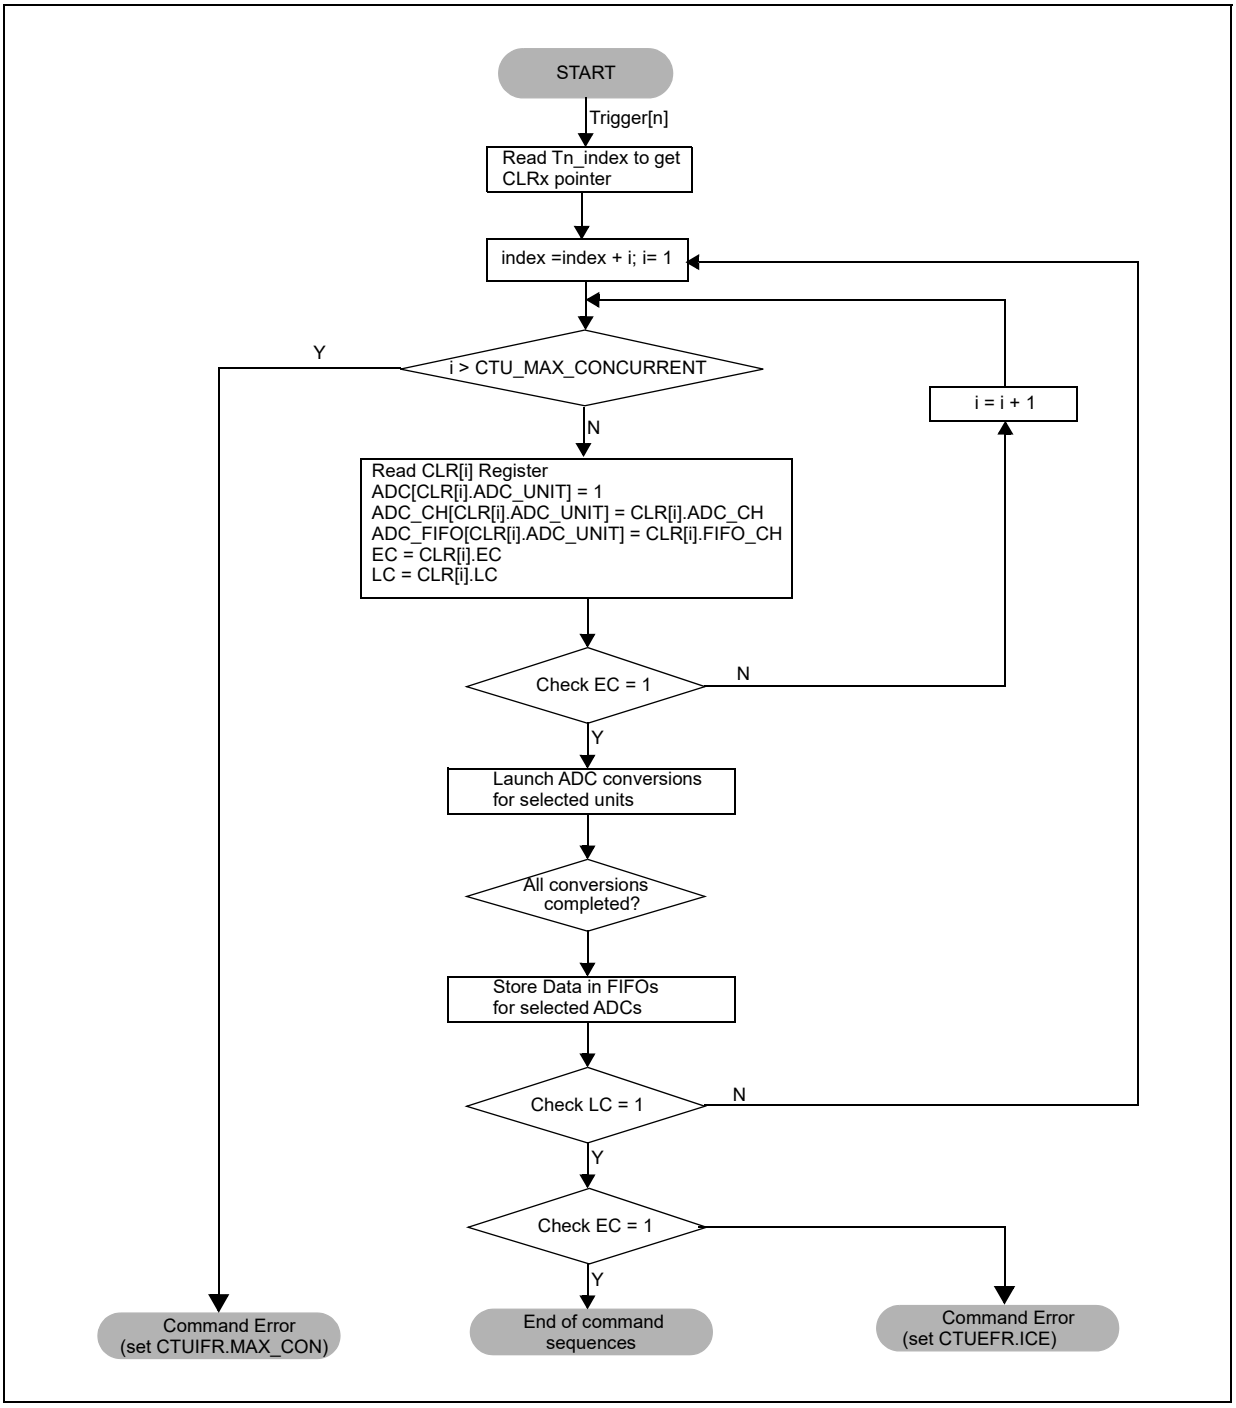
- **Single Conversion Mode:** Only 1 ADC would be selected to perform conversion at a time.
- **Multiple Conversion Mode:** Maximum 4 ADCs can be selected to perform sampling and conversion at the same time. The storage of results can be done in series (if same FIFO is selected for different ADCs) or in parallel (if different FIFOs are selected for different ADCs). If same FIFO is selected for multiple ADCs and converted data is available in the same cycle, then command register with least index will have higher priority, for example ADC number of CLR_1 will be having higher priority over ADC number of CLR_2 and so on. Otherwise, the first ADC which ends its conversion, will write its data first in the selected FIFO.

Each trigger source can generate a sequence of conversion windows. Each conversion window can be programmed to select 1 or more ADCs to start sampling and conversion together. The last of the conversion window is identified using EC bit of the CLRx register. If EC bit is ‘1’ it implies the end of present conversion window and CTU will then start generating ADC commands.

Similarly, last of the conversion sequences for a trigger event is identified using LC bit. If LC bit is ‘1’ it implies the end of the conversion sequence for the particular trigger source (*Figure 375*).

The number of maximum concurrent conversions is limited by a static design parameter (CTU_MAX_CONCURRENT=4). If CLRx are programmed in such a way that it exceeds the concurrent conversions from CTU_MAX_CONCURRENT then an error flag is generated (CTUIFR.MAXCON).

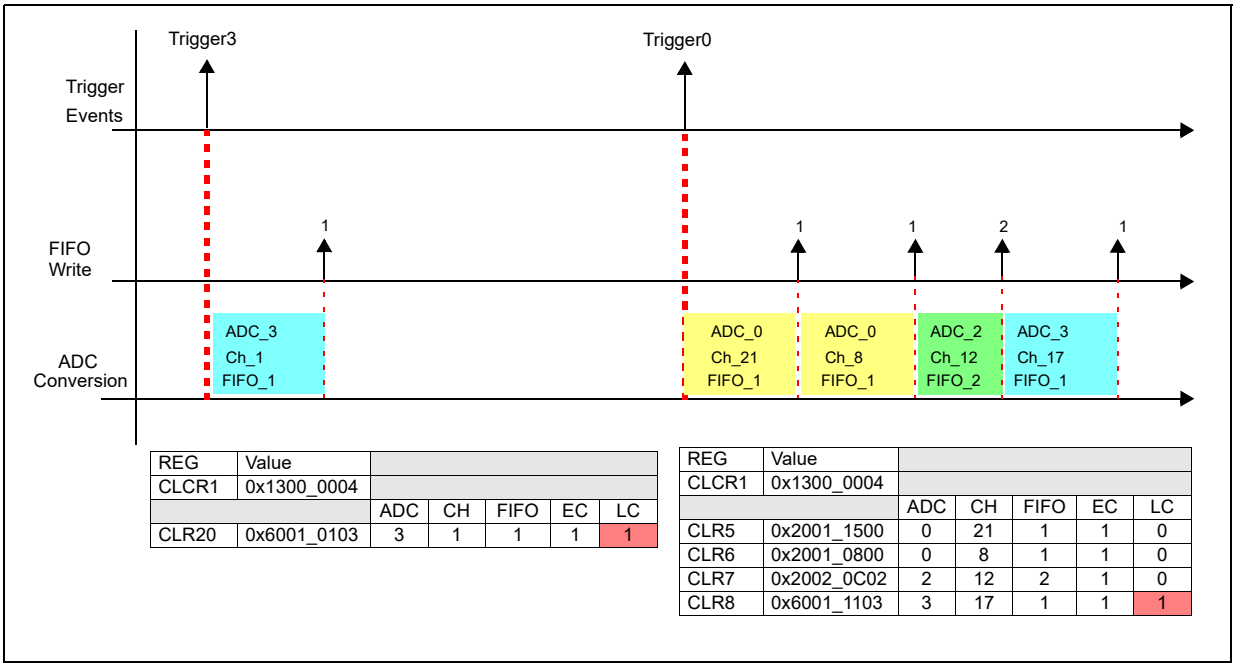
EC bit must be set for both conditions - ‘end of concurrent conversion’ and ‘end of conversion sequences’.



Note: If LC bit is 1 and EC bit is not set, then it implies an error condition and ICE error flag is set.

For multiple conversion mode, maximum 4 command registers are evaluated starting from the base command as is pointed by CLCRx register. And, for a series of concurrent conversions, the next command registers are taken as incremented from the previous concurrent conversion.

As there can be maximum 64 command registers, it is possible that a roll-over condition occurs for selecting next command register. In such case, roll-over happens and next command is taken from CLR1 register.

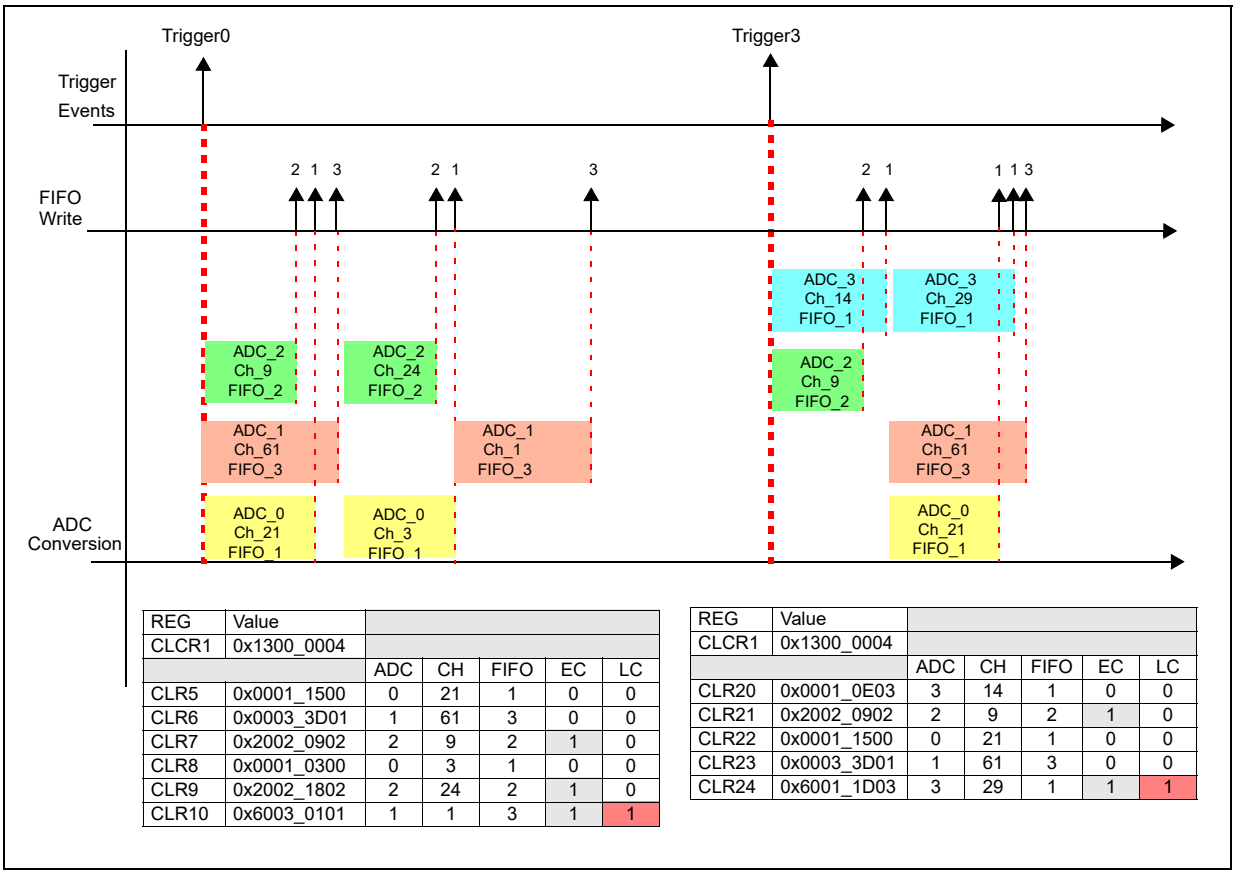


For example Trigger 0 generates command starting from CLR63. If 3 ADCs are to be triggered concurrently then commands will be generated as according to CLR63, CLR64 and CLR1 registers.

Figure 375. ADC command generation flow chart

The conversion timing diagram is shown as below to illustrate single conversion sequences.

Figure 376. Single mode conversion example



REG	Value					
CLCR1	0x1300_0004					
		ADC	CH	FIFO	EC	LC
CLR20	0x6001_0103	3	1	1	1	1

REG	Value					
CLCR1	0x1300_0004					
		ADC	CH	FIFO	EC	LC
CLR5	0x2001_1500	0	21	1	1	0
CLR6	0x2001_0800	0	8	1	1	0
CLR7	0x2002_0C02	2	12	2	1	0
CLR8	0x6001_1103	3	17	1	1	1

An example of multi-mode conversion is as below:

Figure 377. Multi mode conversion example

REG	Value

CLR23	0x0003_3D01	1	61	3	0	0
CLR24	0x6001_1D03	3	29	1	1	1

The interrupt request bit (CIR) is used as an interrupt request to the CPU when ADC will complete the command (LC=1) with this bit set and it is only for CTU internal use.

35.6.2 ADC results

ADC results can be stored in the channel relevant standard result register and/or in one of the 8 FIFOs. The different FIFOs allow to dispatch ADC results according to the their type of acquisition (ex: phase current, rotor position, ground-noise, other). Each FIFO has its own interrupt and DMA request signal (plus an individual overflow error bit in the FIFO status register). The storage location is specified in the ADC command, that is the FIFOs are available only in CTU Control Mode.

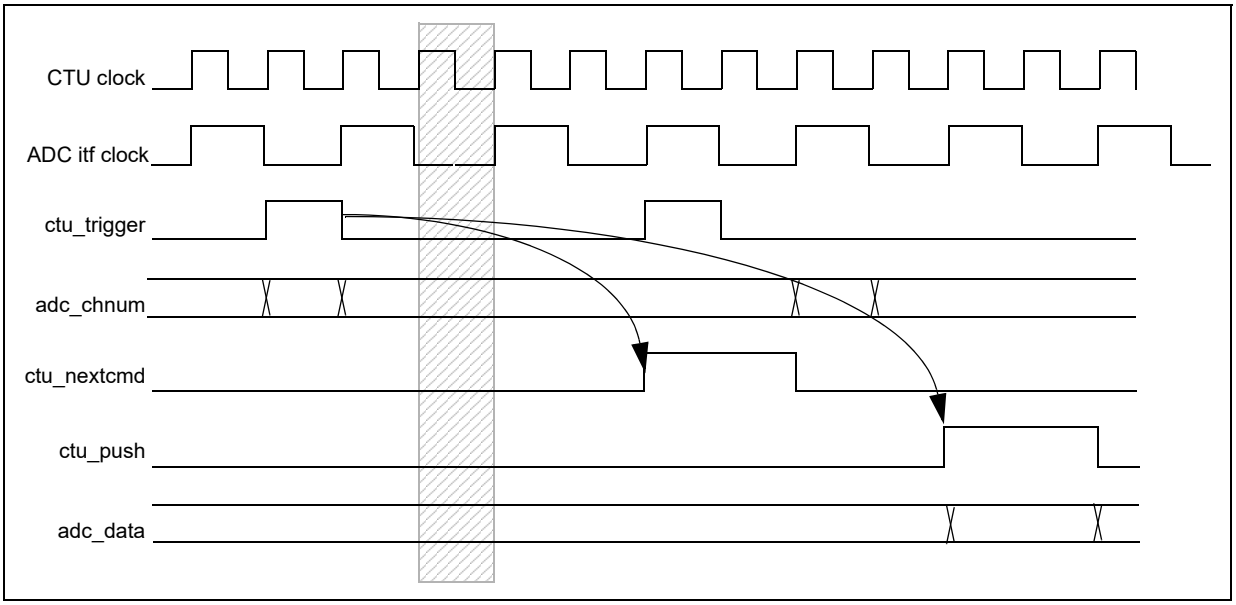
Each entry of a FIFO is 32-bits and it stores converted ADC data and the associated channel number.

The FIFOs are implemented as a peripheral inside the addressing space of the CTU. The ADC communicates with this unit by sending a converted data. The depth of each FIFO can be customized to prevent overflow. A low depth FIFO can be utilized for low acquisition rate conversion and high depth FIFO can be utilized for current acquisitions.

Results in each FIFO can be read by 32-bits read transaction (both the result and the channel number are read in order to avoid blind acquisitions).

The result registers (only for the FIFOs) can be read from 2 different addresses in the CTU memory map. The format of the result depends on the address from which it is read. The available formats are unsigned right-justified format *FIFO right aligned register n (FRn)* (conversion result is unsigned right-justified data, that is the bits [11:0] are used for 10-bit resolution and the bits [15:12] always return zero when read) and signed left-justified format *FIFO left aligned register n (FLn)* (conversion result is signed left-justified data, that is the bit [15] is reserved for sign and is always read as zero for this ADC, the bits[14:3] represents the 1-b ADC data).

35.6.3 ADC-CTU interface timing



CTU is able to command a single conversion to one of the 4 ADCs (single conversion mode) or to many ADCs at the same time (multi-conversion mode).

CTU clock must be synchronous with the ADC digital interface module clock and must be same or faster than ADC digital interface module clock.

In single conversion mode it is possible to send command one at a time to the selected ADC. A new command can be sent only when the ongoing ADC completes its conversion (correspondent next_command is provided from the CTU_ADC interface). If it tries to send a new command before the next_command an overrun error occurs.

In multi-conversion mode, more than 1 ADCs are selected to start conversion. The channel number of these ADCs will be decided based on the respective command register. Similarly the FIFO in which the converted data is to be stored can be programmed differently for each ADC. For the next multi-conversion mode, the state machine waits till all conversions in the ongoing cycle has been completed. If it tries to send a new command before the next_command an overrun error occurs.

Figure 378. ADC-CTU interface timing

35.7 Low power mode

To reduce power consumption, stop mode mechanism is implemented in the SoC. This is done by generating a stop request from the magic carpet to ECTU. When ECTU receives the stop signals it provides following outputs:

1. ipg_stop_ack : This output is immediately asserted in the same cycle of stop mode request.
2. ipg_stop_ack_MT: This output is generated after synchronization of stop mode request on MT_clk.

It is not possible to stop only one of the 2 clocks and only one stop mode request is used for both.

The ECTU IP does not stop its state machine on receiving the stop mode request. Its stopped only when the magic carpet module gates the clocks. Therefore it is possible that the stop mode request may arrive during an ongoing conversion and as the acknowledge is immediately asserted, ECTU clock gets gated before saving the conversion result. It may result in inconsistent FIFO status.Therefore the software must ensure that there is no ongoing conversion before entering the STOP mode. This is applicable only for software controlled STOP mode.

It is also possible that ADC command generator state machine is waiting for the last command before the clock is gated. And when the clock is restarted, ECTU state machine may be out-of-sync with ADC digital interface. Therefore, a CTUCR.CTU_ADC_RESET bit is provided to reset the state machine and to restart the conversion after exiting from stop mode. It can be used for both software or hardware controlled STOP mode.

35.8 Safety features

35.8.1 Conversion time check

Conversion time for an ADC is defined as the time interval between start of a conversion and the end of a conversion (time between *ctu_trigger* and *ctu_nextcmd* in *Figure 378*). For the safety purposes it is useful to check if the ongoing conversion gets over within a specified time range. The value should be chosen considering the fact that the *ctu_nextcmd* is generated one cycle earlier than the actual end of conversion.

There is a 16-bit internal counter running on system interface clock (read/write bus clock), and starts counting at the start of a conversion. Every start of a conversion (ctu_trigger pulse) resets the counter. As all conversions (single as well as parallel) start with the same trigger, there is a single counter only for all conversions (supports maximum 4 parallel conversions).

For each ongoing conversion (maximum 4 parallel conversions), the conversion time check is done using CTU_EXPECTED_x and CTU_CNT_RANGE_x registers. These are 4 registers available to measure conversion time for 4 possible parallel conversions. In case of a single conversion, only CTU_EXPECTED_1/CTU_CNT_RANGE_1 registers are used. In case of two parallel conversions, CTU_EXPECTED_1/CTU_EXPECTED_2 registers are used and so on.

The conversion time range is programmed using CTU_CNT_RANGE_x bits. If a bit of this register is set, the correspondent bit of the CTU_EXPECTED_x register is used to compare time interval with the internal real time counter.

35.8.2 CTU reset

It is possible that CTU state machine is waiting for end of conversion signal from ADC, and due to any fault it does not arrive. Therefore it is required to reset the CTU state machine to start next conversion.

In case of any need to reset the CTU, following methods can be used.

- CTUCR.CTU_ADC_reset

  This bit when set by software, generates an internal pulse which puts the ADC command state machine in a reset state. This condition is treated similar as ‘last_command’ condition has occured and state machine comes out of the conversion mode for the particular trigger conversion sequence. Next trigger events (internal or external) would be treated normally.

- ADCDIG.MCR.CTUEN

  These bits are available in the SAR ADC Digital Interface and are used to program ADC Digital Interface in CTU mode. These bits are connected to *ctuen*<> inputs of the CTU. If all of the ADC interfaces connected to a CTU reset their respective CTUEN bits then ADC command state machine would be reset. If any of the ADC interface remains with CTUEN set, then ADC command state machine would not be reset.

The above methods reset only the state machine and do not reset any of control/status bits in CTU.

35.8.3 Motor function iMonitor

To enhance safety of the complete motor control computation cycle, a motor function monitor using a 32-b CRC engine is available. This engine updates a CRC based on following:

- Type of triggers generated (external trigger, eTimer<x>_trigger, ADC_trigger) along-with timestamp
- ADCs which are triggered for conversion
- ADC channel numbers
- ADC FIFO's numbers
- ADC end of conversion events along-with timestamp
- CTU error signals

All above information are used in CRC computation alongwith the timestamp provided by the TGS counter.

The algorithm for CRC is CRC-32 (Ethernet):

$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$

The initial seed of the CRC is 0xFFFF_FFFF. The design implementation executes the CRC computation in a single cycle (parallel data loading) for each input.

Based on the programming of various command registers, input triggers events, ADC conversion time, it is possible to compute CRC during application development. Thus calculated CRC can be programmed in CTU_EXP_CRC_VAL as expected CRC for each MRS cycle.

CRC computation is triggered by the MRS event and a check with expected CRC (CTU_EXP_CRC_VAL) is performed at the next MRS event. In case of a mismatch, an error flag (CTUEFR.CRC_ERR) is generated as well as a signal is sent to FCCU.

To keep a check on any error condition during the MRS cycle, all error events related to CTUEFR[10:0] bits are latched. These latched error flags are XORed with the computed CRC[10:0] bits before its compared with the expected CRC. This ensures that no error condition has occured in the MRS cycle apart from the normal CRC check.

Based on a certain programming sequence of ADC command registers, Trigger sources etc, it provides an unique combination of events in a MRS cycle resulting in unique checksum. With the CRC comparison, it is ensured that all events have occured in the expected manner thus ensuring the safety of the motor control loop.

The checksum engine is controlled using CTUCR.CTU_CRC_EN bit and works as below:

Table 473. CRC computation steps

Cycle	CRC state	CRC input (32-bit)	CRC computation enable condition	Description
1	IDLE	If (trigger_event) {12'b0, Ext_trigger, eTimer2_trigger, eTimer1_trigger, |(ctu_trigger), TGS_Counter[15:0]} elsif (ctu_push_event) {ctu_push[15:0], TGS_Counter[15:0]}	If any of the trigger events (eTimer1, eTimer2, Ext_Trigger, ADC_trigger) occured, or ctu_push (end of conv) occured then only the CRC is computed else retains its previous value. **ctu_push** computations are enabled by CTU_MASK_CRC_VAL.MASK_PUSH=0 condition TGS_Counter computations are masked using CTU_MASK_CRC_VAL.MASK_TIMESTAMP = "111" else always enabled	Individual mask bits are available for trigger inputs. MASK_ext_TRG, MASK_eTimer2_TRG, MASK_eTimer1_TRG, MASK_ADC_TRG. If any trigger input is masked then the corresponding CRC input bit is put to 1'b0. Also, if any ctu_push events are occured in non-IDLE states, then that is latched and used in computation only in IDLE state.
2	TRIGGER	{16'b0, ctu_trigger[15:0]}	CTU_MASK_CRC_VAL.MASK_ADC_NUM=0	Each bit is used for each ADC as per its position.
3	ADC_CH_0	{4'b0, ctu_adc_channel[27:0]}	CTU_MASK_CRC_VAL.MASK_ADC_CH=0	7 bits are assigned for channel information for each ADC. [27:0] contains information about ADC0-3
4	ADC_CH_1	{4'b0, ctu_adc_channel[59:32]}	CTU_MASK_CRC_VAL.MASK_ADC_CH=0 & (Number of ADCs > 4)	7 bits are assigned for channel information for each ADC. [59:32] contains information about ADC4-7
5	ADC_CH_2	{4'b0, ctu_adc_channel[91:64]}	CTU_MASK_CRC_VAL.MASK_ADC_CH=0 & (Number of ADCs > 8)	7 bits are assigned for channel information for each ADC. [91:64] contains information about ADC8-11
6	ADC_CH_3	{4'b0, ctu_adc_channel[123:96]}	CTU_MASK_CRC_VAL.MASK_ADC_CH=0 & (Number of ADCs > 12)	7 bits are assigned for channel information for each ADC. [123:96] contains information about ADC12-15
7	FIFO_0	{ctu_fifo[31:0]}	CTU_MASK_CRC_VAL.MASK_ADC_FIFO=0	4 bits are assigned for FIFO information for each ADC. [31:0] contains information about ADC0-7
8	FIFO_1	{ctu_fifo[63:32]}	CTU_MASK_CRC_VAL.MASK_ADC_FIFO=0 & (Number of ADCs > 8)	4 bits are assigned for FIFO information for each ADC. [63:32] contains information about ADC8-15

Note: The CRC method when enabled provides a deterministic checksum calculation based on a defined set of trigger commands. During development once the configuration is validated, its associated CRC output can be read and stored as a reference value which will be checked for each conversion cycle and accordingly error alarm would be generated.

35.9 CTU error flags examples

Following examples are related to multiple programming mode only with maximum four concurrent conversions.

35.9.1 Invalid command error

This error condition occurs in following conditions:

- EC=0 and LC=1 in a command register
- Same ADC number appears more than once in CLRx in multiple conversion mode

Table 474. Invalid command error example

Trigger	Conversion cycle	CLRx[0:3]	Behavior
1	concurrent #1	0x00_01_05_01 0x00_02_04_00 0x00_04_03_02 0x02_01_02_03	- Conversion triggered for: ADC_1 Chnum_5 FIFO_1 ADC_0 Chnum_4 FIFO_2 ADC_2 Chnum_3 FIFO_4 ADC_3 Chnum_2 FIFO_1
	concurrent #2 (last command)	0x00_01_03_01 0x40_02_03_02 0x60_01_05_03	- Conversion triggered for: ADC_1 Chnum_3 FIFO_1 ADC_2 Chnum_3 FIFO_2 ADC_3 Chnum_5 FIFO_1 - EC=1 but LC=0 so CTUEFR.ICE error flag will be set. - LC=EC=1 so it will be considered as last command.
2	concurrent #1	0x00_01_03_01 0x00_02_02_01 0x60_01_05_03	- Conversion triggered for: ADC_1 Chnum_3 FIFO_1 ADC_3 Chnum_5 FIFO_1 - As ADC_1 is repeated therefore CTUEFR.ICE error flag will be set.

35.9.2 Maximum concurrent conversion error

This error occurs when number of conversions in a concurrent conversion exceeds 4. If it happens no conversion takes place and the trigger source is terminated. CTU then waits for next trigger.

Table 475. Maximum concurrent conversion error example

Trigger	Conversion cycle	CLRx[0:3]	Behavior
1	concurrent #1	0x00_01_05_01 0x00_02_04_00 0x00_04_03_02 0x00_01_02_03	- No conversion triggered - CTUEFR.MAX_CON error flag is set as EC bit is not set in these 4 command registers. - It is the last command for Trigger_1.
2	concurrent #1	0x00_01_03_01 0x40_02_03_02 0x00_01_05_03 0x40_01_05_03	- No conversion triggered - CTUEFR.MAX_CON error flag is set as EC bit is not set in these 4 command registers. - EC=1 but LC=0 so CTUEFR.ICE error flag will be set. - It is the last command for Trigger_2.

35.10 Register description

All registers are 32-bit wide.

The following sections detail the individual registers.

35.10.1 Synchronization

The following kind of synchronization mechanism are used:

1. The MRS occurrence can start the synchronization of the data from the ipg_clk domain to the MT_clk domain. This mode is used for all double-buffered registers.
2. TGSISR_RE bit is used to synchronize TGSISR register. When the user set TGSISR_RE the value write in theTGSISR is used.
3. The synchronization from the ipg_clk domain to the MT_clk domain is continuously performed for all not double-buffered registers (such as CTUCR, CTUIFR and so on). In this case two consecutive pulse will be filtered if it happens in a time less than 3 ipg_clk + 4 mt_clk. For this reason is not possible to write two consecutive software trigger in a time less than the specified one.
4. Similarly, when a software trigger is generated using CTUCR, the corresponding interrupt flags in CTUIFR will be set only after 3 ipg_clk+4 mt_clk delay. This is due to the internal synchronization logic present between 2 clock domains.

35.10.2 Double buffered registers

Some registers of the CTU are double buffered. This mechanism is necessary if we will be sure that data write from CPU bus will be stable when are used from CTU kernel. When MRS is set, the data stored in a register in ipg_clk clock domain will be copied into the same registers in the other clock domain. To avoid error condition due to a MRS signal that arrive when a write operation is not fully completed following two bits are used.

1. GRE (General register enable)
2. FGRE (General register disable)

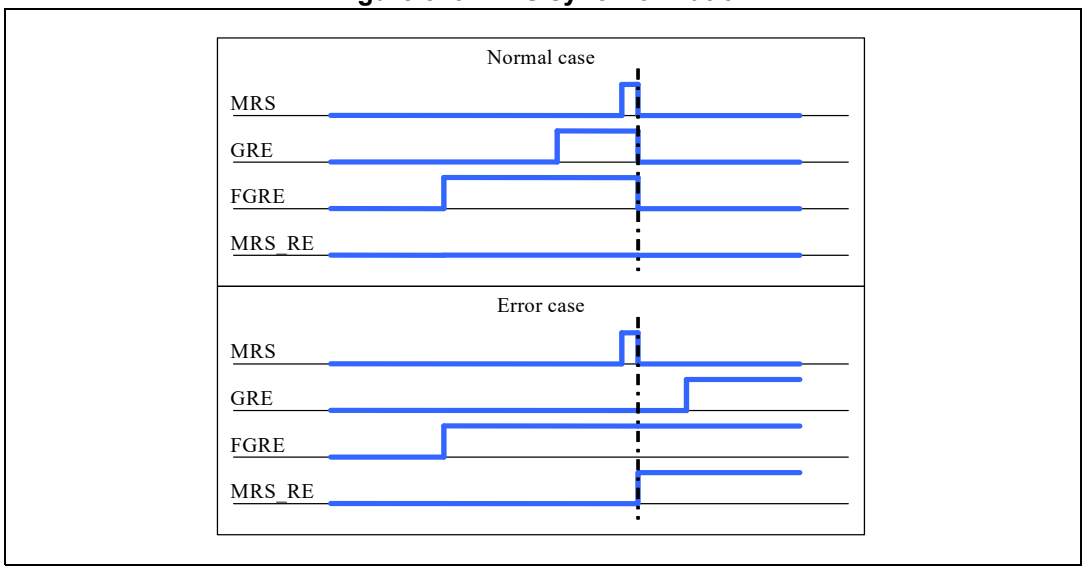
The reload of all double-buffered registers is enabled by setting the GRE (General reload enable) bit in the CTU control register in order to guarantee the consistency of all double-buffered registers. The user must ensure that the trigger command list is updated before

that a MRS occurs. If the update is not performed, the previous values of all double-buffered registers remain active and the CTU will optionally perform an interrupt request.

All the double-buffered registers use the same bit (General Reload Enable - GRE) to enable the reload when the MRS occurs. This bit is used to signal that the user has updated the registers and so a reload can be performed without any problem. The MRS bit is R/S (Read/Set). If the bit is 1 the reload can be performed, while if this bit is 0, the reload is not performed. A correct reload resets this bit. It is also possible to reset this bit by software setting CGRE bit. This bit can be reset in a software way but, anyway, it is reset when GRE bit is at zero.

In order to verify if a reload error occurs, FGRE (**Flag GRE bit in the CTU Control Register**) bit is used. When one of the double-buffered registers is written, FGRE flag is set to 1 and it is reset by a correct reload.

When the MRS occurs while FGRE =1 and GRE =1, a correct reload is performed (because all intended registers have been updated before the MRS occurs).



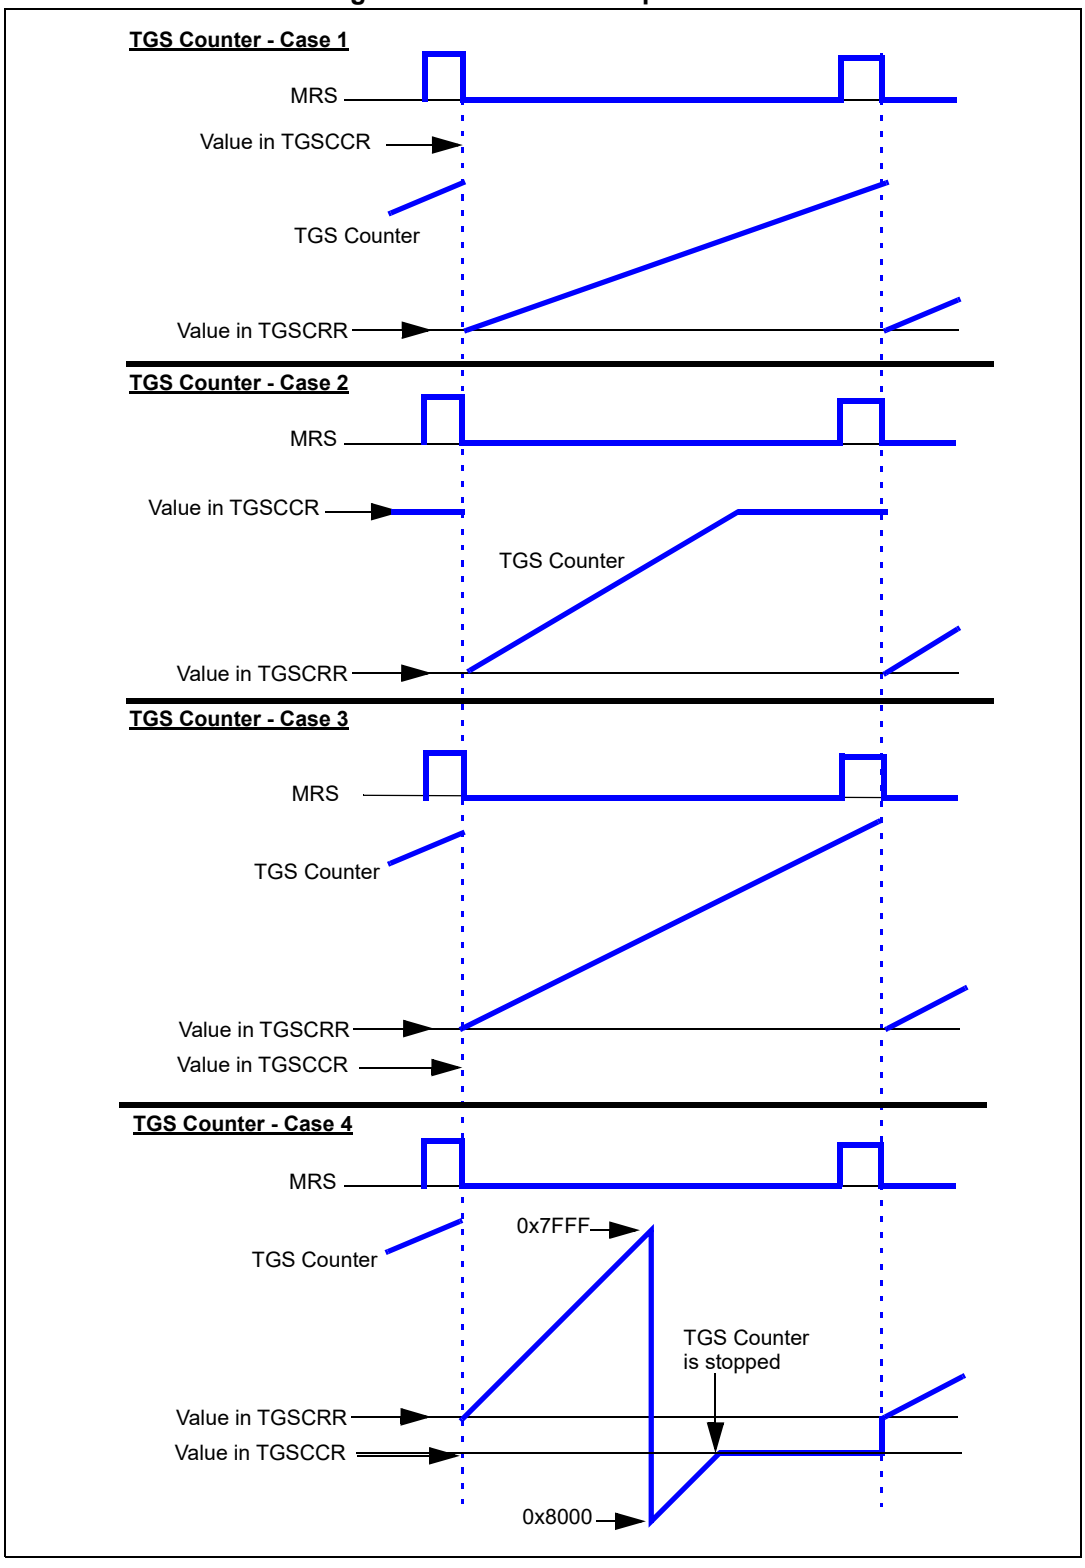
If FGRE=1 and GRE=0, a reload is not performed, the error flag (MRS_RE) is set and (if enabled) an interrupt for an error is performed (in this case at least one register was written but the update has not been ended before the MRS occurrence).

If FGRE=0 it is not necessary to perform a reload because all the double-buffered registers are unchanged.

If GRE=1 with FGRE=0, a MRS_RE is generated on the next master reload.

Because of the two asynchronous domains an error is provided if the GRE FGRE and MRS in the Motor control clock domain are not in the explained configuration. It is possible that an error is generated and GRE and FGRE are set. This is due to the time needed for the synchronization. If the MRS happens when GRE in the motor control domain is reset and the GRE in the motor control domain is not yet reset the error is provided. The following figure shows the timing diagram in the motor control clock domain of a correct reload and of an mistaken reload.

Figure 379. MRS synchronization



35.10.3 TGS counter precision

The TGS Counter must to be able to count as the one of the PWM: from negative to positive, that is from 0x8000 to 0x7FFF. In the figure below are shown some cases in order to explain the TGS counter operation. The compare operation to stop the TGS Counter is not enabled during the first counting cycle in order to allow the counting if the value of the TGSCRR is the same of the TGSCCR.

The precision is mandatory in motor control application, then the timing of the trigger generation must be deterministic. An offset of one or two clock cycles can be acceptable, but also the offset should be deterministic. After the design phase, the offset must be specified in user documentation.

If the TGS counter contains the same value of TGSCCR register an error is generated.

Figure 380. TGS counter precision

The precision is mandatory in motor control application, then the timing of the trigger generation must be deterministic. An offset of one or two clock cycles can be acceptable, but also the offset should be deterministic.

The trigger for the SU is generated always when the counter reaches the value in the trigger compare register. The number of clocks required to reach the value in the register starting from a new master reload is equal to:

$$(TxCR \times (Pres + 1)) + 1$$

35.10.4 Memory map

Table 476. TGS registers

Address offset	Register	Double buffered	Synchronization	Reset value
0x0000	Trigger Generator Subunit Input Selection Register (TGSISR)	Yes	TGSISR_RE	0x0000 0000

Figure 394. Commands list register *n* (CLR*n*)

Table 493. CLR*n* field descriptions

Field	Description
0 CIR	Command Interrupt Request 0 disabled 1 enabled
1 LC	1 implies Last sequence for the trigger
2 EC	1 implies End of the concurrent conversion
12:15 FIFO_CH	FIFO number for the conversion. Max number supported is 8.
17:23 ADC_CH	ADC Channel number. Max number supported is 2^7.
28:31 ADC_UNIT	ADC unit number. Max number supported is 4.

35.10.19 Control register (CR)

The reset value must be corrected as per parameter CTU_NUM_FIFO.

CTU_NUM_FIFO=4 : Reset Value = 0x000F_0000,

CTU_NUM_FIFO=8 : Reset Value = 0x00FF_0000,

CTU_NUM_FIFO=12 : Reset Value = 0x0FFF_0000,

CTU_NUM_FIFO=16 : Reset Value = 0xFFFF_0000

The present design supports CTU_NUM_FIFO=8.

Figure 395. Control register (CR)

Table 494. CR field descriptions

Field	Description
0:15 EMPTY_CLR[15:0]	Empty Clear These bits reset the interrupt related to the empty flag even if the fifo is still empty. These bits are set by hardware with a positive edge on the empty flag and are reset by writing 1 in this field or writing a data in the fifo. When this bit is reset, FIFO empty interrupts are not generated even if FCRx.EMPTY_ENx & SRx.EMPTYx bits are set.
16:31 DMA_EN[15:0]	DMA Enable This bit enables the DMA interface for the FIFOx. 0 disabled 1 enabled

Field	Description
8 FIFO_OVERRUN5	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
9 FIFO_OVERFLOW5	This bit is automatically put to one if the number of words became higher than the value set in the threshold 5. This bit is a read only bit.
10 FIFO_EMPTY5	This bit is set to one if the fifo 5 is empty. This bit is a read only bit.
11 FIFO_FULL5	This bit is set to one if the fifo 5 is full. This bit is a read only bit.
12 FIFO_OVERRUN4	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
13 FIFO_OVERFLOW4	This bit is automatically put to one if the number of words became higher than the value set in the threshold 4. This bit is a read only bit.
14 FIFO_EMPTY4	This bit is set to one if the fifo 4 is empty. This bit is a read only bit.
15 FIFO_FULL4	This bit is set to one if the fifo 4 is full. This bit is a read only bit.
16 FIFO_OVERRUN3	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
17 FIFO_OVERFLOW3	This bit is automatically put to one if the number of words became higher than the value set in the threshold 3. This bit is a read only bit.
18 FIFO_EMPTY3	This bit is set to one if the fifo 3 is empty. This bit is a read only bit.
19 FIFO_FULL3	This bit is set to one if the fifo 3 is full. This bit is a read only bit.
20 FIFO_OVERRUN2	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
21 FIFO_OVERFLOW2	This bit is automatically put to one if the number of words became higher than the value set in the threshold 2. This bit is a read only bit.
22 FIFO_EMPTY2	This bit is set to one if the fifo 2 is empty. This bit is a read only bit.
23 FIFO_FULL2	This bit is set to one if the fifo 2 is full. This bit is a read only bit.
24 FIFO_OVERRUN1	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
25 FIFO_OVERFLOW1	This bit is automatically put to one if the number of words became higher than the value set in the threshold 1. This bit is a read only bit.
26 FIFO_EMPTY1	This bit is set to one if the fifo 1 is empty. This bit is a read only bit.

Table 501. ST1 field descriptions (continued)

Field	Description
27 FIFO_FULL1	This bit is set to one if the fifo 1 is full. This bit is a read only bit.
28 FIFO_OVERRUN0	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing '1' to it.
29 FIFO_OVERFLOW0	This bit is automatically put to one if the number of words became higher than the value set in the threshold 0. This bit is a read only bit.
30 FIFO_EMPTY0	This bit is set to one if the fifo 0 is empty. This bit is a read only bit.
31 FIFO_FULL0	This bit is set to one if the fifo 0 is full. This bit is a read only bit.

Table 502. ST2 field descriptions

Field	Description
0 FIFO_OVERRUN15	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
1 FIFO_OVERFLOW15	This bit is automatically put to one if the number of words became higher than the value set in the threshold 15. This bit is a read only bit.
2 FIFO_EMPTY15	This bit is set to one if the fifo 15 is empty. This bit is a read only bit.
3 FIFO_FULL15	This bit is set to one if the fifo 15 is full. This bit is a read only bit.
4 FIFO_OVERRUN14	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
5 FIFO_OVERFLOW14	This bit is automatically put to one if the number of words became higher than the value set in the threshold 14. This bit is a read only bit.
6 FIFO_EMPTY14	This bit is set to one if the fifo 14 is empty. This bit is a read only bit.
7 FIFO_FULL14	This bit is set to one if the fifo 14 is full. This bit is a read only bit.
8 FIFO_OVERRUN13	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
9 FIFO_OVERFLOW13	This bit is automatically put to one if the number of words became higher than the value set in the threshold 13. This bit is a read only bit.
10 FIFO_EMPTY13	This bit is set to one if the fifo 13 is empty. This bit is a read only bit.
11 FIFO_FULL13	This bit is set to one if the fifo 13 is full. This bit is a read only bit.
12 FIFO_OVERRUN12	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
13 FIFO_OVERFLOW12	This bit is automatically put to one if the number of words became higher than the value set in the threshold 12. This bit is a read only bit.
14 FIFO_EMPTY12	This bit is set to one if the fifo 12 is empty. This bit is a read only bit.
15 FIFO_FULL12	This bit is set to one if the fifo 12 is full. This bit is a read only bit.
16 FIFO_OVERRUN11	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing ‘1’ to it.
17 FIFO_OVERFLOW11	This bit is automatically put to one if the number of words became higher than the value set in the threshold 11. This bit is a read only bit.
18 FIFO_EMPTY11	This bit is set to one if the fifo 11 is empty. This bit is a read only bit.

Table 502. ST2 field descriptions (continued)

Field	Description
19 FIFO_FULL11	This bit is set to one if the fifo 11 is full. This bit is a read only bit.
20 FIFO_OVERRUN10	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing '1' to it.
21 FIFO_OVERFLOW10	This bit is automatically put to one if the number of words became higher than the value set in the threshold 10. This bit is a read only bit.
22 FIFO_EMPTY10	This bit is set to one if the fifo 10 is empty. This bit is a read only bit.
23 FIFO_FULL10	This bit is set to one if the fifo 10 is full. This bit is a read only bit.
24 FIFO_OVERRUN9	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing '1' to it.
25 FIFO_OVERFLOW9	This bit is automatically put to one if the number of words became higher than the value set in the threshold 9. This bit is a read only bit.
26 FIFO_EMPTY9	This bit is set to one if the fifo 9 is empty. This bit is a read only bit.
27 FIFO_FULL9	This bit is set to one if the fifo 9 is full. This bit is a read only bit.
28 FIFO_OVERRUN8	This bit is set to 1 if a write operation occurred when corresponding FIFO_FULL flag is set. This flag can be cleared by writing '1' to it.
29 FIFO_OVERFLOW8	This bit is automatically put to one if the number of words became higher than the value set in the threshold 8. This bit is a read only bit.
30 FIFO_EMPTY8	This bit is set to one if the fifo 8 is empty. This bit is a read only bit.
31 FIFO_FULL8	This bit is set to one if the fifo 8 is full. This bit is a read only bit.

11 T4_SG	Trigger 4 software generated when written ’1’. Writing a one has some effect on the module, but it always reads as zero.
12 T3_SG	Trigger 3 software generated when written ’1’. Writing a one has some effect on the module, but it always reads as zero.
13 T2_SG	Trigger 2 software generated when written ’1’. Writing a one has some effect on the module, but it always reads as zero.
14 T1_SG	Trigger 1 software generated when written ’1’. Writing a one has some effect on the module, but it always reads as zero.
15 T0_SG	Trigger 0 software generated when written ’1’. Writing a one has some effect on the module, but it always reads as zero.
23 CTU_CRC_EN	0 CRC computation not enabled 1 CRC computation enabled
24 CTU_ADC_reset	CTU ADC state machine reset when written ‘1’. Writing a one has some effect on the module, but it always reads as zero.
25 CTU_ODIS	CTU output disable 0 output enabled 1 output disabled

Table 509. CTUCR field descriptions (continued)

Field	Description
26 FILTER_enable	This bit is used to synchronize the Filter register value. It is set by the user and automatically reset when it is reloaded in MT_clk domain. The reloaded bit in MT_clk domain gets reset by MRS.
27 CGRE	Clear GRE
28 FGRE	GRE Flag (some double buffered register has been written)
29 MRS_SG	MRS software generated when written ‘1’. Writing a one has some effect on the module, but it always reads as zero.
30 GRE	General Reload Enable
31 TGSISR_RE	TGS Input Selection Register Reload Enable. Is set by the user and reset automatically when its reloaded in MT_clk domain. The reloaded bit in MT_clk domain gets reset by MRS.

28 MASK_PUSH	1 ctu_push signals will not be used in CRC computation. Input to CRC will be 16'h0 always 0 ctu_push signals will be used in CRC computation (This flag control usage of ctu_push for all ADCs. Either all ctu_push's will be used or none)
29 MASK_ADC_FIFO	1 ADC FIFO information will not be used in CRC computation. Input to CRC will be 4'h0 always 0 ADC FIFO information will be used in CRC computation (This flag control usage of FIFO numbers for all ADCs. Either all FIFO# will be used or none)
30 MASK_ADC_CH	1 ADC channel information will not be used in CRC computation. Input to CRC will be 7'b0 always 0 ADC channel information will be used in CRC computation (This flag control usage of ADC CH_NUM for all ADCs. Either all will be used or none)
31 MASK_ADC_NUM	1 Triggered ADC information will not be used in CRC compuration. Input to CRC will be 4'b0 0 Triggered ADC information will be used in CRC computation

36 Motor Control Pulse Width Modulator Module (FlexPWM)

36.1 Introduction

36.1.1 Overview

The pulse width modulator module (FlexPWM) contains one or more PWM submodules each of which is set up to control a single half-bridge power stage. There may also be one or more fault channels.

This PWM is capable of controlling most motor types: AC induction motors (ACIM), Permanent Magnet AC motors (PMAC), both brushless (BLDC) and brush DC motors (BDC), switched (SRM) and variable reluctance motors (VRM), and stepper motors.

36.1.2 Features

- 16 bits of resolution for center, edge aligned, and asymmetrical PWMs
- PWM outputs can operate as complimentary pairs or independent channels
- Can accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Synchronization to external hardware or other PWM supported
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software-control for each PWM output
- All outputs can be programmed to change simultaneously via a "Force Out" event
- PWMX pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Enhanced dual edge capture functionality
- The option to supply the source for each complementary PWM signal pair from any of the following:
  - External digital pin
  - Internal timer channel
  - External ADC input, taking into account values set in ADC high and low limit registers

36.1.3 Modes of Operation

Care must be exercised when using this module in certain chip operating modes. Some motors (such 3-phase AC motors) require regular software updates for proper operation. Failure to do so could result in destroying the motor or inverter. Because of this, PWM outputs are placed in their inactive states in STOP mode, and optionally under WAIT/HALT mode and debug mode. PWM outputs will be reactivated (assuming they were active to begin with) when these modes are exited.

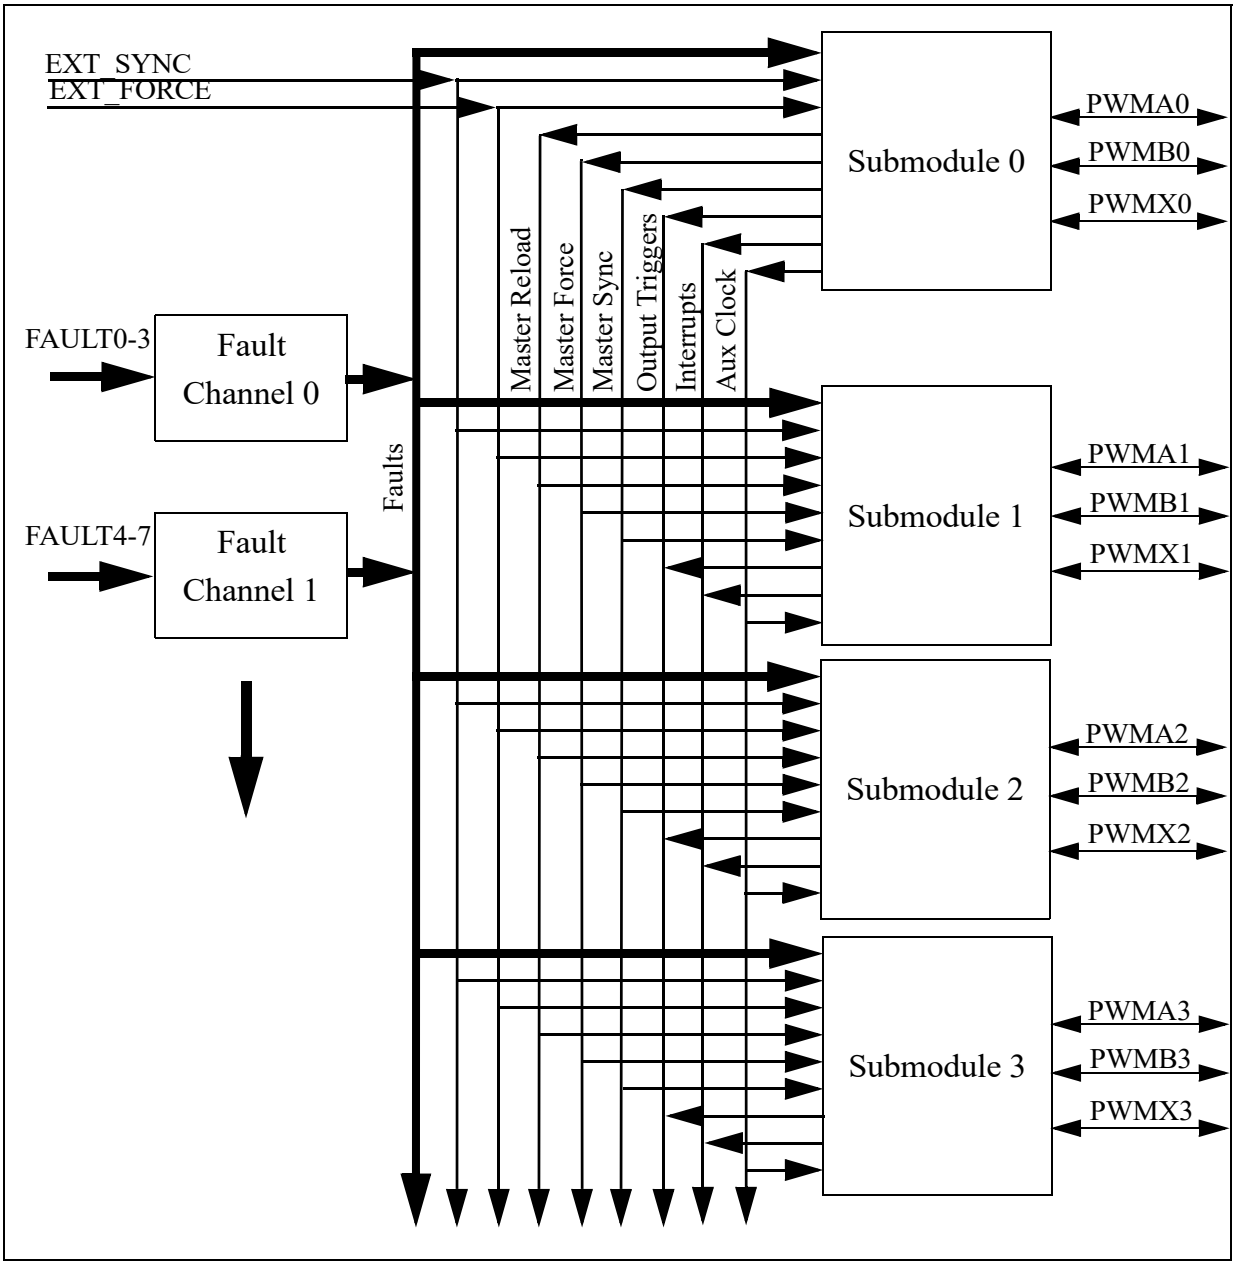

Table 518. Modes When PWM Operation is Restricted

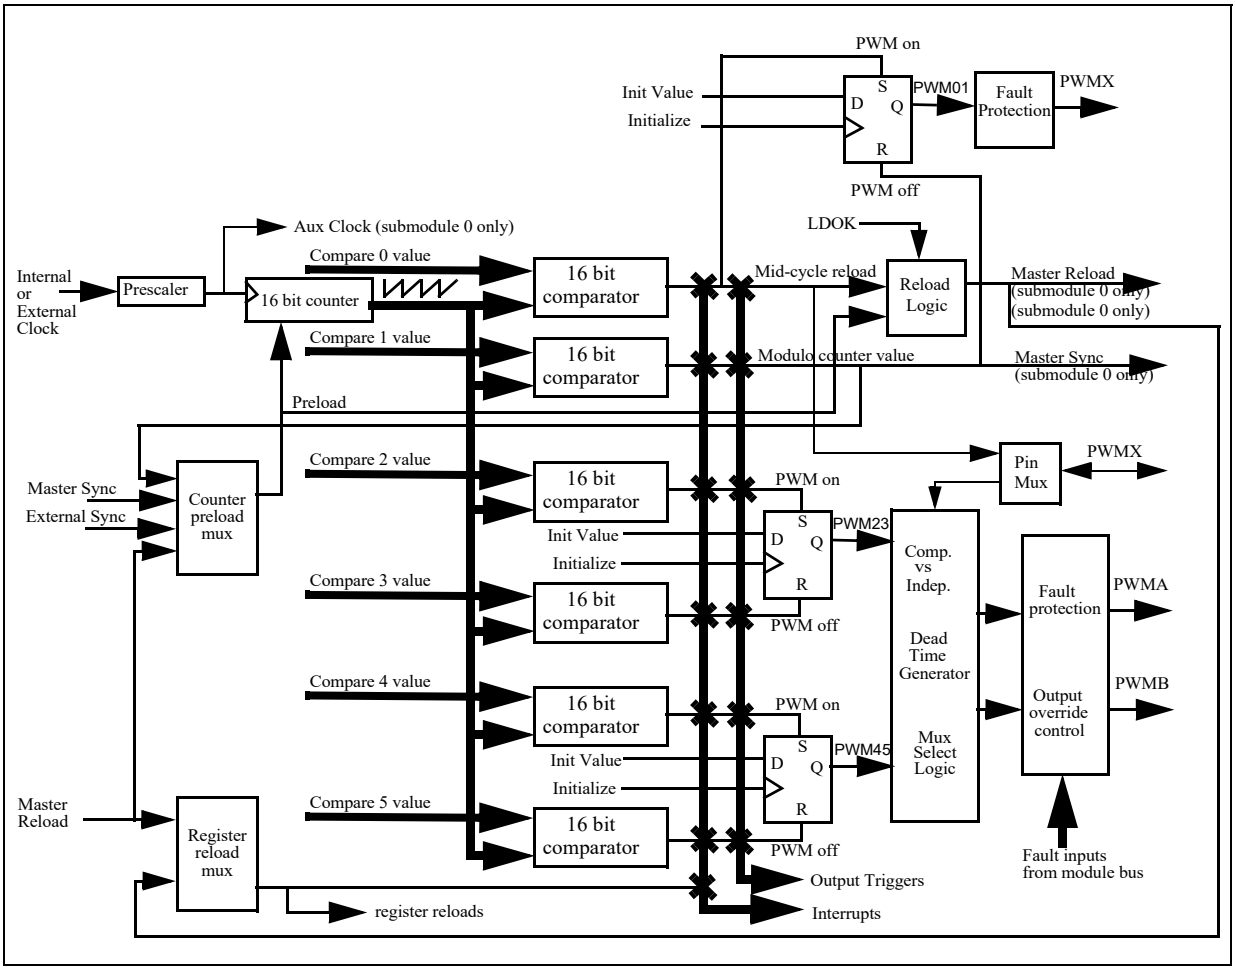
Mode	Description
STOP	Peripheral and CPU clocks are stopped. PWM outputs are driven inactive.
WAIT/HALT	CPU clocks are stopped while peripheral clocks continue to run. PWM outputs are driven inactive as a function of the WAITEN bit. WAIT mode may be referred to as HALT mode at the SoC level.
DEBUG	CPU and peripheral clocks continue to run, but CPU maybe stalled for periods of time. PWM outputs are driven inactive as a function of the DBGEN bit.

36.1.4 Block Diagrams



36.1.4.1 Module Level

Figure 419. PWM Block Diagram

36.1.4.2 PWM Submodule

Figure 420. PWM Submodule Block Diagram

36.2 External Signal Descriptions

The PWM module has external pins named PWMA[n], PWMB[n], PWMX[n], FAULT[n], EXT_SYNC, EXT_FORCE, EXTA[n], and EXTB[n]. The PWM module also has an on chip input called EXT_CLK and an on-chip output called OUT_TRIG[n].

36.2.1 PWMA[n] and PWMB[n] - External PWM Pair

These pins are the output pins of the PWM channels. They can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

36.2.2 PWMX[n] - Auxiliary PWM signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or they can be used to generate the IPOL bit during deadtime correction.

36.2.3 FAULT[n] - Fault inputs

These are input pins for disabling selected PWM outputs.

36.2.4 EXT_SYNC - External Synchronization Signal

This input signal allows a source external to the PWM to initialize the PWM counter. In this manner the PWM can be synchronized to external circuitry.

36.2.5 EXT_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner the PWM can be synchronized to external circuitry. An example would be to simultaneously switch all of the PWM outputs on a commutation boundary for trapezoidal control of a BLDC motor. The boundary can be established via external logic or an on-chip timer.

36.2.6 EXTA[n] and EXTB[n] - Alternate PWM Control Signals

These pins allow an alternate source to control the PWMA and PWMB outputs although typically, the EXTA input will be used for the generation of a complementary pair. Typical connections include ADC results registers, TMR outputs, GPIO inputs, and comparator outputs. The SIM chapter of the chip system spec will describe the possible connections and the bits to control any muxing.

36.2.7 OUT_TRIG0[n] and OUT_TRIG1[n] - Output Triggers

These outputs allow the PWM submodules to control timing of the ADC conversions. See *Section 36.3.16: Output Trigger Control register n (TCTRLn)* for a description of how to enable these outputs and how the compare registers match up to the output triggers.

36.2.8 EXT_CLK - External Clock Signal

This on-chip input signal allows an on-chip source external to the PWM (typically a Timer) to control the PWM clocking. In this manner the PWM can be synchronized to the Timer. This signal must be generated synchronously to the PWM's clock since it is not resynchronized in the PWM.

36.2.9 EXT_SWITCH - External Switch Signal

This input signal allows a source external to the PWM to control the PWM generation source within submodule1. This signal only functions on submodule1 and selects the source of the generated PWM signal to be either submodule1 or submodule0.

36.3 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level and the address offset is defined at the module level. There are a set of registers for each PWM submodule, for the configuration logic, and for each Fault channel.

Registers are only accessible using 16- or 32-bit accesses. Byte accesses are not allowed.

These registers are repeated for each PWM submodule. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is $50. This is the base address of the PWM module plus an offset based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same offset.

36.3.1 Module Memory Map

Table 519 is the FlexPWM memory map.

The actual availability and number of registers and their configuration are chip-specific. For this information, see "Device Configuration" chapter.

36.3.2 Counter register *n* (CNT*n*)

This read-only register displays the state of the signed 16-bit submodule counter.

Offset: 0x0000 + *n**0x50 (*n*=0 to 3) Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 421. Counter register *n* (CNT*n*)

Table 520. CNT*n* field descriptions

Field	Description
0:15 CNT	Counter Register These read only bits show the current value of the PWM submodule counter.

36.3.3 Initial Count register n (INITn)

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of INIT_SEL) or when FORCE is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle.

Offset: 0x0002 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	INIT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 422. Initial Count register *n* (INIT*n*)

Table 521. INIT*n* field descriptions

Field	Description
0:15 INIT	Initial Count Register This 16-bit signed value is the initial count value for the PWM in PWM clock periods

Note: The INIT register is buffered. The value written does not take effect until the MCTRL[LDOK] bit is set and the next PWM load cycle begins or CTRL1[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

36.3.4 Control 2 register n (CTRL2n)

Offset: 0x0004 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 423. Control 2 register *n* (CTRL2*n*)

Table 522. CTRL2*n* field descriptions

Field	Description
0 DBGEN	Debug Enable When set to one, the PWM will continue to run while the chip is in debug mode. If the device enters debug mode and this bit is zero, then the PWM outputs will be disabled until debug mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in debug mode. The key point is PWM parameter updates will not occur in debug mode. Any motors requiring such updates should be disabled during debug mode. If in doubt, leave this bit set to zero.
1 WAITEN	WAIT Enable When set to one, the PWM will continue to run while the chip is in WAIT/HALT mode. In this mode, the peripheral clock continues to run but the CPU clock does not. If the device enters WAIT/HALT mode and this bit is zero, then the PWM outputs will be disabled until WAIT/HALT mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in WAIT/HALT mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in WAIT/HALT mode. The key point is PWM parameter updates will not occur in this mode. Any motors requiring such updates should be disabled during WAIT/HALT mode. If in doubt, leave this bit set to zero. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in WAIT/HALT mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in WAIT/HALT mode. The key point is PWM parameter updates will not occur in this mode. Any motors requiring such updates should be disabled during WAIT/HALT mode. If in doubt, leave this bit set to zero.

Table 522. CTRL2*n* field descriptions (continued)

Field	Description
2 INDEP	Independent or Complementary Pair Operation This bit determines if the PWMA and PWMB channels will be independent PWMs or a complementary PWM pair. 1 PWMA and PWMB outputs are independent PWMs 0 PWMA and PWMB form a complementary PWM pair
3 PWM23_INIT	PWM23 Initial Value This read/write bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT, *Figure 478: PWM Generation Hardware*, is asserted.
4 PWM45_INIT	PWM45 Initial Value This read/write bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT, *Figure 478: PWM Generation Hardware*, is asserted.
5 PWMX_INIT	PWMX Initial Value This read/write bit determines the initial value for PWMX and the value to which it is forced when FORCE_INIT, *Figure 478: PWM Generation Hardware*, is asserted.
6:7 INIT_SEL	Initialization Control Select These read/write bits control the source of the INIT signal which goes to the counter. 00 Local sync (PWMX) causes initialization 01 Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0 10 Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0 11 EXT_SYNC causes initialization
8 FRCEN	Force Initialization Enable This bit allows the FORCE_OUT signal to initialize the counter without regard to the signal selected by INIT_SEL. This is a software controlled initialization. 1 Initialization from a Force Out event is enabled 0 Initialization from a Force Out event is disabled
9 FORCE	Force Initialization If the FORCE_SEL bits are set to 000, writing a 1 to this bit results in a Force Out event. This causes the following actions to be taken: – The PWMA and PWMB output pins will assume values based on the SEL23 and SEL45 bits. – If the FRCEN bit is set, the counter value will be initialized with the INIT register value.

Table 522. CTRL2*n* field descriptions (continued)

Field	Description
10:12 FORCE_SEL	Force Source Select This read/write bit determines the source of the FORCE OUTPUT signal for this submodule. 000 The local force signal, FORCE, from this submodule is used to force updates 001 The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0 010 The local reload signal from this submodule is used to force updates without regard to the state of LDOK 011 The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0 100 The local sync signal from this submodule is used to force updates 101 The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0 110 The external force signal, EXT_FORCE, from outside the PWM module causes updates 111 Reserved
13 RELOAD_SEL	Reload Source Select This read/write bit determines the source of the RELOAD signal for this submodule. When this bit is set, the LDOK bit in submodule 0 should be used since the local LDOK bit will be ignored. 1 The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it will force the RELOAD signal to logic 0. 0 The local RELOAD signal is used to reload registers.
14:15 CLK_SEL	Clock Source Select These read/write bits determine the source of the clock signal for this submodule. 00 The IPBus clock is used as the clock for the local prescaler and counter. 01 EXT_CLK is used as the clock for the local prescaler and counter. 10 Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it will force the clock to logic 0. 11 Reserved

36.3.5 Control 1 register n (CTRL1n)

Offset: 0x0006 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	LDFQ				HALF	FULL	DT		0	PRSC			PHSSHFT	LDMOD	0	DBLEN
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Figure 424. Control 1 register *n* (CTRL1*n*)

Table 523. CTRL1*n* field descriptions

Field	Description
0:3 LDFQ	Load Frequency These buffered read/write bits select the PWM load frequency according to *Table 524*. Reset clears the LDFQ bits, selecting loading every PWM opportunity. A PWM opportunity is determined by the HALF and FULL bits. **Note:** The LDFQx bits take effect when the current load cycle is complete regardless of the state of the LDOK bit. Reading the LDFQx bits reads the buffered values and not necessarily the values currently in effect.
4 HALF	Half Cycle Reload This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be half way through the PWM cycle. 1 Half-cycle reloads enabled 0 Half-cycle reloads disabled
5 FULL	Full Cycle Reload This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either the HALF or FULL bit must be set in order to move the buffered data into the registers used by the PWM generators. If both the HALF and FULL bits are set, then reloads can occur twice per cycle. 1 Full-cycle reloads enabled 0 Full-cycle reloads disabled
6:7 DT	Deadtime These read only bits reflect the sampled values of the PWMX input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.
9:11 PRSC	Prescaler These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CLK_SEL as illustrated in *Table 525*.
12 PHSSHFT	Phase Shift Mode Enable This read/write bit is only functional in submodule 0. It is used to enable the EXT_SWITCH input to select the source of the generated PWM23/PWM45 signals within submodule 0. If this enable is clear or the EXT_SWITCH signal is 0, then the PWM23/PWM45 signals generated within submodule 0 are used by the force out logic in submodule 0. If this enable is set and the EXT_SWITCH signal is also set, then the PWM23/PWM45 signals from submodule 1 are used by the force out logic in submodule 0. 1 Phase shifted mode is enabled. The EXT_SWITCH input is used to select generated PWM source for force out logic in submodule 0 0 Phase shifted mode is disabled. The EXT_SWITCH input is ignored. Normal operation

Table 523. CTRL1*n* field descriptions (continued)

Field	Description
13 LDMOD	Load Mode Select This read/write bit selects the timing of loading the buffered registers for this submodule. 1 Buffered registers of this submodule are loaded and take effect immediately upon LDOK being set 0 Buffered registers of this submodule are loaded and take effect at the next PWM reload if LDOK is set
15 DBLEN	Double Switching Enable This read/write bit enables the double switching PWM behavior. 1 Double switching enabled 0 Double switching disabled

Table 524. PWM Reload Frequency

LDFQ	PWM reload frequency
0000	Every PWM opportunity
0001	Every 2 PWM opportunities
0010	Every 3 PWM opportunities
0011	Every 4 PWM opportunities
0100	Every 5 PWM opportunities
0101	Every 6 PWM opportunities
0110	Every 7 PWM opportunities
0111	Every 8 PWM opportunities
1000	Every 9 PWM opportunities
1001	Every 10 PWM opportunities
1010	Every 11 PWM opportunities
1011	Every 12 PWM opportunities
1100	Every 13 PWM opportunities
1101	Every 14 PWM opportunities
1110	Every 15 PWM opportunities
1111	Every 16 PWM opportunities

Table 525. PWM Prescaler

PRSC	PWM clock frequency
000	f_{clk}
001	$f_{clk}/2$
010	$f_{clk}/4$
011	$f_{clk}/8$
100	$f_{clk}/16$
101	$f_{clk}/32$
110	$f_{clk}/64$
111	$f_{clk}/128$

Note: Reading the PRSCx bits reads the buffered values and not necessarily the values currently in effect. The PRSCx bits take effect at the beginning of the next PWM cycle and only when the load okay bit, LDOK, is set or LDMOD is set. This field cannot be written when LDOK is set.

36.3.6 Value 0 register n (VAL0n)

Offset: 0x0008 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	VAL0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 425. Value 0 register *n* (VAL0*n*)

Table 526. VAL0*n* field descriptions

Field	Description
0:15 VAL0	Value Register 0

The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWMX signal is set and the local sync signal is reset.

Note: The VAL0 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL0 cannot be written when LDOK is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.

36.3.7 Value 1 register n (VAL1n)

Offset: 0x000A + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	VAL1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 426. Value 1 register *n* (VAL1*n*)

Table 527. VAL1*n* field descriptions

Field	Description
0:15 VAL1	Value Register 1

The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter will reload itself with the contents of the INIT register and assert the local sync signal while resetting PWMX

Note: The VAL1 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL1 cannot be written when LDOK is set. Reading VAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

If VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. The PWMX output will be low for a minimum of one count every cycle after the count reaches VAL1.

When the Master Sync signal (only originated by the Local Sync from submodule 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without duty cycle limitation

36.3.8 Value 2 register n (VAL2n)

Offset: 0x000C + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 431. Output Control register *n* (OCTRL*n*)

Table 532. OCTRL*n* field descriptions

Field	Description
0 PWMA_IN	PWMA Input This read only bit shows the logic value currently being driven into the PWMA input.
1 PWMB_IN	PWMB Input This read only bit shows the logic value currently being driven into the PWMB input.
2 PWMX_IN	PWMX Input This read only bit shows the logic value currently being driven into the PWMX input.
5 POLA	PWMA Output Polarity This bit inverts the PWMA output polarity. 1 PWMA output inverted. A low level on the PWMA pin represents the "on" or "active" state. 0 PWMA output not inverted. A high level on the PWMA pin represents the "on" or "active" state.
6 POLB	PWMB Output Polarity This bit inverts the PWMB output polarity. 1 PWMB output inverted. A low level on the PWMB pin represents the "on" or "active" state. 0 PWMB output not inverted. A high level on the PWMB pin represents the "on" or "active" state.
7 POLX	PWMX Output Polarity This bit inverts the PWMX output polarity. 1 PWMX output inverted. A low level on the PWMX pin represents the "on" or "active" state. 0 PWMX output not inverted. A high level on the PWMX pin represents the "on" or "active" state.
10:11 PWMAFS	PWMA Fault State These bits determine the fault state for the PWMA output during fault conditions and STOP mode. It may also define the output state during WAIT/HALT mode and DEBUG mode depending on the setting of WAITEN and DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.
12:13 PWMBFS	PWMB Fault State These bits determine the fault state for the PWMB output during fault conditions and STOP mode. It may also define the output state during WAIT/HALT mode and DEBUG mode depending on the setting of WAITEN and DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.
14:15 PWMXFS	PWMX Fault State These bits determine the fault state for the PWMX output during fault conditions and STOP mode. It may also define the output state during WAIT/HALT mode and DEBUG mode depending on the setting of WAITEN and DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.

36.3.13 Status register n (STSn)

Figure 432. Status register *n* (STS*n*)

Table 533. STS*n* field descriptions

Field	Description
1 RUF	Registers Updated Flag This read only flag is set when one of the INIT, VALx, or PRSC registers has been written resulting in non-coherent data in the set of double buffered registers. Clear RUF by a proper reload sequence consisting of a reload signal while LDOK = 1. Reset clears RUF. 1 At least one of the double buffered registers has been updated since the last reload. 0 No register update has occurred since last reload.
2 REF	Reload Error Flag This read/write flag is set when a reload cycle occurs while LDOK is 0 and the double buffered registers are in a non-coherent state (RUF = 1). Clear REF by writing a logic one to the REF bit. Reset clears REF. 1 Reload signal occurred with non-coherent data and LDOK = 0 0 No reload error occurred
3 RF	Reload Flag This read/write flag is set at the beginning of every reload cycle regardless of the state of the LDOK bit. Clear RF by writing a logic one to the RF bit when VALDE is clear (non-DMA mode). RF can also be cleared by the DMA done signal when VALDE is set (DMA mode). Reset clears RF. 1 New reload cycle since last RF clearing 0 No new reload cycle since last RF clearing
4 CFA1	Capture Flag A1 This bit is set when the word count of the Capture A1 FIFO (CA1CNT) exceeds the value of the CFAWM field. This bit is cleared by writing a one to this bit position if CA1DE is clear (non-DMA mode) or by the DMA done signal if CA1DE is set (DMA mode). Reset clears this bit.
5 CFA0	Capture Flag A0 This bit is set when the word count of the Capture A0 FIFO (CA0CNT) exceeds the value of the CFAWM field. This bit is cleared by writing a one to this bit position if CA0DE is clear (non-DMA mode) or by the DMA done signal if CA0DE is set (DMA mode). Reset clears this bit.
6 CFB1	Capture Flag B1 This bit is set when the word count of the Capture B1 FIFO (CB1CNT) exceeds the value of the CFBWM field. This bit is cleared by writing a one to this bit position if CB1DE is clear (non-DMA mode) or by the DMA done signal if CB1DE is set (DMA mode). Reset clears this bit.

Table 533. STS*n* field descriptions (continued)

Field	Description
7 CFB0	Capture Flag B0 This bit is set when the word count of the Capture B0 FIFO (CB0CNT) exceeds the value of the CFBWM field. This bit is cleared by writing a one to this bit position if CB0DE is clear (non-DMA mode) or by the DMA done signal if CB0DE is set (DMA mode). Reset clears this bit.
8 CFX1	Capture Flag X1 This bit is set when the word count of the Capture X1 FIFO (CX1CNT) exceeds the value of the CFXWM field. This bit is cleared by writing a one to this bit position if CX1DE is clear (non-DMA mode) or by the DMA done signal if CX1DE is set (DMA mode). Reset clears this bit.
9 CFX0	Capture Flag X0 This bit is set when the word count of the Capture X0 FIFO (CX0CNT) exceeds the value of the CFXWM field. This bit is cleared by writing a one to this bit position if CX0DE is clear (non-DMA mode) or by the DMA done signal if CX0DE is set (DMA mode). Reset clears this bit.
10:15 CMPF	Compare Flags These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position. 1 A compare event has occurred for a particular VALx value. 0 No compare event has occurred for a particular VALx value.

36.3.14 Interrupt Enable register n (INTENn)

Offset: 0x001C + *n**0x50 (*n*=0 to 3) Access: R/W

Table 534. INTEN*n* field descriptions

Field	Description
2 REIE	Reload Error Interrupt Enable This read/write bit enables the reload error flag (REF) to generate CPU interrupt requests. Reset clears RIE. 1 REF CPU interrupt requests enabled 0 REF CPU interrupt requests disabled
3 RIE	Reload Interrupt Enable This read/write bit enables the reload flag (RF) to generate CPU interrupt requests. Reset clears RIE. 1 RF CPU interrupt requests enabled 0 RF CPU interrupt requests disabled

Table 534. INTEN*n* field descriptions (continued)

Field	Description
4 CA1IE	Capture A 1 Interrupt Enable This bit allows the CFA1 flag to create an interrupt request to the CPU. Do not set both this bit and the CA1DE bit. 1 Interrupt request enabled for CFA1 0 Interrupt request disabled for CFA1
5 CA0IE	Capture A 0 Interrupt Enable This bit allows the CFA0 flag to create an interrupt request to the CPU. Do not set both this bit and the CA0DE bit. 1 Interrupt request enabled for CFA0 0 Interrupt request disabled for CFA0
6 CB1IE	Capture B 1 Interrupt Enable This bit allows the CFB1 flag to create an interrupt request to the CPU. Do not set both this bit and the CB1DE bit. 1 Interrupt request enabled for CFB1 0 Interrupt request disabled for CFB1
7 CB0IE	Capture B 0 Interrupt Enable This bit allows the CFB0 flag to create an interrupt request to the CPU. Do not set both this bit and the CB0DE bit. 1 Interrupt request enabled for CFB0 0 Interrupt request disabled for CFB0
8 CX1IE	Capture X 1 Interrupt Enable This bit allows the CFX1 flag to create an interrupt request to the CPU. Do not set both this bit and the CX1DE bit. 1 Interrupt request enabled for CFX1 0 Interrupt request disabled for CFX1
9 CX0IE	Capture X 0 Interrupt Enable This bit allows the CFX0 flag to create an interrupt request to the CPU. Do not set both this bit and the CX0DE bit. 1 Interrupt request enabled for CFX0 0 Interrupt request disabled for CFX0
10:15 CMPIE	Compare Interrupt Enables These bits enable the CMPF flags to cause a compare interrupt request to the CPU. 1 The corresponding CMPF bit will cause an interrupt request. 0 The corresponding CMPF bit will not cause an interrupt request.

36.3.15 DMA Enable register n (DMAENn)

Offset: 0x001E + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	VALDE	FAND	CAPTDE		CA1DE	CA0DE	CB1DE	CB0DE	CX1DE	CX0DE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 434. DMA Enable register *n* (DMAEN*n*)

Table 535. DMAEN*n* field descriptions

Field	Description
6 VALDE	Value Registers DMA Enable This read/write bit enables DMA write requests for the VALx registers when RF is set. Reset clears VALDE. 1 DMA write requests for the VALx registers enabled 0 DMA write requests disabled
7 FAND	FIFO Watermark AND Control This read/write bit works in conjunction with the CAPTDE field when it is set to watermark mode (CAPTDE = 01). While the CAxDE, CBxDE, and CXxDE bits determine which FIFO watermarks the DMA read request is sensitive to, this bit determines if the selected watermarks are AND'ed together or OR'ed together in order to create the request. 1 Selected FIFO watermarks are AND'ed together. 0 Selected FIFO watermarks are OR'ed together.
8:9 CAPTDE	Capture DMA Enable Source Select These read/write bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00 Read DMA requests disabled 01 Exceeding a FIFO watermark sets the DMA read request. This requires at least 1 of the CA1DE, CA0DE, CB1DE, CB0DE, CX1DE, or CX0DE bits to also be set in order to determine which watermark(s) the DMA request is sensitive to. 10 A local sync (VAL1 matches counter) sets the read DMA request. 11 A local reload (RF being set) sets the read DMA request.
10 CA1DE	Capture A1 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture A1 FIFO data when CFA1 is set. Reset clears CA1DE. Do not set both this bit and the CA1IE bit.
11 CA0DE	Capture A0 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture A0 FIFO data when CFA0 is set. Reset clears CA0DE. Do not set both this bit and the CA0IE bit.
12 CB1DE	Capture B1 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture B1 FIFO data when CFB1 is set. Reset clears CB1DE. Do not set both this bit and the CB1IE bit.
13 CB0DE	Capture B0 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture B0 FIFO data when CFB0 is set. Reset clears CB0DE. Do not set both this bit and the CB0IE bit.
14 CX1DE	Capture X1 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X1 FIFO data when CFX1 is set. Reset clears CX1DE. Do not set both this bit and the CX1IE bit.
15 CX0DE	Capture X0 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X0 FIFO data when CFX0 is set. Reset clears CX0DE. Do not set both this bit and the CX0IE bit.

36.3.16 Output Trigger Control register n (TCTRLn)

Offset: 0x0020 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 435. Output Trigger Control register *n* (TCTRL*n*)

Table 536. TCTRL*n* field descriptions

Field	Description
10:15 OUT_TRIG_EN	Output Trigger Enables These bits enable the generation of OUT_TRIG0 and OUT_TRIG1 outputs based on the counter value matching the value in one or more of the VAL0-5 registers. VAL0, VAL2, and VAL4 are used to generate OUT_TRIG0 and VAL1, VAL3, and VAL5 are used to generate OUT_TRIG1. The OUT_TRIGx signals are only asserted as long as the counter value matches the VALx value, therefore up to six triggers can be generated (three each on OUT_TRIG0 and OUT_TRIG1) per PWM cycle per submodule. 1 OUT_TRIGx will set when the counter value matches the VALx value. 0 OUT_TRIGx will not set when the counter value matches the VALx value.

36.3.17 Fault Disable Mapping register n (DISMAPn)

This register determines which PWM pins are disabled by the fault protection inputs, illustrated in *Figure 482: Deadtime Insertion and Fine Control Logic* in *Section 36.4.3.11: Fault Protection*. Reset sets all of the bits in the fault disable mapping register.

Offset: 0x0022 + *n**0x50 (*n*=0 to 3) Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 537. DISMAP*n* field descriptions

Field	Description
4:7 DISX	PWMX Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULTx inputs. The PWMX output will be turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of the DISX field. A reset sets all DISX bits.

Table 537. DISMAP*n* field descriptions (continued)

Field	Description
8:11 DISB	PWMB Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULTx inputs. The PWMB output will be turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of the DISB field. A reset sets all DISB bits.
12:15 DISA	PWMA Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULTx inputs. The PWMA output will be turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of the DISA field. A reset sets all DISA bits.

36.3.18 Deadtime Count 0 register n (DTCNT0n)

Deadtime operation is only applicable to complementary channel operation. The 11-bit values written to these registers are in terms of IPBus clock cycles regardless of the setting of PRSC and/or CLK_SEL. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles.

Offset: 0x0024 + *n**0x50 (*n*=0 to 3) Access: R/W

Figure 439. Capture Control A register *n* (CAPTCTRLA*n*)

Table 540. CAPTCTRLA*n* field descriptions

Field	Description
0:2 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO.
3:5 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO.
6:7 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, CFA1 and CFA0, won't be set until the word count of the corresponding FIFO is greater than this water mark level.
8 EDGCNTA_EN	Edge Counter A Enable This bit enables the edge counter which counts rising and falling edges on the PWMA input signal. 1 Edge counter enabled 0 Edge counter disabled and held in reset.
9 INP_SELA	Input Select A This bit selects between the raw PWMA input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 1 Output of edge counter/compare selected as source. 0 Raw PWMA input signal selected as source. **Note:** When INPSELA = 1, the internal edge counter is enabled and the rising and/or falling edges specified by the EDGA0 and EDGA1 fields are ignored. The software must still place a value other than 00 in either or both of the EDGA0 and/or EDGA1 fields in order to enable one or both of the capture registers.

Table 540. CAPTCTRLA*n* field descriptions (continued)

Field	Description
10:11 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00 Disabled 01 Capture falling edges 10 Capture rising edges 11 Capture any edge
12:13 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00 Disabled 01 Capture falling edges 10 Capture rising edges 11 Capture any edge
14 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 1 One shot mode is selected If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMA bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMA bit is cleared. No further captures will be performed until the ARMA bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMA bit is then cleared. 0 Free running mode is selected If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMA bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.
15 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). To restart capture operations clear this bit, read CVAL2 and CVAL3 until CA0CNT and CA1CNT are 0, then set ARMA. 1 Input capture operation as specified by the EDGAx bits is enabled. 0 Input capture operation is disabled.

Table 547. CVAL0CYC*n* field descriptions

Field	Description
2:013:15 CVAL0CYC	Capture Value 0 Cycle

This read only register stores the cycle number corresponding to the value captured in CVAL0. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. Eventually, this counter rolls over to 0. This is actually a 4 deep FIFO and not a single register.

Table 558. OUTEN field descriptions

Field	Description
4:7 PWMA_EN	PWMA Output Enables These bits enable the PWMA outputs of each submodule. These bits should be set to 0 (output disabled) when a PWMA pin is being used for input capture. 1 PWMA output enabled 0 PWMA output disabled
8:11 PWMB_EN	PWMB Output Enables These bits enable the PWMB outputs of each submodule. These bits should be set to 0 (output disabled) when a PWMB pin is being used for input capture. 1 PWMB output enabled 0 PWMB output disabled
12:15 PWMX_EN	PWMX Output Enables These bits enable the PWMX outputs of each submodule. These bits should be set to 0 (output disabled) when a PWMX pin is being used for input capture or deadtime correction. 1 PWMX output enabled 0 PWMX output disabled

36.3.38.2 Mask register (MASK)

Offset: 0x0142 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0				MASKA				MASKB				MASKX			
W	UPDATE_MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 458. Mask register (MASK)

Note: The MASKx bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Refer to Figure 479 to see how FORCE_OUT is generated. Reading the MASK bits reads the buffered value and not necessarily the value currently in effect. This double buffering can be overridden by setting the UPDATE_MASK bits.

Table 559. Mask Register (MASK) field descriptions

Field	Description
0:3 UPDATE_MASK	Update Mask Bits Immediately These self-clearing bits force the MASK* bits to be immediately updated within each of the submodules without waiting for a FORCE_OUT event. Software may write to any or all of these bits and may set these bits in the same write operation that updates the MASKA, MASKB, and MASKX fields of this register. 1 Immediate operation. MASK* bits within the corresponding submodules are updated on the following clock edge after setting this bit 0 Normal operation. MASK* bits within the submodules aren't updated until a FORCE_OUT event occurs within the submodule
4:7 MASKA	PWMA Masks These bits mask the PWMA outputs of each submodule forcing the output to logic 0 prior to consideration of the output polarity. 1 PWMA output masked 0 PWMA output normal
8:11 MASKB	PWMB Masks These bits mask the PWMB outputs of each submodule forcing the output to logic 0 prior to consideration of the output polarity. 1 PWMB output masked 0 PWMB output normal
12:15 MASKX	PWMX Masks These bits mask the PWMX outputs of each submodule forcing the output to logic 0 prior to consideration of the output polarity. 1 PWMX output masked 0 PWMX output normal

36.3.38.3 Software Controlled Output register (SWCOUT)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 459. Software Controlled Output register (SWCOUT)

Note: These bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Refer to Figure 479 to see how FORCE_OUT is generated. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Table 560. SWCOUT field descriptions

Field	Description
8 OUT23_3	Software Controlled Output 23_3 This bit is only used when SEL23 for submodule 3 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM23 0 A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM23
9 OUT45_3	Software Controlled Output 45_3 This bit is only used when SEL45 for submodule 3 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 3 instead of PWM45 0 A logic 0 is supplied to the deadtime generator of submodule 3 instead of PWM45
10 OUT23_2	Software Controlled Output 23_2 This bit is only used when SEL23 for submodule 2 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM23 0 A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM23
11 OUT45_2	Software Controlled Output 45_2 This bit is only used when SEL45 for submodule 2 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 2 instead of PWM45 0 A logic 0 is supplied to the deadtime generator of submodule 2 instead of PWM45
12 OUT23_1	Software Controlled Output 23_1 This bit is only used when SEL23 for submodule 1 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM23 0 A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM23
13 OUT45_1	Software Controlled Output 45_1 This bit is only used when SEL45 for submodule 1 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 1 instead of PWM45 0 A logic 0 is supplied to the deadtime generator of submodule 1 instead of PWM45
14 OUT23_0	Software Controlled Output 23_0 This bit is only used when SEL23 for submodule 0 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM23 0 A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM23
15 OUT45_0	Software Controlled Output 45_0 This bit is only used when SEL45 for submodule 0 is set to 0b10. It allows software control of which signal is supplied to the deadtime generator of that submodule. 1 A logic 1 is supplied to the deadtime generator of submodule 0 instead of PWM45 0 A logic 0 is supplied to the deadtime generator of submodule 0 instead of PWM45

36.3.38.4 Deadtime Source Select register (DTSRCSEL)

Offset: 0x0146 Access: R/W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 460. Deadtime Source Select register (DTSRCSEL)

Note: The deadtime source select bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Refer to Figure 479 to see how FORCE_OUT is generated. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Table 561. DTSRCSEL field descriptions

Field	Description
0:1 SEL23_3	PWM23_3 Control Select This field selects possible over-rides to the generated PWM23 signal in submodule 3 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM23_3 signal is used by the deadtime logic. 01 Inverted generated PWM23_3 signal is used by the deadtime logic. 10 OUT23_3 bit is used by the deadtime logic. 11 EXTA[3] signal is used by the deadtime logic.
2:3 SEL45_3	PWM45_3 Control Select This field selects possible over-rides to the generated PWM45 signal in submodule 3 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM45_3 signal is used by the deadtime logic. 01 Inverted generated PWM45_3 signal is used by the deadtime logic. 10 OUT45_3 bit is used by the deadtime logic. 11 EXTB[3] signal is used by the deadtime logic.
4:5 SEL23_2	PWM23_2 Control Select This field selects possible over-rides to the generated PWM23 signal in submodule 2 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM23_2 signal is used by the deadtime logic. 01 Inverted generated PWM23_2 signal is used by the deadtime logic. 10 OUT23_2 bit is used by the deadtime logic. 11 EXTA[2] signal is used by the deadtime logic.
6:7 SEL45_2	PWM45_2 Control Select This field selects possible over-rides to the generated PWM45 signal in submodule 2 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM45_2 signal is used by the deadtime logic. 01 Inverted generated PWM45_2 signal is used by the deadtime logic. 10 OUT45_2 bit is used by the deadtime logic. 11 EXTB[2] signal is used by the deadtime logic.

Table 561. DTSRCSEL field descriptions (continued)

Field	Description
8:9 SEL23_1	PWM23_1 Control Select This field selects possible over-rides to the generated PWM23 signal in submodule 1 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM23_1 signal is used by the deadtime logic. 01 Inverted generated PWM23_1 signal is used by the deadtime logic. 10 OUT23_1 bit is used by the deadtime logic. 11 EXTA[1] signal is used by the deadtime logic.
10:11 SEL45_1	PWM45_1 Control Select This field selects possible over-rides to the generated PWM45 signal in submodule 1 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM45_1 signal is used by the deadtime logic. 01 Inverted generated PWM45_1 signal is used by the deadtime logic. 10 OUT45_1 bit is used by the deadtime logic. 11 EXTB[1] signal is used by the deadtime logic.
12:13 SEL23_0	PWM23_0 Control Select This field selects possible over-rides to the generated PWM23 signal in submodule 0 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM23_0 signal is used by the deadtime logic. 01 Inverted generated PWM23_0 signal is used by the deadtime logic. 10 OUT23_0 bit is used by the deadtime logic. 11 EXTA[0] signal is used by the deadtime logic.
14:15 SEL45_0	PWM45_0 Control Select This field selects possible over-rides to the generated PWM45 signal in submodule 0 that will be passed to the deadtime logic upon the occurrence of a "Force Out" event in that submodule. 00 Generated PWM45_0 signal is used by the deadtime logic. 01 Inverted generated PWM45_0 signal is used by the deadtime logic. 10 OUT45_0 bit is used by the deadtime logic. 11 EXTB[0] signal is used by the deadtime logic.

36.3.38.5 Master Control register (MCTRL)

Offset: 0x0148 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	IPOL				RUN				0				LDOK			
W									CLDOK							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 461. Master Control register (MCTRL)

Note: The relationship between the fields of MCTRL and the submodules is as follows:

- *Field[3] refers to submodule 3.*
- *Field[2] refers to submodule 2.*
- *Field[1] refers to submodule 1.*

- *Field[0] refers to submodule 0.*

Table 562. MCTRL field descriptions

Field	Description
0:3 IPOL	Current Polarity This buffered read/write bit is used to select between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output in each submodule. IPOL is ignored in independent mode. 1 PWM45 (*Figure 420*) is used to generate complementary PWM pair 0 PWM23 (*Figure 420*) is used to generate complementary PWM pair **Note:** The IPOL bit does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading the IPOL bit reads the buffered value and not necessarily the value currently in effect.
4:7 RUN	Run This read/write bit enables the clocks to the PWM generator in each submodule. When RUN equals zero, the submodule counter is reset. A reset clears RUN. 1 PWM generator enabled 0 PWM generator disabled **Note:** For proper initialization of the LDOK and RUN bits, see *Section 36.4.4.5*.
8:11 CLDOK	Clear Load Okay This write only bit is used to clear the LDOK bit. Write a 1 to this location to clear the corresponding LDOK. If a reload occurs with LDOK set at the same time that CLDOK is written, then the reload will not be performed and LDOK will be cleared. This bit is self clearing and always reads as a 0.
12:15 LDOK	Load Okay This read/set bit loads the PRSC bits of CTRL1 and the INIT and VALx registers into a set of buffers in each submodule. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if LDMOD is clear or immediately if LDMOD is set. Set LDOK by reading it when it is logic zero and then writing a logic one to it. The VALx, INIT, and PRSC registers cannot be written while LDOK is set. In master relaod mode (CTRL2[RELOAD_SEL]=1) it is only required to set the LDOK bit for submodule 0, but it is recommended to also set the LDOK bits for the corresponding slave submodules in order to prevent unwanted writes to the registers in the slave submodules. LDOK is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic 1 to CLDOK. This bit cannot be written with a zero. LDOK can be set in DMA mode when the DMA indicates that it has completed the update of all PRSC, INIT, and VALx registers. Reset clears LDOK. 1 Load prescaler, modulus, and PWM values 0 Do not load new values

Note: For proper initialization of the LDOK and RUN bits, see Section 36.4.4.5.

36.3.39 Fault Channel Registers

The base address of the fault logic is equal to the base address of the mcPWM plus an offset of $14C.

36.3.39.1 Fault Control register (FCTRL)

Offset: 0x014C Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	FLVL				FAUTO				FSAFE				FIE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 462. Fault Control register (FCTRL)

Table 563. MCTRL field descriptions

Field	Description
0:3 FLVL	Fault Level These read/write bits select the active logic level of the individual fault inputs. A reset clears FLVL. 1 A logic 1 on the fault input indicates a fault condition. 0 A logic 0 on the fault input indicates a fault condition.
4:7 FAUTO	Automatic Fault Clearing These read/write bits select automatic or manual clearing of faults. A reset clears FAUTO. 1 Automatic fault clearing. PWM outputs disabled by this fault are enabled when the FFPINx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits without regard to the state of FFLAGx bit. 0 Manual fault clearing. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear at the start of a half cycle or full cycle depending the state of the FFULL bits. This is further controlled by the FSAFE bits.
8:11 FSAFE	Fault Safety Mode These read/write bits select the safety mode during manual fault clearing. A reset clears FSAFE. 1 Safe mode. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear and the FFPINx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits. 0 Normal mode. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits without regard to the state of the FFPINx bit. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAP).
12:15 FIE	Fault Interrupt Enables This read/write bit enables CPU interrupt requests generated by the FAULTx pins. A reset clears FIE. 1 FAULTx CPU interrupt requests enabled 0 FAULTx CPU interrupt requests disabled

Note: The FFPINx bit may indicate a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency.

The fault protection circuit is independent of the FIEx bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register.

36.3.39.2 Fault Status register (FSTS)

Offset: 0x014E Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 463. Fault Status register (FSTS)

Table 564. FSTS field descriptions

Field	Description
3 FTEST	Fault Test These read/write bit is used to simulate a fault condition. Setting this bit will cause a simulated fault to be sent into all of the fault filters. The condition will propagate to the fault flags and possibly the PWM outputs depending on the DISMAP settings. Clearing this bit removes the simulated fault condition. 1 Cause a simulated fault 0 No fault
4:7 FFPIN	Filtered Fault Pins These read-only bits reflect the current state of the filtered FAULTx pins converted to high polarity. A logic 1 indicates a fault condition exists on the filtered FAULTx pin. A reset has no effect on FFPIN.
8:11 FFULL	Full Cycle These read/write bits are used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. 1 PWM outputs are re-enabled only at the start of a full cycle. 0 PWM outputs are re-enabled at the start of a full or half cycle.
12:15 FFLAG	Fault Flags These read-only flag is set within two CPU cycles after a transition to active on the FAULTx pin. Clear FFLAGx by writing a logic one to it. A reset clears FFLAG. 1 Fault on the FAULTx pin 0 No fault on the FAULTx pin

Figure 464. Fault Filter register (FFILT)

The settings in this register are shared among each of the fault input filters.

Table 565. FFILT field descriptions

Field	Description
0 GSTR	Fault Glitch Stretch Enable This bit is used to enable the fault glitch stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 1 Input fault signals will be stretched to at least 2 IPBus clock cycles. 0 Fault input glitch stretching is disabled.
5:7 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in *Section 36.3.39.4*.
8:15 FILT_PER	Fault Filter Period These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in *Section 36.3.39.4*.

36.3.39.4 Input Filter Considerations

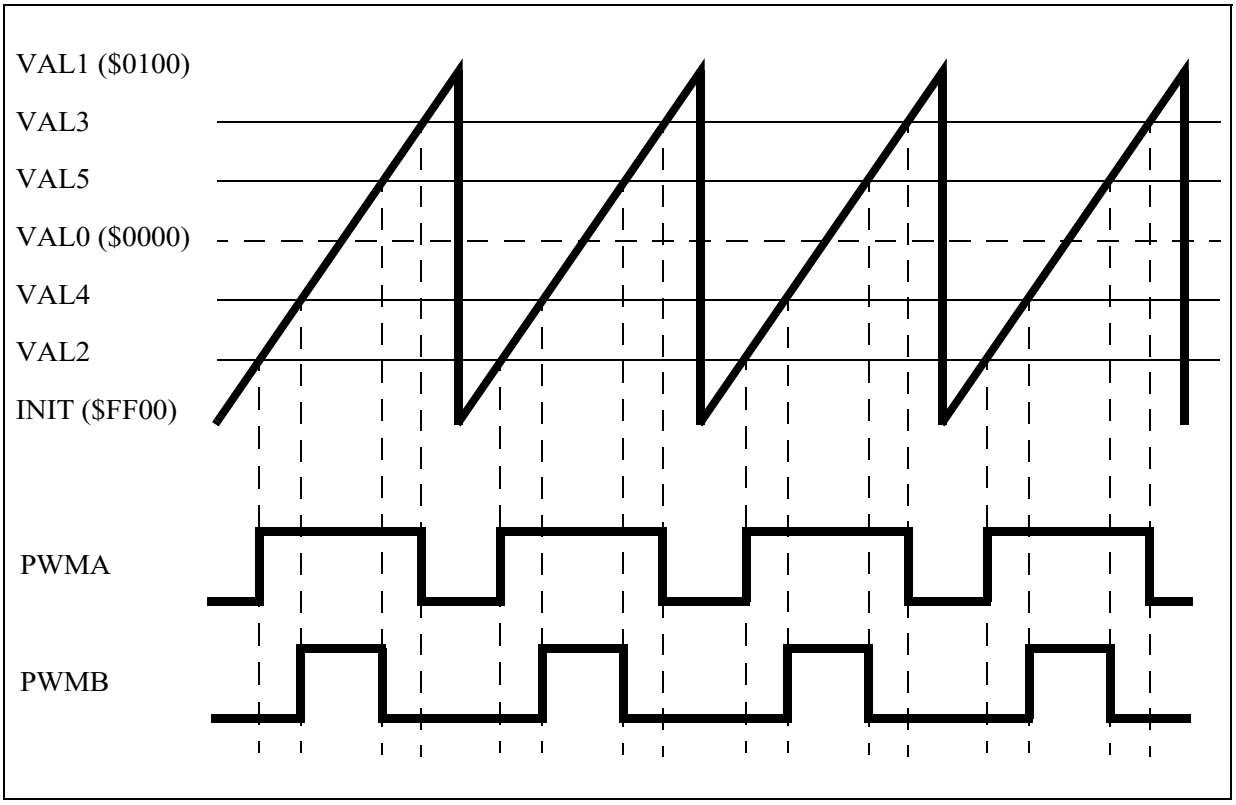
The FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x IPBus clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set the FFLAG and FFPIN bits of the FSTS register.

36.4 Functional Description

36.4.1 Block Diagram

A block diagram of the PWM is shown in *Figure 419*.



36.4.2 PWM Capabilities

This section describes some capabilities of the PWM module.

36.4.2.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in *Figure 465*.

Figure 465. Center Aligned Example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

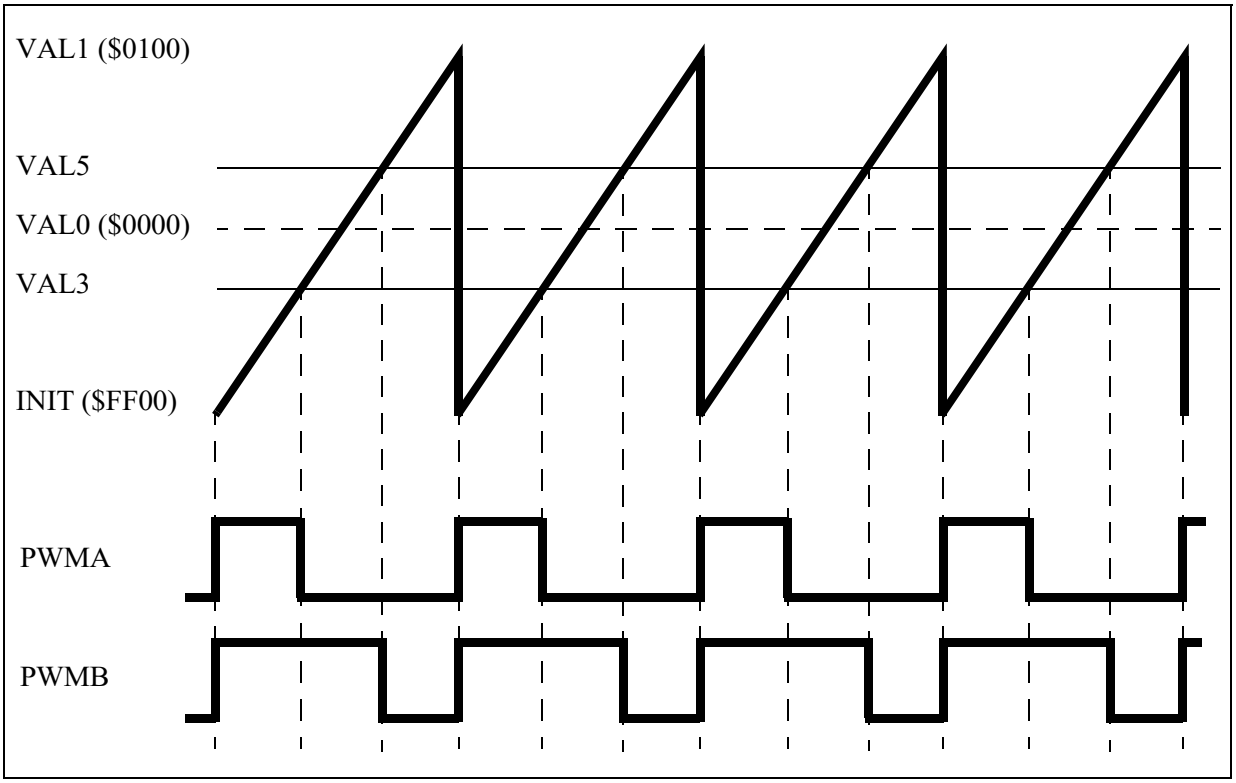


Figure 465 also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center alignment between the signals is not restricted to symmetry around the zero count value, as any other number

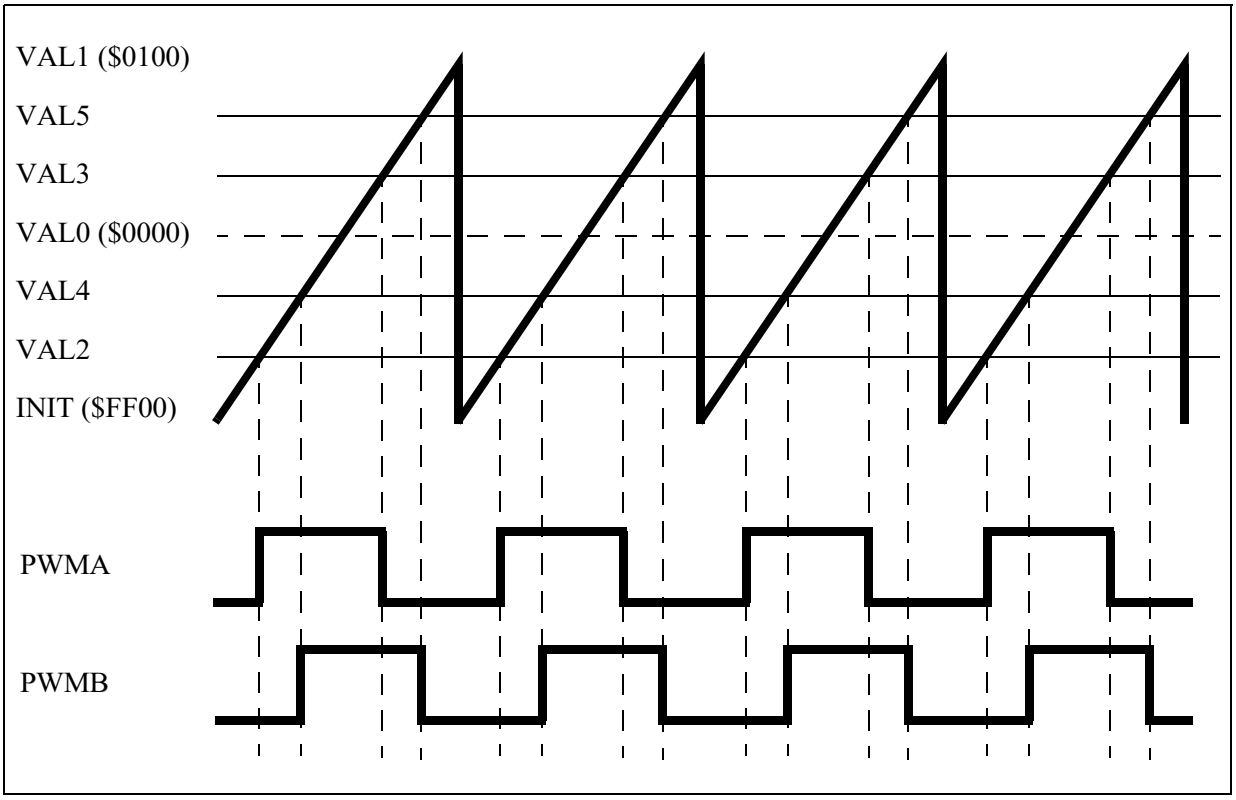
would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

36.4.2.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as illustrated in *Figure 466*. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

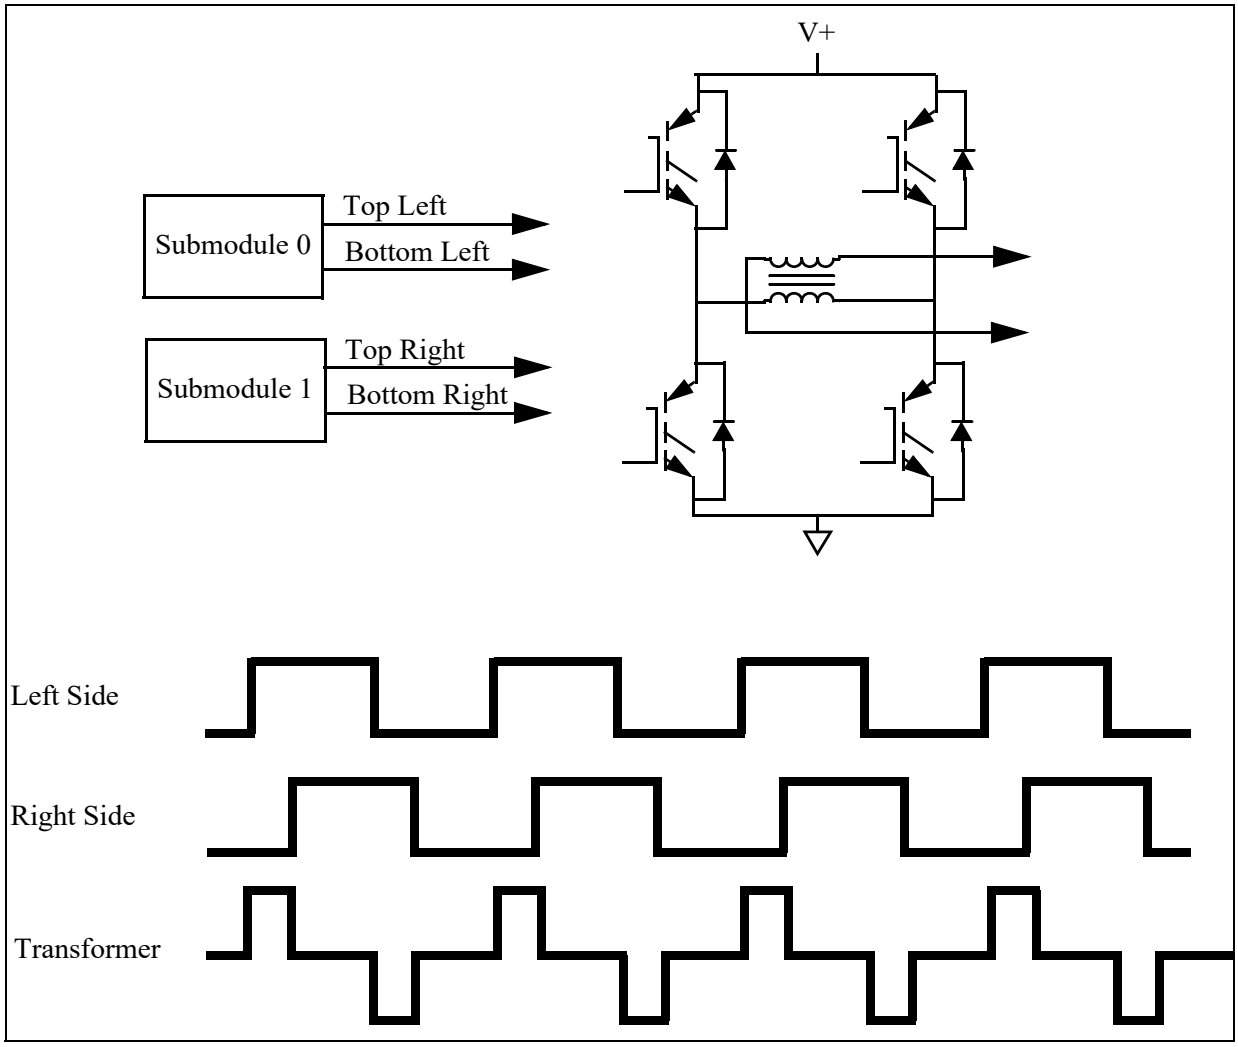
Figure 466. Edge Aligned Example (INIT=VAL2=VAL4)



With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the motor voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

36.4.2.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases ARE applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as illustrated in *Figure 467*. This results in certain



advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

Figure 467. Phase Shifted Outputs Example

An additional benefit of phase shifted PWMs can be seen in *Figure 468*. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

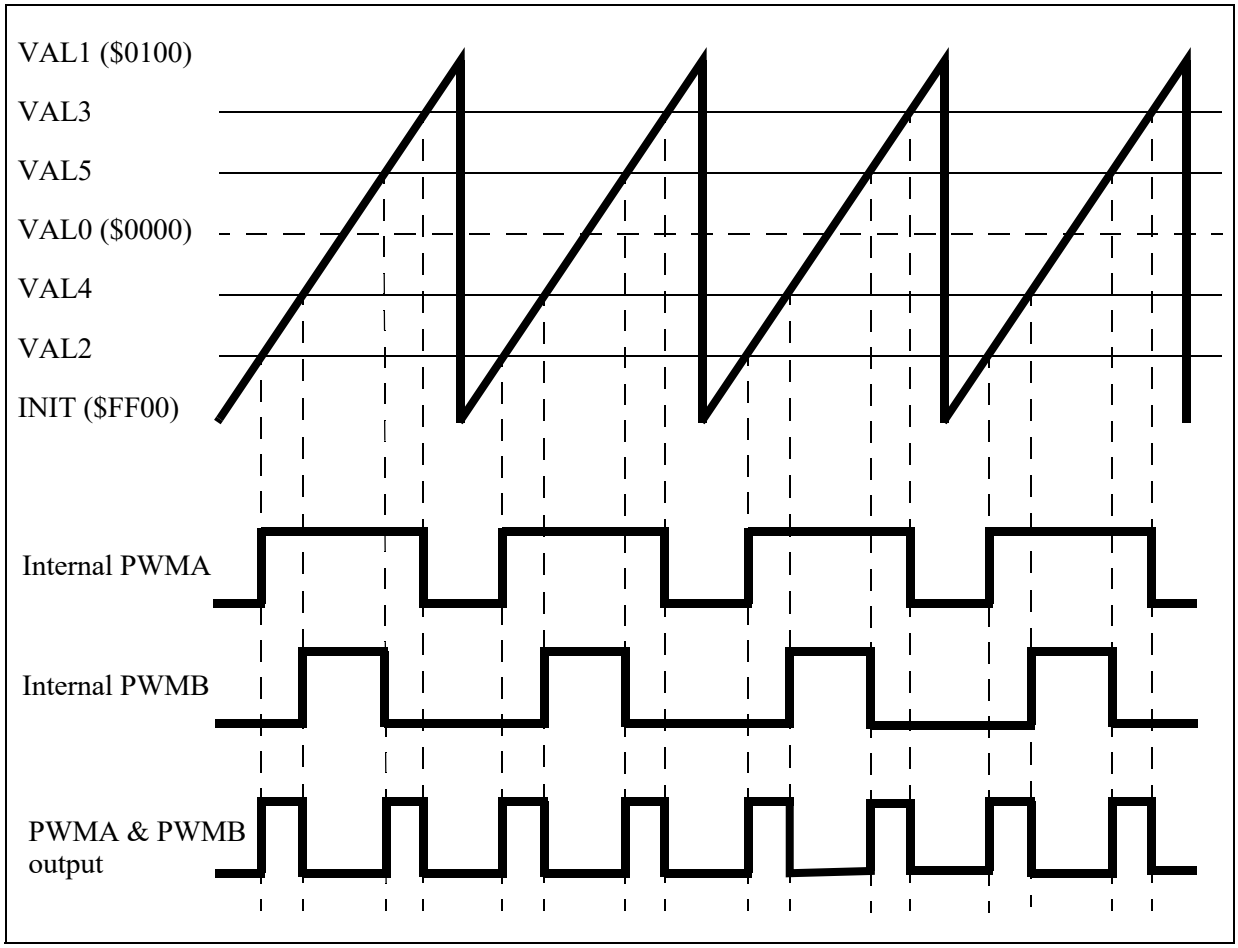


Figure 468. Phase Shifted PWMs Applied to a Transformer Primary

36.4.2.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWMA in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (see *Figure 479*) as shown in *Figure 469*. The DBLPWM signal can be run through the deadtime insertion logic.

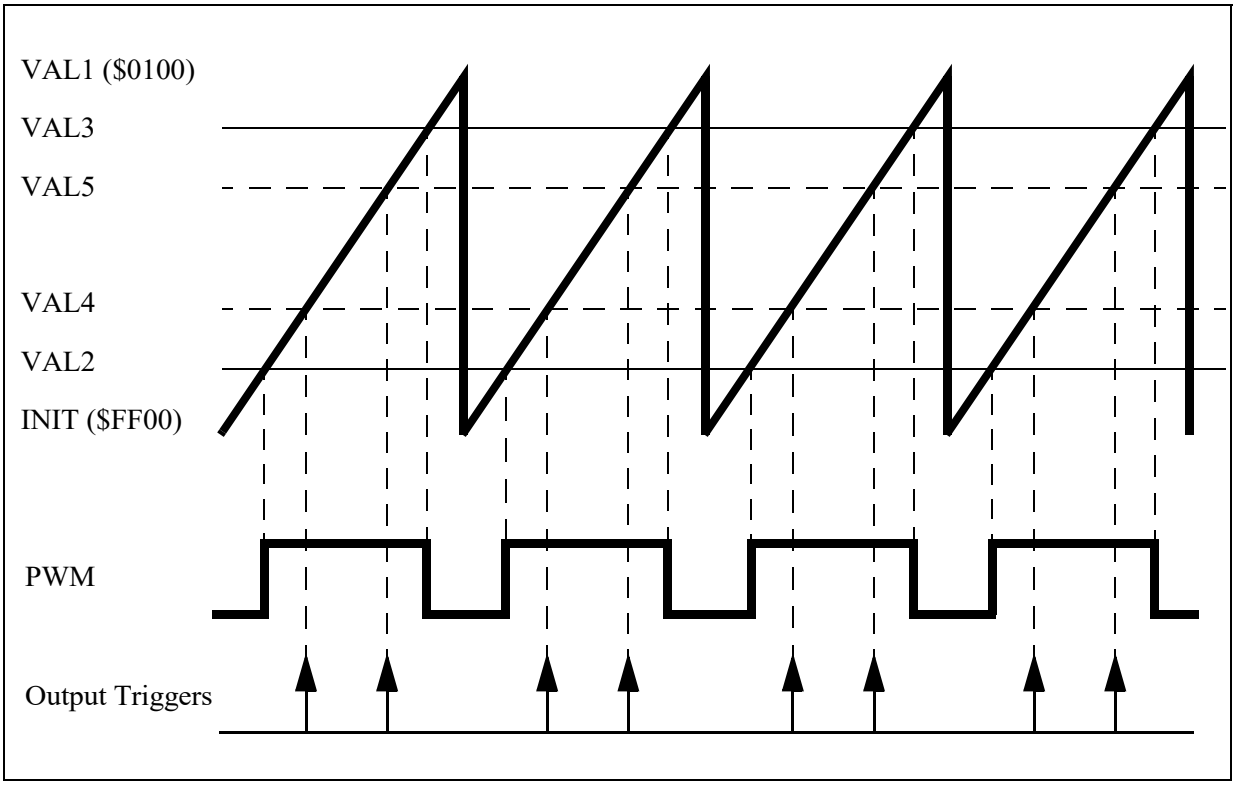

Figure 469. Double Switching Output Example

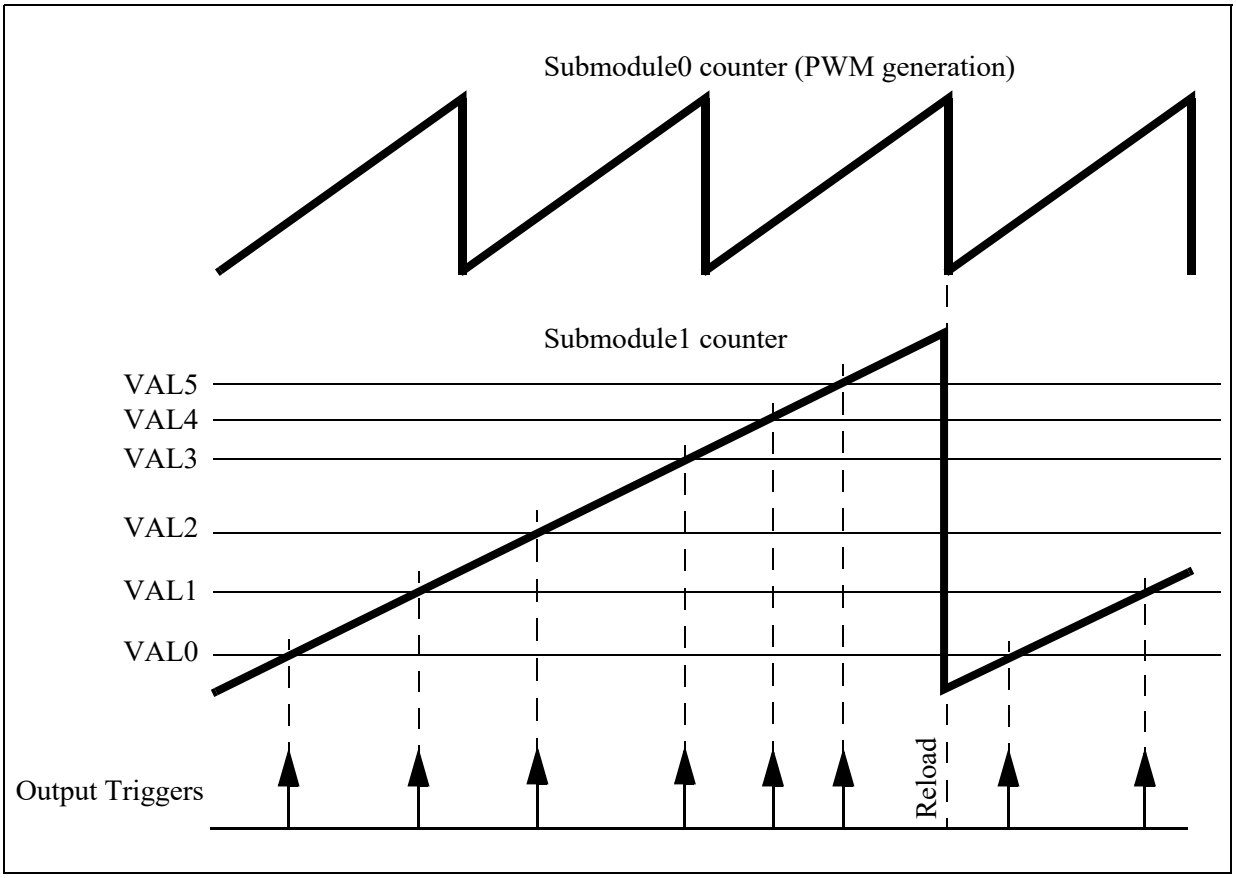
36.4.2.5 ADC Triggering



In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. *Figure 470* shows how this is accomplished. When specifying complimentary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators are free to perform other functions. In this example, the software doesn't have to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

Figure 470. Multiple Output Trigger Generation in Hardware

Since each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. *Figure 471* shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In *Figure 471*, ALL submodule comparators are shown being used for ADC trigger generation.

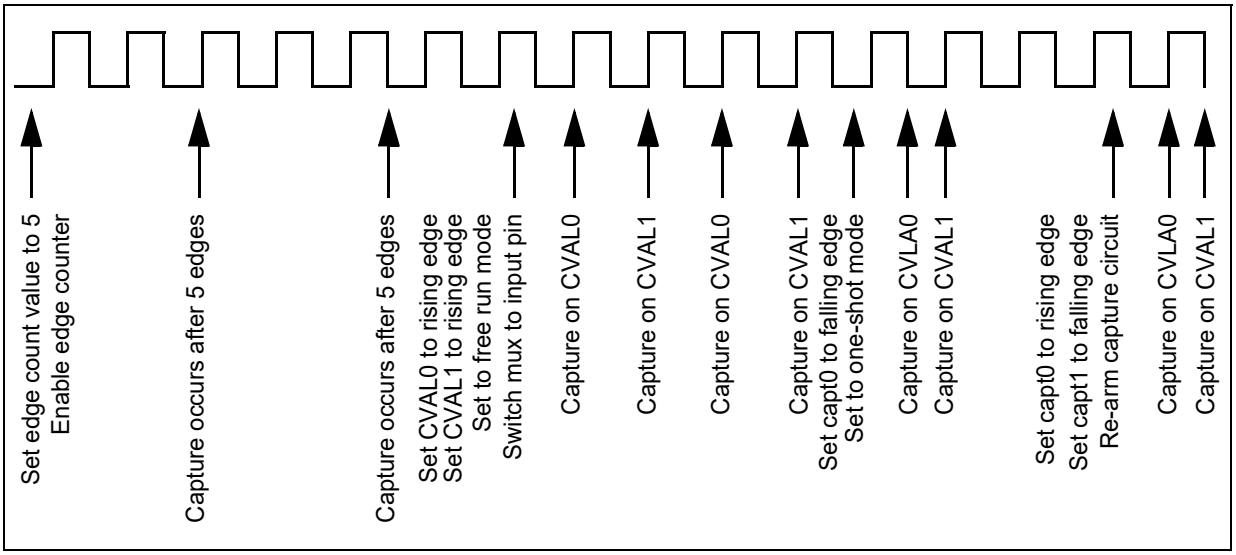


Figure 471. Multiple Output Triggers Over Several PWM Cycles

36.4.2.6 Enhanced Capture Capabilities (E-Capture)

When a PWM pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. *Figure 472* illustrates some of the functionality of the E-Capture circuit.

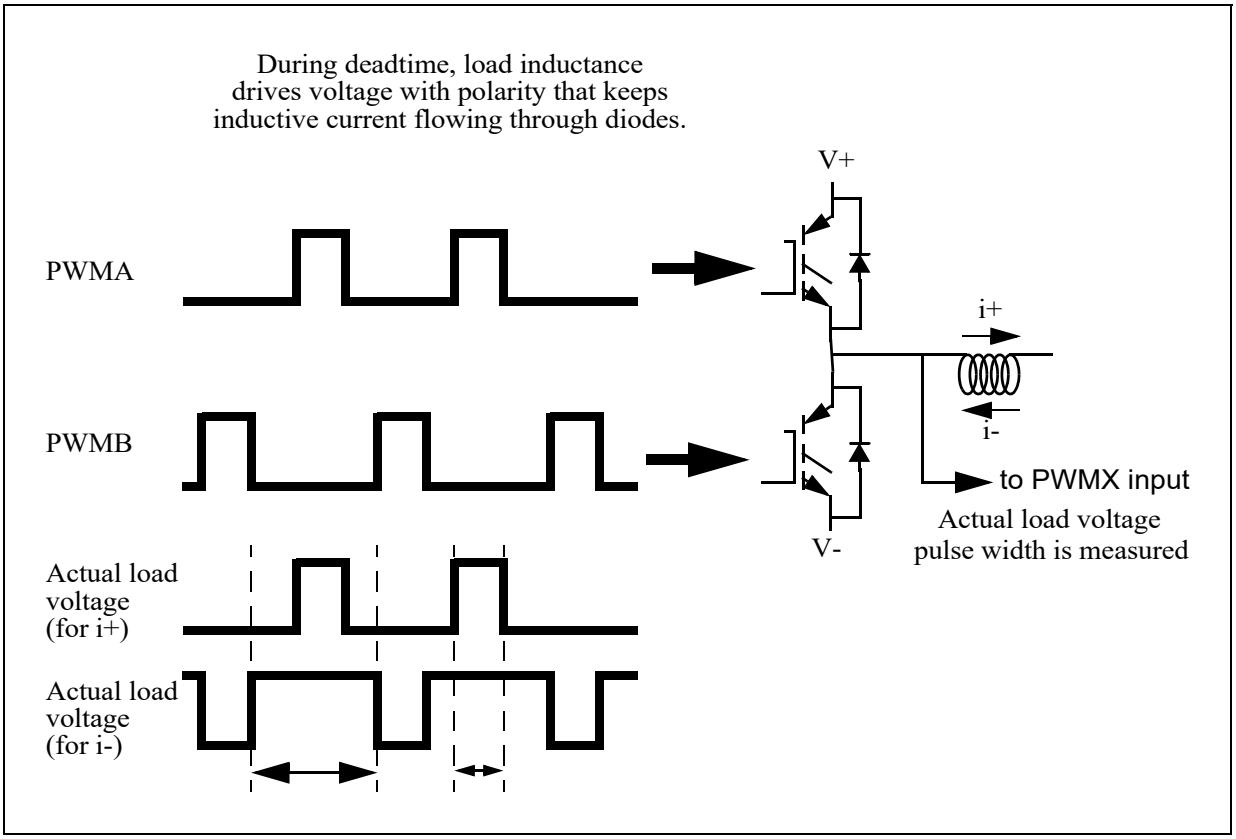

Figure 472. Capture Capabilities of the E-Capture Circuit

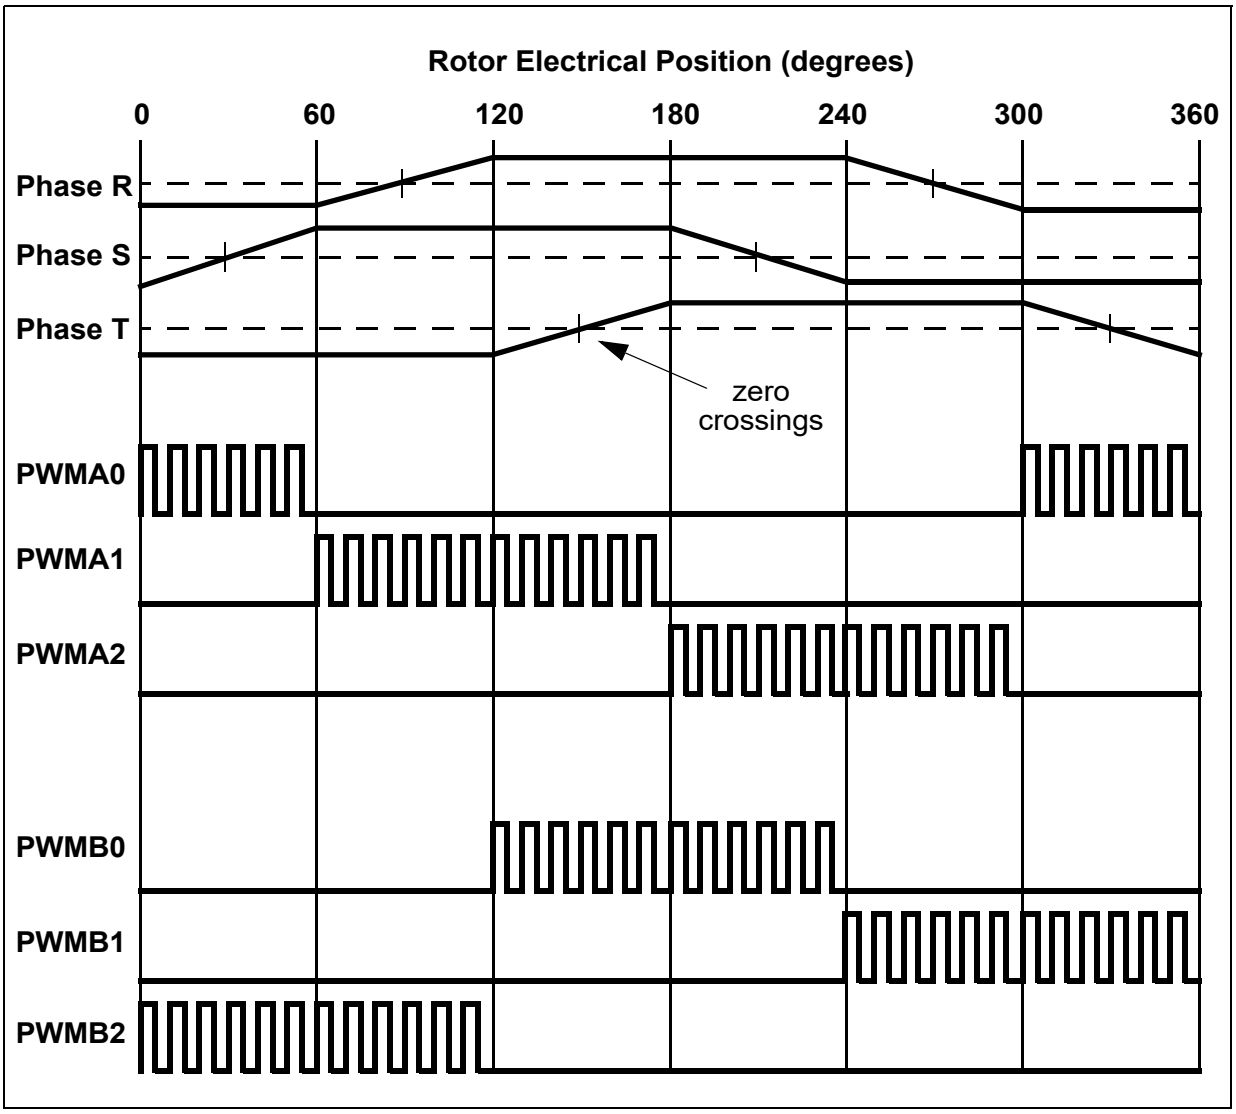
When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example PWMX) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. As an example, consider *Figure 473*. In this application the output of a PWM power stage is connected to the PWMX pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays.

Note: CVAL0-CVAL1 are used for PWMx, CVAL2 and CVAL3 are used for PWMA and finally, VAL4 and CVAL5 are used for PWMB.

Figure 473. Output Pulse Width Measurement Possible with the E-Capture Circuit

36.4.2.7 Synchronous Switching of Multiple Outputs



Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event using the SWCOUT and DTSRCSEL registers. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

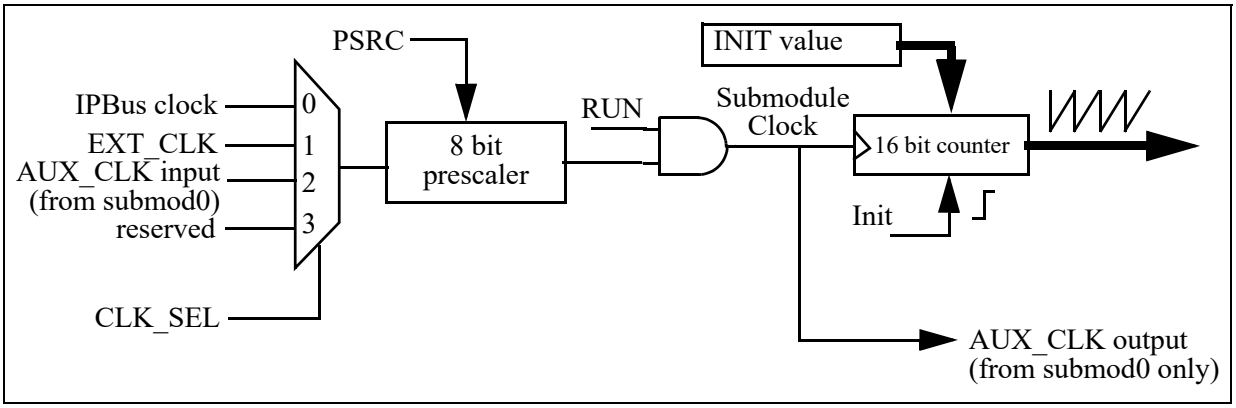
Figure 474 shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of *Figure 474* are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the

back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

Figure 474. Sensorless BLDC Commutation Using the Force Out Function

36.4.2.8 Phase shifted full bridge for DC/DC converters

Use CTRL1[PHSSHFT] to allow the EXT_SWITCH input to control the output of PWMA0/PWMB0. The EXT_SWITCH input switches the source of the submodule0 output from the VAL* registers within submodule0 to the VAL* registers in submodule1. This muxing can be seen in *Figure 478*.



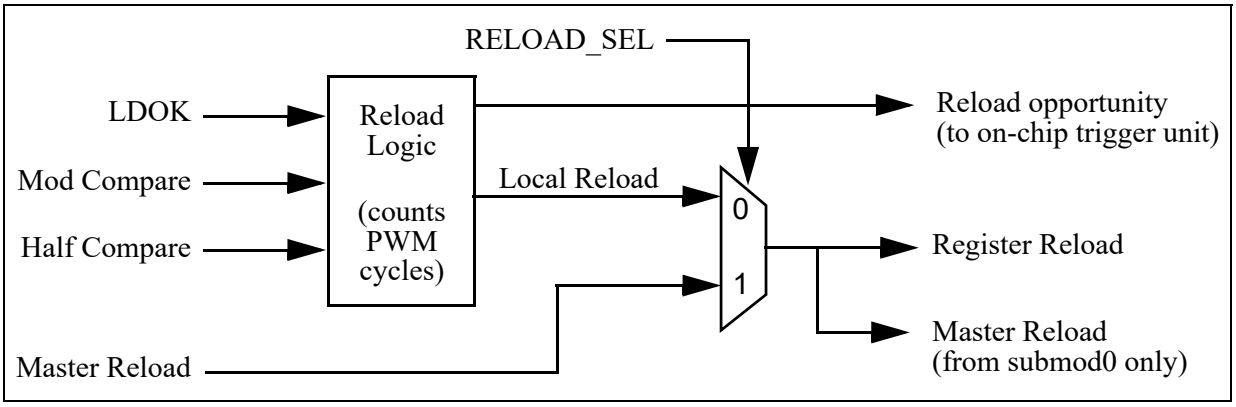
36.4.3 Functional Details

This section describes the implementation of various features of the PWM in greater detail.

36.4.3.1 PWM Clocking

Figure 475 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT_CLK, and AUX_CLK. The EXT_CLK is generated by an on-chip resource such as a Timer module and goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8 bit prescaler and RUN bit from submodule0 can control all of the submodules. When AUX_CLK is selected as the source for the submodule clock, the RUN bit from submodule0 is used instead of the local RUN bit from this submodule.

Figure 475. Clocking Block Diagram for Each PWM Submodule



To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, PRSC, in the control register (CTRL1), select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload cycle begins or LDMOD is set.

36.4.3.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using the LDFQ bits and the FULL bit. A half cycle reload option is also supported (HALF) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in *Figure 476* the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

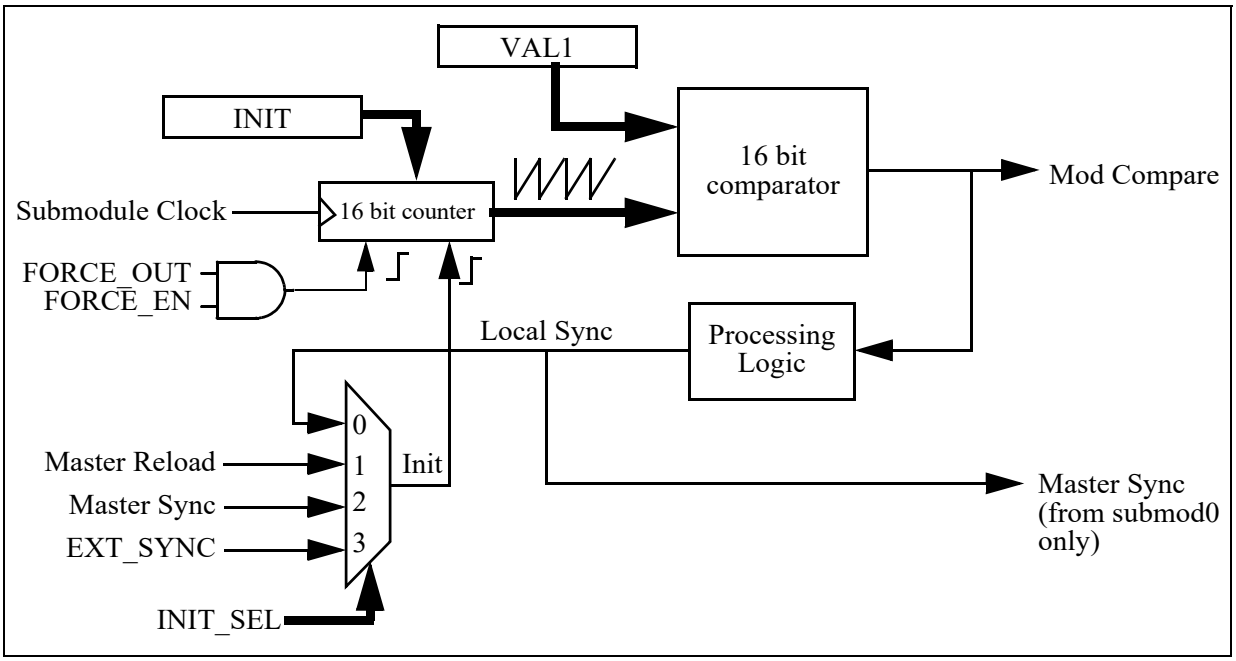


Figure 476. Register Reload Logic

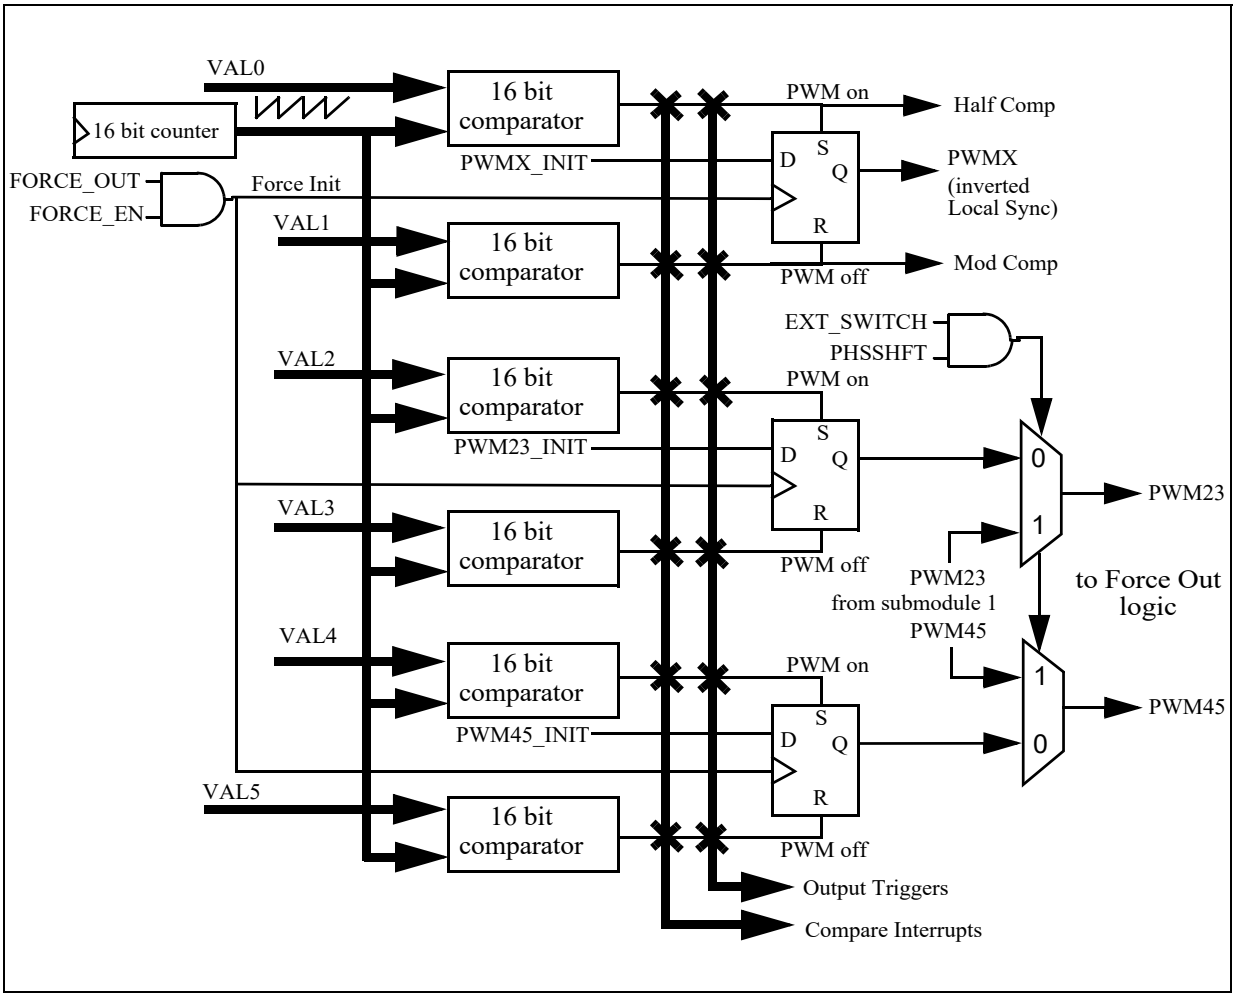
36.4.3.3 Counter Synchronization

Referring to *Figure 477*, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

Figure 477. Submodule Timer Synchronization

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.



If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that the FORCE_EN bit is set. As indicated by *Figure 477*, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

36.4.3.4 PWM Generation

Figure 478 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register is used to control the turn on edge while a second comparator and VALx register control the turn off edge.

Figure 478. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a rising edge of the Local Sync signal, comparator 1 generates a falling edge. Comparator 1 is also hardwired to the reload logic to generate the half cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal effectively turning it into an auxiliary PWM signal (PWMX) assuming that the PWMX pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating 3 PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

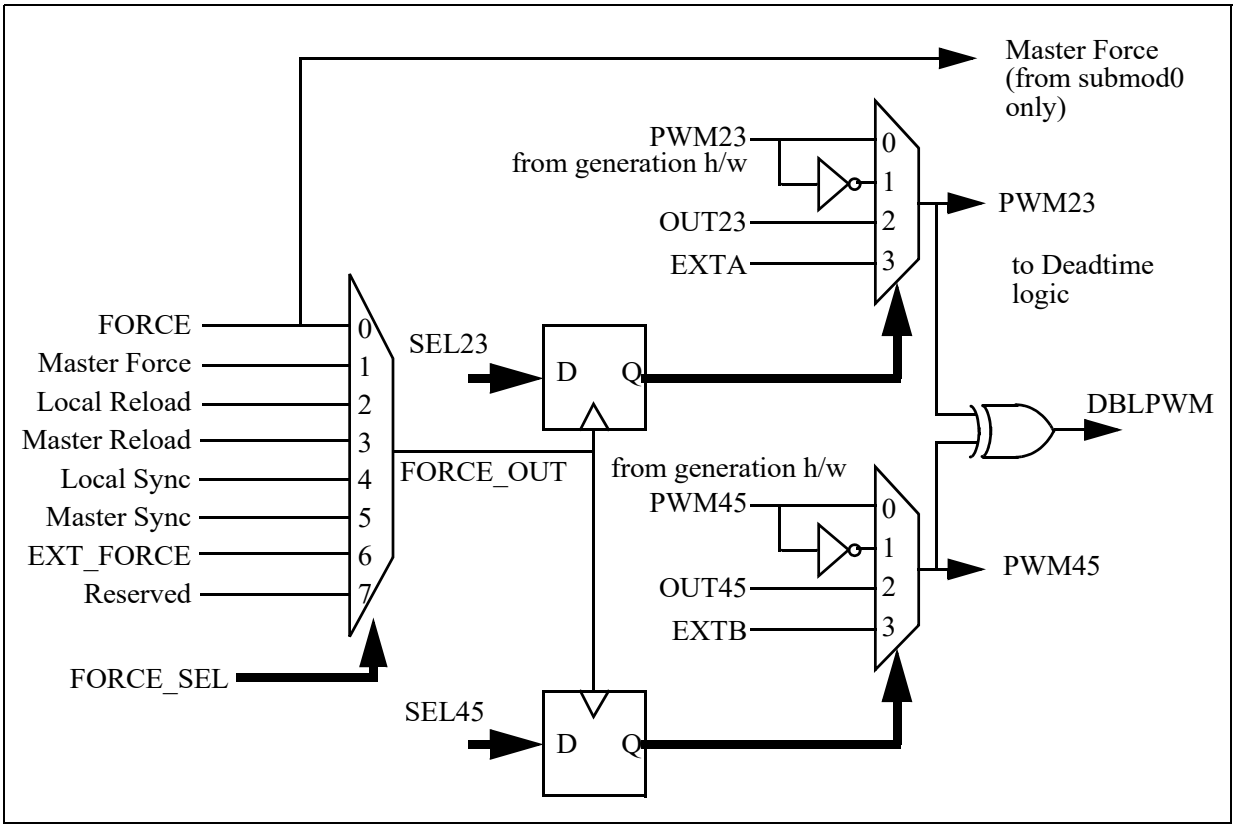
The muxes for PWM23 and PWM45 shown in *Figure 478* are only in submodule0.

If the comparators assert both the set and reset of the flip-flop at the same time, then the flop output goes to 0.

36.4.3.5 Output Compare Capabilities

By using the VALx registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high.
- An output compare sets the output low.
- An output compare generates an interrupt.
- An output compare generates an output trigger.



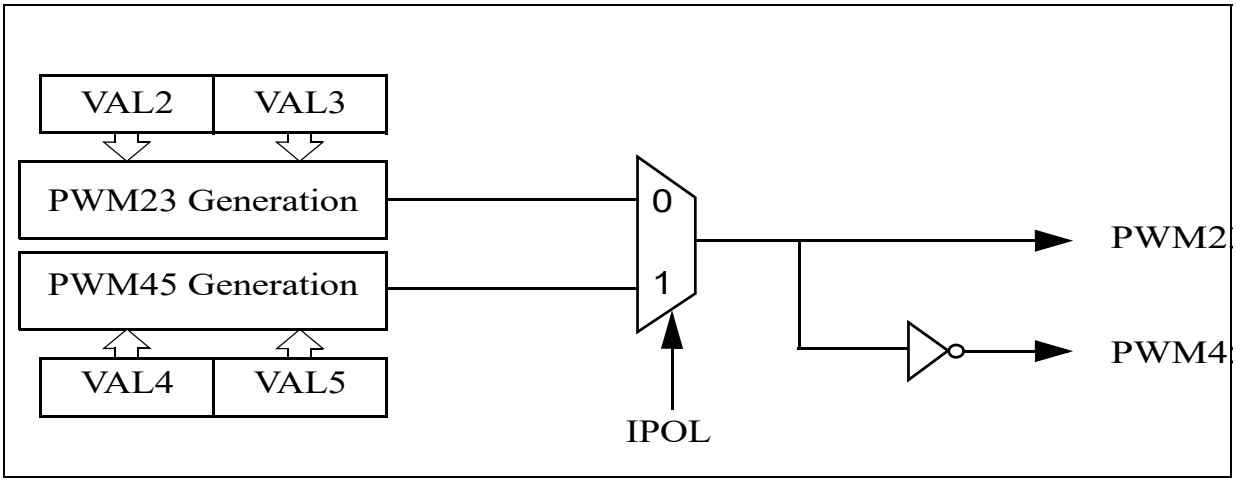
Referring again to *Figure 478*, an output compare is initiated by programming a VALx register for a timer compare which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWMA signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWMA signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

36.4.3.6 Force Out Logic

For each submodule software can select between seven signal sources for the FORCE_OUT signal: the local FORCE bit, the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, or the EXT_FORCE signal from on or off chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master signals or EXT_FORCE signal should be selected.

Figure 479 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the EXTA or EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE_OUT event occurs, these values are presented to the signal selection mux which immediately switches the requested signal to the output of the mux for further processing downstream.

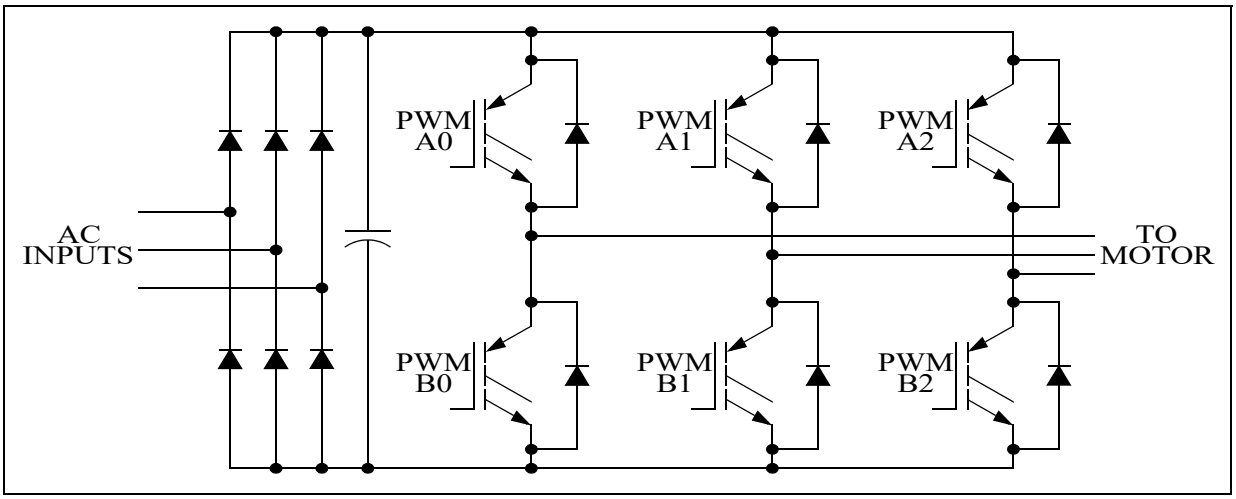
Figure 479. Force Out Logic



The local FORCE signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the local FORCE bit of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

36.4.3.7 Independent or Complementary Channel Operation

Writing a logic one to the INDEP bit of the CNFG register configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

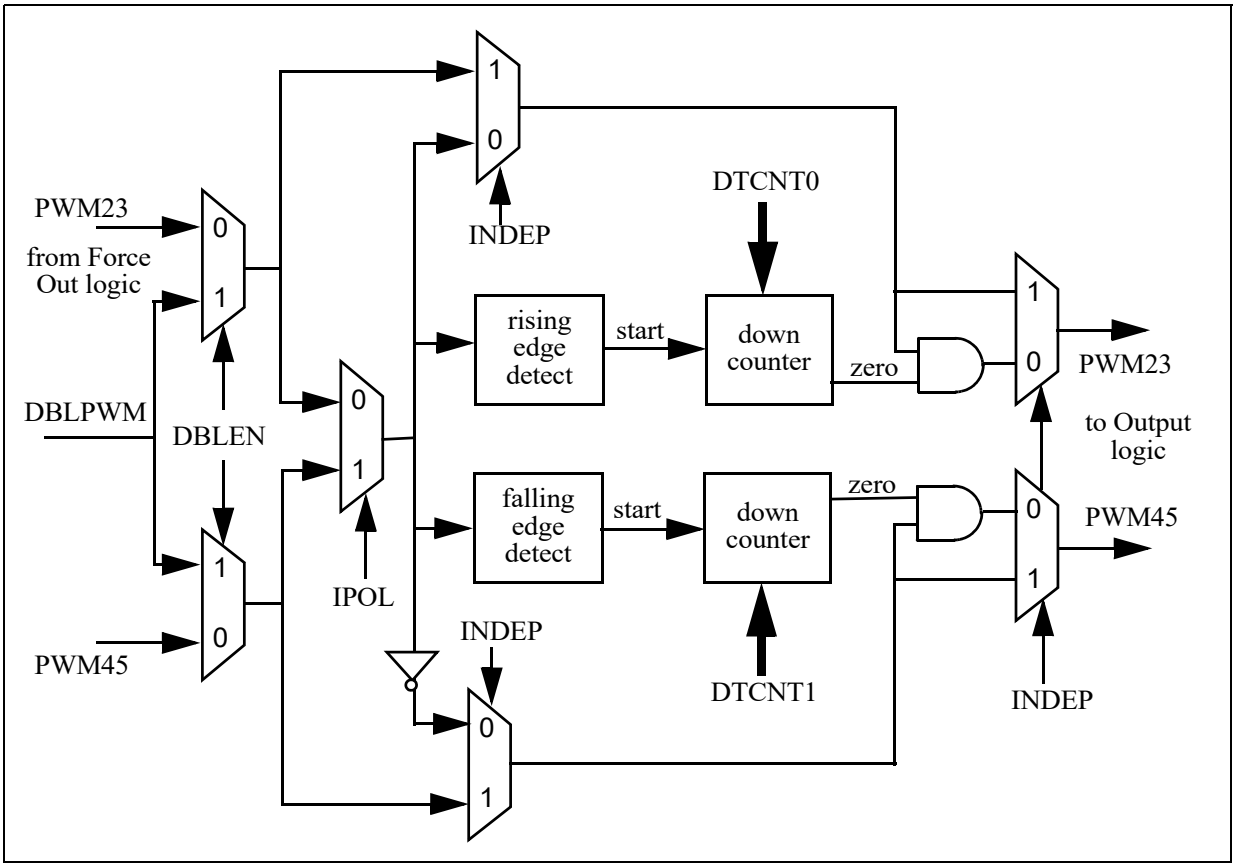


Writing a logic zero to the INDEP bit configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in *Figure 480* in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by the IPOL bit.

Figure 480. Complementary Channel Pair

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in *Figure 481*.

Figure 481. Typical 3 Phase AC Motor Drive

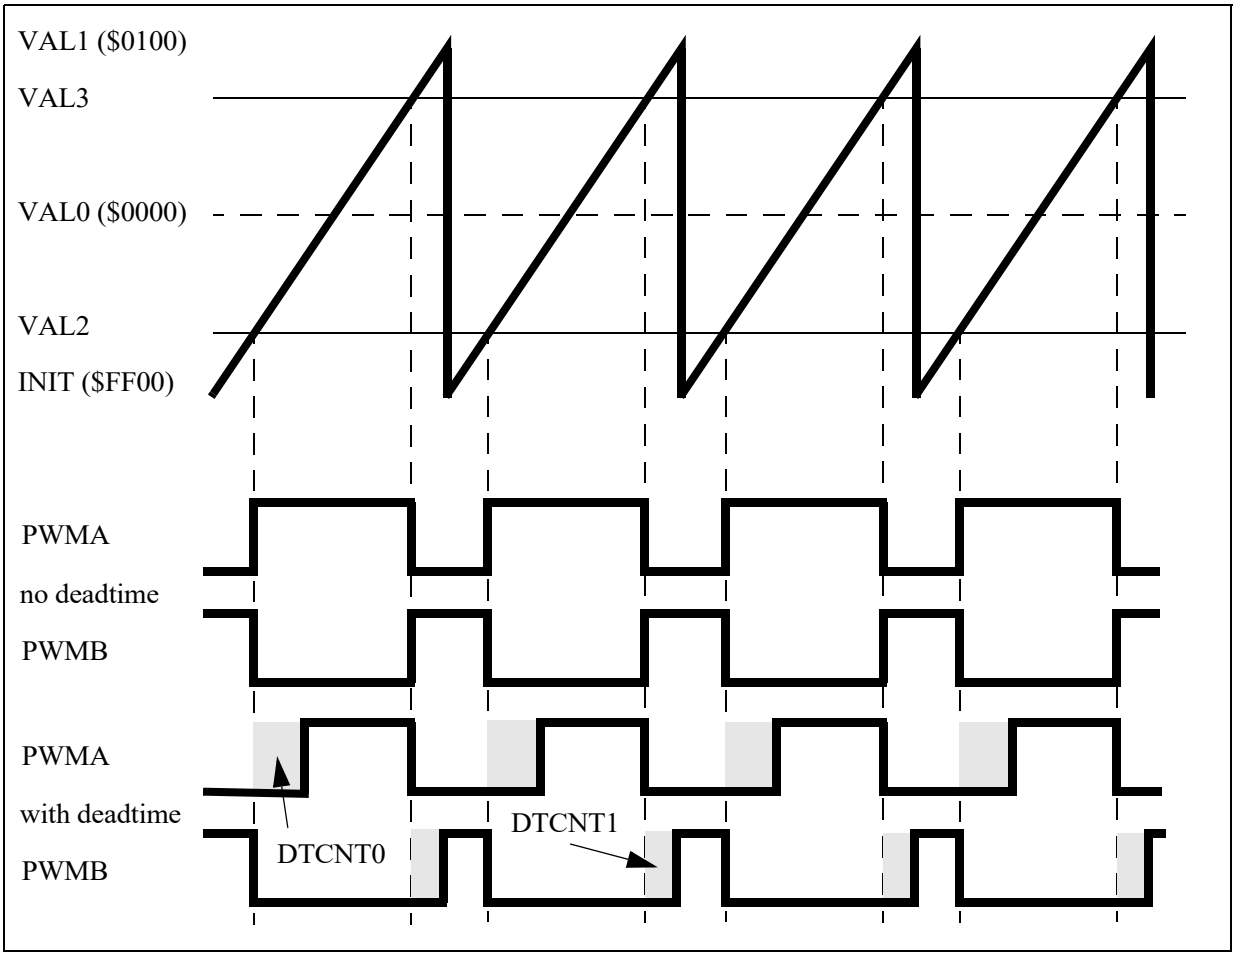


Complementary operation allows the use of the deadtime insertion feature.

36.4.3.8 Deadtime Insertion Logic

Figure 482 shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

Figure 482. Deadtime Insertion and Fine Control Logic



While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in *Figure 482*. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

Note: To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. However, the transistor's characteristics may cause its switching-off time to be longer than its switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in Figure 483

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

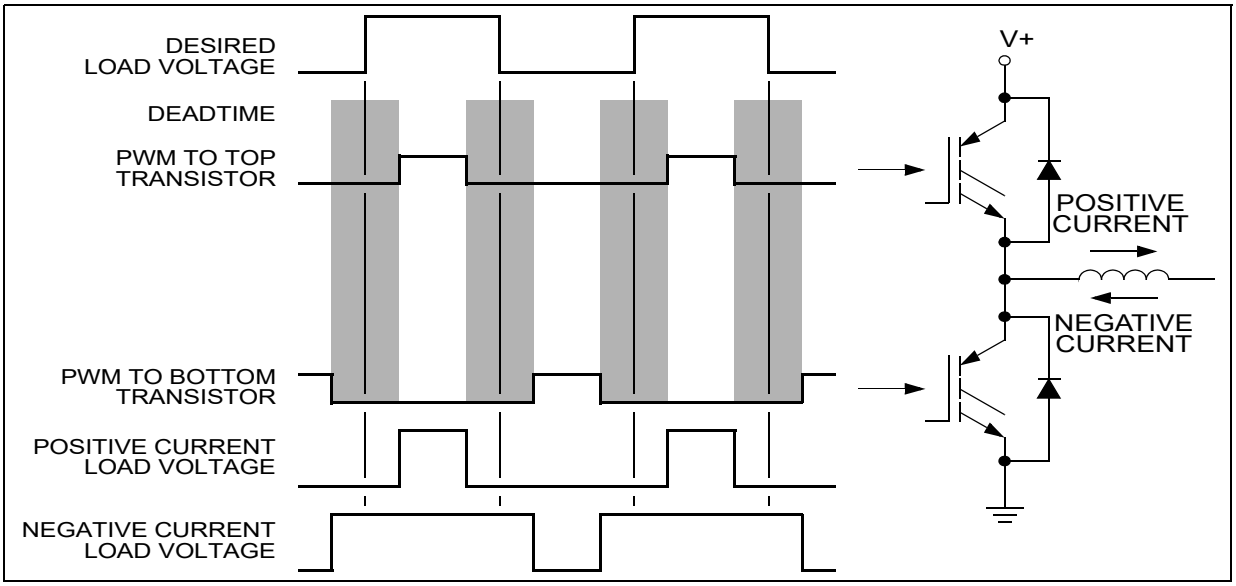


Figure 483. Deadtime Insertion

36.4.3.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See *Figure 484*. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

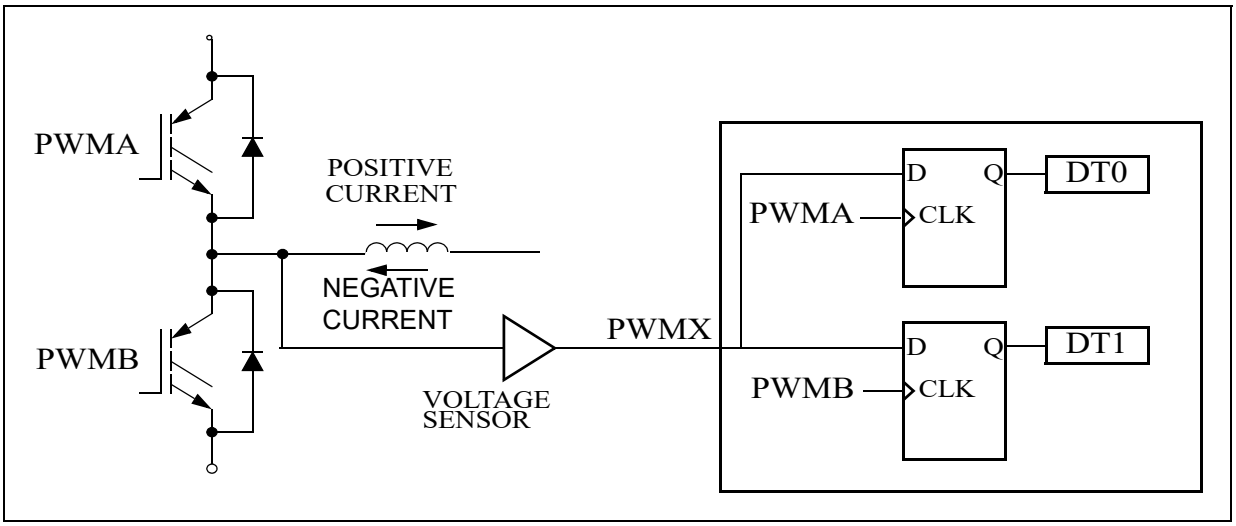
Figure 484. Deadtime Distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths where shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor current for that pair. See *Figure 484*. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMx, for that driver.
- The state of the odd/even correction bit, IPOL, for that driver.



To correct deadtime distortion, software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

36.4.3.8.2 Manual Correction

To detect the current status, the voltage on each PWMx pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in the DTx bits in the CTRL1 register. The DTx bits are a timing marker especially indicating when to toggle between PWM value registers. Software can then set the IPOL bit to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to DTx values.

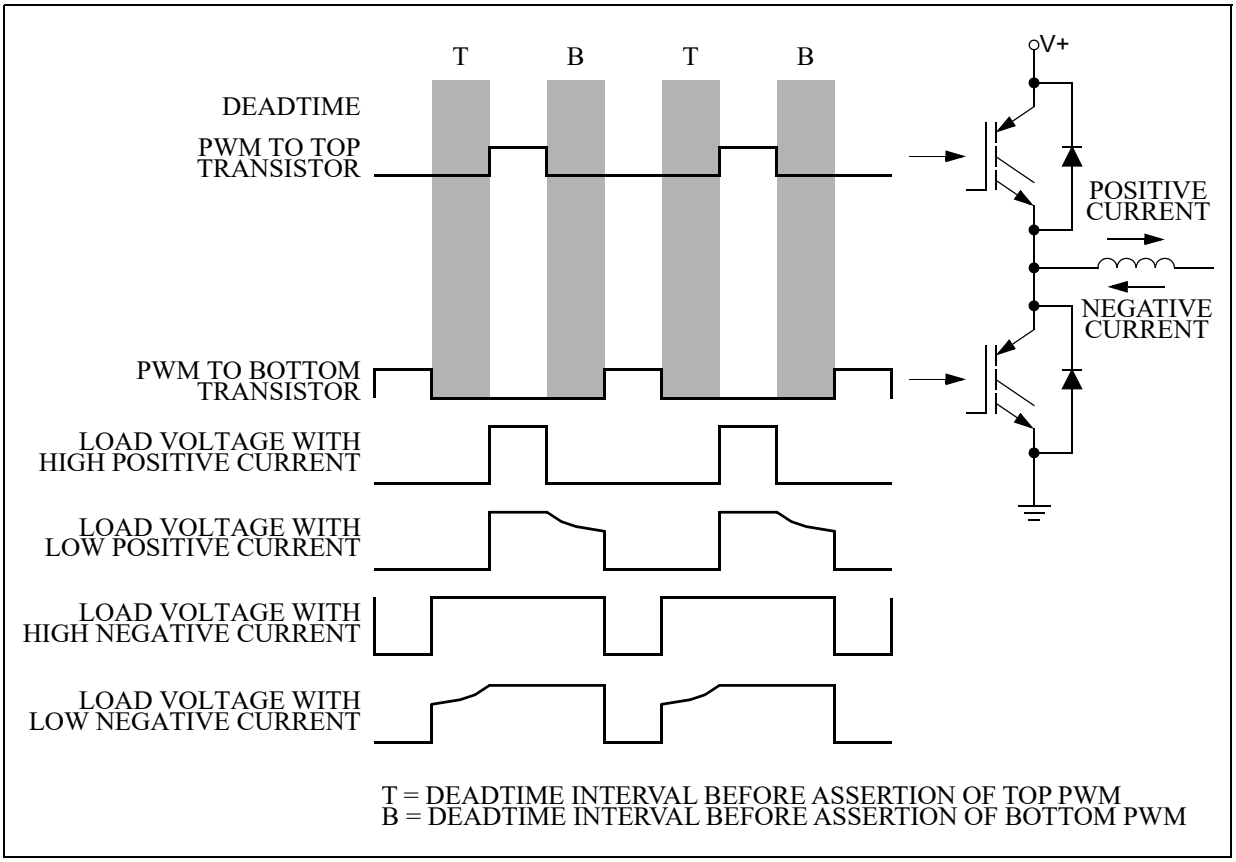


Figure 485. Current-status Sense Scheme for Deadtime Correction

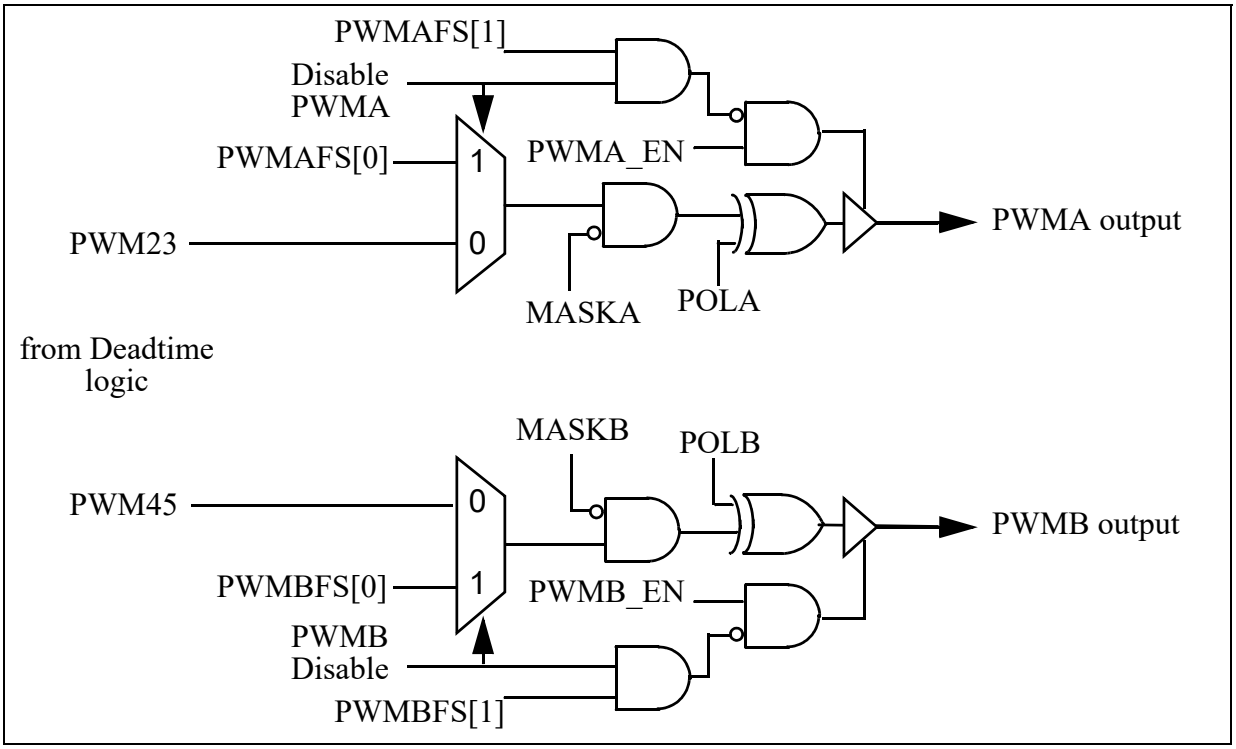
Both D flip-flops latch low, DT0 = 0, DT1 = 0, during deadtime periods if current is large and flowing out of the complementary circuit. See *Figure 485*. Both D flip-flops latch the high, DT0 = 1, DT1 = 1, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results will be DT0 = 0 and DT1 = 1. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

Figure 486. Output Voltage Waveforms

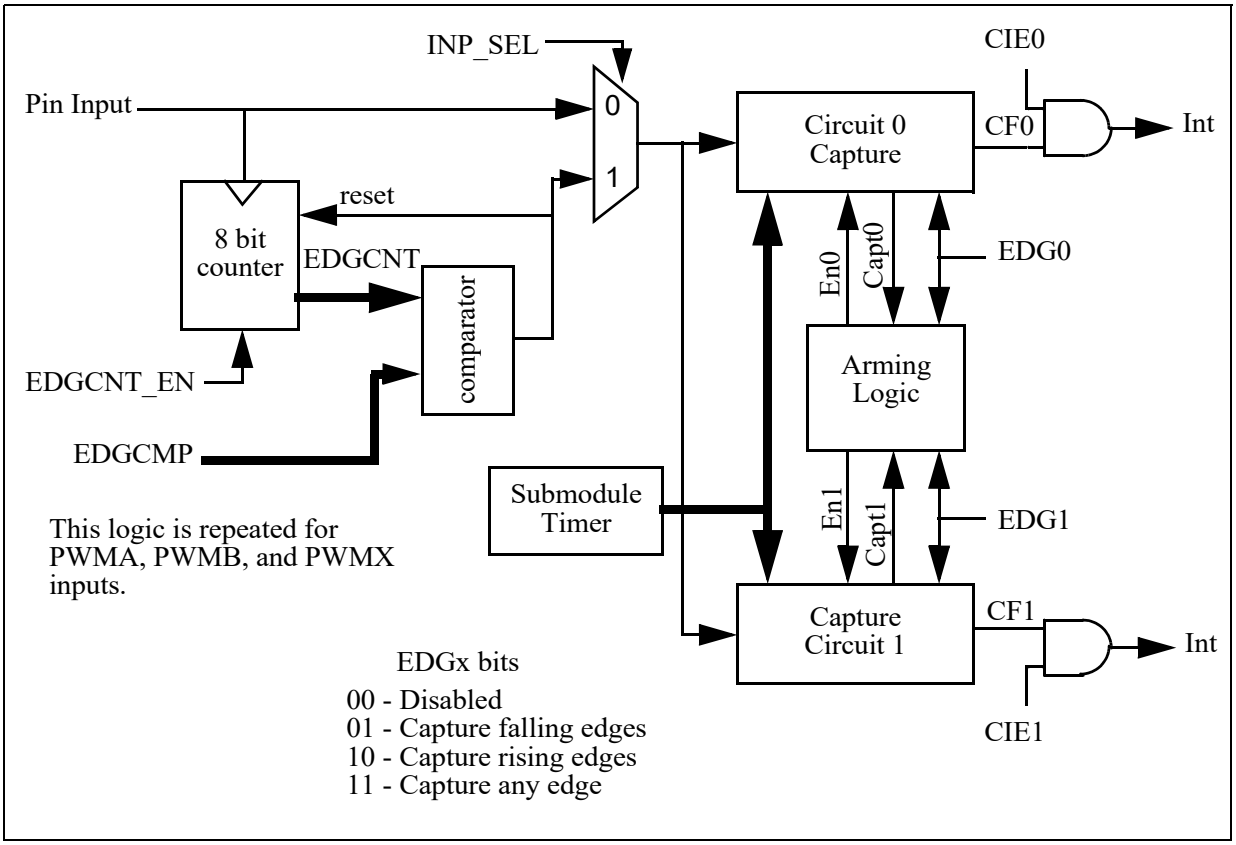


36.4.3.9 Output Logic

Figure 487 shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic in *Figure 487* are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program the POLA and POLB bits before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the PWMxFS fields.

Figure 487. Output Logic Section



36.4.3.10 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

Figure 488 illustrates the block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8 bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8 bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this feature is useful for dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

Figure 488. Enhanced Capture (E-Capture) Logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by the EDGx1 and EDGx0 bits whose functionality is listed in *Figure 488*. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

36.4.3.11 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via the FLVL bits. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of the PWMxFS bits.

The fault decoder disables PWM pins selected by the fault logic and the disable mapping register (DISMAP). See *Figure 489* for an example of the fault disable logic. Each bank of bits in DISMAP control the mapping for a single PWM pin. Refer to *Table 566*.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

Figure 489. Fault Decoder for PWMA

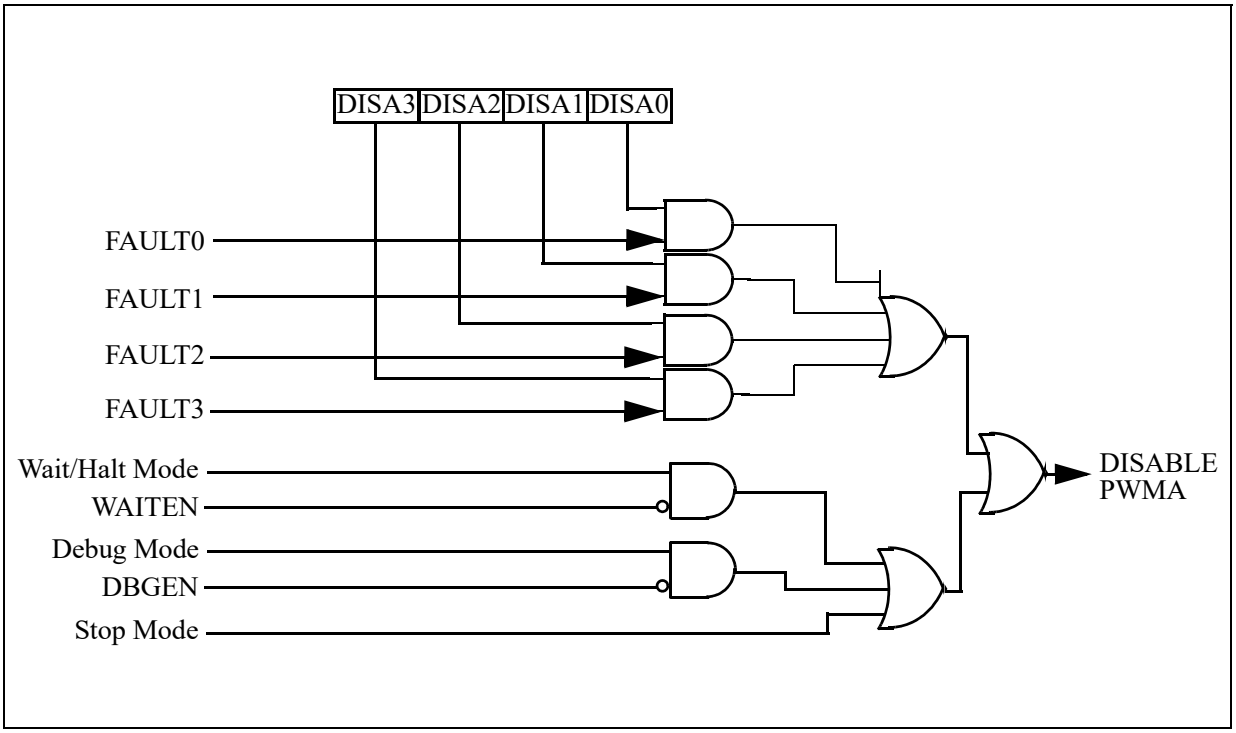


Table 566. Fault Mapping

PWM Pin	Controlling Register Bits
PWMA	DISA[3:0]
PWMB	DISB[3:0]
PWMX	DISX[3:0]

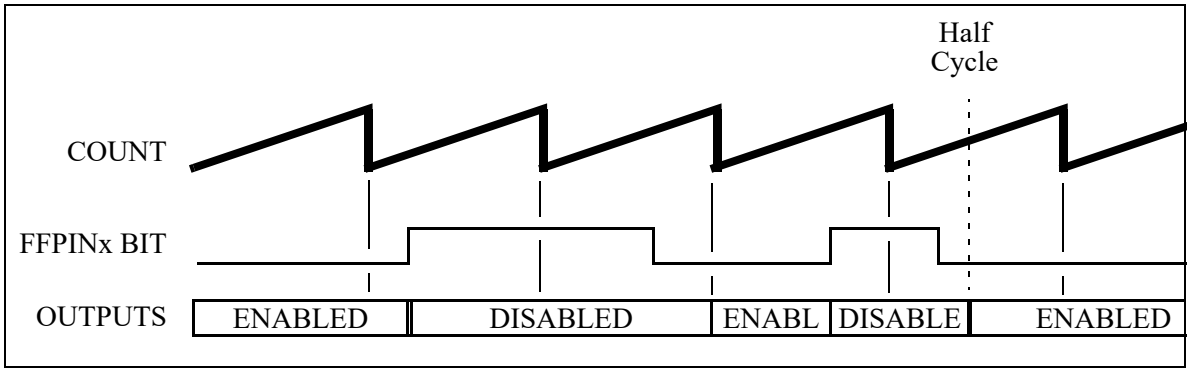
36.4.3.11.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with the FILT_PER field of the FFILTx register. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using the FILT_CNT field of the same register. Setting FILT_PER to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FLVLx is set), the corresponding FFPINx and fault flag, FFLAGx, bits are set. The FFPINx bit remains set as long as the filtered FAULTx pin is zero. Clear FFLAGx by writing a logic 1 to FFLAGx.

If the FIEx, FAULTx pin interrupt enable bit is set, the FFLAGx flag generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears the FFLAGx flag by writing a logic one to the bit.
- Software clears the FIEx bit by writing a logic zero to it.
- A reset occurs.



Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

36.4.3.11.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for automatic clearing.

When FAUTOx is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See *Figure 490*. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle. Clearing the FFLAGx flag does not affect disabled PWM pins when FAUTOx is set.

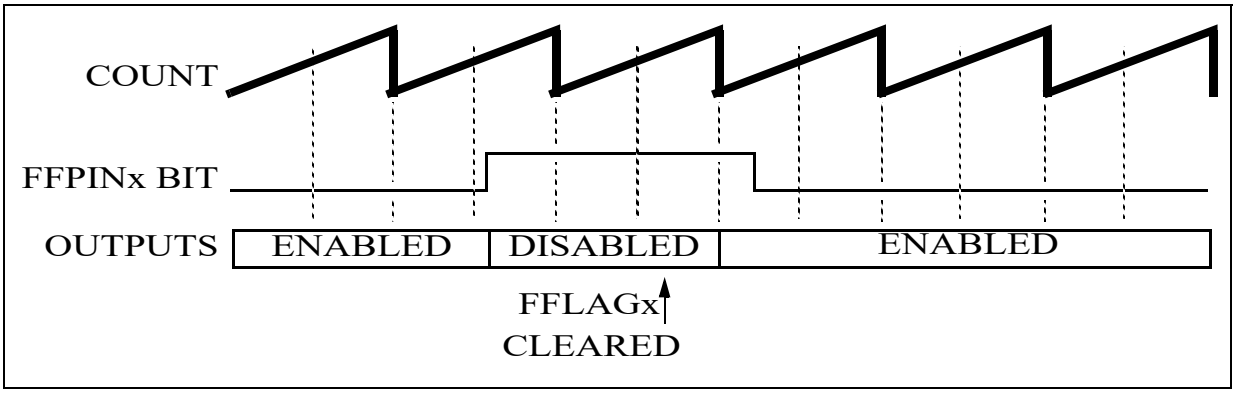
Figure 490. Automatic Fault Clearing

36.4.3.11.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits, FSAFEx, are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag.
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See *Figure 491*. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.
- If the fault safety mode bits, FSAFEx, are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag.
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See *Figure 492*. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.

Figure 491. Manual Fault Clearing (FSAFE=0)



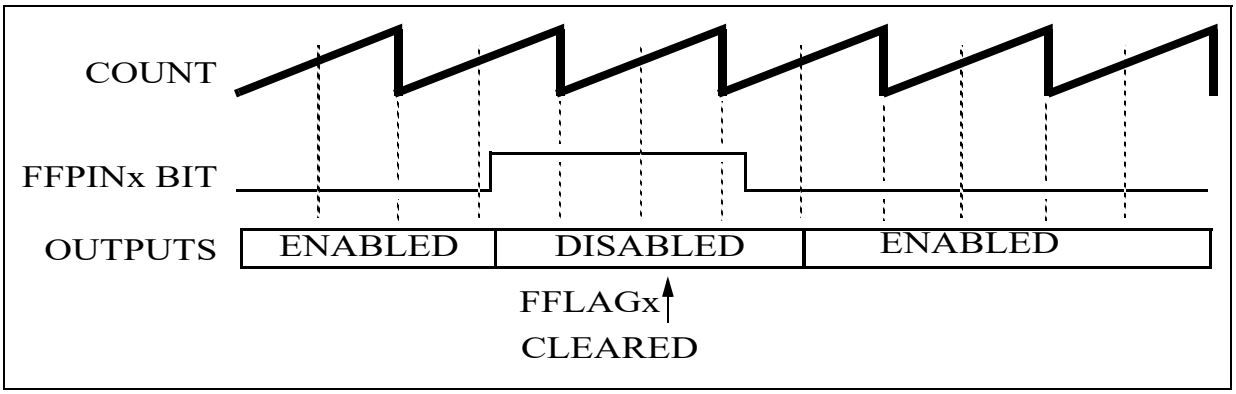


Figure 492. Manual Fault Clearing (FSAFE=1)

Note: Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or EXTA and EXTB. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, RUN equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, RUN equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

36.4.3.11.4 Fault Testing

The FTEST bit is used to simulate a fault condition on each of the fault inputs.

36.4.4 PWM Generator Loading

36.4.4.1 Load Enable

The LDOK bit enables loading of the following PWM generator parameters:

- The prescaler divisor: from the PRSC bits in the CTRL1 register.
- The PWM period and pulse width: from the INIT and VALx registers.

LDOK allows software to finish calculating all of these PWM parameters so they can be synchronously updated. The PSRC, INIT, and VALx registers are loaded by software into a set of outer buffers. When LDOK is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transfered to the inner set of registers immediately upon setting LDOK

if LDMOD is set. Set LDOK by reading it when it is a logic zero and then writing a logic one to it. After loading, LDOK is automatically cleared.

36.4.4.2 Load Frequency

The LDFQ bits in the CTRL1 register select an integral loading frequency of one to 16 PWM reload opportunities. The LDFQ bits take effect at every PWM reload opportunity, regardless the state of the LDOK bit. The HALF and FULL bits in the CTRL1 register control reload timing. If FULL is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If HALF is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both HALF and FULL are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

Figure 493. Full Cycle Reload Frequency Change

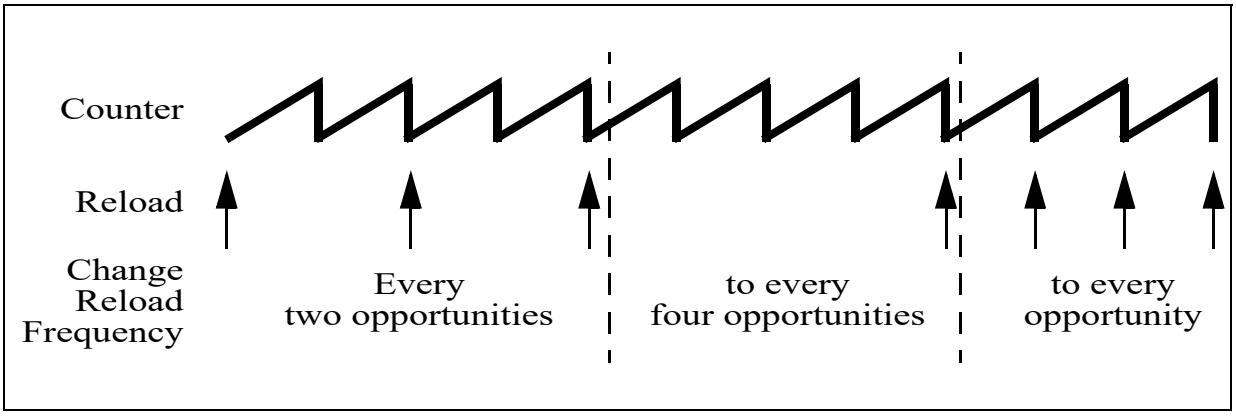

Figure 494. Half Cycle Reload Frequency Change

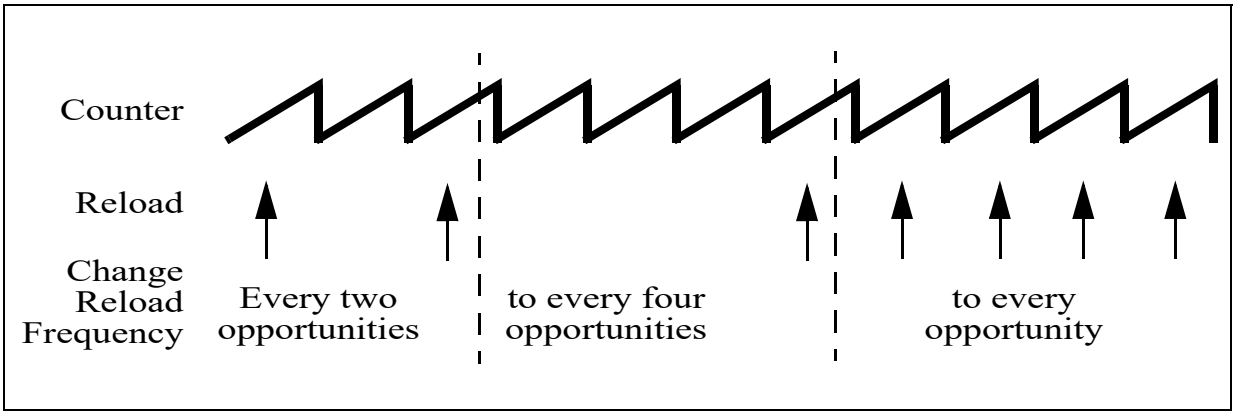

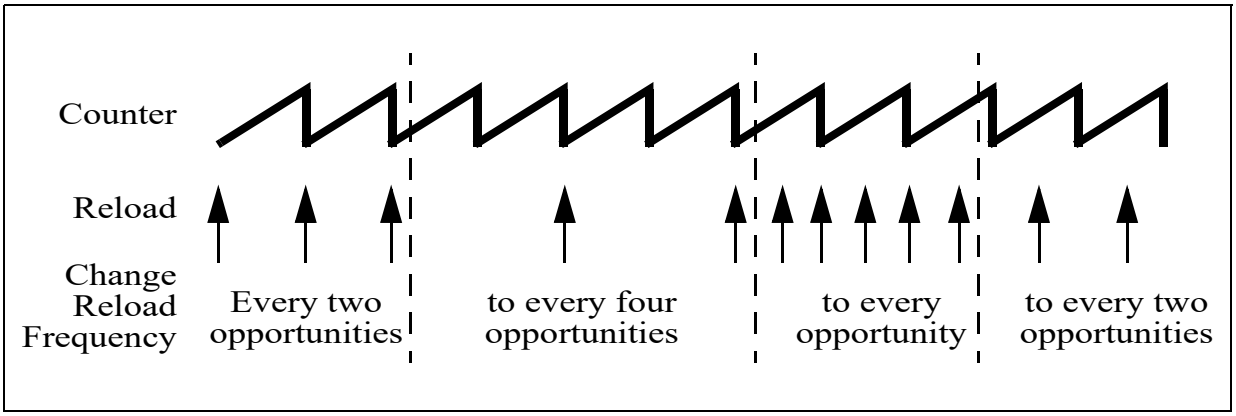

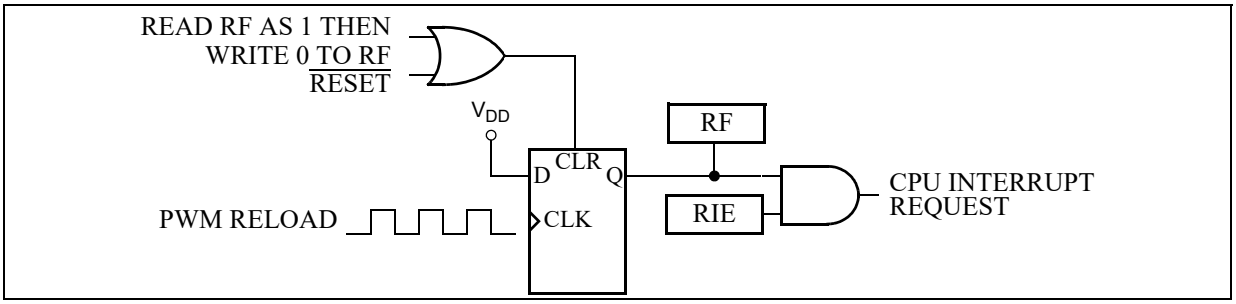

Figure 495. Full and Half Cycle Reload Frequency Change

36.4.4.3 Reload Flag

At every reload opportunity the PWM Reload Flag (RF) in the CTRL1 register is set. Setting RF happens even if an actual reload is prevented by the LDOK bit. If the PWM reload interrupt enable bit, RIE is set, the RF flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When RIE is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

Figure 496. PWMF Reload Interrupt Request

36.4.4.4 Reload Errors

Whenever one of the VAL or PSRC registers is updated, the RUF flag is set to indicate that the data is not coherent. RUF will be cleared by a successful reload which consists of the reload signal while LDOK is set. If RUF is set and LDOK is clear when the reload signal occurs, a reload error has taken place and the REF bit is set. If RUF is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

36.4.4.5 Initialization

Initialize all registers and set the LDOK bit before setting the RUN bit.

Note: Even if LDOK is not set, setting RUN also sets the RF flag. To prevent a CPU interrupt request, clear the RIE bit before setting RUN.

The PWM generator uses the last values loaded if RUN is cleared and then set while LDOK equals zero.

When the RUN bit is cleared:

- The RF flag and pending CPU interrupt requests are not cleared.
- All fault circuitry remains active.
- Software/external output control remains active.
- Deadtime insertion continues during software/external output control.

36.5 Resets

The mcPWM module can only be reset by the IPG_HARD_ASYNC_RESET_B signal. This forces all registers to their reset states and tri-states the PWM outputs.

36.6 Clocks

Each PWM submodule receives it's own copy of the IPBus Clock. This allows for better power management by turning off the clock to unused submodules. The fault logic also has its own version of the IPBus clock.

Table 567. Clock Summary

Clock	Used by
ipg_clk_sub0	Submodule 0
ipg_clk_sub1	Submodule 1
ipg_clk_sub2	Submodule 2
ipg_clk_sub3	Submodule 3
ipg_clk_flt	Fault logic

36.7 Interrupts

Each of the submodules within the mcPWM can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 568. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_comp0	CMPF_0	CMPIE_0	Submodule 0 compare interrupt	Compare event has occurred
ipi_int_capt0	CFA1_0, CFA0_0, CFB1_0, CFB0_0, CFX1_0, CFX0_0	CFA1IE_0, CFA0IE_0, CFB1IE_0, CFB0IE_0, CFX1IE_0, CFX0IE_0	Submodule 0 input capture interrupt	Input capture event has occurred

Table 568. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_reload0	RF_0	RIE_0	Submodule 0 reload interrupt	Reload event has occurred
ipi_int_comp1	CMPF_1	CMPIE_1	Submodule 1 compare interrupt	Compare event has occurred
ipi_int_capt1	CFA1_1, CFA0_1, CFB1_1, CFB0_1, CFX1_1, CFX0_1	CFA1IE_1, CFA0IE_1, CFB1IE_1, CFB0IE_1, CFX1IE_1, CFX0IE_1	Submodule 1 input capture interrupt	Input capture event has occurred
ipi_int_reload1	RF_1	RIE_1	Submodule 1 reload interrupt	Reload event has occurred
ipi_int_comp2	CMPF_2	CMPIE_2	Submodule 2 compare interrupt	Compare event has occurred
ipi_int_capt2	CFA1_2, CFA0_2, CFB1_2, CFB0_2, CFX1_2, CFX0_2	CFA1IE_2, CFA0IE_2, CFB1IE_2, CFB0IE_2, CFX1IE_2, CFX0IE_2	Submodule 2 input capture interrupt	Input capture event has occurred
ipi_int_reload2	RF_2	RIE_2	Submodule 2 reload interrupt	Reload event has occurred
ipi_int_comp3	CMPF_3	CMPIE_3	Submodule 3 compare interrupt	Compare event has occurred
ipi_int_capt3	CFA1_3, CFA0_3, CFB1_3, CFB0_3, CFX1_3, CFX0_3	CFA1IE_3, CFA0IE_3, CFB1IE_3, CFB0IE_3, CFX1IE_3, CFX0IE_3	Submodule 3 input capture interrupt	Input capture event has occurred
ipi_int_reload3	RF_3	RIE_3	Submodule 3 reload interrupt	Reload event has occurred
ipi_int_rerr	REF_0	REIE_0	Submodule 0 reload error interrupt	Reload error has occurred

	REF_2	REIE_2	Submodule 2 reload error interrupt	
	REF_3	REIE_3	Submodule 3 reload error interrupt	
ipi_int_fault	FFLAG	FIE	Fault input interrupt	Fault condition has been detected

36.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered VALx registers.

Table 569. DMA Summary

DMA Request	DMA Enable	Name	Description
Submodule 0 read request	CX0DE_0	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_0	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CA0DE_0	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_0	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_0	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_0	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_0	Capture FIFO read request source select	Selects source of read DMA request
Submodule 0 write request	VALDE_0	VALx write request	VALx registers need to be updated
Submodule 1 read request	CX0DE_1	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_1	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CA0DE_1	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_1	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_1	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_1	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_1	Capture FIFO read request source select	Selects source of read DMA request
Submodule 1 write request	VALDE_1	VALx write request	VALx registers need to be updated
Submodule 2 read request	CX0DE_2	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_2	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CA0DE_2	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_2	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_2	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_2	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_2	Capture FIFO read request source select	Selects source of read DMA request
Submodule 2 write request	VALDE_2	VALx write request	VALx registers need to be updated

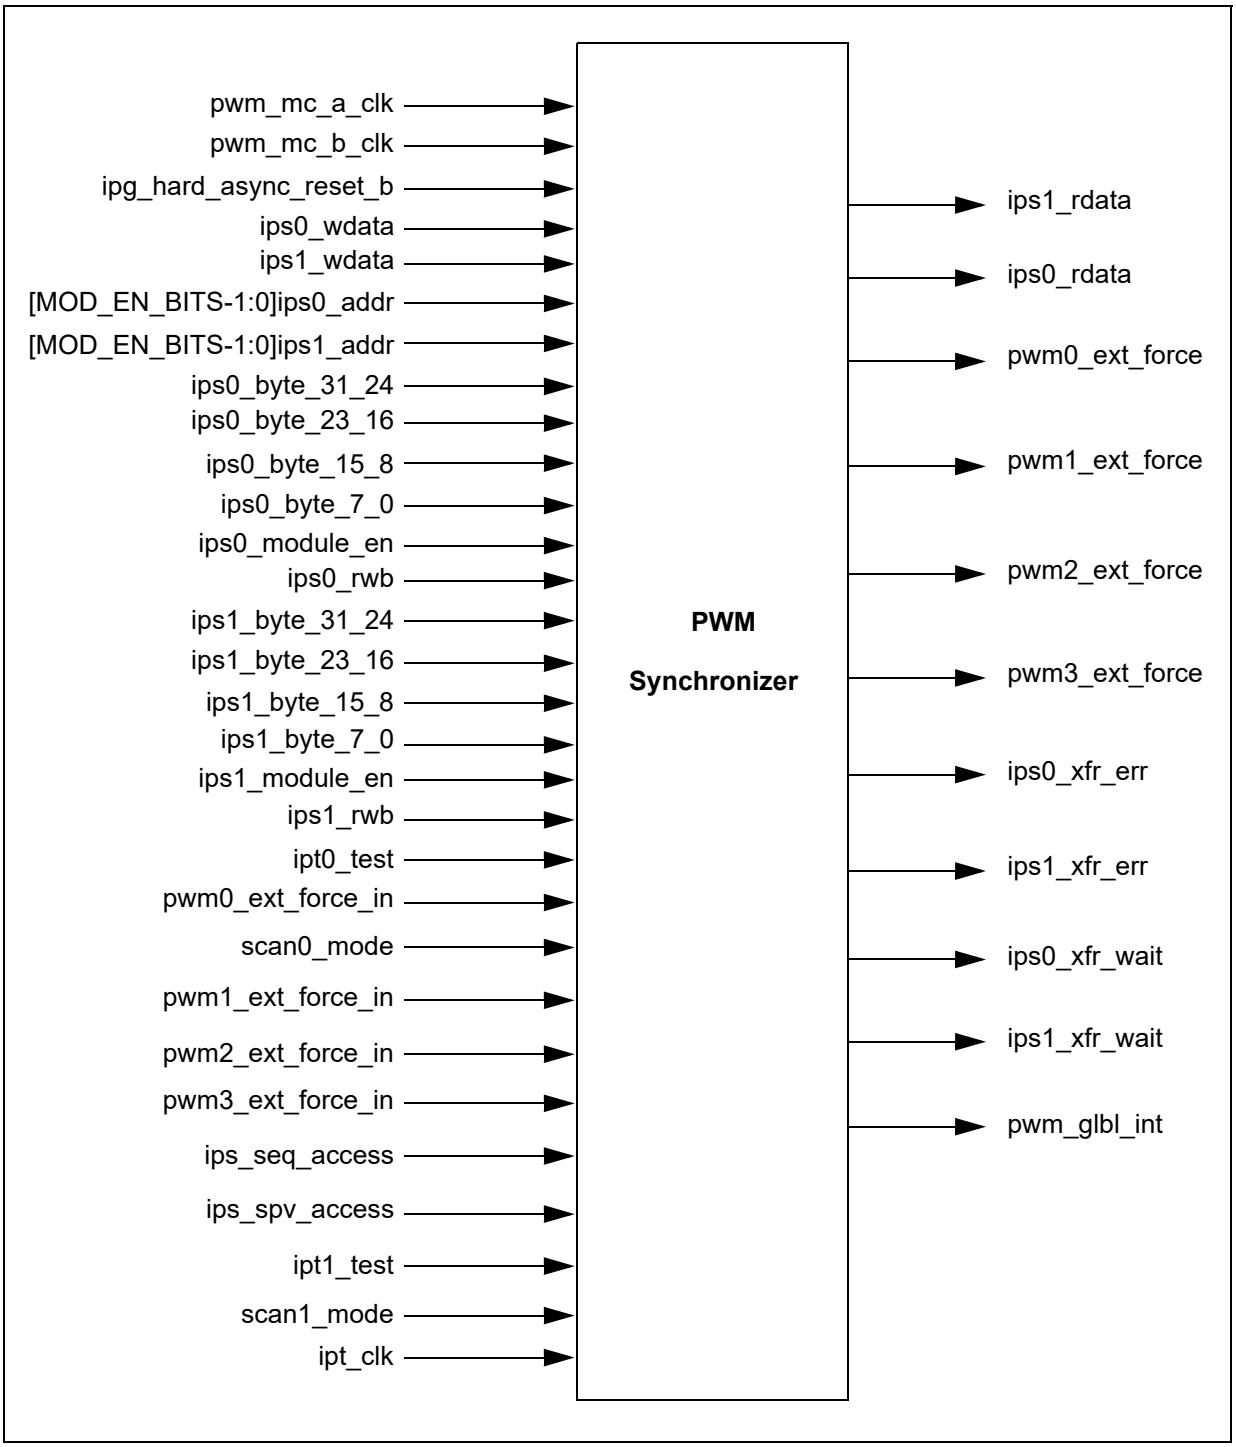

Table 569. DMA Summary (continued)

DMA Request	DMA Enable	Name	Description
Submodule 3 read request	CX0DE_3	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_3	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CA0DE_3	Capture FIFO A0 read request	CVAL2 contains a value to be read
	CA1DE_3	Capture FIFO A1 read request	CVAL3 contains a value to be read
	CB0DE_3	Capture FIFO B0 read request	CVAL4 contains a value to be read
	CB1DE_3	Capture FIFO B1 read request	CVAL5 contains a value to be read
	CAPTDE_3	Capture FIFO read request source select	Selects source of read DMA request
Submodule 3 write request	VALDE_3	VALx write request	VALx registers need to be updated

37 PWM Synchronizer

37.1 Introduction

Figure 497. Block Diagram

37.2 Main Features

- Start synchronously the triggers for PWM0, PWM1, PWM2, PWM3 in full sync option.
- Start synchronously triggers for PWM0, PWM1 and PWM2, PWM3 independently in the half sync option.
- Two independent interfaces (PBRIDGE_0, PBRIDGE_1).
- Allows Read back of the 4 PWM triggers (to check if triggers are sent or not).
- Clocked by the 2 motor control clocks.
- Four bits wide pre-scaler for the two clocks.
- 12 bits delay counters (max delay (34 µs to 546 µs)).
- One global IRQ interrupt to notify the start of either of PWMx trigger and misconfiguration error.
- All Registers are byte-wise, half-word and word writable.

37.3 Memory map and register description

This section provides a detailed description of all registers accessible in the PWM synchronizer.

37.3.1 Memory map

Table 570 gives an overview of the implemented PWM synchronizer registers.

Table 570. PWM synchronizer memory map

Address offset	Register	Location
PBRIDGE_0

30 INT3	0 No interrupt was generated. 1 PWM3 interrupt was generated.
31 INT2	0 No interrupt was generated. 1 PWM2 interrupt was generated.

37.4 Programming Sequence

For half sync mode

1. Program the relevant prescalar register first (PWM_SYNCHR_PRE_SCALAR0/1) to divide the clock.
2. Then the remaining configuration registers (such as PWM_SYNCHR_CONFIG0/1 and PWM_SYNCHR_INT_EN0/1), in any order.
3. Finally the relevant start register, PWM_SYNCHR_STRT0/1.

For full sync mode

1. Program PBRIDGE_0 and PBRIDGE_1 prescalar registers first (PWM_SYNCHR_PRE_SCALAR1 and PWM_SYNCHR_PRE_SCALAR0) with the same value.
2. Configure registers PWM_SYNCHR_CONFIG0 and PWM_SYNCHR_CONFIG1 with the same value, 1, for HALF_FULL0 and HALF_FULL1 fields.
3. PWM_SYNCHR_DLY_CNTR0 and PWM_SYNCHR_DLY_CNTR1 with the required delay values and optionally the PWM_SYNCHR_INT_EN0 and PWM_SYNCHR_INT_EN1 interrupt enable registers.
4. Finally the PWM_SYNCHR_STRT0 and PWM_SYNCHR_STRT1, in any order.

37.5 Functional description

The PWM synchronizer has two clocks and two separate PBRIDGE interfaces to guarantee the separation and redundancy of motor control sub-system 0 (made by eTimer0/1, PWM0/1, ADC0/1/2/B) and motor control sub-system 1 (made by eTimer2/3, PWM2/3, ADC3/4/5/B1).

The synchronizer is built in such a way that it is split in the two different LBISTpartitions, having few signals crossing the partitions. The idea is to have two sub-modules in PWM synchronizer, one for managing PBRIDGE_0 and triggers for PWM0/1 and a similar one for managing PBRIDGE_1 and triggers for PWM2/3. These two sub-modules are interconnected with glue logic in between them.

The two PBRIDGE interfaces work independently. There are two modes to generate triggers namely full sync *Figure 512* and half sync *Figure 513* mode. In full sync mode, all the four trigger outputs are generated at the same time after the programmed delays, based on the respective trigger enables, after sync start bits(FH0, FH1) are written, for both of the interface, PBRIDGE_0 and PBRIDGE_1.

In half sync mode, the respective two triggers are generated, after the programmed delay, depending on which trigger is enabled. Writing FH0 may generate both pwm0_ext_force0 and pwm1_ext_force and writing FH1 may generate both pwm2_force_ext and pwm3_ext_force outputs, as shown in *Figure 513*. The four programmed delays are independent. At the time of generation of trigger outputs, the interrupts are also generated and their status latched, based on their respective enable values.

38 Enhanced Motor Control Timer (eTimer)

38.1 Introduction

38.1.1 Overview

An eTimer module provides:

- Six identical counter/timer channels
- One watchdog timer function (might not be available on every eTimer module instance)

Each 16-bit counter/timer channel contains a prescaler, a counter, a load register, a hold register, two queued capture registers, two compare registers, two compare preload registers, and four control registers.

Note: This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The Load register provides the initialization value to the counter when the counter's terminal value has been reached. For true modulo counting the counter can also be initialized by the CMPLD1 or CMPLD2 registers.

The Hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters coherently.

The Capture registers enable an external signal to take a "snap shot" of the counter's current value.

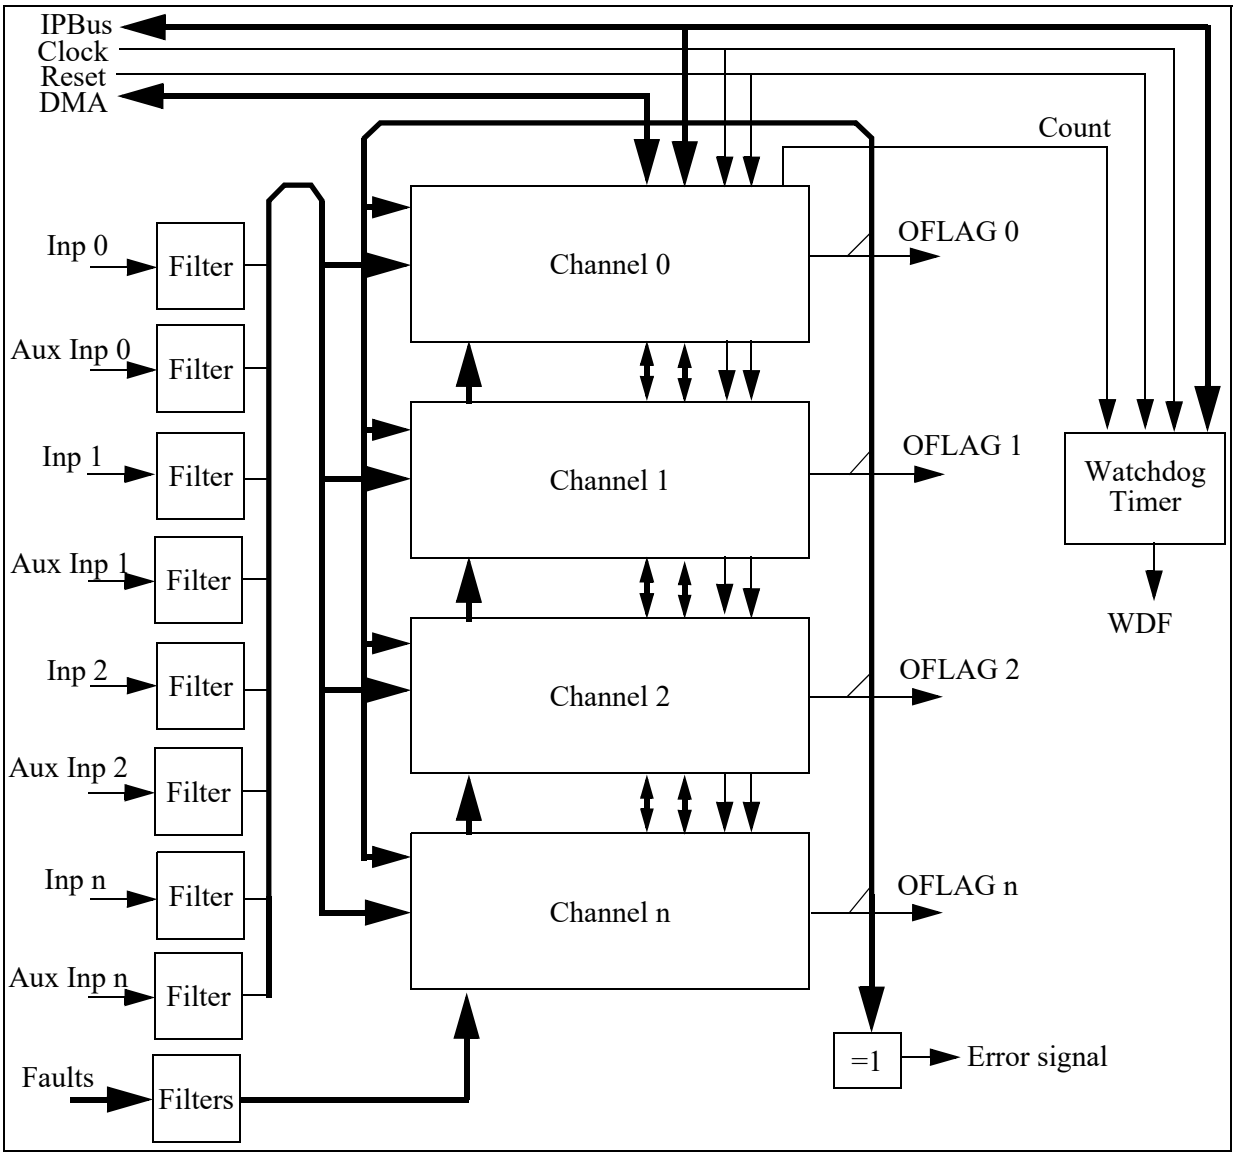
The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG signal can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The Prescaler provides different time bases useful for clocking the counter/timer.

The Counter provides the ability to count internal or external events.

Within the eTimer module, the input pins are shareable.

38.1.2 Features



The eTimer module design includes these distinctive features:

- 16-bit counters/timers: 6
- Count up/down
- Counters are cascadable
- Enhanced programmable up/down modulo counting
- Max count rate equals peripheral clock/2 for external clocks
- Max count rate equals peripheral clock for internal clocks
- Count once or repeatedly
- Counters are preloadable
- Compare registers are preloadable
- Counters can share available input pins
- Separate prescaler for each counter
- Each counter has capture and compare capability
- Continuous and single shot capture for enhanced speed measurement
- DMA support of capture registers and compare registers
- 32-bit watchdog capability to detect stalled quadrature counting (might not be available on every eTimer module instance)
- OFLAG comparison for safety critical applications
- Programmable operation during debug mode and stop mode
- Programmable input filter
- Counting start can be synchronized across counters.

38.1.3 Module block diagram

The eTimer block diagram is shown in *Figure 515*.

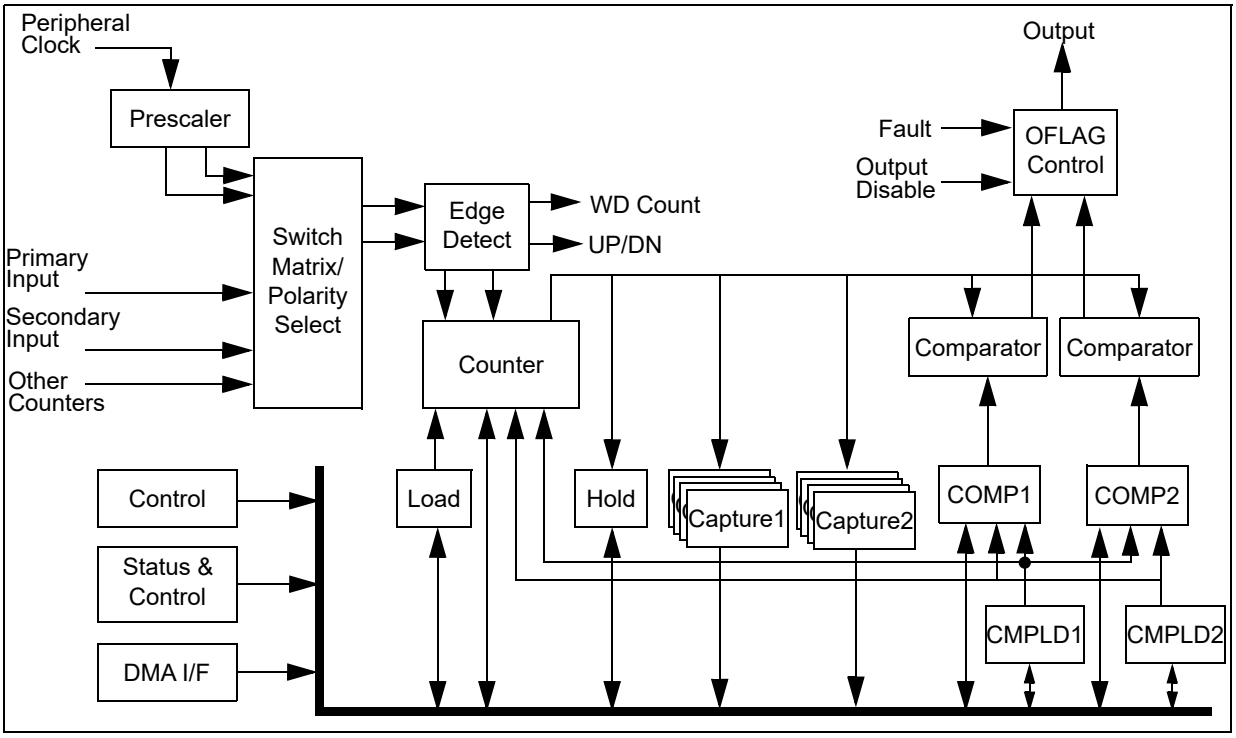


Figure 515. eTimer Block Diagram

38.1.4 Channel block diagram

Each of the timer/counter channels within the eTimer are shown in *Figure 516*.

Figure 516. eTimer channel block diagram

38.2 External signal descriptions

The eTimer module has:

- Six external signals that can be used as either inputs or outputs
- Interfaces to the Peripheral Bus
- Two auxiliary inputs

38.2.1 TIO[*n*:0] - Timer Input/Outputs

These pins can be independently configured to be either timer input sources or output flags. In *Figure 516*, the TIO signals are shown as the Primary Inputs and the Outputs from the OFLAG Control block

38.2.2 TAI[*n*:0] - Timer Auxiliary Inputs

These pins act as alternate input choices for the timer channels. The TAI signals are shown as Aux Inp 1..n in *Figure 515*.

38.3 Functional Description

38.3.1 General

Each channel has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a “count with direction” format.
- The counter’s terminal count value (modulo) is programmable.
  - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count “rolls over” to zero.

The external inputs to each counter/timer are shareable among each of the channels within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be “captured”
- They can be used to generate interrupt requests

The polarity of the external inputs is selectable.

The primary output of each channel is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is programmable.

Any channel can be assigned as a “Master”. A master’s compare signal can be broadcasted to the other channels within the module. The other channels can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a Master channel’s compare event occurs.

38.3.2 Counting Modes

The selected external signals are sampled at the eTimer’s base clock rate and then run through a transition detector. The maximum count rate is one-half of the eTimer’s base clock rate when using an external signal. Internal clock sources can be used to clock the counters at the eTimer’s base clock rate.

If a counter is programmed to count to a specific value and then stop, the CNTMODE field in the CTRL1 register is cleared when the count terminates.

38.3.2.1 STOP Mode

If the CNTMODE field is set to ‘000’, the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

38.3.2.2 COUNT Mode

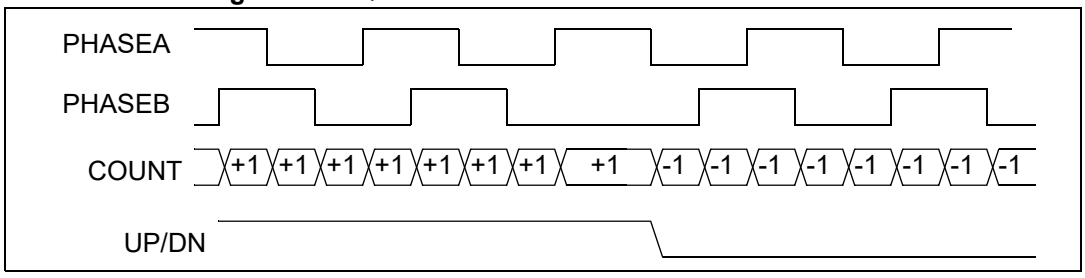
If the CNTMODE field is set to ‘001’, the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as “widgets” on a conveyor belt passing a sensor. If the selected input is inverted by setting the PIPS bit, then the negative edge of the selected external input signal is counted.

See *Section 38.3.2.9: CASCADE-COUNT Mode*, through *Section 38.3.2.12: VARIABLE-FREQUENCY PWM Mode*, for additional capabilities of this operating mode.

38.3.2.3 EDGE-COUNT Mode

If the CNTMODE field is set to ‘010’, the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment such as a simple encoder wheel.

38.3.2.4 GATED-COUNT Mode



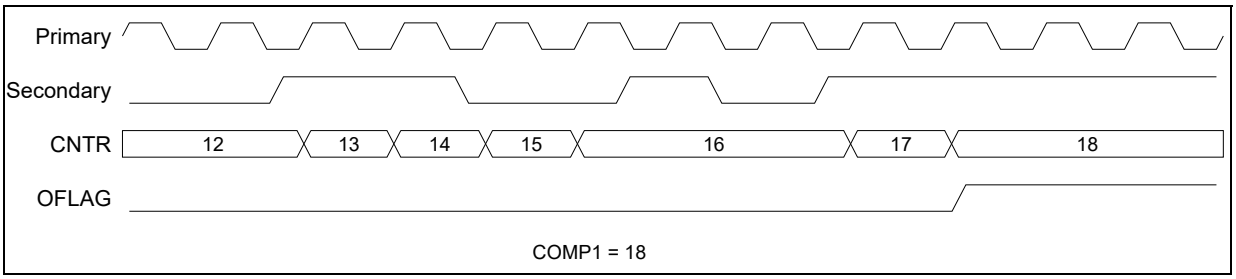
If the CNTMODE field is set to ‘011’, the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting the SIPS bit, then the counter will count while the selected secondary input is low.

38.3.2.5 QUADRATURE-COUNT Mode

If the CNTMODE field is set to ‘100’, the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information.

Figure 517 shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

Figure 517. Quadrature Incremental Position Encoder



38.3.2.6 SIGNED-COUNT Mode

If the CNTMODE field is set to ‘101’, the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

38.3.2.7 TRIGGERED-COUNT Mode

If the CNTMODE field is set to ‘110’, the counter will begin counting the primary clock source after a positive transition (negative if SIPS = 1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. Subsequent secondary positive input transitions will continue to restart and stop the counting until a compare event occurs.

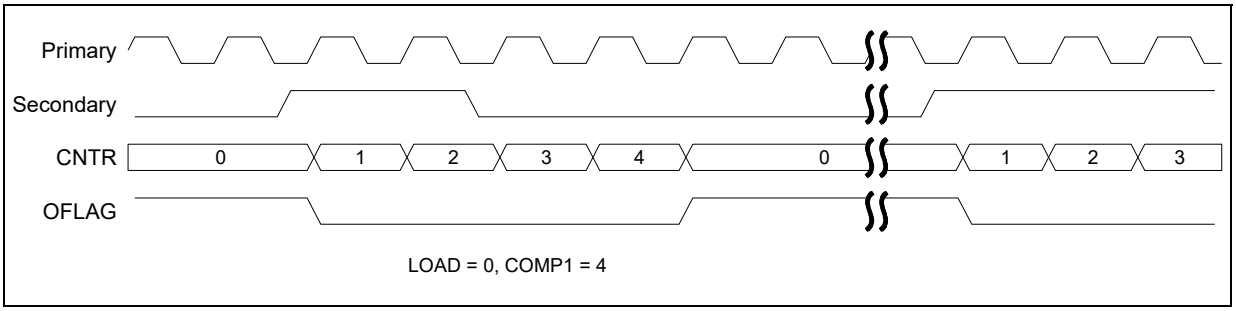


Figure 518. Triggered Count Mode (Length=1)

38.3.2.8 ONE-SHOT Mode

If the CNTMODE field is set to ‘110’, and the counter is set to reinitialize at a compare event (LENGTH =1), and the OFLAG OUTMODE is set to ‘0101’ (cleared on init, set on compare), the counter works in a “One-Shot Mode”. An external events causes the counter to count, when terminal count is reached, the output is asserted. This “delayed” output can be used to provide timing delays.

Figure 519. One-Shot Mode (Length=1)

38.3.2.9 CASCADE-COUNT Mode

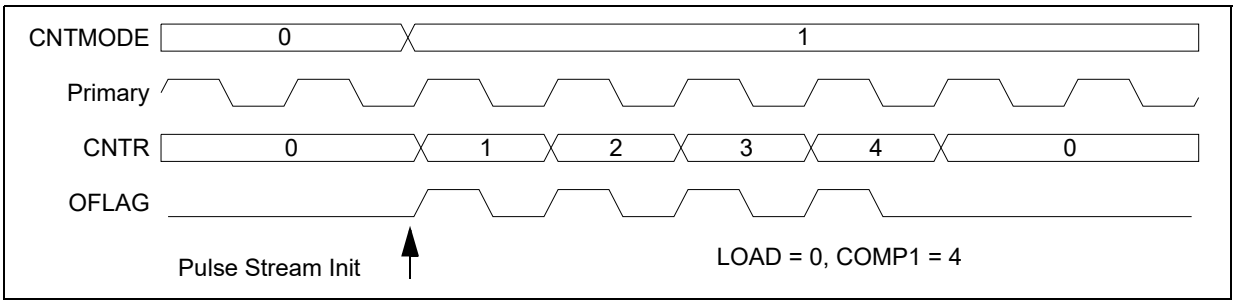
If the CNTMODE field is set to ‘111’, the counter’s input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This “Cascade” or “Daisy-Chained” mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to two counters may be cascaded to create a 32 bit wide synchronous counter.

Whenever any counter is read within a counter module, all of the counters’ values within the module are captured in their respective HOLD registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read

the HOLD registers of the other counters in the chain. The cascaded counter mode is synchronous.

Note: It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a "ripple" mode, where higher order counters will transition a clock later than a purely synchronous design.



A channel can be cascaded with any other channel, but you can't cascade more than 2 channels together. You can create separate cascades of pairs of channels. For example, you can cascade channels 0 and 1 and separately cascade channels 6 and 5. You can't cascade channels 0, 1, and 5.

38.3.2.10 PULSE-OUTPUT Mode

If the counter is setup for CNTMODE = 001, and the OFLAG OUTMODE is set to '1111' (gated clock output), and the ONCE bit is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

Note: This does not work if the PRISRC is set to '11000' (IP_bus/1).

Figure 520. Pulse Output Mode

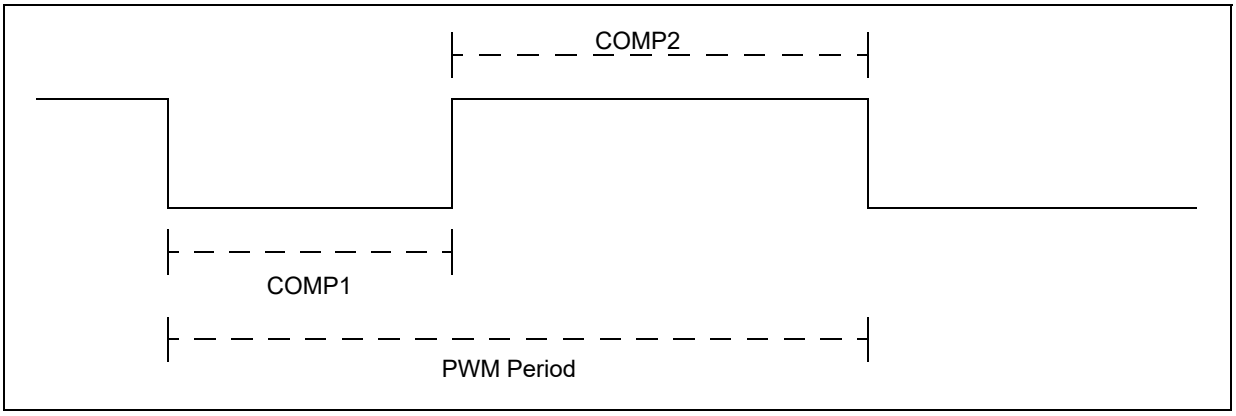
38.3.2.11 FIXED-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count through roll-over (LENGTH = 0), continuous count (ONCE = 0) and the OFLAG OUTMODE is '0111' (set on compare, cleared on counter roll-over) then the counter output yields a Pulse Width Modulated (PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

38.3.2.12 VARIABLE-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count till compare (LENGTH = 1), continuous count (ONCE = 0) and the OFLAG OUTMMODE is '0100' (toggle OFLAG and alternate compare registers) then the counter output yields a Pulse Width Modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

Figure 521. Variable PWM Waveform



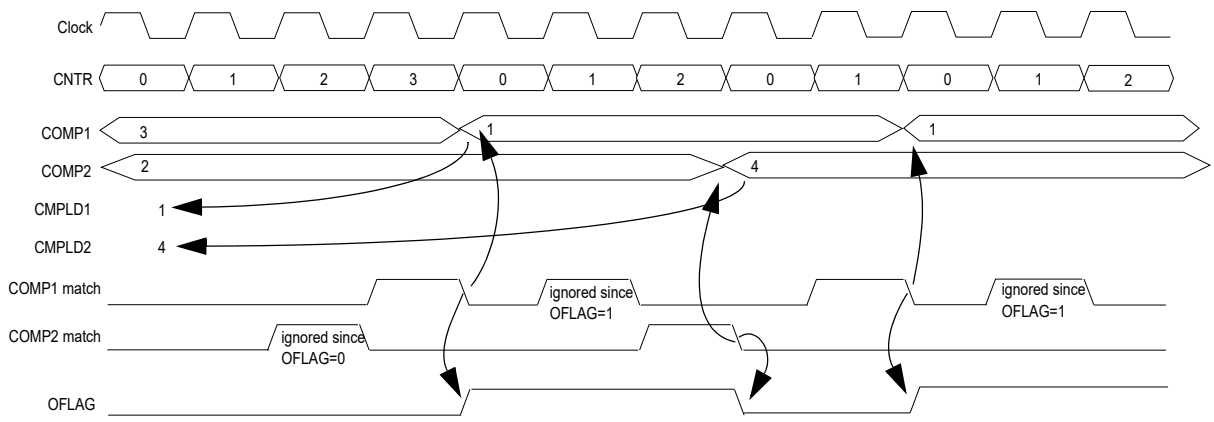


Figure 522. Variable Frequency PWM Mode Timing

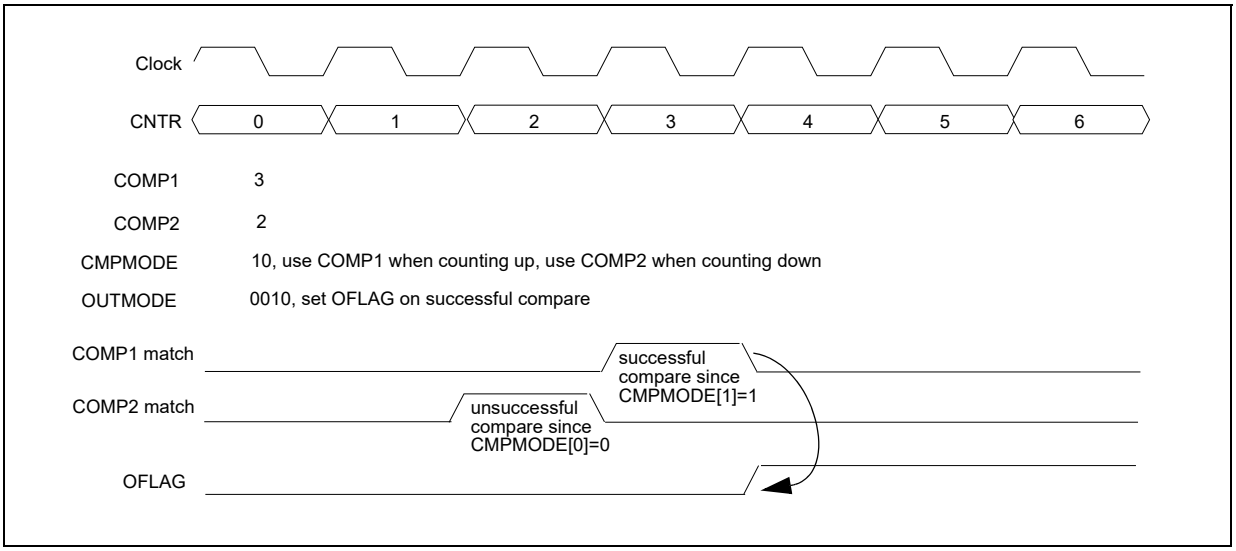
CLC1=010, load COMP1 when CNTR=COMP1,
Load COMP1 with CMPLD1 upon successful compare with the value in COMP1

CLC2=101, load COMP2 when CNTR=COMP2,
Load COMP1 with CMPLD2 upon successful compare with the value in COMP2

38.3.2.13 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability.



The COMP1 register should be set to the desired maximum count value or 0xFFFF to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0x0000 to indicate the minimum unsigned value prior to roll-under.

If the output mode is set to 0100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time. COMP1 is used when OFLAG=0 and COMP2 is used when OFLAG=1. OFLAG can be forced to a value using CTRL2[FORCE] and CTRL2[VAL].

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to 0xFFFF or 0x0000, roll over, then begin counting toward the new value. The check is: CNTR = COMPx, *not* CNTR > COMP1 or CNTR < COMP2.

The use of the CMPLD1 and CMPLD2 registers to preload compare values will help to minimize this problem.

Figure 523. Compare Register and OFLAG Timing

38.3.2.14 Usage of Compare Load Registers

The CMPLD1, CMPLD2 and CCCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. A compare register can be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there is the possibility that the counter may have already counted past the new compare value by the time the compare register is updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are updated in hardware in the same way the counter register is re-initialized to the value stored in the LOAD register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See *Figure 521*.

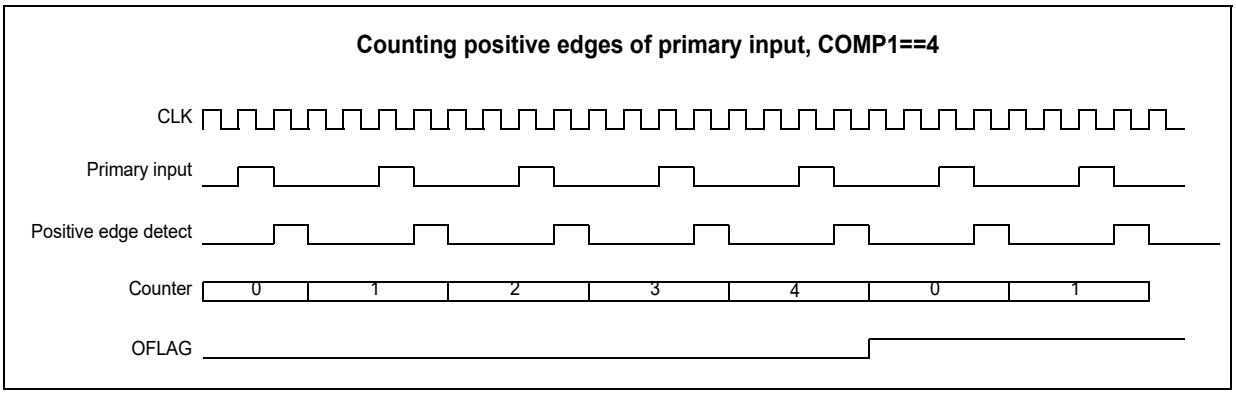
38.3.2.15 MODULO COUNTING Mode

To create a modulo counter using COMP1 and COMP2 as the counter boundaries (instead of 0x0000 and 0xFFFF), set the registers in the following manner. Set CNTMODE to either 100 (quadrature count mode) or 101 (count with direction mode). Use count through roll-over (LENGTH = 0) and continuous count (ONCE = 0). Set COMP1 and CMPLD1 to the upper boundary value. Set COMP2 and CMPLD2 to the lower boundary value. Set CMPMODE = 10 (COMP1 is used when counting up and COMP2 is used when counting down). Set CLC2 = 110 (load CNTR with value of CMPLD2 on COMP1 compare) and CLC1 = 111 (load CNTR with value of CMPLD1 on COMP2 compare).

38.3.2.16 Compare Register and OFLAG Operation

The compare flags and output flag are registered signals and can only change state after the counter reached the compare value. This means that, if the counter is continuously counting, then the compare flag is set on the count after the counter reaches the compare value. When counting is not continuous (such as when using a prescaler or when counting edges on the primary input), the compare flag or OFLAG are not updated until the counter is about to transition to the next count. This means that if the compare value is 4, then the flags will be changed on the same clock edge that transitions the counter from 4 to its next value.

Figure 524. OFLAG timing during non-continuous counting



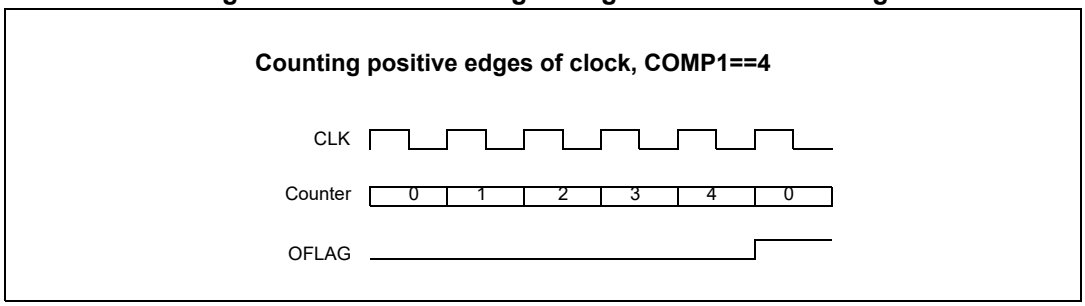


Figure 525. OFLAG timing during continuous counting

38.3.3 Other Features

38.3.3.1 Redundant OFLAG Checking

This mode allows the user to bundle two timer functions generating any pattern to compare their resulting OFLAG behaviors (output signal).

The redundant mode is used to support online checks for functional safety reasons. Whenever a mismatch between the two adjacent channels occurs, it is reported via an interrupt to the core and the two outputs are put into their inactive states. An error is flagged via the RCF flag.

This feature can be tested by forcing a transition on one of the OFLAGs using the VAL and FORCE bits of the channel.

38.3.3.2 Loopback Checking

This mode is always available in that one channel can generate an OFLAG while another channel uses the first channels OFLAG as its input to be measured and verified to be as expected.

38.3.3.3 Input Capture Mode

Input capture is used to measure pulse width (by capturing the counter value on two successive input edges) or waveform period (by capturing the counter value on two consecutive rising edges or two consecutive falling edges). The Capture Registers store a copy of the counter's value when an input edge (positive, negative, or both) is detected. The type of edge to be captured by each circuit is determined by the CPT1MODE and CPT2MODE bits whose functionality is listed in *Table 599*. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

38.3.3.4 Master/Slave Mode

Any timer channel can be assigned as a Master (MSTR = 1). A Master's compare signal can be broadcasted to the other channels within the module. The other counters can be

configured to reinitialize their counters (COINIT = 1) and/or force their OFLAG output signals (COFRC = 1) to predetermined values when a Master counter compare event occurs.

38.3.3.5 Watchdog Timer

Note: The watchdog timer may not be implemented on each eTimer module instance.

The watchdog timer is used to monitor for a stalled count when channel 0 is in quadrature count mode. When the watchdog is enabled, it loads the time-out value into a down counter. The down counter counts as long as channel 0 is in quadrature decode count mode. If this down counter reaches zero, an interrupt is asserted. The down counter is reloaded to the time-out value each time the counter value from channel 0 changes. If the channel 0 count value is toggling between two values (indicating a possibly stalled encoder), then the down counter is not reloaded.

The watchdog function of the eTimer counts using the peripheral bus clock which is the same clock as used by the eTimer counter channels. The watchdog function looks for counting activity in counter #0.

38.4 Memory Map and Registers

38.4.1 Overview

The base address of the eTimer module will differ from chip to chip. All memory mapped registers described below have their location described in relation to the BASE Address.

Note: The actual availability, configuration and number of registers are device-specific. For this information, see Chapter 7: Device configuration.

38.4.2 Module Memory Map

Table 585. eTimer Memory Map

Address offset	Reg Name	Description	Location

1. If applicable. Not all eTimer module instantiations implement a watchdog timer.

38.4.3 Register Descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. There are a set of registers for each timer channel, a set for the watchdog timer, and a set of configuration registers. Some registers are labelled as not byte accessible, however, no error will be generated if they are byte accessed.

38.4.4 Timer Channel Registers

These registers are repeated for each timer channel. The base address of channel 0 is the same as the base address of the eTimer module as a whole. The base address of channel 1 is 0x20. This is the base address of the eTimer module plus an offset based on the number of bytes of registers in a timer channel. The base address of each subsequent timer channel is equal to the base address of the previous channel plus this same offset of 0x20.

38.4.4.1 Compare Register 1n (COMP1n)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP1 can be found in *Section 38.3.2.13: Usage of Compare Registers*.

Offset: 0x0000 + n*0x20 (n=0 to 5) Access: R/W

Field	Description
0:15 COMP2	Compare Register2

38.4.4.3 Capture Register 1n (CAPT1n)

This read-only register stores the value captured from the counter. Exactly when a capture occurs is defined by the CPT1MODE bits. This is actually a 2-deep FIFO and not a single register. This register is not byte accessible.

Offset: 0x0004 + n*0x20 (n=0 to 5) Access: Read-only

Field	Description
0:15 LOAD	Load Register

38.4.4.6 Hold Register n (HOLDn)

This read-only register stores the counter's value whenever any of the other counters within a module are read. This is used to support coherent reading of cascaded counters.

Offset: 0x000A + n*0x20 (n=0 to 5) Access: Read-only

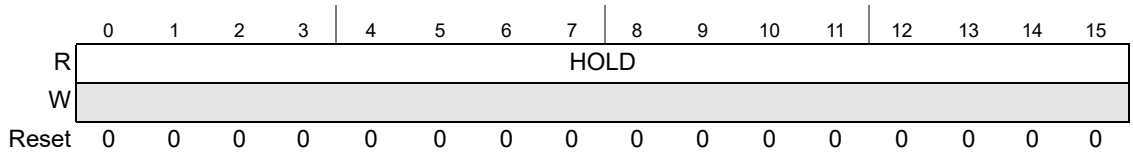

Figure 532. Hold Register n (HOLDn)

Field	Description
0:2 CNTMODE	Count Mode These bits control the basic counting and behavior of the counter. 000 No operation 001 Count rising edges of primary source(1) 010 Count rising and falling edges of primary source(2) 011 Count rising edges of primary source while secondary input high active 100 Quadrature count mode, uses primary and secondary sources 101 Count primary source rising edges, secondary source specifies direction (1 = minus)(3) 110 Edge of secondary source triggers primary count till compare 111 Cascaded counter mode, up/down(4)
3:7 PRISRC	Primary Count Source These bits select the primary count source. 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Reserved 00111 Reserved 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Reserved 01011 Reserved 01100 Reserved 01101 Reserved 01110 Reserved 01111 Reserved 10000 Counter #0 output 10001 Counter #1 output 10010 Counter #2 output 10011 Counter #3 output 10100 Counter #4 output 10101 Counter #5 output 10110 Reserved 10111 Reserved 11000 IP Bus clock divide by 1 prescaler 11001 IP Bus clock divide by 2 prescaler 11010 IP Bus clock divide by 4 prescaler 11011 IP Bus clock divide by 8 prescaler 11100 IP Bus clock divide by 16 prescaler 11101 IP Bus clock divide by 32 prescaler 11110 IP Bus clock divide by 64 prescaler 11111 IP Bus clock divide by 128 prescaler **Note:** A timer selecting its own output as its primary count source is not a legal choice. The result is no counting.
8 ONCE	Count Once This bit selects continuous or one shot counting mode 1 Count until compare and then stop. When output mode $4 is used, the counter re-initializes after reaching the COMP1 value and continues to count to the COMP2 value then stops. 0 Count repeatedly

Table 592. Control Register 1n (CTRL1n) field descriptions (continued)

Field	Description
9 LENGTH	Count Length This bit determines whether the counter counts to the compare value and then re-initializes itself to the value specified in the LOAD, CMPLD1, or CMPLD2 registers, or the counter continues counting past the compare value, to the binary roll over. 1 Count until compare, then reinitialize. The value that the counter is reinitialized with depends on the settings of CLC1 and CLC2. If neither of these indicates the counter is to be loaded from one of the CMPLD registers, then the LOAD register is used to reinitialize the counter upon matching either COMP register. If one of CLC1 or CLC2 indicates that the counter is to be loaded from one of the CMPLD registers, then the counter will reinitialize to the value in the appropriate CMPLD register upon a match with the appropriate COMP register. If both of the CLC1 and CLC2 fields indicate that the counter is to be loaded from the CMPLD registers, then CMPLD1 will have priority if both compares happen at the same value. When output mode $4 is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until COMP1 value is reached, re-initializes, then counts until COMP2 value is reached, re-initializes, then counts until COMP1 value is reached, etc. 0 Continue counting to roll over.
10 DIR	Count Direction This bit selects either the normal count direction up, or the reverse direction, down. 1 Count down 0 Count up
11:15 SECSRC	Secondary Count Source These bits identify the source to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of the CNTR. The selected input can also be used to specify the count direction. The polarity of the signal can be inverted by the bit CTRL2[SIPS]. 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Reserved 00111 Reserved 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Reserved 01011 Reserved 01100 Reserved 01101 Reserved 01110 Reserved 01111 Reserved 10000 Counter #0 output 10001 Counter #1 output 10010 Counter #2 output 10011 Counter #3 output 10100 Counter #4 output 10101 Counter #5 output 10110 Reserved 10111 Reserved 11000 - 11111 Reserved

1. Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1. If primary count source is IP bus clock, only rising edges are counted regardless of PIPS value.
2. IP Bus clock divide by 1 can not be used as a primary count source in edge count mode.
3. Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1.
4. Primary count source must be set to one of the counter outputs.

38.4.4.9 Control Register 2n (CTRL2n)

Offset: 0x0010 + n*0x20 (n=0 to 5) Access: R/W

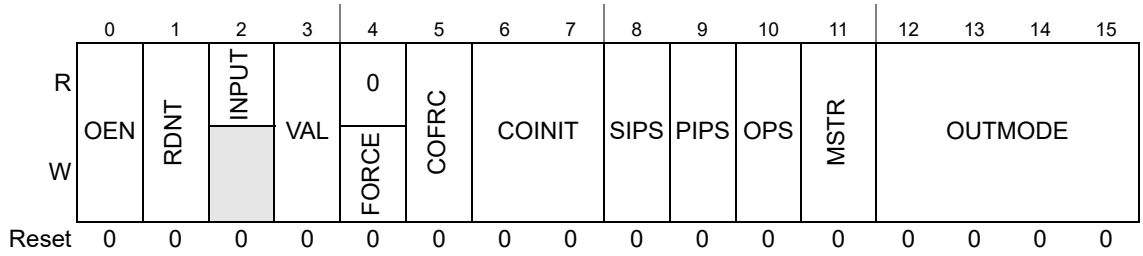

Figure 535. Control Register 2n (CTRL2n)

Table 593. Control Register 2n (CTRL2n) field descriptions

Field	Description
0 OEN	Output Enable This bit determines the direction of the external pin. 1 OFLAG output signal will be driven on the external pin. Other timer channels using this external pin as their input will see the driven value. The polarity of the signal will be determined by the OPS bit. 0 The external pin is configured as an input.
1 RDNT	Redundant Channel Enable This bit enables redundant channel checking between adjacent channels (0 and 1, 2 and 3, 4 and 5). When this bit is clear, the RCF bit in this channel cannot be set. When this bit is set, the RCF bit will be set by a miscompare between the OFLAG of this channel and the OFLAG of its redundant adjacent channel which will cause the output of this channel to go inactive (logic 0 prior to consideration of the OPS bit). 1 Enable redundant channel checking. 0 Disable redundant channel checking.
2 INPUT	External input signal This read only bit reflects the current state of the signal selected via SECSRC after application of the SIPS bit and filtering.
3 VAL	Forced OFLAG Value This bit determines the value of the OFLAG output signal when a software triggered FORCE command occurs.
4 FORCE	Force the OFLAG output This write only bit forces the current value of the VAL bit to be written to the OFLAG output. This bit always reads as a zero. The VAL and FORCE bits can be written simultaneously in a single write operation. Write to the FORCE bit only if OUTMODE is 0000 (software controlled). Setting this bit while the OUTMODE is a different value may yield unpredictable results

Table 593. Control Register 2n (CTRL2n) field descriptions (continued)

Field	Description
5 COFRC	Co-channel OFLAG Force This bit enables the compare from another channel within the module to force the state of this counter's OFLAG output signal. 1 Other channels may force the OFLAG of this channel. 0 Other channels cannot force the OFLAG of this channel.
6:7 COINIT	Co-channel Initialization These bits enable another channel within the module to force the re-initialization of this channel when the other channel has an active compare event 00 Other channels cannot force re-initialization of this channel. 01 Other channels may force a re-initialization of this channel's counter using the LOAD register. 10 Other channels may force a re-initialization of this channel's counter with the CMPLD2 register when this channel is counting down or the CMPLD1 register when this channel is counting up. 11 Reserved
8 SIPS	Secondary Source Input Polarity Select This bit inverts the polarity of the signal selected by the SECSRC bits. 1 Inverted polarity 0 True polarity
9 PIPS	Primary Source Input Polarity Select This bit inverts the polarity of the signal selected by the PRISRC bits. This only applies if the signal selected by PRISRC is not the prescaled IP Bus clock. 1 Inverted polarity 0 True polarity
10 OPS	Output Polarity Select This bit inverts the OFLAG output signal polarity. 1 Inverted polarity 0 True polarity
11 MSTR	Master Mode This bit enables the compare function's output to be broadcasted to the other channels in the module. The compare signal then can be used to reinitialize the other counters and/or force their OFLAG signal outputs. 1 Enable broadcast of compare events from this channel. 0 Disable broadcast of compare events from this channel.

Table 593. Control Register 2n (CTRL2n) field descriptions (continued)

Field	Description
12:15 OUTMODE	Output Mode These bits determine the mode of operation for the OFLAG output signal. 0000 Software controlled 0001 Clear OFLAG output on successful compare (COMP1 or COMP2) 0010 Set OFLAG output on successful compare (COMP1 or COMP2) 0011 Toggle OFLAG output on successful compare (COMP1 or COMP2) 0100 Toggle OFLAG output using alternating compare registers 0101 Set on compare with COMP1, cleared on secondary source input edge 0110 Set on compare with COMP2, cleared on secondary source input edge 0111 Set on compare, cleared on counter roll-over 1000 Set on successful compare on COMP1, clear on successful compare on COMP2 1001 Asserted while counter is active, cleared when counter is stopped. 1010 Asserted when counting up, cleared when counting down. 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Enable gated clock output while counter is active

Figure 537. Status Register n (STSn)

Table 595. Status Register n (STSn) field descriptions

Field	Description
6 WDF	Watchdog Time-out Flag This bit is set when the watchdog times out by counting down to zero. The watchdog must be enabled for time-out to occur and channel 0 must be in quadrature decode count mode (CNTMODE = 100). This bit is cleared by writing a 1 to this bit position after either writing a non-zero value to WDTOL and/or WDTOH or exiting quadrature decode counting mode. This bit is only in channel 0. If the watchdog timer is not implemented, then this bit is read-only zero.
7 RCF	Redundant Channel Flag This bit is set when there is a miscompare between this channel's OFLAG value and the OFLAG value of the corresponding redundant channel. Corresponding channels are grouped together in the following pairs: 0 and 1, 2 and 3, 4 and 5. This bit can only be set if the RDNT bit is set. This bit is cleared by writing a 1 to this bit position. This bit is only in even channels (0, 2, 4).
8 ICF2	Input Capture 2 Flag This bit is set when an input capture event (as defined by CPT2MODE) occurs and the word count of the CAPT2 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF2DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF2DE is set (DMA)
9 ICF1	Input Capture 1 Flag This bit is set when an input capture event (as defined by CPT1MODE) occurs and the word count of the CAPT1 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF1DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF1DE is set (DMA).

Table 595. Status Register n (STSn) field descriptions (continued)

Field	Description
10 IEHF	Input Edge High Flag This bit is set when a positive input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
11 IELF	Input Edge Low Flag This bit is set when a negative input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
12 TOF	Timer Overflow Flag This bit is set when the counter rolls over its maximum value 0xFFFF or 0x0000 (depending on count direction). This bit is cleared by writing a one to this bit location.
13 TCF2	Timer Compare 2 Flag This bit is set when a successful compare occurs with COMP2. This bit is cleared by writing a one to this bit location.
14 TCF1	Timer Compare 1 Flag This bit is set when a successful compare occurs with COMP1. This bit is cleared by writing a one to this bit location.
15 TCF	Timer Compare Flag This bit is set when a successful compare occurs. This bit is cleared by writing a one to this bit location.

38.4.4.12 Interrupt and DMA Enable Register n (INTDMAn)

Table 596. Interrupt and DMA Enable Register n (INTDMAn) field descriptions

Field	Description
0 ICF2DE	Input Capture 2 Flag DMA Enable Setting this bit enables DMA read requests for CAPT2 when the ICF2 bit is set. Do not set both this bit and the ICF2IE bit.
1 ICF1DE	Input Capture 1 Flag DMA Enable Setting this bit enables DMA read requests for CAPT1 when the ICF1 bit is set. Do not set both this bit and the ICF1IE bit.

Table 596. Interrupt and DMA Enable Register n (INTDMAn) field descriptions (continued)

Field	Description
2 CMPLD2DE	Comparator Load Register 2 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD2 register whenever data is transferred out of the CMPLD2 reg into either the CNTR, COMP1, or COMP2 registers.
3 CMPLD1DE	Comparator Load Register 1 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD1 register whenever data is transferred out of the CMPLD1 reg into either the CNTR, COMP1, or COMP2 registers.
6 WDFIE	Watchdog Flag Interrupt Enable Setting this bit enables interrupts when the WDF bit is set. This bit is only in channel 0. If the watchdog timer is not implemented, then this bit serves no purpose.
7 RCFIE	Redundant Channel Flag Interrupt Enable Setting this bit enables interrupts when the RCF bit is set. This bit is only in even channels (0, 2, and 4).
8 ICF2IE	Input Capture 2 Flag Interrupt Enable Setting this bit enables interrupts when the ICF2 bit is set. Do not set both this bit and the ICF2DE bit.
9 ICF1IE	Input Capture 1 Flag Interrupt Enable Setting this bit enables interrupts when the ICF1 bit is set. Do not set both this bit and the ICF1DE bit.
10 IEHFIE	Input Edge High Flag Interrupt Enable Setting this bit enables interrupts when the IEHF bit is set.
11 IELFIE	Input Edge Low Flag Interrupt Enable Setting this bit enables interrupts when the IELF bit is set.
12 TOFIE	Timer Overflow Flag Interrupt Enable Setting this bit enables interrupts when the TOF bit is set.
13 TCF2IE	Timer Compare 2 Flag Interrupt Enable Setting this bit enables interrupts when the TCF2 bit is set.
14 TCF1IE	Timer Compare 1 Flag Interrupt Enable Setting this bit enables interrupts when the TCF1 bit is set.
15 TCFIE	Timer Compare Flag Interrupt Enable Setting this bit enables interrupts when the TCF bit is set.

38.4.4.13 Comparator Load Register 1n (CMPLD1n)

This read/write register is the preload value for the COMP1 register. This register can also be used to load into the CNTR register. This register is not byte accessible. More information on the use of this register can be found in *Section 38.3.2.14: Usage of Compare Load Registers*.

Offset: 0x0018 + n*0x20 (n=0 to 5) Access: R/W

Field	Description
0:2 CLC2	Compare Load Control 2 These bits control when COMP2 is preloaded. It also controls the loading of CNTR. 000 Never preload 001 Reserved 010 Load COMP2 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP2 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP2 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP2 with CMPLD2 upon successful compare with the value in COMP2. 110 Load CNTR with CMPLD2 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD2 upon successful compare with the value in COMP2.
3:5 CLC1	Compare Load Control 1 These bits control when COMP1 is preloaded. It also controls the loading of CNTR 000 Never preload 001 Reserved 010 Load COMP1 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP1 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP1 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP1 with CMPLD2 upon successful compare with the value in COMP2. 110 Load CNTR with CMPLD1 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD1 upon successful compare with the value in COMP2.
6:7 CMPMODE	Compare Mode These bits control when the COMP1 and COMP2 registers are used in regards to the counting direction. 00 COMP1 register is used when the counter is counting up. COMP2 register is used when the counter is counting up. 01 COMP1 register is used when the counter is counting down. COMP2 register is used when the counter is counting up. 10 COMP1 register is used when the counter is counting up. COMP2 register is used when the counter is counting down. 11 COMP1 register is used when the counter is counting down. COMP2 register is used when the counter is counting down.
8:9 CPT2MODE	Capture 2 Mode Control These bits control the operation of the CAPT2 register as well as the operation of the ICF2 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges 11 Capture any edge
10:11 CPT1MODE	Capture 1 Mode Control These bits control the operation of the CAPT1 register as well as the operation of the ICF1 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges 11 Capture any edge

Table 599. Compare and Capture Control Register n (CCCTRLn) field descriptions (continued)

Field	Description
12:13 CFWM	Capture FIFO Watermark This field represents the Watermark level for the CAPT1 and CAPT2 FIFOs. The capture flags, ICF1 and ICF2, will not be set until the word count of the corresponding FIFO is greater than this Watermark level
14 ONESHOT	One Shot Capture Mode This bit selects between free running and one shot mode for the input capture circuitry. 1 One shot mode is selected - If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and the ARM bit is cleared. No further captures will be performed until the ARM bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARM bit is then cleared. 0 Free running mode is selected - If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and capture circuit 1 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.
15 ARM	Arm Capture Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). 1 Input capture operation as specified by the CPT1MODE and CPT2MODE bits is enabled. 0 Input capture operation is disabled.

38.4.4.16 Input Filter Register n (FILTn)

The FILT register Programs the values for the filtering of the corresponding input without regard for the fact that any eTimer channel can use the input as a count source. The FILT register is also used to control the filtering of the corresponding auxilliary input.

Offset: 0x001E + n*0x20 (n=0 to 5) Access: R/W

Figure 542. Input Filter Register n (FILTn)

Table 600. Input Filter Register n (FILTn) field descriptions

Field	Description
5:7 FILT_CNT	Input Filter Sample Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in *Section 38.4.4.16.1: Input Filter Considerations*.
8:15 FILT_PER	Input Filter Sample Period These bits represent the sampling period (in IPBus clock cycles) of the eTimer input signal. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in *Section 38.4.4.16.1: Input Filter Considerations*.

38.4.4.16.1 Input Filter Considerations

The FILT_PER value should be set such that the sampling period is larger the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT + 3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of: (((FILT_CNT + 3) x FILT_PER) + 2) IPBus clock periods.

38.4.5 Watchdog Timer Registers

Note: A watchdog timer may or may not be implemented on each eTimer module instance.

The base address of the Watchdog Timer registers is equal to the base address of the eTimer plus an offset of 0x0100.

38.4.5.1 Watchdog Time-out Low Word Register (WDTOL)

38.5 Resets

The eTimer module can only be reset by a full system reset. This forces all registers to their reset state and clears the OFLAG signals if they are asserted. The counters will be turned off until the settings in the CTRL registers are changed.

38.6 Clocks

Each timer channel receives its own copy of the peripheral bus clock. This allows for better power management by turning off the clock to unused channels. The watchdog timer (if implemented) has its own version of this clock. Each bit of the ENBL register uses the clock for that corresponding channel. The DREQn registers use the clock for channel, 0 but this clock can be turned off after these registers have been programmed.

38.7 Interrupts

The following can generate interrupts within the eTimer.

- Watchdog timer (if implemented)
- Each channel can generate an interrupt from several sources

The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 608. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
Channels 0-*n*	TCF	TCFIE	Compare interrupt	Compare of counter and related compare register
	TCF1	TCF1IE	Compare 1 interrupt	Compare of the counter and COMP1 register
	TCF2	TCF2IE	Compare 2 interrupt	Compare of the counter and COMP2 register
	TOF	TOFIE	Overflow interrupt	Generated on counter roll-over or roll-under
	IELF	IELFIE	Input Low Edge interrupt	Falling edge of the secondary input signal
	IEHF	IEHFIE	Input High Edge interrupt	Rising edge of the secondary input signal
	ICF1	ICF1IE	Input Capture 1 interrupt	Input capture event for CAPT1
	ICF2	ICF2IE	Input Capture 2 interrupt	Input capture event for CAPT2
Watchdog (1)	WDF	WDFIE	Watchdog time-out interrupt	Watchdog has timed out
Redundant Channel Checking	RCF	RCFIE	Redundant Channel Fault interrupt	Miscompare with redundant channel

1. If applicable. Not all instantiations of eTimer implement a watchdog timer.

38.8 DMA

Each channel can request a DMA read access for each of the capture registers and a DMA write request for each of the compare preload registers. The DREQ registers select amongst these 32 DMA request sources to generate the 4 top level DMA request outputs.

Table 609. DMA Summary

DMA Request	DMA Enable	Name	Description
Channels 0-*n*	ICF1DE	CAPT1 read request	CAPT1 contains a value
	ICF2DE	CAPT2 read request	CAPT2 contains a value
	CMPLD1DE	CMPLD1 write request	CMPLD1 needs an update
	CMPLD2DE	CMPLD2 write request	CMPLD2 needs an update

39 System Timer Module (STM)

39.1 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

Note: For chip-specific implementation details of this module's instances, see the chip configuration information.

39.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the PBRIDGE clock divided by an 8-bit prescale value (1 to 256).

39.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

39.1.3 Modes of operation

The STM supports two device modes of operation: Normal and Debug. When the STM is enabled in Normal mode, its counter runs continuously. In Debug mode, operation of the counter is controlled by the FRZ bit in the STM Control Register (STM_CR). If STM_CR[FRZ] is set, the counter is stopped in Debug mode, otherwise it continues to run.

39.2 External signal description

The STM does not have any external interface signals.

39.3 Memory map and register definition

The STM programming model includes a group of 32-bit registers: a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

39.3.1 Memory map

The STM memory map is shown in *Table 610*.

Table 610. STM memory map

Address offset	Register	Location
0x0000	STM Control Register (STM_CR)	*Section 39.3.2.1*

Field	Description
0:31 CMP	Compare value for channel n. If the STM_CCR*n*[CEN] bit is set and the STM_CMP*n* register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIR*n*[CIF] bit is set.

39.4 Functional description

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the PBRIDGE clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode the counter operation is controlled by the STM_CR[FRZ] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode, otherwise it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*) and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing a 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

Note: The STM counter does not advance when the PBRIDGE clock is stopped.

40 Software Watchdog Timer (SWT)

40.1 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

Note: For chip-specific implementation details of this module's instances, see the chip configuration information.

40.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

40.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

40.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR *Section 40.3.1.1: SWT Control Register (SWT_CR)*. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit of the SWT_CR register. See *Section 40.3.1.1: SWT Control Register (SWT_CR)*. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

40.2 External signal description

The SWT module does not have any external interface signals.

40.3 Memory map and register definition

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid.

Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access, otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in *Table 616*.

Table 616. SWT memory map

Table 621. SWT_SR field descriptions

Field	Description
16:31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the soft lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] = 01, two pseudorandom key values are written to service the watchdog, see *Section 40.3.1.1: SWT Control Register (SWT_CR)* for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the soft lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

40.3.1.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Offset: 0x0014 Access: Read-Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CNT																															
W																																
Reset(1)	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

1. SWT_CO will reflect the internal value of the counter when WEN=0, and will be read as 0x0000_0000 when WEN=1

Figure 558. SWT Counter Output Register (SWT_CO)

Table 622. SWT_CO field descriptions

Field	Description
0:31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

40.3.1.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Offset: 0x0018 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 559. SWT Service Key Register (SWT_SK)

Table 623. SWT_SK field descriptions

Field	Description
16:31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] = 01, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^16.

40.4 Functional description

40.4.1 Introduction

The SWT is a 32-bit timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- A control register (SWT_CR),
- An interrupt register (SWT_IR),
- A time-out register (SWT_TO),
- A window register (SWT_WN),
- A service register (SWT_SR),
- A counter output register (SWT_CO), and
- A service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

40.4.1.1 SWR_CR register

The SWT_CR register includes bits to enable the timer, set configuration options and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific[(m)]. If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

40.4.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100 in which case the time-out period is set to 0x100.When the SWT is enabled, this time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed.The source used to drive the down counter and the reset value of the SWT_TO register is device specific, see the device configuration chapter.

40.4.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

m. See SWT section in device configuration chapter.

40.4.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

40.4.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

40.4.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

40.4.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

40.4.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation which is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

40.4.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected which requires writing 0xA602, 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

40.4.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined in *Equation 24*. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

Equation 24

$$SK_{n+1} = (17*SK_n+3) \bmod 2^{16}$$

40.4.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can not be updated while the watchdog is enabled.

40.4.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected in which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

40.4.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to ‘1000’ then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

40.4.5 Time-out

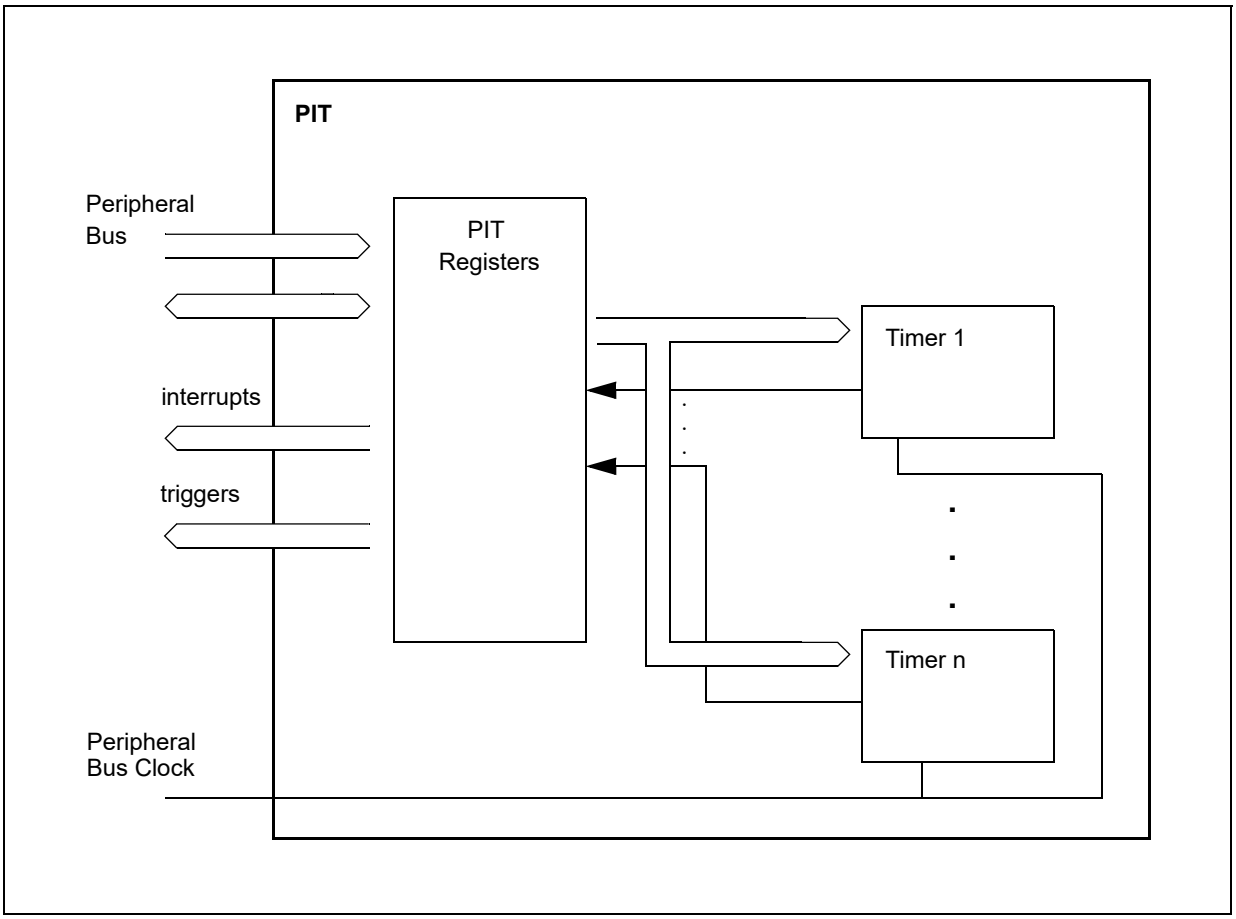
The SWT_CR[ITR] (“Interrupt Then Reset” bit) controls the action taken when a time-out occurs. If the SWT_CR[ITR] bit is not set, a reset is generated immediately on a time-out. If the SWT_CR[ITR] bit is set, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period. If the service sequence is not written before the second consecutive time-out, the SWT generates a system reset. The interrupt is indicated by the time-out interrupt flag (SWT_IR[TIF]). The interrupt request is cleared by writing a one to the SWT_IR[TIF] bit.

40.4.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

41 Periodic Interrupt Timer (PIT)

41.1 Introduction



The PIT timer module is an array of timers that can be used to raise interrupts and trigger DMA channels.

Note: For the chip-specific implementation details of this module's instances see the Device Configuration chapter.

41.1.1 Block diagram

Figure 560 shows the PIT block diagram.

Figure 560. Block diagram of the PIT

Note: Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

41.1.2 Features

The main features of this block are:

- Timers can generate DMA trigger pulses
- Timers can generate interrupts
- All interrupts are maskable
- Independent timeout periods for each timer

41.2 Signal description

This module has no external pins.

41.2.1 Memory map/register description

This section provides a detailed description of all registers accessible in this module.

Note: Reserved registers will read as 0, writes will have no effect.

Table 624. PIT memory map

Figure 562. PIT Timer Load Value Register *n* (LDVAL*n*)

Table 626. LDVAL*n* field descriptions

Field	Description
16:31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

Figure 564. Timer Control Register (TCTRL*n*)

Table 628. TCTRL*n* field descriptions

Field	Description
29 CHN	Chain Mode Bit When activated, timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be chained. 0 Timer is not chained. 1 Timer is chained to previous timer (example, for channel 2 if this bit is set timer2 is chained 1).
30 TIE	Timer Interrupt Enable Bit 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set. When an interrupt is pending (TIF set), enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TIF flag must be cleared first.
31 TEN	Timer Enable Bit This bit enables or disables the timer. 0 Timer n is disabled. 1 Timer n is active.

41.2.1.5 PIT Timer Flag Register *n* (TFLG*n*)

Offset: 0x010C + *n**0x10 (*n* = 0 to 7) Access: User read/write

Figure 565. Timer Flag Register *n* (TFLG*n*)

Table 629. TFLG*n* field descriptions

Field	Description
31 TIF	Timer Interrupt Flag TIF is set to ‘1’ at the end of the timer period. This flag can be cleared only by writing it with 1. Writing 0 has no effect. If enabled (TIE = 1), TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

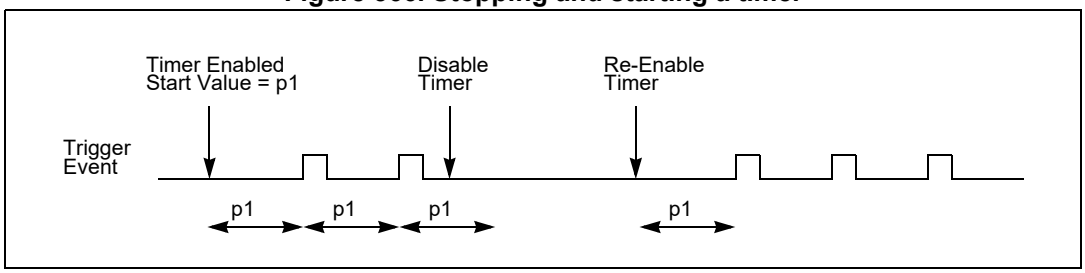
41.3 Functional description

This section provides the functional description of the module.

41.3.1 General

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses as well as to generate interrupts. Each interrupt is available on a separate interrupt line.

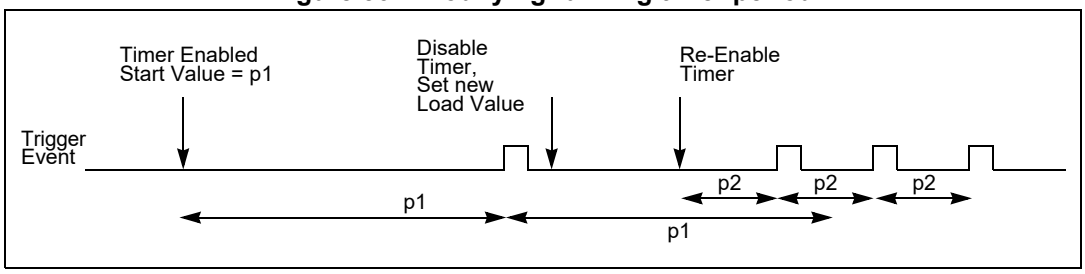
41.3.1.1 Timers



The timers generate triggers at periodic intervals, when enabled. They load their start values, as specified in their LDVAL registers, then count down until they reach 0. Then they load their respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

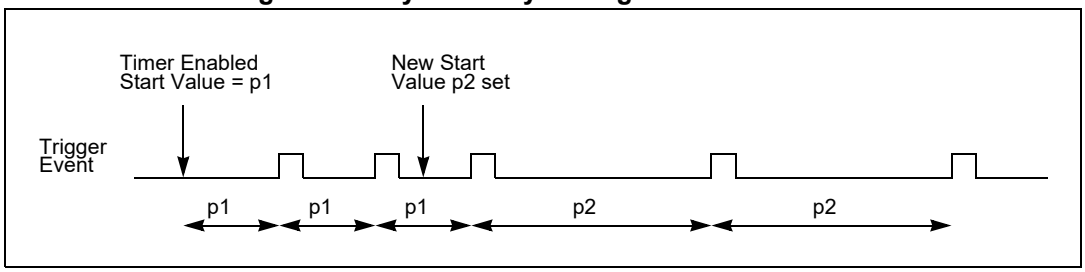
All interrupts can be enabled or masked (by setting the TIE bits in the TCTRL registers). A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.



The counter period can be restarted, by first disabling, then enabling the timer with the TEN bit (see the following figure).

Figure 566. Stopping and starting a timer



The counter period of a running timer can be modified, by first disabling the timer, setting a new load value and then enabling the timer again (see the following figure).

Figure 567. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing the LDVAL register with the new load value. This value will then be loaded after the next trigger event (see the following figure).

Figure 568. Dynamically setting a new load value

41.3.1.2 Debug mode

In debug mode, the timers will be frozen based on field MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system (for example, the timer values) and then continue the operation.

41.3.2 Interrupts

All of the timers support interrupt generation. Refer to the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting the TIE bits. The timer interrupt flags (TIF) are set to '1' when a timeout occurs on the associated timer, and are cleared to '0' by writing a '1' to that TIF bit.

41.3.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer *n*-1 has counted down to 0, counter *n* will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

41.4 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 50 µs.
- Timer 3 creates a trigger event every 1 ms.

First the PIT module must be activated by writing a 0 to field MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns.

Timer 1 needs to trigger every 50 µs/20 ns = 2500 cycles and timer 3 every 1 ms/20 ns = 50000 cycles.

The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) - 1

This means LDVAL1 should be written with 0x000009C4, and LDVAL3 should be written with 0x0000C350.

The interrupt for Timer 1 is enabled by setting bit TCTRL1[TIE]. The timer is started by writing '1' to bit TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore Timer 3 is started by writing a ‘1’ to bit TCTRL3[TEN]; bit TIE stays at 0.

The following example code matches the described setup:

Example 3

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x000009C4; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;        // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;         // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0000C350; // setup timer 3for 1500000 cycles
PIT_TCTRL3 |= TEN;         // start Timer 3
```

42 CAN Subsystem

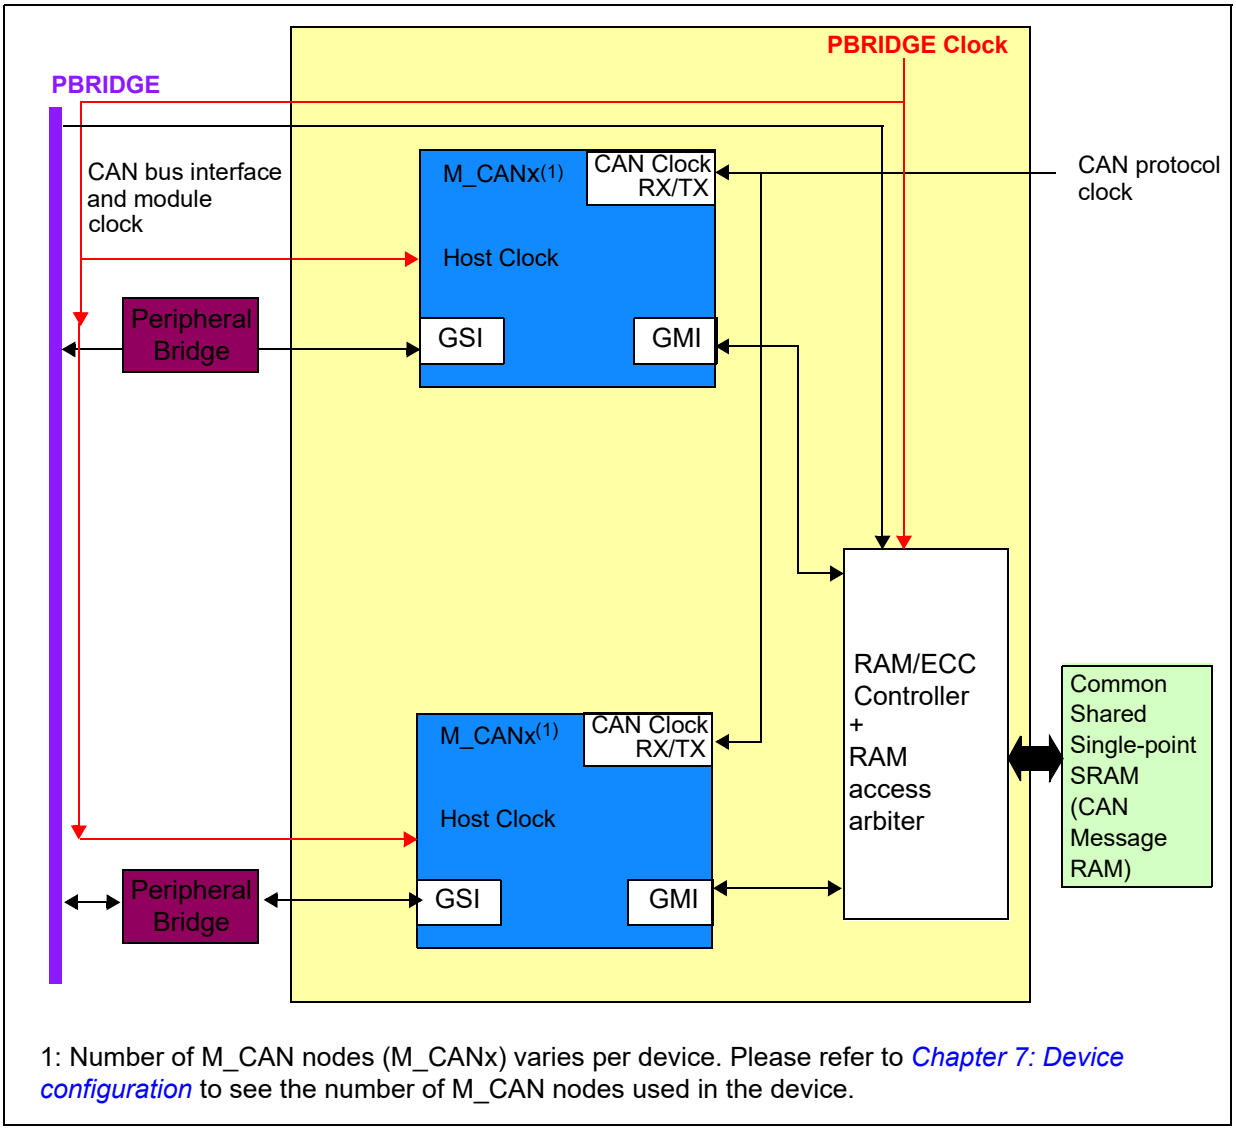
42.1 Introduction

SPC574Sx has two CAN subsystems implemented:

- CAN Subsystem 0
- CAN Subsystem 1

Note: Refer to Section 7.9.1: CAN subsystem configuration in Chapter 7: Device configuration to see the subsystems implementation.

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection from CPU write access. The subsystem follows the little endian format.



Note: Refer to Section 7.9.1: CAN subsystem configuration in Chapter 7: Device configuration to see the number of CAN nodes used in the device.

Table 630. IP user manual versions

IP Name	Version
M_CAN IP	Revision 3.2.1

The general CAN subsystem implementation is shown in *Section 42.2*. It interfaces with the Host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.

Figure 569. CAN subsystem generic block diagram

1: Number of M_CAN nodes (M_CANx) varies per device. Please refer to *Chapter 7: Device configuration* to see the number of M_CAN nodes used in the device.

42.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller

42.3 Modular CAN (M_CAN) cores

M_CAN functionality conforms to CAN specification V2.0B active for each M_CAN node.The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0.Flexible assignment of Message Objects to nodes.
The bit rate can be programmed to values up to 1 Mbit/s for standard CAN frames. High bit rates are possible in CAN FD mode. Additional transceiver hardware is required for connection to the physical layer.

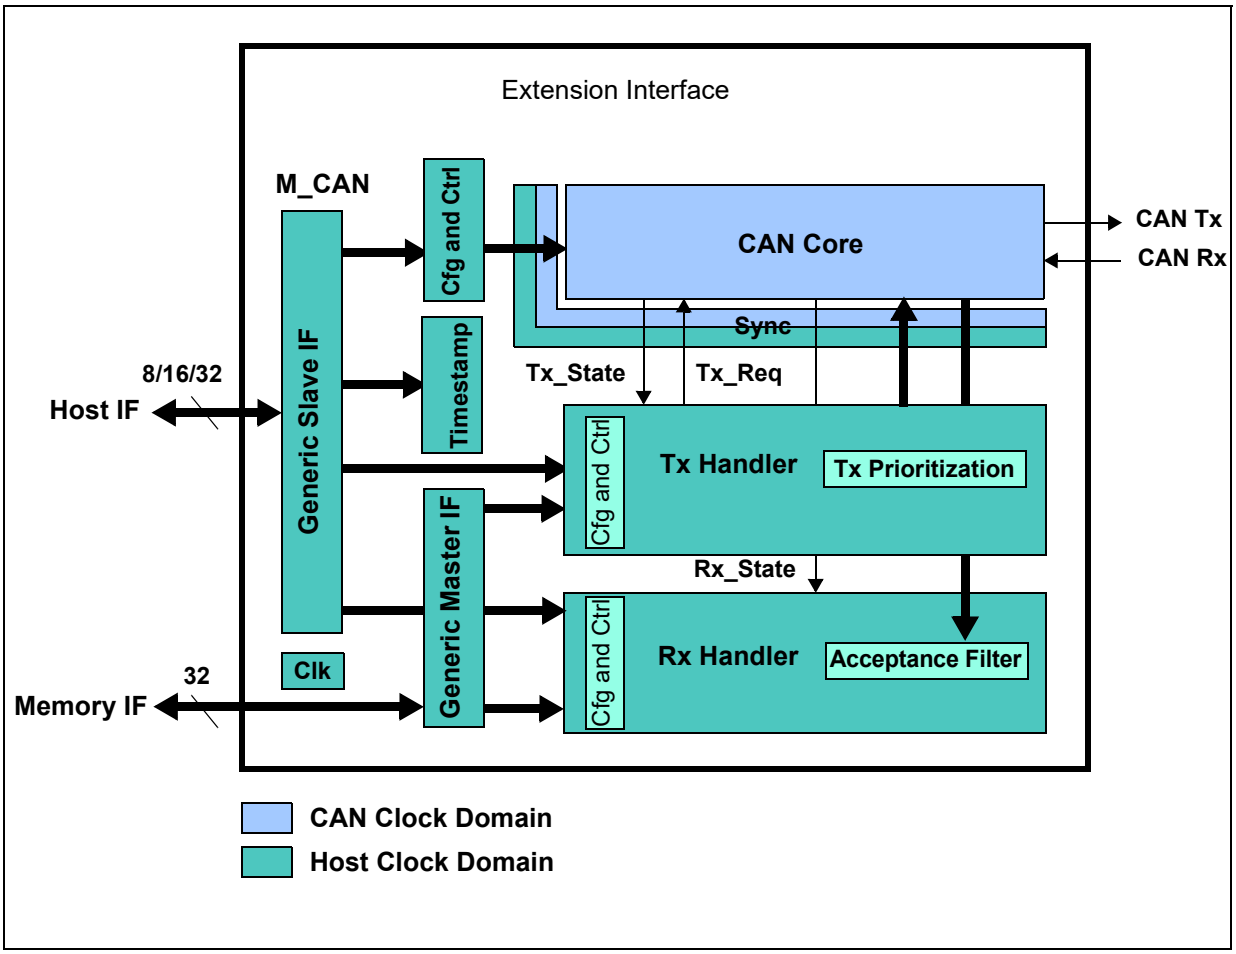
Note: Implemented CAN nodes are fully compliant to ISO CAN FD specification ISO 11898-1: 2015.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.



42.3.1 Features

The following are the features of Modular CAN cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015
- CAN Flexible data-rate (ISO CAN FD) protocol with 64 data bytes on M_CAN is supported
- Bit rates up to 1 Mbit/s in standard CAN mode
- Bit rates up to 8 Mbit/s in ISO CAN FD mode
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bits Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN
- Clock calibration over M_CAN is supported

42.3.2 Block diagram

Figure 570. M_CAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.
- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored

together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bits.
- Extension Interface: All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

42.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

42.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to EINT0 or to EINT1. By default all interrupts are routed to interrupt line EINT0. By programming EINT0 and EINT1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

42.3.5 Memory map and register descriptions

42.3.5.1 Hardware reset description

After hardware reset, the registers of the M_CAN hold the reset values listed in *Table 631*. Additionally the *Bus_Off* state is reset and the M_CAN Tx output is set to *recessive* (HIGH). The value 0x0001 (bit 0 [INIT] of the CCCR register = ‘1’) in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets bit 0 [INIT] of the CCCR register = ‘0’.

42.3.5.2 Register map

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR register is set to '1'.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

Caution: Any write access to reserved or not implemented registers in the 16 KB slot assigned by the peripherals bridge to the M_CAN IP will not generate any bus access error.

Field	Description
0:31 ETV	Endianness Test Value The endianness test value is 0x87654321.

42.3.5.2.3 Data Bit Timing and Prescaler Register (DBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_CAN clock periods. tq = (FBRP + 1) M_CAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (programmed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning that the data for the next bit is available at the first clock edge after the sample point.

Address: 0x000C Access: Read Protected

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 573. Data Bit Timing and Prescaler Register (DBTP)

Table 634. DBTP field descriptions

Field	Description
8 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
11:15 DBRP	Data Baud Rate Prescaler (0x00–0x1F) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
19:23 DTSEG1	Data time segment before sample point (0x0–0x1F) Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 DTSEG2	Data time segment after sample point (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 DSJW	Data (Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.

To achive high bit rates in CAN FD mode for the data phase up to 8 Mbit/s the number of time quanta bits per CAN bit can be chosen down to 4 time quanta per bit time.

42.3.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting CCCR[TEST] to ‘1’. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back mode and software control of M_CAN Tx pin are hardware test modes. Programming of **TX** ≠ ‘00’ may disturb the message transfer on the CAN bus.

25:26 TX	Control of Transmit Pin 00 Reset value, CAN Tx output is controlled by the CAN core, updated at the end of the CAN bit time. 01 Sample Point can be monitored at pin CAN Tx output 10 Dominant (‘0’) level at pin CAN Tx output 11 Recessive (‘1’) at pin CAN Tx output
27 LBCK	Loop Back mode 0 Reset value, Loop Back mode is disabled 1 Loop Back mode is enabled (see *Section 42.3.7.9: Test modes*)

42.3.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR is set. The RAM Watchdog Counter is clocked by the Host clock .

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.
2. These are protected set (p) bits.

Figure 576. CC Control register (CCCR)

Table 637. CCCR field descriptions

Field	Description
16 NISO	Non ISO Operation If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame. 0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	Edge Filtering during Bus Integration 0 Edge filtering disabled 1 Two consecutive dominant tq required to detect an edge for hard synchronization
19 PXHD	Protocol Exception Handling Disable 0 Protocol exception handling enabled 1 Protocol exception handling disabled **Note:** When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
22 BRSE	Bit Rate Switch Enable 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled **Note:** When CAN FD operation is disabled FDOE = ‘0’, BRSE is not evaluated.
23 FDOE	FD Operation Enable 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN b us reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping Host clock and core clock

Table 637. CCCR field descriptions (continued)

Field	Description
29 ASM	Restricted Operation Mode Bit ASM is only set by the Host when both CCE and INIT are set to '1'. The bit is reset by the Host at any time. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started **Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

42.3.5.2.7 Nominal Bit Timing and Prescaler Register (NBTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programed in the range of [4…385] time quanta. The CAN time quantum may be programmed in the range of [1…512] M_CAN clock periods.

Equation 25 tq = (NBRP + 1) M_CAN clock period

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (prog rammed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Address: 0x001C Access: Read Protected

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 579. Timestamp Counter Value Register (TSCV)

Table 640. TSCV field descriptions

Field	Description
16:31 TSC	Timestamp Counter The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = '01', the Timestamp Counter is incremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero. When TSCC.TSS = '10', TSC reflects the external Timestamp Counter value. A write access has no impact.

Note: A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

42.3.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter see *Section 42.3.9*.

Address: 0x0028 Access: RP

R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Figure 582. Error Counter Register (ECR)

Table 643. ECR field descriptions

Field	Description
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR register.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

42.3.5.2.13 Protocol Status Register (PSR)

Reset	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

1. Access type is RX: reset on read.
2. Access type is RS: set on read.

Figure 583. Protocol Status Register (PSR)

Table 644. PSR field descriptions

Field	Description
9:15 TDCV	Transmitter Delay Compensation Value (0x00-0x7F) Position of the secondary sample point, defined by the sum of the measured delay from CAN Tx to CAN Rx and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
17 PXE	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not ha ve its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state

Table 644. PSR field descriptions (continued)

Field	Description
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing – node is synchronizing on CAN communication 01 Idle-node is neither receiver nor transmitter 10 Receiver-node is operating as receiver 11 Transmitter-node is operating as transmitter
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error

The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT.] If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

42.3.5.2.14 Transmitter Delay compensation Register (TDCR)

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 584. Transmitter Delay compensation Register (TDCR)

Table 645. TDCR field descriptions

Field	Description
17:23 TDCO	Transmitter Delay Compensation Offset (0x00-0x7F) Offset value defining the distance between the measured delay from CAN Tx to CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.
25:31 TDCF	Transmitter Delay Compensation Filter Window Length (0x00-0x7F) Defines the minimum value for the SSP position, dominant edges on CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

42.3.5.2.15 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Figure 585. Interrupt Register (IR)

Table 646. IR field descriptions

Field	Description
2 ARA	Access to Reserved Address 0 No access to reserved address occurred 1 Access to reserved address occurred
3 PED	Protocol Error in Data Phase (Data Bit Time is used) 0 No protocol error in data phase 1 Protocol error in data phase detected (PSR.DLEC ≠ 0,7)
4 PEA	Protocol Error in Arbitration Phase (Nominal Bit Time is used) 0= No protocol error in arbitration phase 1= Protocol error in arbitration phase detected (PSR.LEC ≠ 0,7)
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status 0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred

Table 646. IR field descriptions (continued)

Field	Description
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (for example parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (for example ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler – Has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. – Was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler is not able to read a message from the Message RAM in time. In this case message transmission is aborted. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero

Table 646. IR field descriptions (continued)

Field	Description
17 TEFF	Tx Event FIFO Full
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark
19 TEFN	Tx Event FIDO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element
20 TFE	Tx FIFO Empty 0 Tx FIFO non-empty 1 Tx FIFO empty
21 TCF	Transmission Cancellation Finished 0 No transmission cancellation finished 1 Transmission cancellation finished
22 TC	Transmission Completed 0 No transmission completed 1 Transmission completed
23 HPM	High Priority Message 0 No high priority message received 1 High priority message received
24 RF1L	Rx FIFO 1 Message Lost 0 No Rx FIFO 1 message lost 1 Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
25 RF1F	Rx FIFO 1 Full 0 Rx FIFO 1 not full 1 Rx FIFO 1 full
26 RF1W	Rx FIFO 1 Watermark Reached 0 Rx FIFO 1 fill level below watermark 1 Rx FIFO 1 fill level reached watermark
27 RF1N	Rx FIFO 1 New Message 0 No new message written to Rx FIFO 1 1 New message written to Rx FIFO 1
28 RF0L	Rx FIFO 0 Message Lost 0 No Rx FIFO 0 message lost 1 Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
29 RF0F	Rx FIFO 0 Full 0 Rx FIFO 0 not full 1 Rx FIFO 0 full

Table 646. IR field descriptions (continued)

Field	Description
30 RF0W	Rx FIFO 0 Watermark Reached 0 Rx FIFO 0 fill level below watermark 1 Rx FIFO 0 fill level reached watermark
31 RF0N	Rx FIFO 0 New Message 0 No new message written to Rx FIFO 0 1 New message written to Rx FIFO 0

42.3.5.2.16 Interrupt Enable Register (IE)

The settings in the Interrupt Enable register determine which status changes in the Interrupt register will be signaled on an interrupt line.

Figure 594. New Data 1 Register (NDAT1)

Table 655. NDAT1 field descriptions

Field	Description
0:31 ND[31:0]	New Data[31:0] The register holds the New Data flags of Rx Buffers 0 to 31. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ’0’ has no effect. A hard reset will clear the register. 0 Rx Buffer not updated 1 Rx Buffer updated from new message

Figure 607. Tx Buffer Request Pending Register (TXBRP)

Table 668. TXBRP field descriptions

Field	Description
0:31 TRP[31:0]	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – After successful transmission together with the corresponding TXBTO bit – When the transmission has not yet been started at the point of cancellation – When the transmission has been aborted due to lost arbitration – When an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

Figure 608. Tx Buffer Add Request Register (TXBAR)

Table 669. TXBAR field descriptions

Field	Description
0:31 AR[31:0]	Add Request Each Tx Buffer has its own Add Request bit. Writing a '1' will set the corresponding Add Request bit; writing a '0' has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to TXBAR. TXBAR bits are set only for those Tx Buffers configured via TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed. 0 No transmission request added 1 Transmission requested added

Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

42.3.5.2.39 Tx Buffer Cancellation Request Register (TXBCR)

Address: 0x00D4 Access: R/W

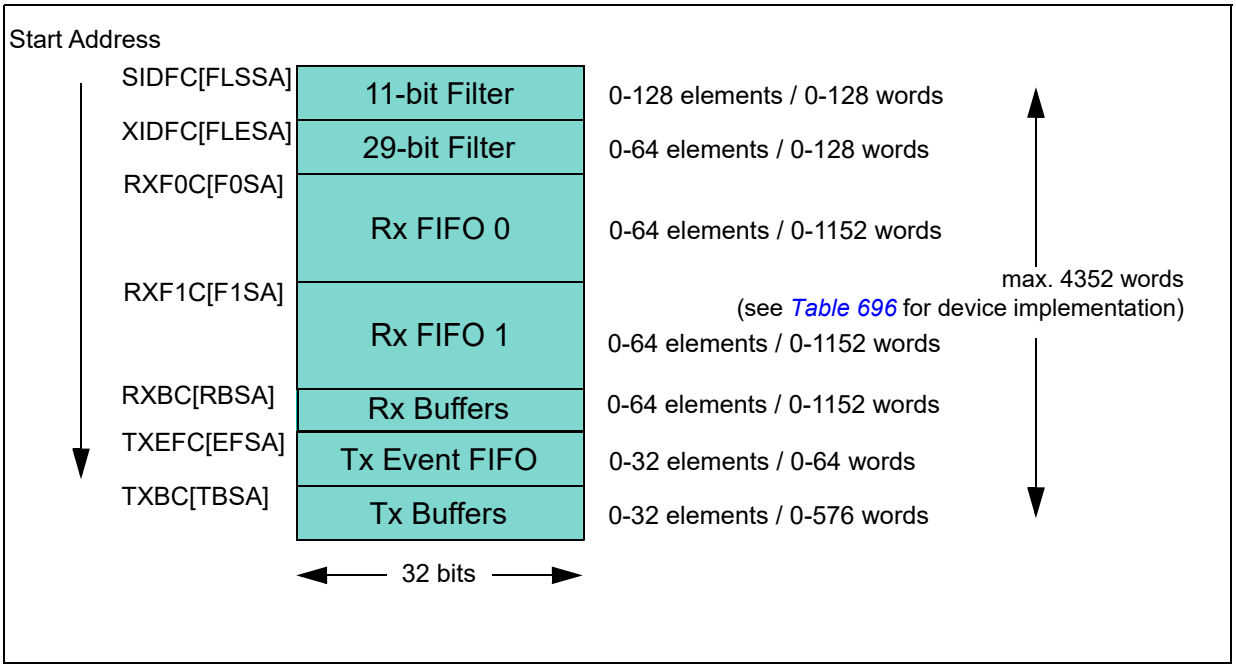
Figure 616. Tx Event FIFO Acknowledge Register (TXEFA)

Table 677. TXEFA field descriptions

Field	Description
27:31 EFAI	Event FIFO Acknowledge Index After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

42.3.6 Message RAM



For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_CAN module.

Note: Because the Message RAM is equipped with ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing, for example, 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 4352 words in the Message RAM (for the chip-specific implementation details of each module's instance, see device configuration chapter). It is not necessary to configure each of the sections listed in *Figure 617*, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC.F0DS, RXESC.F1DS, RXESC.RBDS, and TXESC.TBDS.

Figure 617. Message RAM Configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses such as only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Note: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

42.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

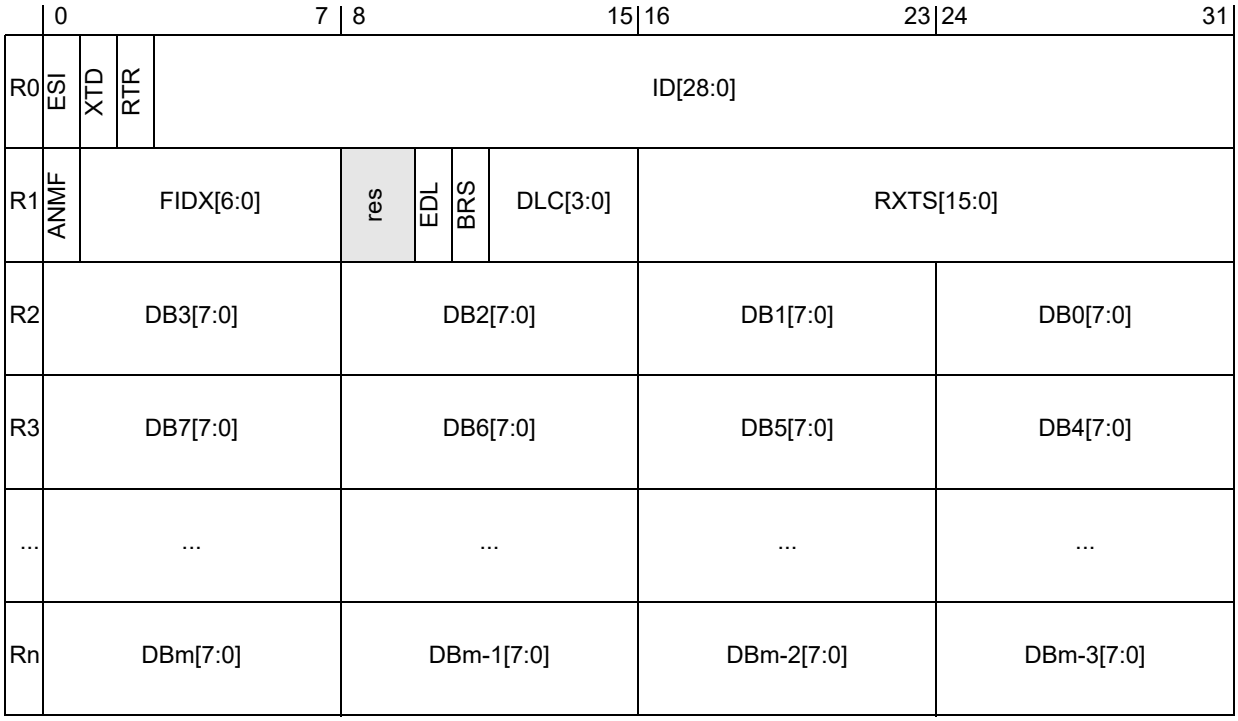


Figure 618. Rx Buffer and FIFO element

Table 678. Rx Buffer and FIFO element descriptions

Field	Description
R0 bit 0 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 bit 1 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 bit 2 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (EDL = '1'), bit RTR reflects the state of the reserved bit r1.
R0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 bit 0 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element

Table 678. Rx Buffer and FIFO element descriptions (continued)

Field	Description
R1 bits 1:7 FIDX[6:0]: Filter Index	0-127=Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 bit 10 EDL: Extended Data Length	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
R1 bit 11 BRS: Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 bits 12:15 DLC[3:0]: Data Length Code	0-8 CAN + CAN FD: Received frame has 0-8 data bytes 9-15 CAN: Received frame has 8 data bytes 9-15 CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
R1 bits 16:31 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 bits 0:7	DB3[7:0]: Data Byte 3
R2 bits 8:15	DB2[7:0]: Data Byte 2
R2 bits 16:23	DB1[7:0]: Data Byte 1
R2 bits 24:31	DB0[7:0]: Data Byte 0
R3 bits 0:7	DB7[7:0]: Data Byte 7
R3 bits 8:15	DB6[7:0]: Data Byte 6
R3 bits 16:23	DB5[7:0]: Data Byte 5
R3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Rn bits 0:7	DBm[7:0]: Data Byte m
Rn bits 8:15	DBm-1[7:0]: Data Byte m-1
Rn bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 to 17) are used for storage of a CAN message's data field.

42.3.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer

configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

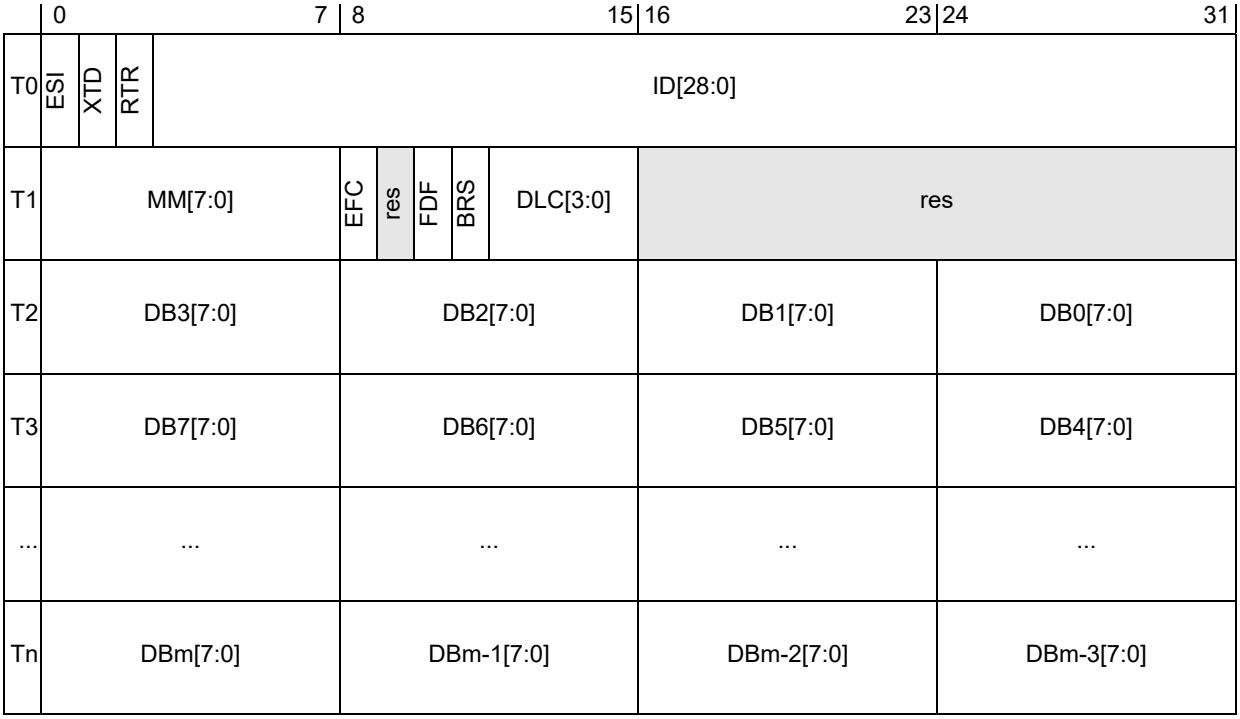

Figure 619. Tx Buffer element

Table 679. Tx Buffer element descriptions

Field	Description
T0 bit 0 ESI: Error State Indicator	0 ESI bit in CAN FD format depends only on error passive flag 1 ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive
T0 bit 1 XTD: Extended Identifier	0 11-bit standard identifier 1 29-bit extended identifier
T0 bit 2 RTR: Remote Transmission Request	0 Transmit data frame 1 Transmit remote frame **Note:** When RTR = 1, the M_CAN transmits a remote frame according to ISO11898-1, even if CCCR.FDOE enables the transmission in CAN FD format.
T0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
T1 bits 0:7 MM[7:0]: Message Marker	Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

Table 679. Tx Buffer element descriptions (continued)

Field	Description
T1 bit 8 EFC **Event FIFO Control**	0 Don't store Tx events 1 Store Tx events
T1 bit 10 FDF **FD Format**	0 Frame transmitted in Classic CAN format 1 Frame transmitted in CAN FD format
T1 bit 11 BRS **Bit Rat Switching**	0 CAN FD frames transmitted without bit rate switching 1 CAN FD frames transmitted with bit rate switching
T1 bits 12:15 DLC[3:0] **Data Length Code**	0-8 Transmit frame with 0-8 data bytes 9-15 Transmit frame with 8 data bytes 9-15 CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
T2 bits 0:7	DB3[7:0]: Data Byte 3
T2 bits 8:15	DB2[7:0]: Data Byte 2
T2 bits 16:23	DB1[7:0]: Data Byte 1
T2 bits 24:31	DB0[7:0]: Data Byte 0
T3 bits 0:7	DB7[7:0]: Data Byte 7
T3 bits 8:15	DB6[7:0]: Data Byte 6
T3 bits 16:23	DB5[7:0]: Data Byte 5
T3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Tn bits 0:7	DBm[7:0]: Data Byte m
Tn bits 8:15	DBm-1[7:0]: Data Byte m-1
Tn bits 16:23	DBm-2[7:0]: Data Byte m-2
Tn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.

42.3.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

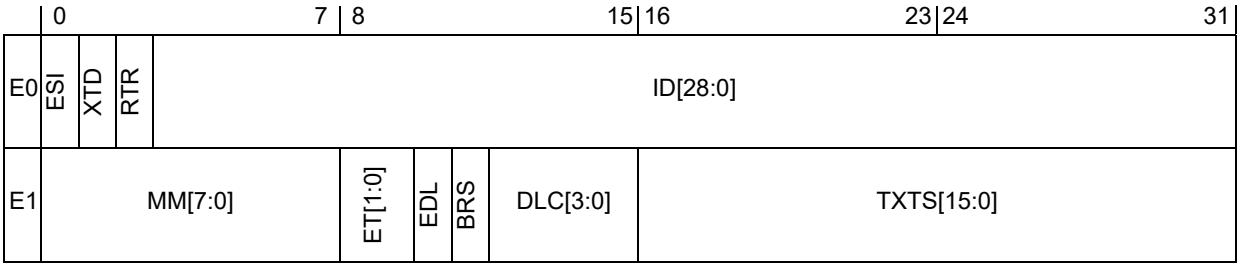

Figure 620. Tx Event FIFO element

Table 680. Tx Event FIFO element descriptions

Field	Description
E0 bit 0 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 bit 1 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.
E1 bit 8:9 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching

Table 680. Tx Event FIFO element descriptions (continued)

Field	Description
E1 bits 12:15 DLC[3:0]	Data Length Code 0-8 CAN + CAN FD: frame with 0-8 data bytes transmitted 9-15 CAN: frame with 8 data bytes transmitted 9-15 CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
E1 bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

42.3.6.4 Standard Message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0 to 127).

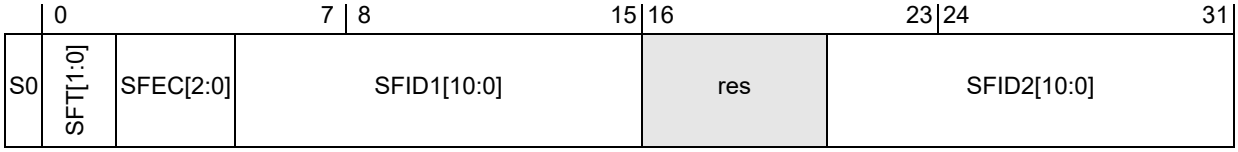

Figure 621. Standard Message ID Filter element

Table 681. Standard Message ID Filter element descriptions

Field	Description
Bits 0:1 SFT[1:0]	Standard Filter Type 00 Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 01 Dual ID filter for SFID1 or SFID2 10 Classic filter: SFID1 = filter, SFID2 = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored

Table 681. Standard Message ID Filter element descriptions (continued)

Field	Description
Bits 5:15 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31 SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: 1) SFEC = '001'...'110' Second ID of standard ID filter element 2) SFEC = '111' Filter for Rx Buffers or for debug messages
	SFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN Host clock period in case the filter matches.
	SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

42.3.6.5 Extended Message ID Filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0 to 63).

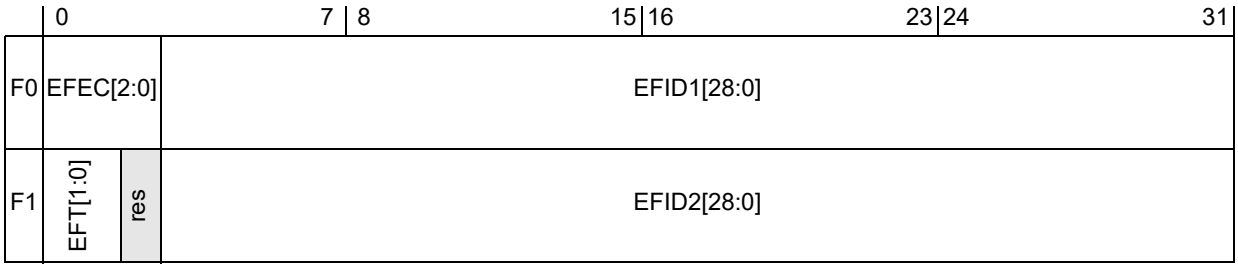

Figure 622. Extended Message ID Filter element

Table 682. Extended Message ID Filter element description

Field	Description
F0 bits 0:2 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 bits 3:31 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see *Section 42.3.10.1.5*) is used.
F1 bits 0:1 EFT[1:0]	Extended Filter Type 00 Range filter from EFID1 to EFID1 (EFID2 ≥ EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
F1 bits 3:31 EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = '001'...'110' Second ID of extended ID filter element 2) EFEC = '111' Filter for Rx Buffers or for debug messages EFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.
