Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = ‘1’. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS–High Priority Message Status
- RXF0S–Rx FIFO 0 Status
- RXF1S–Rx FIFO 1 Status
- TXFQS–Tx FIFO/Queue Status
- TXBRP–Tx Buffer Request Pending
- TXBTO–Tx Buffer Transmission Occurred
- TXBCF–Tx Buffer Cancellation Finished
- TXEFS–Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writable while CCCR[CCE] = ‘0’

- TXBAR–Tx Buffer Add Request
- TXBCR–Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

Following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
     while (read_data != 0x003){
        write(M_CAN0,0xF,driver.regs.can0_cccr.addr,0x003);
           read_data = read(M_CAN0,0xF,driver.regs.can0_cccr.addr);
     };
```

```
-- Configuring the time stamp and timeout registers
     write(M_CAN0,0xF,driver.regs.can0_tscc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_tocc.addr,0x000);

-- Configuring the interrupt registers
     write(M_CAN0,0xF,driver.regs.can0_ie.addr,0xFFFFFFFF);
     write(M_CAN0,0xF,driver.regs.can0_ils.addr,0x00000002);
     write(M_CAN0,0xF,driver.regs.can0_ile.addr,0x00000003);

     write(M_CAN0,0xF,driver.regs.can0_gfc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_xidam.addr,0x00FFFFFF);

-- Writing the start addresses of all the M_CAN Buffers
     generate and drive M_CAN0 can0_rxf0c keeping {
                                          .f0sa == 0x100;
                                          .f0s  == 0x03;
                                          .f0wm == 0x01;

```

42.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers or a Tx FIFO, or both, or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

42.3.7.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = *recessive* signifies a CAN FD frame, FDF = *dominant* signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = *dominant* and BRS = *recessive*. The coding of res = *recessive* is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = *recessive* and res = *recessive*, it will signal a Protocol Exception Event by setting bit PSR.PXE. When Protocol Exception Handling is enabled (CCCR.PXHD = ‘0’), this causes the operation state to change from Receiver (PSR.ACT = “10”) to Integrating (PSR.ACT = “00”) at the next sample point. In case Protocol Exception Handling is disabled (CCCR.PXHD = ‘1’), the M_CAN will treat a *recessive* res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = ‘1’, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = ‘0’, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = ‘0’, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘0’, only bit FDF of a Tx Buffer element is evaluated. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘1’, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitrationphase. In this case disable the CAN FD bit rate switching option for transmissions
- During system startup all nodes are transmitting Classic CAN messages until it is verified thatthey are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to *Table 683*.

Table 683. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is *recessive*. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing & Prescaler Register NBTP. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing & Prescaler Register DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (CAN clock). Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit ESI (Error Status Indicator) is determined by the transmitter’s error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted *recessive*, else it is transmitted *dominant*.

42.3.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via CAN Tx output pin the M_CAN the transmitted data from its local CAN transceiver via CAN Rx input pin. The received data is delayed by the transmitter delay. In case this delay is greater than NTSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is

introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

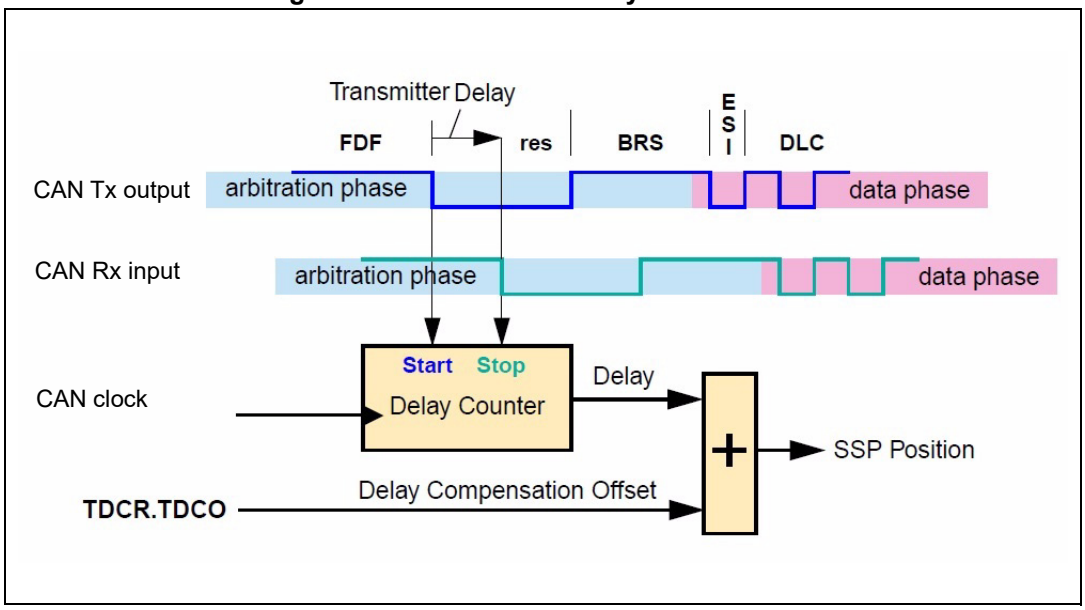
42.3.7.4.1 Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_CAN's Tx output through the transceiver to the CAN Rx input plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.



The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than 6 bit times in the data phase
- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

Figure 623 below describes how the Transceiver Delay Compensation measurement.

If transmitter delay compensation is enabled by programming DBTP.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input CAN Rx input of the transmitter. The resolution of this measurement is one mtq.

Figure 623. Transceiver Delay measurement

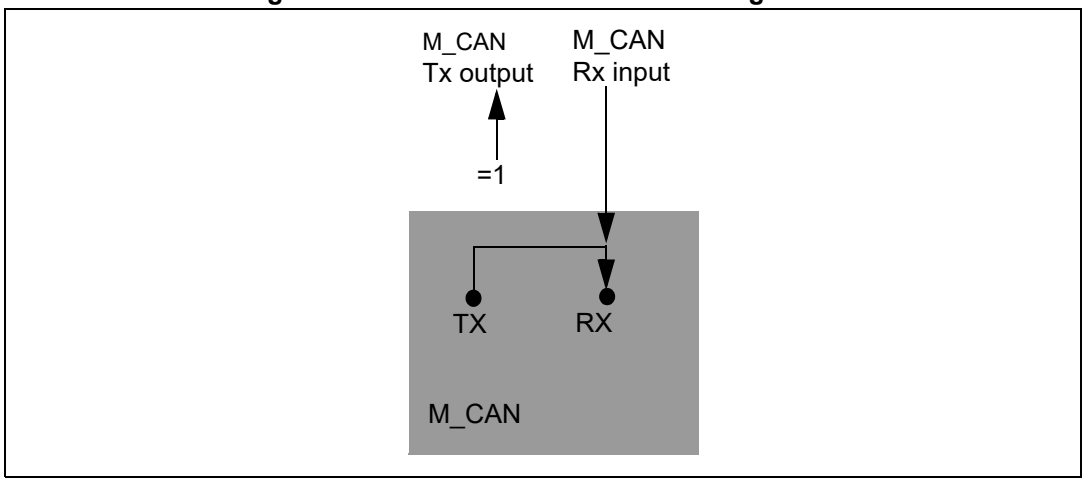
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a to early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on CAN Rx input, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF AND CAN Rx input is low.

42.3.7.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCR.ASM. The bit can only be set by the Host when both CCCR.CCE and CCCR.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.



If the M_CAN is connected to a Clock Calibration on CAN Unit, CCCR.ASM is controlled by “calibration OK” input. In case “calibration OK” switches to ‘0’, bit CCCR.ASM is set. When “calibration OK” switches back to ‘1’, bit CCCR.ASM returns to the previously written value. The state of CCCR.ASM is the written value while “calibration OK” input is at ‘1’. The input is hardwired to ‘1’ when there is no Clock Calibration on CAN Unit connected.

42.3.7.6 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

Figure 624 shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

Figure 624. Pin control in Bus Monitoring mode

42.3.7.7 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

42.3.7.7.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful

transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = ‘10’ (transmission in spite of cancellation).

42.3.7.8 Power down (Sleep mode)

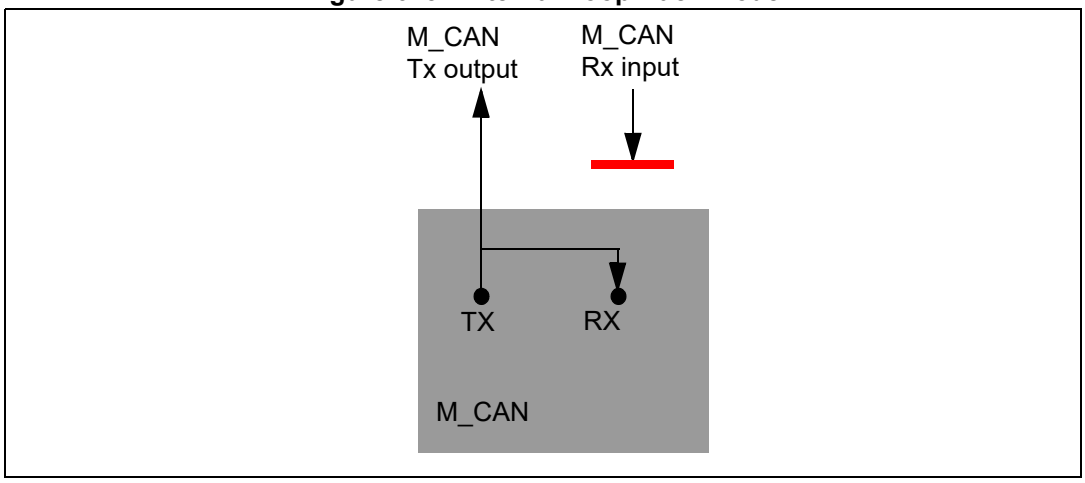
The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and Host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

42.3.7.9 Test modes

To enable write access to register TEST (see *Section 42.3.5.2.4: Test Register (TEST)*), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN Tx output pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN’s bit timing and it can drive constant dominant or recessive values. The actual value at M_CAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].



Note: Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

42.3.7.9.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. *Figure 625* shows the connection of Tx and Rx signals to the M_CAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the CAN Tx output pin.

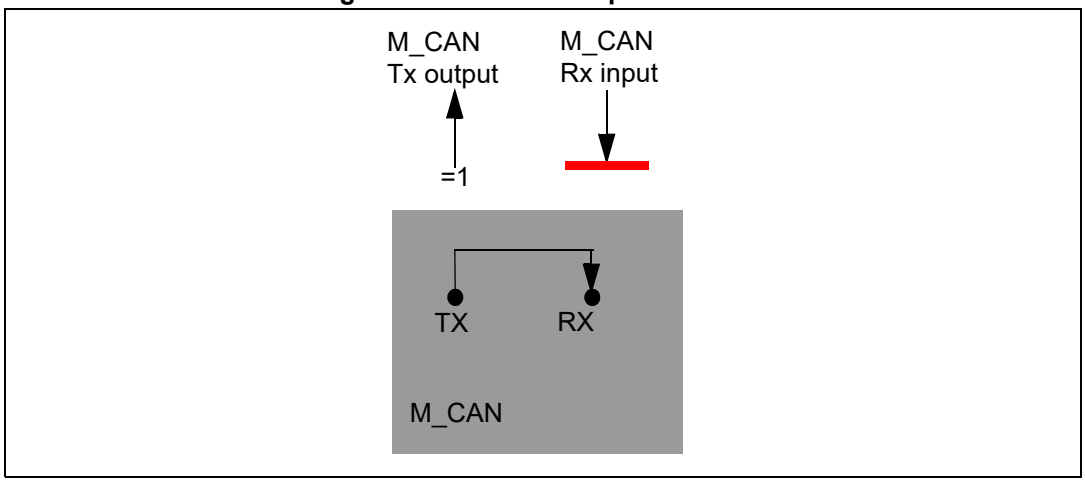


Figure 625. External Loop Back mode

42.3.7.9.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the CAN Tx output and Rx input pins. In this mode M_CAN Tx pin is disconnected from the M_CAN and M_CAN Tx pin is held recessive. *Figure 626* shows the connection of M_CAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

Figure 626. Internal loop back mode

42.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer /Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

42.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = ‘0’. It is stopped when CCCR[INIT] = ‘1’, for exampewhen the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core’s sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

42.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

42.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (such as,CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC.

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Section 42.3.10.2.2: Rx FIFO Overwrite Mode* have to be considered.

Note: When an accepted message is written to one of the two Rx FIFOs, or into a Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

42.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SFID1/SFID2 resp. EFID1/EFID2. There are two possibilities when range filtering is used together with extended frames:

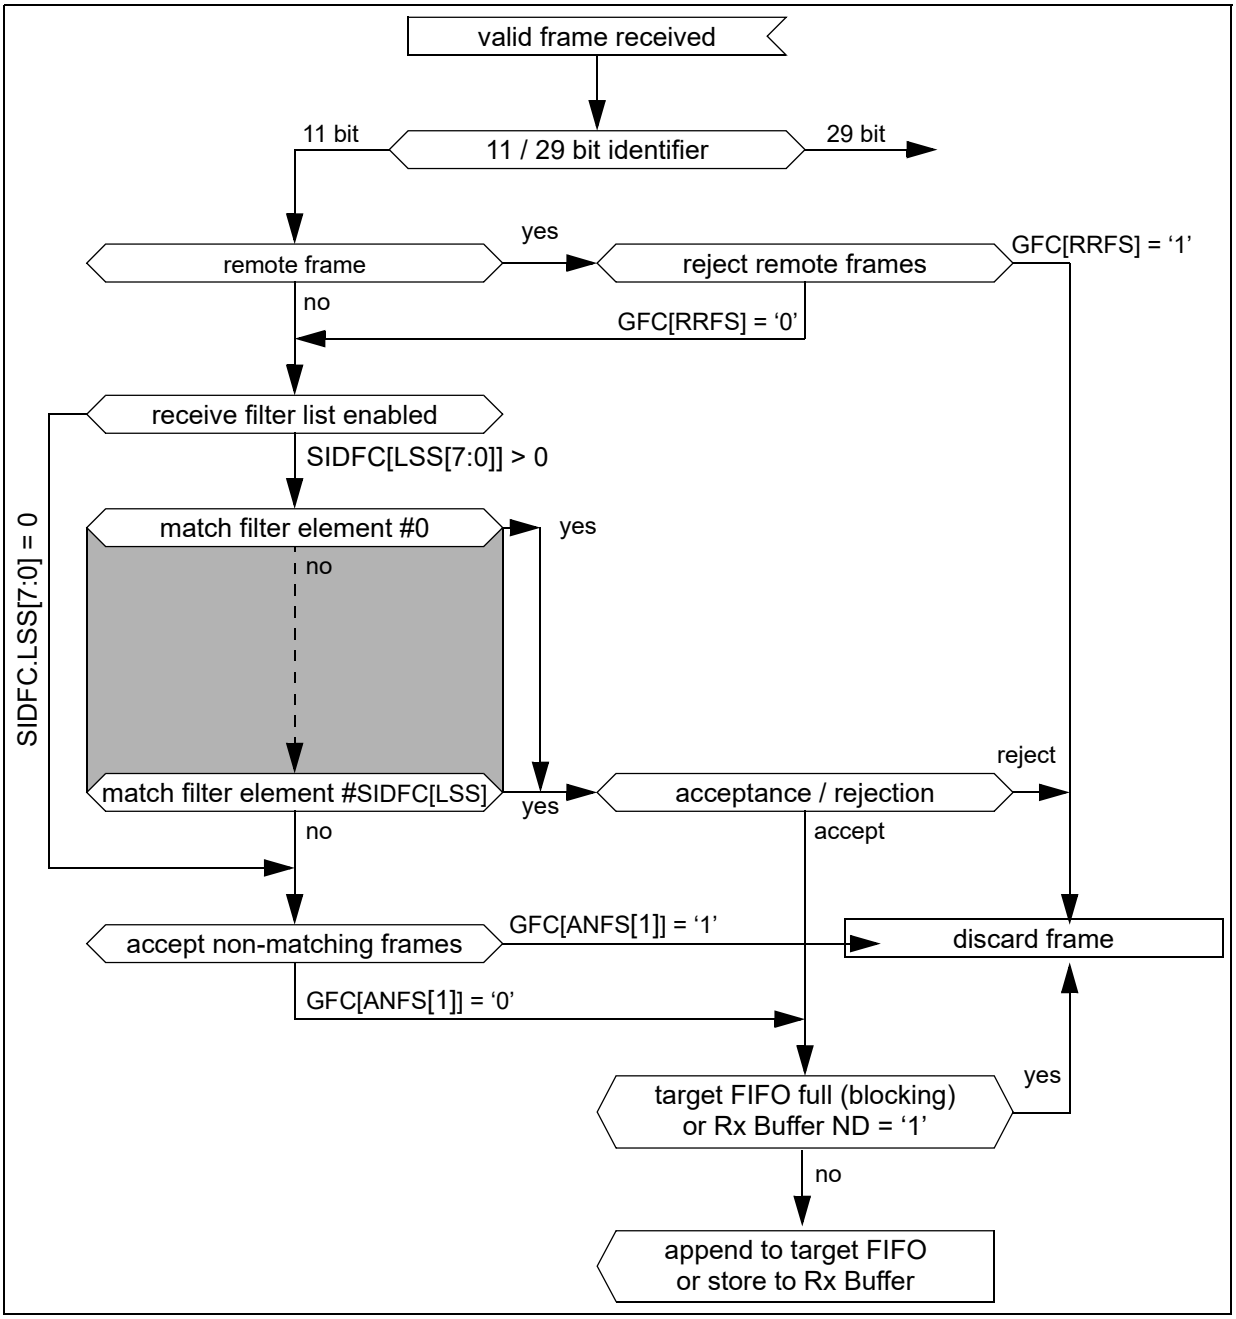
- EFT = '00': The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = '11': The Extended ID AND Mask (XIDAM) is not used for range filtering

42.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1 = SFID2 resp. EFID1 =EFID2.

42.3.10.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1/EFID2 is used as Message ID filter, while SFID2/EFID2 is used as filter mask.



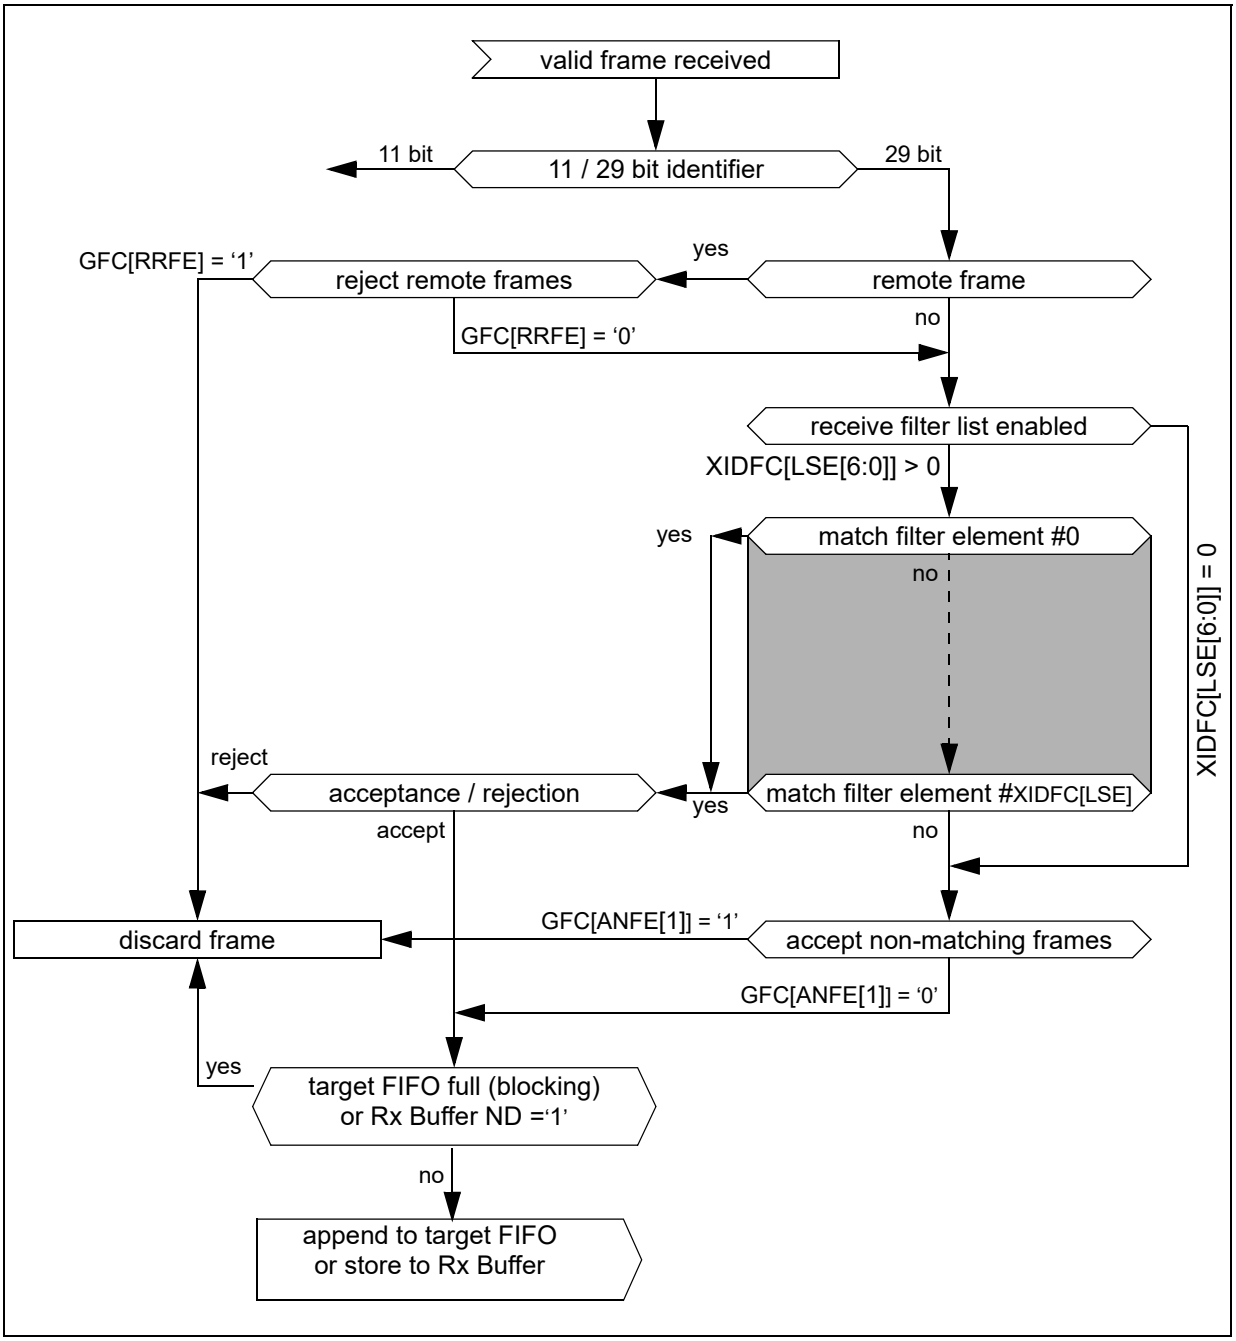
A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

42.3.10.1.4 Standard message ID filtering

Figure 621 shows the flow for standard message ID (11-bit Identifier) filtering.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 627. Standard Message ID Filter Path



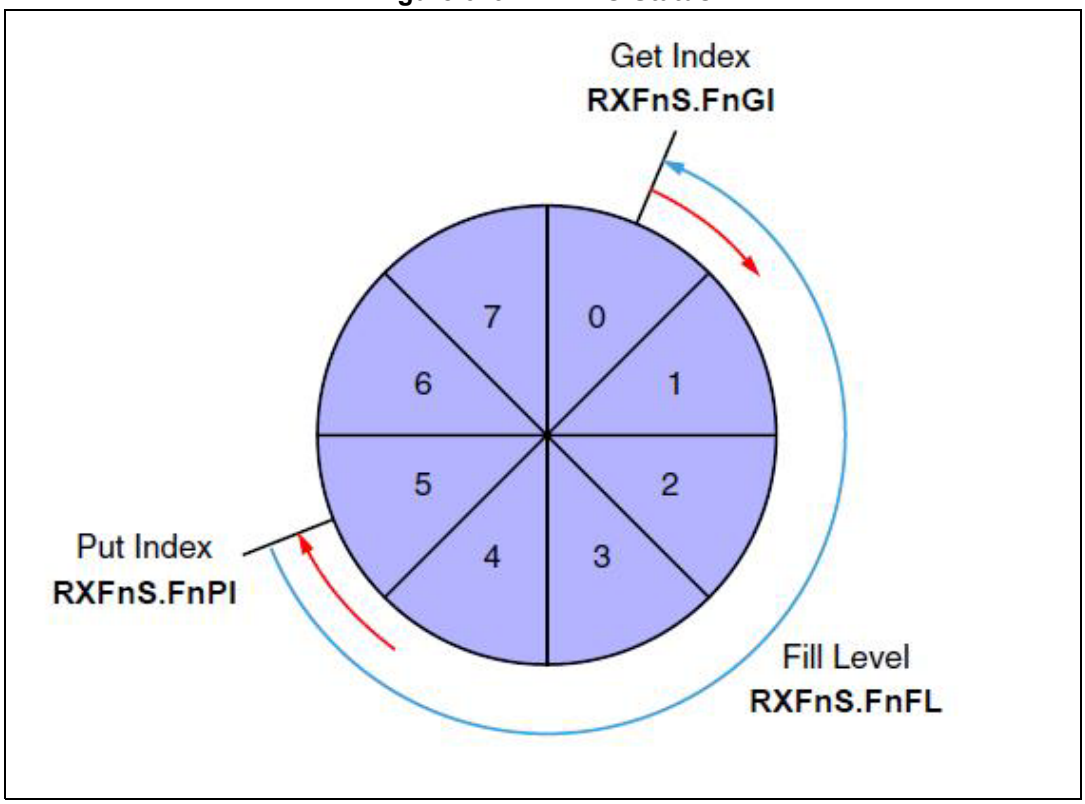
42.3.10.1.5 Extended message ID filtering

Figure 628 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in *Section 42.3.5.2.21: Extended ID Filter Configuration Register (XIDFC)*.

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the

Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 628. Extended Message ID Filter Path



42.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see *Section 42.3.10.1: Acceptance filtering*. The Rx FIFO element is described in *Section 42.3.6.1: Rx Buffer and FIFO element*.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IR.RFnW is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag IR.RFnF is set.

Figure 629. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI × FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 684. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10

Table 684. Rx Buffer / FIFO Element Size (continued)

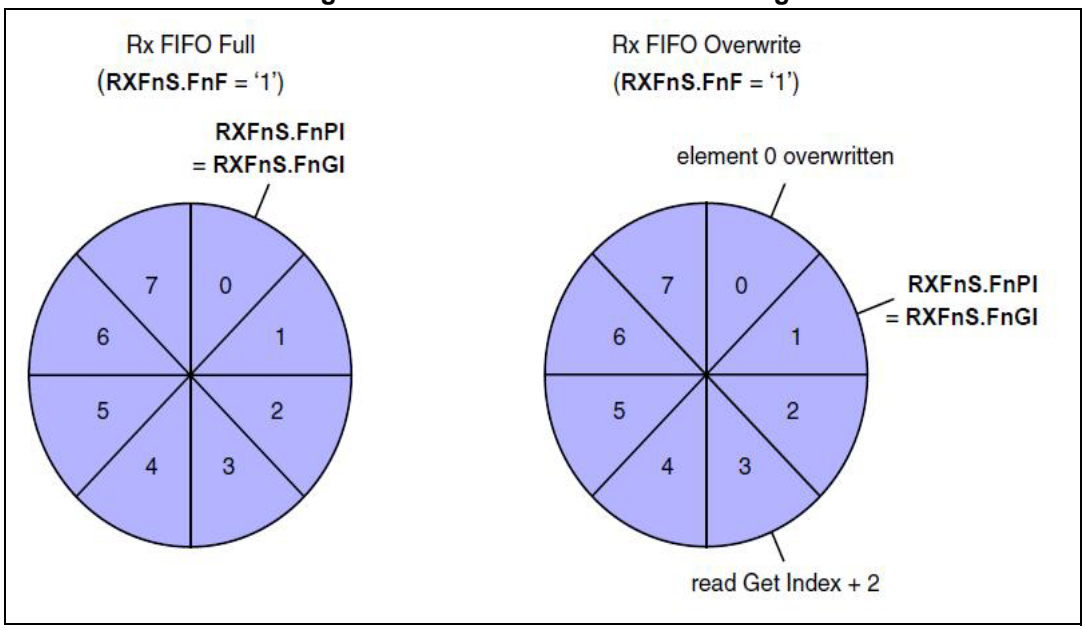
RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
110	48	14
111	64	18

42.3.10.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IR.RFnL is set.



42.3.10.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. *Figure 630* shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 630. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = '0').

42.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (see *Section 42.3.6.4: Standard Message ID Filter element* and *Section 42.3.6.5: Extended Message ID Filter element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 685. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

42.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

42.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (for example #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (see *Section 42.3.6.1: Rx Buffer and FIFO element*).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = '111' have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while DMA request output is activated. The behavior is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets the DMA acknowledge input . This resets the DMA request output. Now the M_CAN is prepared to receive the next set of debug messages.

42.3.12.1 Filtering for Debug Messages

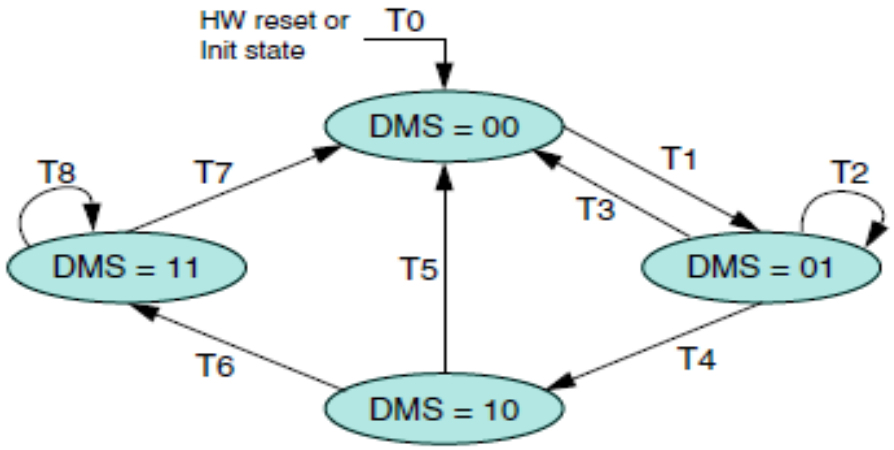
Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to '111'. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 /EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 686. Example Filter Configuration for debug messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101

Table 686. Example Filter Configuration for debug messages (continued)



Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

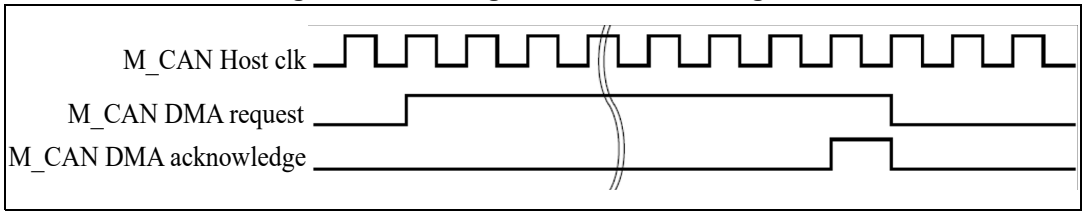
42.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S.DMS.

Figure 631. Debug Message Handling State Machine

T0: Reset m_cam_dma_req output, enable reception of debug messages A, B, and C
T1: Reception of debug message A
T2: Reception of debug message A
T3: Reception of debug message C
T4: Reception of debug message B
T5: Reception of debug messages A, B
T6: Reception of debug message C
T7: DMA transfer completed
T8: Reception of debug message A,B,C (message rejected)



42.3.12.3 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message

handling state machine enters idle state (DMS = ‘00’) and waits for reception of the next debug messages.

Figure 632. Timing of DMA interface signals

Note: If the DMA unit activates input M_CAN DMA acknowledge signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

42.3.13 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in the *Note: on page 1201*.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

42.3.13.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU’s CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If for example CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR.TXP = ‘0’).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

42.3.13.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see *Table 687*). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

Table 687. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

42.3.13.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to ‘0’. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = ‘1’) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a ‘1’ to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

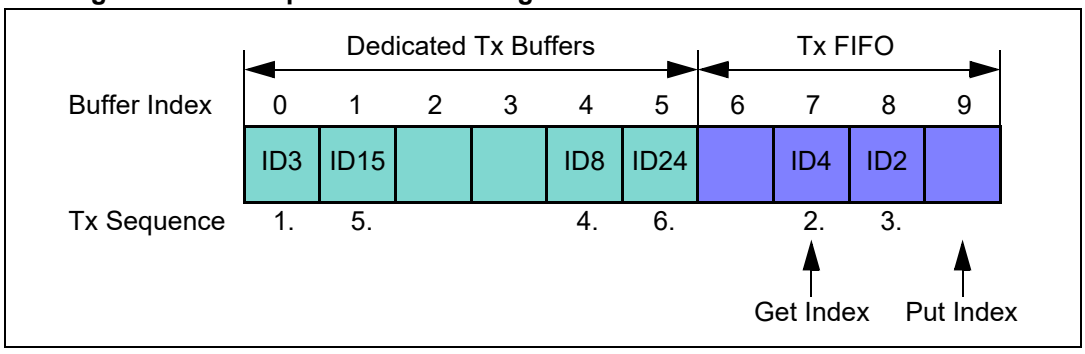
When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The

Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see *Table 687*). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

42.3.13.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.



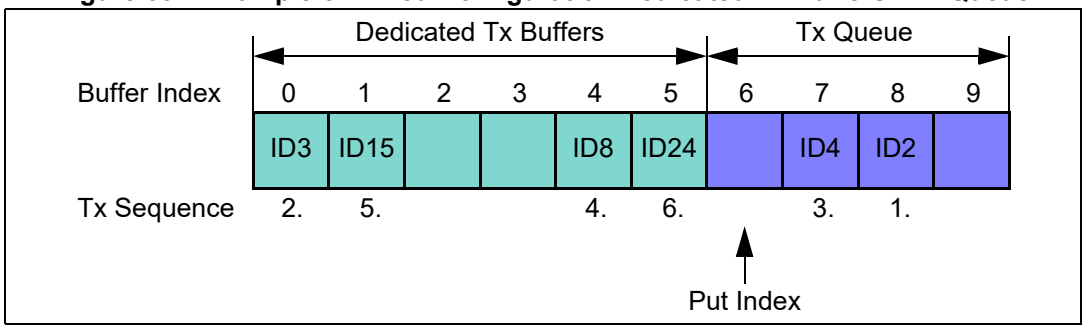
The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see *Table 687*). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

42.3.13.5 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 633. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO



Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

42.3.13.6 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 634. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

42.3.13.7 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a ‘1’ to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to ‘1’.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

42.3.13.8 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored

in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in the Note *Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.*. When a Tx Event FIFO full condition is signaled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

42.3.14 FIFO acknowledge handling

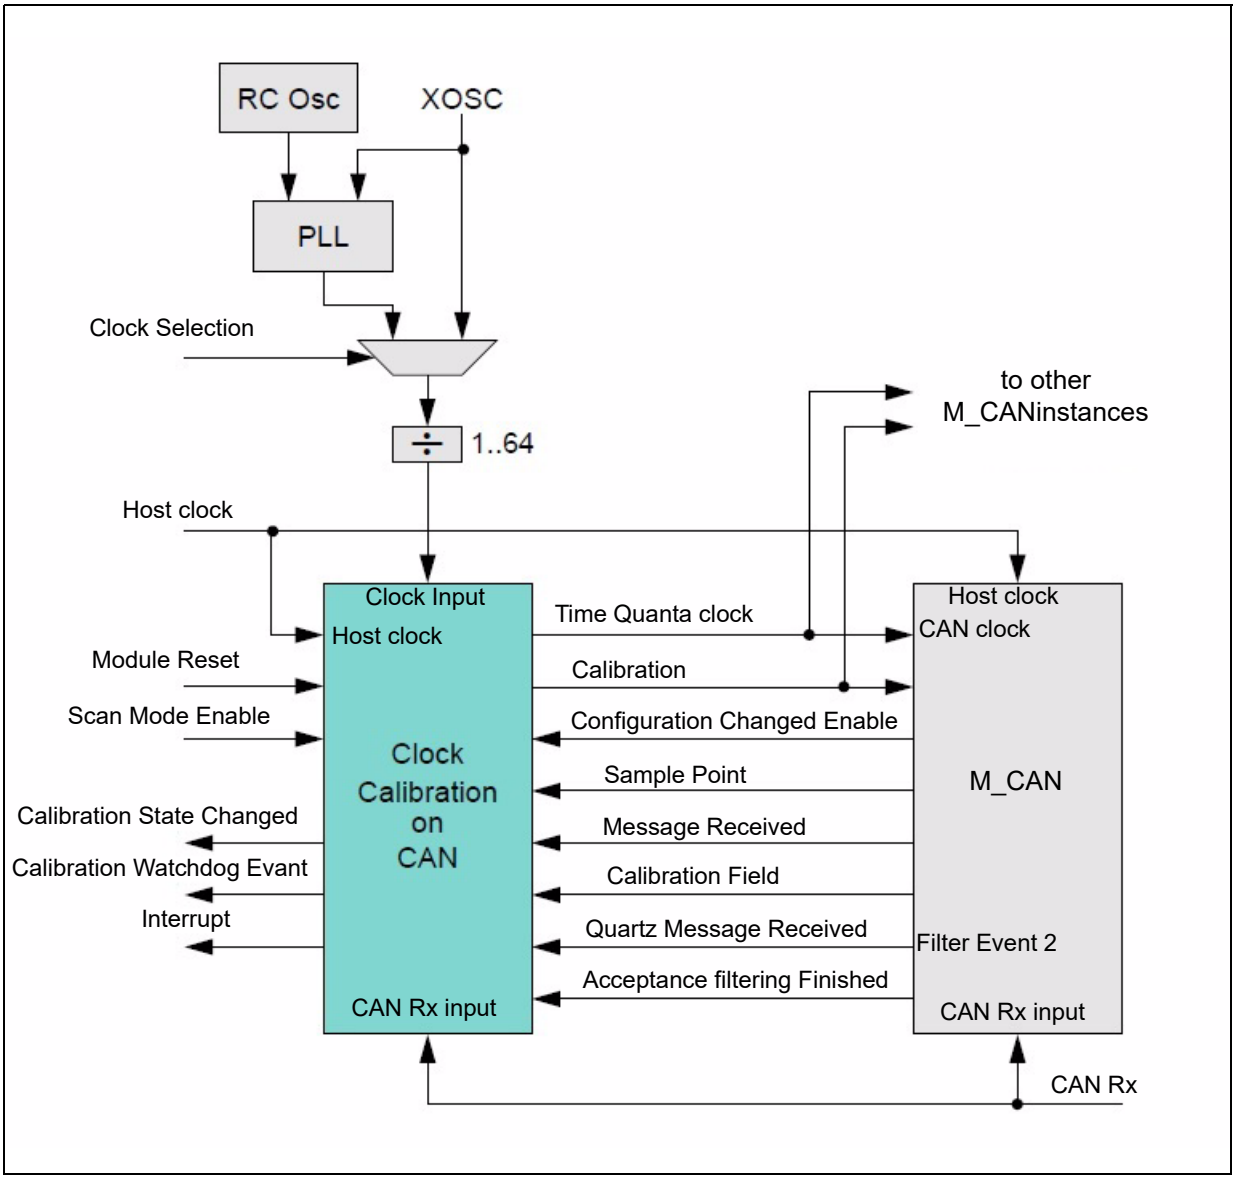
The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see *Section 42.3.5.2.28: Rx FIFO 0 Acknowledge Register (RXF0A)* and *Section 42.3.5.2.46: Tx Event FIFO Acknowledge Register (TXEFA)*). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

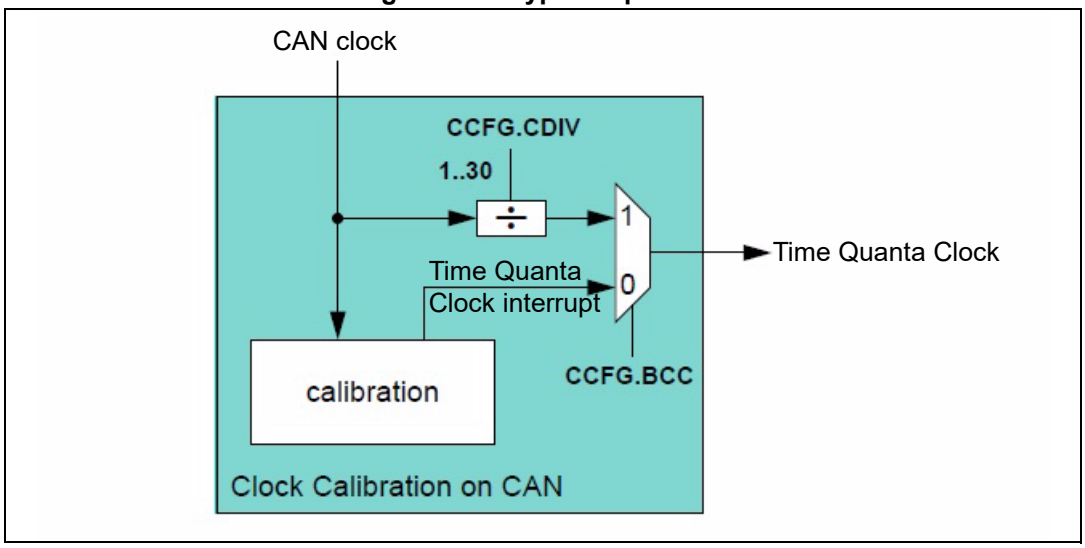
42.3.15 Clock Calibration on CAN Unit (CCCU)



This section describes an add-on for the M_CAN modules that generates a calibrated CAN Time Quanta Clock from an on-chip RC-oscillator clock by evaluating CAN messages received by the attached M_CAN. Calibration on CAN is only possible when the M_CAN is operated in standard CAN mode.

Note: If calibration unit is intended to generate the protocol clock, then it is mandatory to configure calibration unit and MCAN1 before use the other CAN controller like MCAN2 and MCAN3, because the calibrated clock is generated through MCAN1.

Figure 635 shows the interface of the Clock Calibration on CAN Unit. The clock multiplexer controlled by clock input from Clock Select multiplexer controls whether the clock from the



PLL or XOSC is routed to Clock Select multiplexer input. The calibrated Time Quanta Clock is routed to all CAN instances. In case of a successful calibration this is signaled via Calibration.

Figure 635. Connection of Clock Calibration on CAN Unit to M_CAN

CPU accesses to the Clock Calibration on CAN Unit use the Host clock connected to Host clock input from Clock Select Multiplexer. Clock calibration is bypassed when CCFG.BCC = '1'. In this case, the clock from Clock Select multiplexer is routed through a clock divider to Time Quanta Clock output (see *Figure 636*).

Figure 636. Bypass operation

42.3.15.1 Operating Conditions

The Clock Calibration on CAN Unit is designed to operate under the following conditions:

- Clock input from PLL (clock input from Clock Select multiplexer) between 80 MHz and 500 MHz
- M_CAN bit rates between 125 kbit/s and 1 Mbit/s
- Clock for Host accesses (Host clock) is 40/50 MHz

The Clock Calibration on CAN Unit generates a calibrated Time Quanta clock in the range from 0.5 MHz to 25 MHz.

Note: The M_CAN requires that the CAN clock is always below or equal to the Host clock (CAN clock ≤ Host clock). This has to be considered when the Clock Calibration on CAN Unit is bypassed (CCFG.BCC = '1').

42.3.15.2 Calibration Accuracy

The calibration accuracy in state Precision_Calibrated depends on:

- The dynamic clock tolerance at the clock input from clock select multiplexer
- The measurement error. For each bit sequence used for calibration measurement, there is a maximum error of one clock input from Clock Select multiplexer period. The number of bits used for measurement of the bit time is 32 or 64-bit, depending on configuration of CCFG.CFL.
- Tolerable error in calibration mechanism

The distance between two calibration messages has to be chosen to fit the clock tolerance requirements of the attached M_CANs.

Note: Dynamic clock tolerance is the clock frequency variation between two calibration messages, such as, caused by change of temperature or operating voltage.

42.3.15.3 Memory map and register description

42.3.15.3.1 Hardware Reset Description

After hardware reset, the registers of the Clock Calibration on CAN Unit hold the reset values listed in *Table 688*.

The Clock Calibration on CAN Unit allocates an address space of 16 bytes. All registers are organized as 32-bit registers. The Clock Calibration on CAN Unit is accessible by the Host CPU using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access). Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when Configuration Change Enable input = ‘1’. Configuration Change Enable signal is activated when the M_CAN control bits CCCR.CCE = ’1’ AND CCCR.INIT = ‘1’.

Table 688. CCCU memory map

Address Offset	Register Name	Access(1)	Reset value	Location
0x0000	Core Release Register (CREL)	R	0x1114_0729	*Section 42.3.15.3.2*

1. Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when Configuration Change Enable input = ‘1’. Configuration Change Enable signal is activated when the M_CAN control bits CCCR.CCE = ‘1’ AND CCCR.INIT = ‘1’.

Figure 638. Calibration Configuration Register (CCFG)

Table 691. CCFG field descriptions

Field	Description
0 SWR	Software Reset Writing a ‘1’ to this bit will reset the calibration FSM to state Not_Calibrated (CSTAT.CALS = ‘00’). The Calibration Watchdog value CWD.WDV is also reset. Registers CCFG, CSTAT and the Calibration Watchdog configuration CWD.WDC are unchanged. The bit remains set until reset has completed.
12:15 CDIV	Clock Divider The clock divider has to be configured when the clock calibration is bypassed (BCC = ‘1’) to assure that the M_CAN requirement CAN clock <= Host clock is fulfilled. 0000 Divide by 1 0001 Divide by 2 0010 Divide by 4 0011 Divide by 6 0100 Divide by 8 0101 Divide by 10 0110 Divide by 12 0111 Divide by 14 1000 Divide by 16 1001 Divide by 18 1010 Divide by 20 1011 Divide by 22 1100 Divide by 24 1101 Divide by 26 1110 Divide by 28 1111 Divide by 30
16:23 OCPM	Oscillator Clock Periods Minimum (0x00–0xFF) Configures the minimum number of clock input from Clock Select multiplexer periods in two CAN bit times. OCPM is used in Basic Calibration to avoid false measurements in case of glitches on the bus line. The configured number of clock input from Clock Select multiplexer periods is OCPM × 32. The configuration depends on the clock input from Clock Select multiplexer frequency (80 MHz to 500 MHz) and the bit rate configured in the attached M_CANs (125 kbit/s to 1 Mbit/s). It is recommended to configure a value slightly below two CAN bit times. The reset value is 1.6 bit times at 80 MHz clock input from Clock Select multiplexer and 1 Mbit/s CAN bit rate.
24 CFL	Calibration Field Length 0 Calibragation field length is 32 bits. 1 Calibragation field length is 64 bits.

Table 691. CCFG field descriptions (continued)

Field	Description
25 BCC	Bypass Clock Calibration If this bit is set, the clock input clock input from Clock Select multiplexer is routed to the Time Quanta clock output through a clock divider configurable via CDIV, Calibration is always ‘1’. In this case the baud rate prescaler of the connected M_CANs has to be configured to generate the M_CAN internal time quanta clock. 0 Clock calibration unit generates Time Quanta clock 1 Clock calibration unit bypassed **Note:** As long as clock input from Clock Select multiplexer is equal or above 80 MHz the Clock Calibration on CAN Unit is functional, even when BCC = ‘1’. The calibration state can be read from register CSTAT.
27:31 TQBT	Time Quanta per Bit Time (0x04–0x19) Configures the number of time quanta per bit time. Same value as configured in the attached M_CANs. The range of the resulting Time Quanta clock is from 0,5 MHz (bit rate of 125 kbit/s with 4 tq per bit time) to 25 MHz (bit rate of 1 Mbit/s with 25 tq per bit time). Valid values are 4 to 25. Configured values below 4 are interpreted as 4, values above 25 are interpreted as 25.

42.3.15.3.5 Calibration Watchdog Register (CWD)

The calibration watchdog is started after the first falling edge when the calibration FSM is in state Not_Calibrated (CSTAT.CALS = ‘00’). In this state the calibration watchdog monitors the Message Received input. In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM stays in state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When in state Basic_Calibrated (CSTAT.CALS = ‘01’), the calibration watchdog is restarted with each Message Received = ‘1’). In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM returns to state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When a quartz message was received, state Precision_Calibrated (CSTAT.CALS = ‘10’) is entered and the calibration watchdog is restarted. In this state the calibration watchdog monitors the Quartz Message Received input. In case no message from a quartz controlled node was received by the attached M_CAN until the calibration watchdog has counted down to zero, the calibration FSM transits back to state Basic_Calibrated (CSTAT.CALS = ‘01’).

The Calibration Watchdog Counter is clocked by the Sample Point input. The duration of a cu_spt pulse is one Time Quanta clock period. The signal is active when the CAN protocol engine on the attached M_CAN is started, that is when the INIT bit is reset.

A calibration watchdog event is signaled by Calibration Watchdog Event output. The duration of aCalibration Watchdog Event pulse is one Host clock period.

A calibration watchdog event also sets interrupt flag **CUIR.CWE**. If enabled by **CUIE.CWEE**, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag **CUIR.CWE** is reset.

42.3.15.3.6 CU Interrupt Register (CUIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ’0’ has no effect. A hard reset will clear the register. The configuration of CUIE controls whether an interrupt is generated.

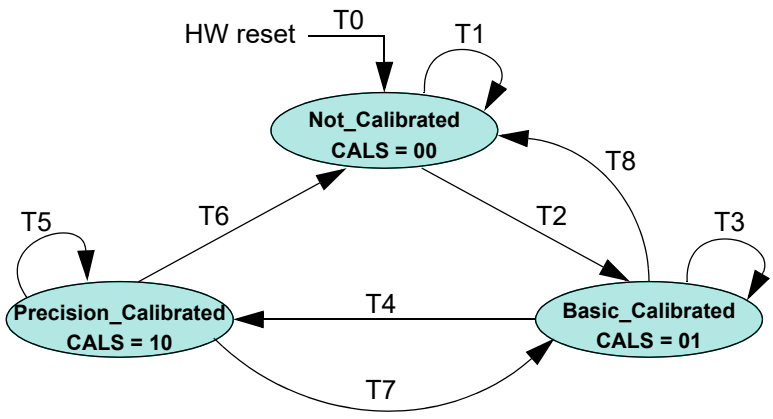
42.3.15.4 Functional Description



Calibration of the Time Quanta clock via CAN messages is performed by adapting a clock divider that generates the CAN protocol time quantum tq from the clock input from Clock Select multiplexer .

- First step: Basic Calibration–The minimum distance between two edges from recessive to dominant is measured, this time to be assumed two CAN bit times, counted in PLL clock periods. The clock divider is updated each time a new measurement finds a smaller distance between edges. Basic calibration is achieved when the CAN protocol

controller detects a valid CAN message. This is signaled to the Calibration on CAN unit by Message Received input signal.

- Second step: Precision Calibration – The calibration state machine measures the length of a longer bit sequence inside a CAN frame by counting the number of clock input from Clock Select multiplexer periods. The length of this bit sequence can be configured to 32 or 64 bits via CCFG.CLF. For a calibration field length of 32/64 bit a calibration message with at least 2/6 byte data field is required. The counter is controlled by Calibration Field and Sample Point input signals. The counter is enabled when Calibration Field is set and stops after the configured number of bits has been received. Received bits are signaled by the M_CAN by Sample Point signal. Precision calibration is based on the new clock divider value calculated from the measurement of the longer bit sequence.

Figure 643. Calibration FSM

T0: HW reset

T1: Check for minimum

T2: Message Received = ‘1’

T3: Evaluate messages

T4: Quartz Message Received = ‘1’

T5: Evaluate quartz messages

T6: Configuration Change Enabled = ‘1’

T7: Watchdog event: no quartz message received

T8: Watchdog event: no message received
or Configuration Change Enabled = ‘1’

A change of the calibration state is signaled via by Calibration State Changed output. The duration of a Calibration State Changed output pulse is one Host clock period.

A change of the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

Until precision calibration is achieved (Calibration=‘1’), the attached M_CANs operate in a restricted mode (no frame transmission, no error or overload flag transmission, no error counting). In case calibration of the PLL is done by software by evaluating the calibration status from register CSTAT, the attached M_CANs have to be set to restricted operation

mode (CCCR.ASM = ‘1’) until the Calibration on CAN unit is in state Precision_Calibrated (see *Section 42.3.15.4.3: Software Calibration*).

Precision calibration may be performed only on valid CAN frames transmitted by a node with a stable, quartz-controlled clock. Calibration frames are detected by the M_CAN’s acceptance filtering and are signaled to the Clock Calibration on CAN Unit by Quartz Message Received, to be connected to one of the M_CAN’s Filter Event outputs, signal. A filter element and an Rx Buffer have to be configured in the attached M_CAN to identify and store calibration messages. After reception of a calibration message the Rx Buffer’s new data flag has to be reset to enable signaling of the next calibration message.

In case there is only one CAN transmitter with a quartz clock in the network, this node has to transmit its first message after startup with at least one ‘1010’ sequence in the data field or in the identifier. This assures that the non-quartz nodes can enter state Basic_Calibrated and then acknowledge the quartz node’s messages.

Precision calibration must be repeated in predefined maximum intervals supervised by the calibration watchdog.

Note: When the Clock Calibration on CAN Unit transits from state Precision_Calibrated back to Basic_Calibrated, the calibration OK signal is deasserted, the attached M_CANs complete ongoing transmissions, and then enter restricted operation (no frame transmission, no error or overload flag transmission, no error counting).

42.3.15.4.1 Configuration

The Clock Calibration on CAN Unit is configured via register CCFG. The register is only writeable while Configuration Change Enable = ‘1’, that is when the attached M_CAN has CCCR.CCE and CCCR.INIT set.

For basic calibration the minimum number of oscillator periods between two consecutive falling edges at CAN receive input pin is measured. The number of clock periods depends on the clock frequency applied at clock input from clock select multiplexer. In case the measured number of clock periods is below the minimum configured by CCFG.OCPM, for example due to a glitch on CAN receive input, the value is discarded and measurement continues.

It is recommended to configure CCFG.OCPM slightly below two CAN bit times:

CCFG.OCPM < ((2 x CAN bit time) / Clock input from Clock Select multiplexer period) / 32

The length of the bit field used for precision calibration can be configured to 32 or 64 bits via CCFG.CFL. The number of bits used for precision calibration has an impact on calibration accuracy and the maximum distance between two calibration messages. The reception of the bits is signaled by the attached M_CAN by Sample Point input.

The number of time quanta per bit time configured by CCFG.TQBT is used together with the measured number of oscillator clock periods CSTAT.OCPC to define the number of oscillator clocks per bit time.

When the clock calibration is bypassed by configuring CCFG.BCC = ‘1’, the internal clock divider has to be configured via CCFG.CDIV to fulfill the condition CAN clock $\leq$ Host clock.

Note: When clock calibration on CAN is active (CCFG.BCC = ‘0’), the baud rate prescaler of the attached M_CANs has to be configured to inactive.

42.3.15.4.2 Status signaling

The status of the Clock Calibration on CAN Unit can be monitored by reading register CSTAT. When in state Precision_Calibrated the oscillator clock period counter CSTAT.OCPC signals the number of oscillator clock periods in the calibration field while CSTAT.TQC signals the number of time quanta in the calibration field.

The calibration state is monitored by CSTAT.CALS. A change of the calibration state is signalled at the module interface by Calibration State Changed. The duration of a Calibration State Changed pulse is one Host clock period. A change of the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

A calibration watchdog event is signalled by Calibration Watchdog Event output. The duration of a Calibration Watchdog Event output pulse is one Host clock period. A calibration watchdog event also sets interrupt flag CUIR.CWE. If enabled by CUIE.CWEE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CWE is reset

42.3.15.4.3 Software Calibration

The Clock Calibration on CAN Unit also supports software calibration of the clock generated from an adjustable PLL, connected to the clock input, from Clock Select multiplexer. For this purpose the clock from Clock Select multiplexer has to be routed to Time Quanta clock output by programming CCFG.BCC = ‘1’. The Clock Calibration on CAN Unit’s internal clock divider has to be configured via CCFG.CDIV to meet the clock requirements of the attached M_CANs. All other configuration parameters have to be set via CCFG as if the Clock Calibration on CAN Unit is generating Time Quanta clock.

For startup the M_CANs attached to the Clock Calibration on CAN Unit have to be configured for Restricted Operation (CCCR.ASM = ‘1’). The PLL clock has to be adjusted until the Clock Calibration on CAN Unit has reached state Precision_Calibrated. Now the software has to reset CCCR.ASM and the M_CANs can start normal operation.

During operation the software has to check regularly whether the Clock Calibration on CAN Unit is still in state Precision_Calibrated. In case the Clock Calibration on CAN Unit has left state Precision_Calibrated due to drift of the PLL clock, the attached M_CANs have to be set into Restricted Operation Mode by programming CCCR.INIT, CCCR.CCE, and CCCR.ASM to ‘1’.

After the PLL clock has been adjusted successfully (Clock Calibration on CAN Unit is in state Precision_Calibrated), the M_CANs can be set to normal operation again.

42.4 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note: From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

42.4.1 Features

- Active low asynchronous reset
- 1–CPU + up to 5–CAN arbiter
- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth
- Time slot is defined as one peripheral clock cycle

42.4.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
  - CPU obtains every 2nd slot
  - CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
  - CPU obtains no time slots
  - CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains every 2nd time slot
  - Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains no time slots
  - Active CAN 1/2 obtains every 2nd time slot

42.5 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are detailed in *Section 42.8: Shared memory map*.

42.5.1 ECC controller

The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access.

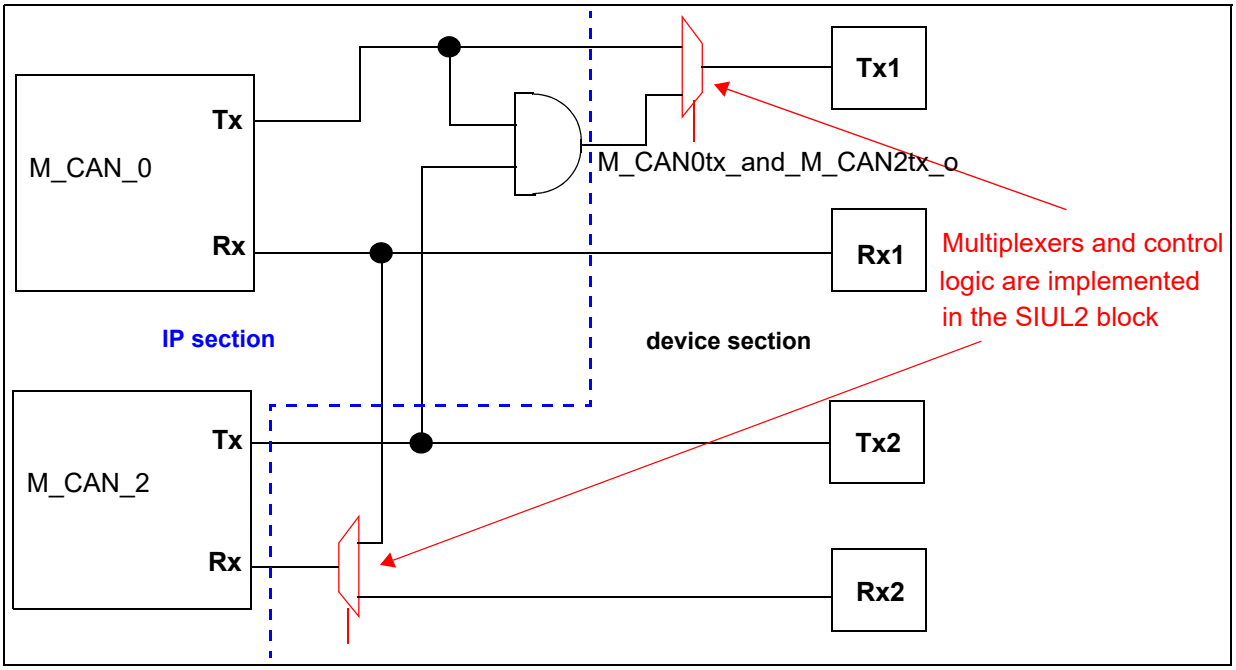
The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2-bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors display the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

Note:
The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

42.5.1.1 Features



The ECC module supports the following:

- ecc_error = ‘00’ No error is detected in the read data from memory
- ecc_error = ‘01’ This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.
- ecc_error = ‘10’ This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- ecc_error = ‘11’ This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

42.6 CAN nodes 0 and 2 I/Os sharing

Each CAN node has its Tx/Rx signals connected to separated GPIO pairs. It is required for M_CAN_0 and M_CAN_2 to share one common GPIO pair. This feature is described in *Figure 644*.

Figure 644. CAN Subsystem_0 M_CAN_0 and M_CAN_2 connections to GP I/Os

42.7 External signal description

The CAN subsystem has following external pins.

- M_CAN_x_RX: M_CAN x receive input
- M_CAN_x_TX: M_CAN x transmit output
- M_CAN_x_RXFD: M_CAN_x Receive Fast Data control signal
- M_CAN_x_TXFD: M_CAN_x Transmit Fast Data control signal

42.8 Shared memory map

Table 696 shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 696. Shared memory map versus CAN transmit, receive and filters elements

Start Address Offset (byte)	End Address Offset (byte)	CAN block/sub block		Comment
CAN Subsystem 0 - APB Bridge 0				
0x06E0	0x0EFF	M_CAN0	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 2	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			Reserved	
0x1880	0x1CFF	M_CAN2	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 2	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			Reserved	
CAN Subsystem 1 - APB Bridge 1				
0x0000	0x081F	M_CAN1	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 1	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			Reserved	

Note: There is no write access protection from a CAN module to the message memory space. The write access protection is only for CPU access to the message memory.

The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters and the Tx/Rx buffers used, it is mandatory for the user to configure the start address registers, specified in Table 697, in order to fit the memory mapping specified in Table 696.

The CPU uses the peripheral interface to access the memory locations. It must be noted that there is no transfer error reported to the CPU in case of access to reserved memory locations.

Table 697. Detailed mapping in CAN subblocks

CAN subblock	Element name	Comment

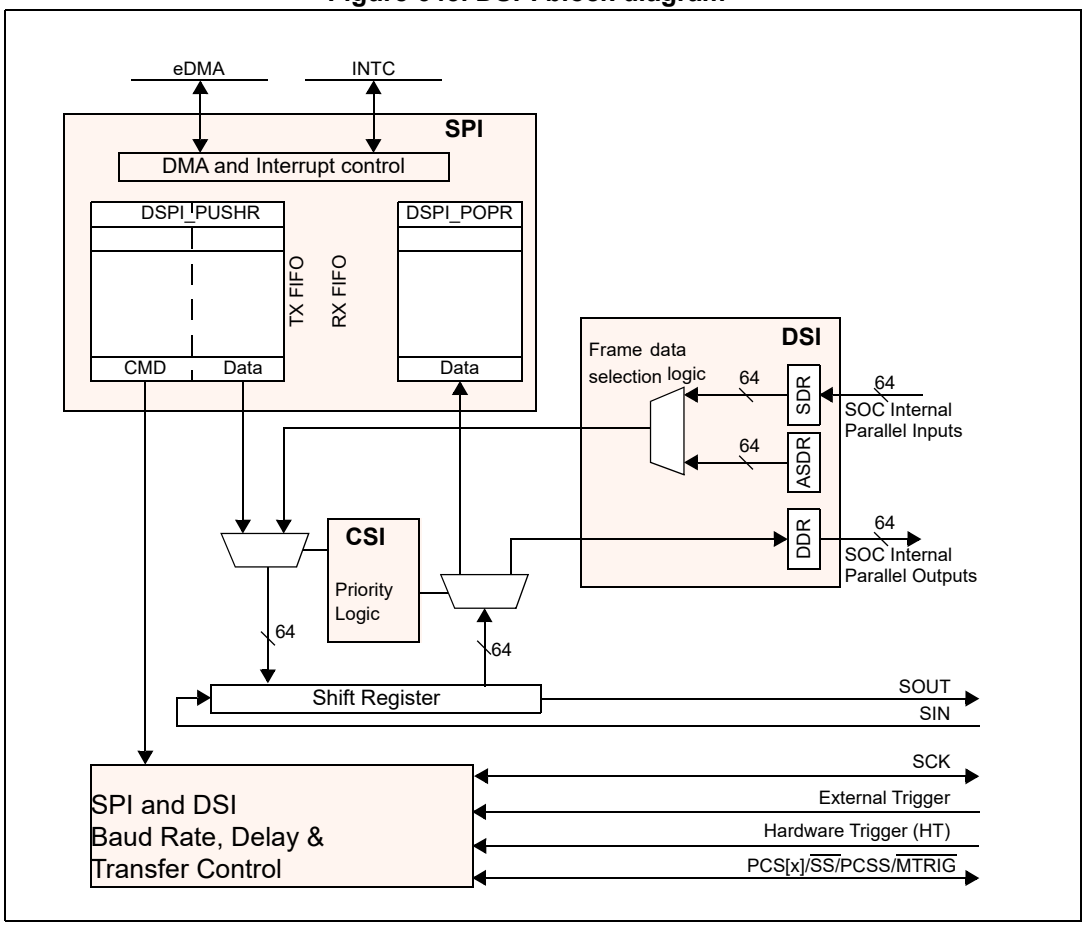
43 Deserial Serial Peripheral Interface (DSPI)

43.1 Introduction



The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note: For the chip-specific implementation details of this module's instances, see Chapter 7: Device configuration: Section 7.9.2: DSPI configuration.

43.1.1 Block diagram

Figure 645 provides the block diagram of this module.

Figure 645. DSPI block diagram (1)

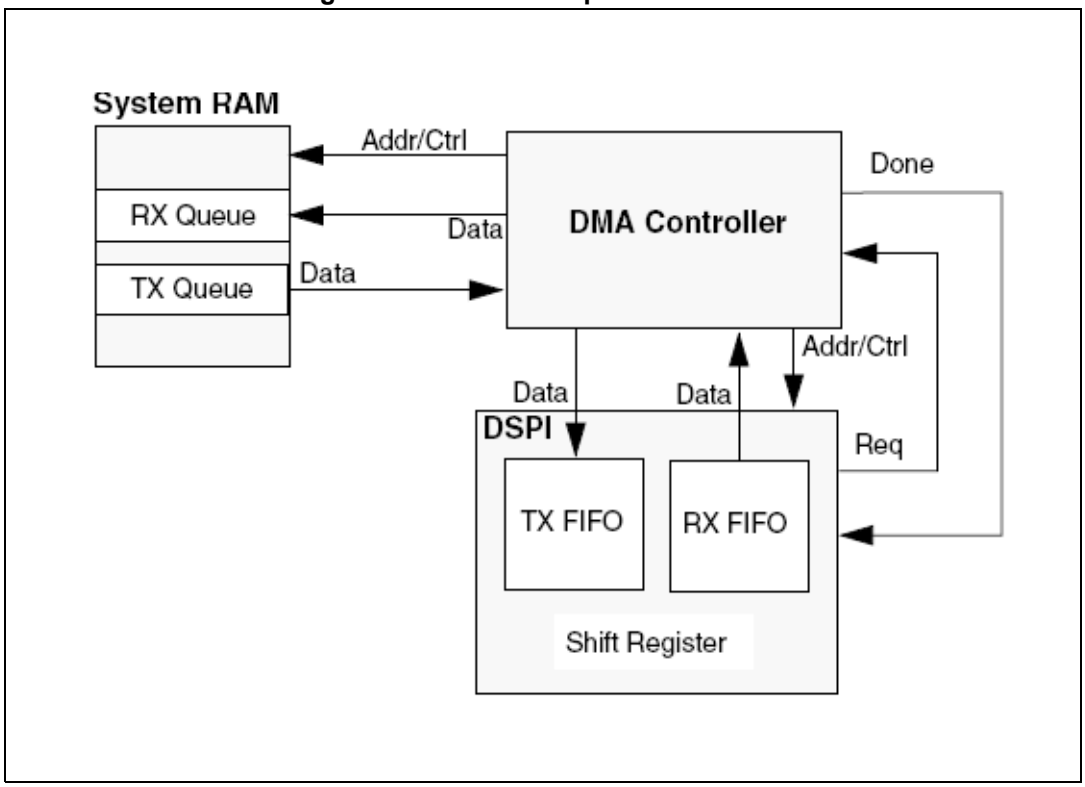
1. CSI and DSI features are not supported

43.1.2 Features

The DSPI supports these features:

- full-duplex, four-wire synchronous transfers
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection
- buffered transmit operation using the TX FIFO with depth of 4 entries
- buffered receive operation using the RX FIFO with depth of 4 entries
- asynchronous clocking scheme for Register and Protocol interfaces
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- visibility into TX and RX FIFOs for ease of debugging
- programmable transfer attributes on a per-frame basis:
  - 8 transfer attribute registers along with 8 extended transfer attribute registers
  - serial clock with programmable polarity and phase
  - various programmable delays
  - programmable serial frame size of 4 to 64 bits, expandable by software control: SPI frames longer than 32 bits can be supported using the continuous selection format
  - continuously held chip select capability
  - parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer
- deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- interrupt conditions:
  - End Of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame Complete (TCF)
  - Transfers due from current Command frame Complete (CMDTCF)
  - Transfer of current SPI frame Complete (SPITCF)
  - attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
  - data present in TX FIFO while CMD FIFO is empty (TFIWF)
- global interrupt request line
- modified SPI transfer formats for communication with slower peripheral devices
- power-saving architectural features
  - support for stop mode
  - support for doze mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.



- Two sources of serialized data:
  - DSPI memory-mapped register
  - Parallel input signals
  - Programmable selection of source data on bit basis
- Deserialized data provided as Parallel Output signals and as bits in a memory-mapped register
- interrupt conditions:
  - Deserialized data matches pre-programmed pattern (DDIF)
- DMA request support for following conditions: deserialized data matches pre-programmed pattern (DDIF)
- Transfer initiation conditions:
  - Continuous
  - Edge sensitive hardware trigger
  - Change in data
- Support for parallel and serial chaining of several DSPI modules inside the MCU
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics
- Continuous serial communications clock

43.1.3 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. *Figure 646* shows a system example with DMA, DSPI and external queues in system RAM.

Figure 646. DSPI with queues and DMA

43.1.4 Modes of operation

The DSPI modes of operation that can be divided into two categories:

- Module-specific modes
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes
  - External Stop mode
  - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

43.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

43.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI bus master. In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

43.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

43.1.4.4 External Stop mode

External Stop mode is used for MCU power management. The DSPI supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary it signals that the protocol clock to the DSPI module may be shut off.

43.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

43.2 DSPI signal description

This section provides the DSPI signals description.

Table 698 lists the signals that may connect off chip depending on device implementation.

Table 698. DSPI signal description

Signal	Description	I/O
PCS0/ $\overline{SS}$	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[1:3]	Master mode: Peripheral Chip Select 1–3 Slave mode: Unused	O
PCS4/ $\overline{MTRIG}$	Master mode: Peripheral Chip Select 4 Slave mode: Master Trigger	O
PCS5/ $\overline{PCSS}$	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[6:7]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O

43.2.1 PCS0/$\overline{SS}$ — Peripheral Chip Select 0 / Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low $\overline{SS}$ signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

43.2.2 PCS[1:3] — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

43.2.3 PCS4/$\overline{MTRIG}$ — Peripheral Chip Select 4 / Master Trigger

In master mode, PCS4 is a Peripheral Chip Select output signal.

In slave mode, the active low $\overline{MTRIG}$ is an output trigger signal that indicates that a change in data to be serialized has occurred. The $\overline{MTRIG}$ pulse is four protocol clock cycles in duration. If the DSPI is in slave mode and the MTO is disabled, the PCS4/$\overline{MTRIG}$ signal is unused.

43.2.4 PCS5/$\overline{PCSS}$ — Peripheral Chip Select 5 / Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{PCSS}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

43.2.5 PCS[6:7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

43.2.6 SIN — Serial Input

SIN is a serial data input signal.

43.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

43.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

43.2.9 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPI*x*_POPR also results in a transfer error.

Note: For the chip-specific implementation details of this module's registers, see Chapter 7: Device configuration: Section 7.9.2.3: DSPI registers.

43.2.9.1 DSPI Module Configuration Register (DSPI*x*_MCR)

The DSPI*x*_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Figure 647. DSPI Module Configuration Register (DSPI*x*_MCR)

Table 700. DSPI*x*_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2:3 DCONF	DSPI Configuration Selects among the different configurations of the DSPI. 00 SPI 01 Reserved 10 Reserved 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/$\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS[5] is used as the Peripheral Chip Select[5] signal. 1 PCS[5]/$\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8 PCSIS7	Peripheral Chip Select 7 Inactive State Determines the inactive state of PCS7 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS7 is low. 1 The inactive state of PCS7 is high.
9 PCSIS6	Peripheral Chip Select 6 Inactive State Determines the inactive state of PCS6 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS6 is low. 1 The inactive state of PCS6 is high.

Table 700. DSPI*x*_MCR field descriptions (continued)

Field	Description
10 PCSIS5	Peripheral Chip Select 5 Inactive State Determines the inactive state of PCS5 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS5 is low. 1 The inactive state of PCS5 is high.
11 PCSIS4	Peripheral Chip Select 4 Inactive State Determines the inactive state of PCS4 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS4 is low. 1 The inactive state of PCS4 is high.
12 PCSIS3	Peripheral Chip Select 3 Inactive State Determines the inactive state of PCS3 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS3 is low. 1 The inactive state of PCS3 is high.
13 PCSIS2	Peripheral Chip Select 2 Inactive State Determines the inactive state of PCS2 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS2 is low. 1 The inactive state of PCS2 is high.
14 PCSIS1	Peripheral Chip Select 1 Inactive State Determines the inactive state of PCS1 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS1 is low. 1 The inactive state of PCS1 is high.
15 PCSIS0	Peripheral Chip Select 0 Inactive State Determines the inactive state of PCS0 when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCS0 is low. 1 The inactive state of PCS0 is high.
16 DOZE	Doze Enable Provides support for an externally controlled Doze mode power-saving mechanism. 0 Doze mode has no effect on DSPI. 1 Doze mode disables DSPI.

Table 700. DSPI*x*_MCR field descriptions (continued)

Field	Description
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI effectively putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 1. When DSPI is used in Slave Mode, it is recommended to leave this bit set to '0', since a slave does not have control over master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (both TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO and the CMD FIFO. Writing a '1' to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.
21 CLR_RXF	Flushes the RX FIFO Writing a '1' to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22:23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
24:27	Reserved This read-only bitfield is reserved and always has the value zero.

Table 700. DSPI*x*_MCR field descriptions (continued)

Field	Description
28 XSPI	Extended SPI Mode This bit enables usage of CTARE (Command and Transfer Attribute Register Extended) Registers. CTARE registers allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled which allows the user to send multiple Data Frames using a single Command Frame. When MCR[DIS_TXF] is asserted, the Extended SPI Mode cannot be used to transmit SPI frames which are more than 16 bits in size. 0 Normal SPI Mode. Frame size can be up to 16 bits. Command Cycling is not available in this mode. 1 Extended SPI Mode. Up to 32-bit SPI Frames along with Command Cycling Enabled
29 FCPCS	Fast Continuous PCS Mode This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR. The firmware should select appropriate masks when providing continuous frames via the PUSHR. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers.

43.2.9.2 DSPI Transfer Count Register (DSPI*x*_TCR)

The DSPI*x*_TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the DSPI is in the Running state.

Figure 648. DSPI Transfer Count Register (DSPI*x*_TCR)

Table 701. DSPI*x*_TCR field descriptions

Field	Description
0:15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the DSPI makes. The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16:31	Reserved This read-only bitfield is reserved and always has the value zero.

43.2.9.3 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI*x*_CTAR*n*)

CTARs are used to define different transfer attributes. Do not write to the CTARs while the DSPI is in the Running state.

In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the DSPI is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTARs is used. When the DSPI is configured as an SPI bus slave, the CTAR0 register is used.

Figure 649. DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI*x*_CTAR*n*)

Table 702. DSPI*x*_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in *Table 703*. See the BR field description for details on how to compute the baud rate. Refer to *Table 703* for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid FMSZ field value is 3.There is a constraint on the minimum allowable Frame size, which depends on the Register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. Min. Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol Clock Frequency f_r = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by (PBR x BR) / (1 + DBR) However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'f_p' can be equal to, less than or greater than 'f_r' purely based on user requirement.

Table 702. DSPI*x*_CTAR*n* field descriptions (continued)

Field	Description
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to '1'. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8:9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer to *Section 43.4.3.2: PCS to SCK delay (t_{CSC})* for more details. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10:11 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12:13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer to *Section 43.4.3.4: Delay after transfer (t_{DT})* for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.

Table 702. DSPI*x*_CTAR*n* field descriptions (continued)

Field	Description
14:15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16:19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_p) \times PCSSCK \times CSSCK$ 0000 Delay scaler value = 2 0001 Delay scaler value = 4 0010 Delay scaler value = 8 0011 Delay scaler value = 16 0100 Delay scaler value = 32 0101 Delay scaler value = 64 0110 Delay scaler value = 128 0111 Delay scaler value = 256 1000 Delay scaler value = 512 1001 Delay scaler value = 1024 1010 Delay scaler value = 2048 1011 Delay scaler value = 4096 1100 Delay scaler value = 8192 1101 Delay scaler value = 16384 1110 Delay scaler value = 32768 1111 Delay scaler value = 65536 Refer to *Section 43.4.3.2: PCS to SCK delay (t_{CSC})* for more details.
20:23 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_p) \times PASC \times ASC$ See Delay Scaler Encoding table in CTAR*n*[CSSCK] bit field description for scaler values. Refer to *Section 43.4.3.3: After SCK delay (t_{ASC})* for more details.

Table 702. DSPI*x*_CTAR*n* field descriptions (continued)

Field	Description
24:27 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_p) \times PDT \times DT$ See Delay Scaler Encoding table in CTAR*n*[CSSCK] bit field description for scaler values.
28:31 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = $(f_p/PBR) \times [(1+DBR)/BR]$ 0000 Baud rate scaler = 2 0001 Baud rate scaler = 4 0010 Baud rate scaler = 6 0011 Baud rate scaler = 8 0100 Baud rate scaler = 16 0101 Baud rate scaler = 32 0110 Baud rate scaler = 64 0111 Baud rate scaler = 128 1000 Baud rate scaler = 256 1001 Baud rate scaler = 512 1010 Baud rate scaler = 1024 1011 Baud rate scaler = 2048 1100 Baud rate scaler = 4096 1101 Baud rate scaler = 8192 1110 Baud rate scaler = 16384 1111 Baud rate scaler = 32768

Figure 650. DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI*x*_CTAR0_SLAVE)

Table 704. DSPI*x*_CTAR0_SLAVE field descriptions

Field	Description
0:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTAR0_SLAVE[FMSZ[5]], CTAR0_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as the CPHA bit is set to ‘1’. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9:31	Reserved This read-only bitfield is reserved and always has the value zero.

Table 705. DSPI*x*_CTAR1_SLAVE field descriptions

Field	Description
0:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTAR1_SLAVE[FMSZ[5]], CTAR1_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as the CPHA bit is set to ‘1’. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9:31	Reserved This read-only bitfield is reserved and always has the value zero.

43.2.9.6 DSPI Status Register (DSPI*x*_SR)

SR contains status and flag bits. The bits reflect the status of the DSPI and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear most of the flag bits in the SR by writing a '1' to them. Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Figure 652. DSPI Status Register (DSPI*x*_SR)

Table 706. DSPI*x*_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a '1' to it. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2	Reserved Write of any value has no effect; read value is always 0.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a '1' to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.

Table 706. DSPI*x*_SR field descriptions (continued)

Field	Description
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing '1' to it. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5	Reserved Write of any value has no effect; read value is always 0.
6 TFFF	Transmit FIFO Fill Flag Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer to *Section 43.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* for more details. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9	Reserved Write of any value has no effect; read value is always 0.
10 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a '1' to it. 0 No parity error. 1 Parity error has occurred.
11	Reserved Write of any value has no effect; read value is always 0.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a '1' to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.

Table 706. DSPI*x*_SR field descriptions (continued)

Field	Description
13 TFIWF	Transmit FIFO Invalid Write Flag Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full.The CMDFFF is cleared by writing a ‘1’ to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16:19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20:23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24:27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28:31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

43.2.9.7 DSPI DMA/Interrupt Request Select and Enable Register (DSPI*x*_RSER)

The DSPI*x*_RSER controls DMA and interrupt requests. Do not write to the RSER while the DSPI is in the Running state.

Figure 653. DSPI DMA/Interrupt Request Select and Enable Register (DSPI*x*_RSER)

Table 707. DSPI*x*_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable Enables the CMDFFF flag in the SR to generate a request. The CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 CMDFFF interrupts or DMA requests are disabled. 1 CMDFFF interrupts or DMA requests are enabled.
2	Reserved Write of any value has no effect; read value is always 0.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request. 0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
5	Reserved Write of any value has no effect; read value is always 0.

Table 707. DSPI*x*_RSER field descriptions (continued)

Field	Description
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the TFFF flag bit in the SR is set and the TFFF_RE bit in the RSER is set, this bit selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable The CMDTCF_RE bit enables CMDTCF flag in the SR to generate an interrupt request. 0 CMDTCF interrupt requests are disabled. 1 CMDTCF interrupt requests are enabled.
9	Reserved Write of any value has no effect; read value is always 0.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11	Reserved Write of any value has no effect; read value is always 0.
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the SR to generate an interrupt request. 0 TFIWF interrupt requests are disabled. 1 TFIWF interrupt requests are enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled 1 RFDF interrupt or DMA requests are enabled
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.

Table 707. DSPI*x*_RSER field descriptions (continued)

Field	Description
16 CMDFFF_DIRS	Command FIFO FIll DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the CMDFFF flag bit in the SR is set, and the CMDFFF_RE bit in the RSER is set, the CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
17:31	Reserved This read-only bitfield is reserved and always has the value zero.

43.2.9.8 DSPI PUSH FIFO Register In Master Mode (DSPI*x*_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO. Data written to this register is transferred to the TX FIFO and/or CMD FIFO. Eight- or sixteen-bit write accesses to the Data Field of PUSHR transfers the 16-bit Data field of PUSHR to the TX FIFO. Write accesses to the Command Field of PUSHR transfers the 16-bit Command Field of PUSHR to the CMD FIFO. The register structure is different in master and slave modes. In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In slave mode, CMD FIFO is unused and hence the 16-bit Command Field of PUSHR is reserved.

Unless Extended SPI Mode is being used, the TX FIFO and CMD FIFO must be filled simultaneously. In other words, write accesses must be given to both Data and Command fields of PUSHR for every PUSHR operation performed when MCR[XSPI] is 0. When Extended SPI Mode is disabled, since both TX FIFO and CMD FIFO are written to and read from simultaneously, they can be thought of as a single 32-bit FIFO.

When Extended SPI Mode is enabled, TX FIFO and CMD FIFO can be written independently. A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register will not update the FIFO. Hence any reads performed during Module disable mode will return the last PUSHR write performed when Module was enabled.

Figure 654. DSPI PUSH FIFO Register In Master Mode (DSPI*x*_PUSHR)

Table 708. DSPI*x*_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable Selects a Continuous Selection Format. The bit is used in SPI master mode. The bit enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame, since EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1:3 CTAS	Clock and Transfer Attributes Select Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI slave mode, CTAR0 is used. See *Chapter 7: Device configuration* to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter Clears the SPI_TCNT field in the TCR. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame will cause this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE—This bit enables parity bit transmission and parity reception check for the SPI frame. MASC—The current frame has the “after SCK” delay masked if this bit is asserted. See *Section 43.4.4.6: Fast Continuous Selection Format* for more details. **Note:** This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE - No parity bit included/checked. MASC - TASC delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - TASC delay is masked in the current frame.

Table 708. DSPI*x*_PUSHR field descriptions (continued)

Field	Description
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP—It controls the polarity of the parity bit transmitted and checked. MCSC—The next frame has the “PCS to SCK” delay masked if this bit is asserted. See *Section 43.4.4.6: Fast Continuous Selection Format* for more details. **Note:** This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - TCSC delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - TCSC delay is masked in the next frame.
8 PCS7	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[7] signal. 1 Assert the PCS[7] signal.
9 PCS6	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[6] signal. 1 Assert the PCS[6] signal.
10 PCS5	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[5] signal. 1 Assert the PCS[5] signal.
11 PCS4	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[4] signal. 1 Assert the PCS[4] signal.
12 PCS3	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[3] signal. 1 Assert the PCS[3] signal.
13 PCS2	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[2] signal. 1 Assert the PCS[2] signal.
14 PCS1	Peripheral Chip Select Selects which PCS signals are to be asserted for the transfer. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU. 0 Negate the PCS[1] signal. 1 Assert the PCS[1] signal.

16:31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

43.2.9.9 DSPI PUSH FIFO Register In Slave Mode (DSPI*x*_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO. Data written to this register is transferred to the TX FIFO. Eight or 16-bit write accesses to the Data Field of PUSHR transfers the 16-bit Data Field of PUSHR to the TX FIFO. The register structure is different in master and slave modes. In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In slave mode, CMD FIFO is unused and hence the 16-bit Command Field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

43.2.9.10 DSPI POP FIFO Register (DSPI*x*_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

43.2.9.11 DSPI Transmit FIFO Registers (DSPI*x*_TXFRn)

TXFRn provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRn registers does not alter the state of the TX FIFO. Reading DSPI*x*_TXFRn registers is invalid for a DSPI Master when being used in the Extended SPI (XSPI) Mode.

43.2.9.13 DSPI Clock and Transfer Attributes Register Extended (DSPI*x*_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame. These registers are valid only when DSPI*x*_MCR[XSPI] is set.

When the DSPI is configured as an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used. When the DSPI is configured as an SPI bus slave, the CTARE0 register is used.

Table 713. DSPI*x*_CTARE*n* field descriptions

Field	Description
15 FMSZE	Frame Size Extended This field is valid only when DSPI*x*_MCR[XSPI] is set. This field concatenated with DSPI*x*_CTAR[FMSZ] defines the frame size of the SPI frames to be transmitted. Effective frame size is the concatenation of {DSPI*x*_CTAR[FMSZ], DSPI*x*_CTARE[FMSZE]} plus 1. 0 Default Mode. Up to 16-bit SPI frames can be transferred. 1 Up to 32-bit SPI frames can be transferred. Each frame transfer will be a result of 2 TX FIFO Pops.
21:31 DTCP	Data Transfer Count Preload This field is valid only when DSPI*x*_MCR[XSPI] is set. This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame that selected this DSPI*x*_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is ‘1’.

43.2.9.14 DSPI Status Register Extended (DSPI*x*_SREX)

The DSPI*x*_SREX contains status fields. The fields reflect the status of the DSPI and indicate the occurrence of events. This register is not writable.

Table 714. DSPI*x*_SREX field descriptions

Field	Description
24:27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28:31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

43.3 Register classification for safety

The registers of this module are classified as per safety requirements as follows:

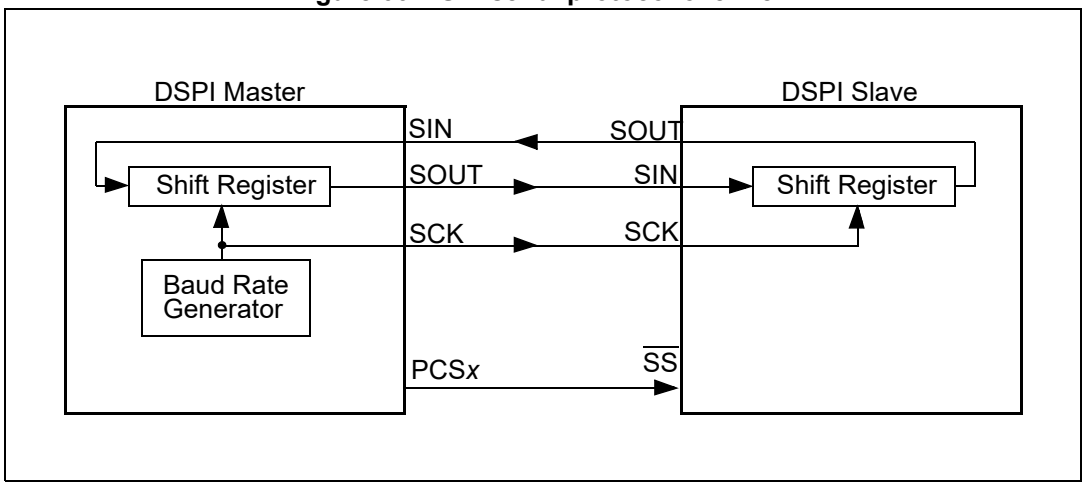
- **Safety Critical:** There are no safety critical registers in this module.
- **Safety Relevant:** The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU. The registers containing these fields must be protected by periodic CRC or equivalent check implemented at chip level. The following register bits/fields are classified in this category:
  - DSPI Module Configuration Register (DSPI*x*_MCR)
  - DSPI Transfer Count Register (DSPI*x*_TCR)
  - DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI*x*_CTAR*n*)
  - DSPI Clock and Transfer Attributes Extended Register (In Master Mode) (DSPI*x*_CTARE*n*)
  - DSPI DMA/Interrupt Request Select and Enable Register (DSPI*x*_RSER)
  - DSPI PUSH FIFO Register In Master Mode (DSPI*x*_PUSHR) [0:15]
- **Safety Latent:** The register bits/fields in this category should be protected by LBIST at chip level. The following register bits/fields are classified in this category:
  - DSPI Status Register (DSPI*x*_SR) [0:15] (for stuck at 0)
  - DSPI Status Register Extended (DSPI*x*_SREX) [0:8] (for stuck at 0)
- **Non-Safety:** All other registers and bits fall in this category.

43.4 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

SPI — DSPI operates as a basic SPI or a queued SPI.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI configuration. See *Section 43.2.9.1: DSPI Module Configuration Register (DSPIx_MCR)* for the DSPI configuration values.



The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command. The Extended SPI Mode (DSPI*x*_MCR[XSPI]) further allows the usage of CTARE*n* (CTAR*n* Extended) registers which allows the user to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

See DSPI Clock and Transfer Attributes Registers for information on the fields of the CTARs.

See DSPI Clock and Transfer Attributes Registers Extended for information on the fields of the CTARE registers.

Typical master to slave connections are shown in *Figure 661*. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the TCF bit in the SR is set to indicate a completed transfer.

Figure 661. SPI serial protocol overview

Generally more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to *Chapter 7: Device configuration* for the number of PCS signals used in this MCU.

43.4.1 Start and Stop of DSPI transfers

The DSPI has two operating states: STOPPED and RUNNING. The states are independent of DSPI configuration. The default state of the DSPI is STOPPED. In the STOPPED state no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results. In the RUNNING state serial transfers take place.

The TXRXS bit in the SR indicates what state the DSPI in. The bit is set if the module in RUNNING state.

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

43.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The DSPI is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer. The received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI. The FIFO buffers operation is described in *Section 43.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*, *Section 43.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* and *Section 43.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism*. The interrupt and DMA request conditions are described in *Section 43.4.8*.

The SPI configuration supports two block-specific modes —master mode and slave mode. In master mode, the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry. In slave mode, the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

43.4.2.1 Master Mode

In SPI master mode the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals. The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI master mode, each SPI frame to be transmitted has a command associated with it allowing for transfer attribute control on a frame by frame basis. In Extended SPI Master Mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI Mode allows for larger frame sizes of up to 32 bits.

43.4.2.2 Slave Mode

In SPI slave mode the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase and

frame size must be set for successful communication with a SPI master. The SPI slave mode transfer attributes are set in the CTAR0 and CTARE0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

43.4.2.3 FIFO Disable Operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately; setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO Disable mechanisms are transparent to the user and to host software; Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO is disabled (CMD FIFO is also disabled), the TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in SR, SREX behave as if there is a one-entry FIFO but the contents of the TXFR registers, TXNXTPTR and CMDNXTPTR are undefined. Likewise, when the RX FIFO is disabled, the RFDF, RFOF and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

43.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO are used separately. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

43.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. Writing a ‘1’ to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See *Section 43.4.8.2: Transmit FIFO Fill interrupt or DMA request* for details.

The DSPI ignores attempts to push data to a full TX FIFO, the state of the TX FIFO does not change and no error condition is indicated.

43.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. When Extended SPI Mode (DSPI*x*_MCR[XSPI]) is enabled, if the frame size of SPI Data to be transmitted is more than 16 bits, then it causes two Data entries to be popped from TX FIFO simultaneously which are transferred to the shift register. The first of the two popped entries forms the 16 LSB bits of the SPI frame. Such an operation also causes TX FIFO Counter to decrement by two. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave's DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See *Section 43.4.8.7: Transmit FIFO Underflow interrupt request* for details.

43.4.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. When Extended SPI Mode (DSPI*x*_MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together. When Extended SPI Mode (DSPI*x*_MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPI*x*_MCR[XSPI]) is disabled, every CMDFIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPI*x*_MCR[XSPI]) is enabled, every CMDFIFO entry can have multiple TXFIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives FMSZ and FMSZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO are used separately. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

43.4.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

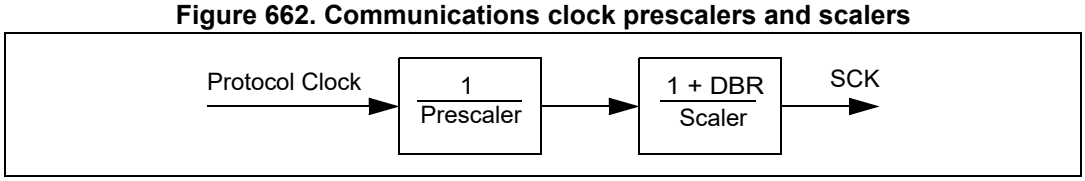
The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

43.4.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

43.4.2.6.2 Draining the RX FIFO



Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a ‘1’ to it.

43.4.3 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. *Figure 662* shows conceptually how the SCK signal is generated.

Figure 662. Communications clock prescalers and scalers

43.4.3.1 Baud rate generator

The baud rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. *Table 715* shows an example of how to compute the baud rate.

Table 715. Baud rate computation example

f_p	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note: The clock frequencies mentioned in Table 715 are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

43.4.3.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See *Table 716* for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*n* registers select the PCS to SCK delay by the formula in the CSSCK field description. *Table 716* shows an example of how to compute the PCS to SCK delay.

Table 716. PCS to SCK delay computation example

f_p	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

Note: The clock frequency mentioned in Table 716 is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

43.4.3.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. See *Table 717* for an illustration of the After SCK delay. The PASC and ASC fields in the CTAR*n* registers select the After SCK Delay by the formula in the ASC field description. *Table 717* shows an example of how to compute the After SCK delay.

Table 717. After SCK delay computation example

f_p	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

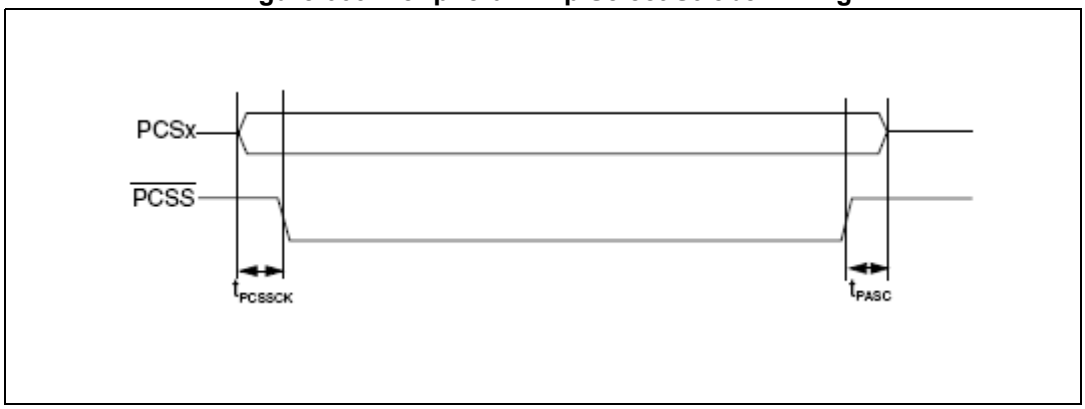
Note: The clock frequency mentioned in Table 717 is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

43.4.3.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See *Table 718* for an illustration of the delay after transfer. the pdt and dt fields in the CTAR*n* registers select the Delay after Transfer by the formula in the DT field description. *Table 718* shows an example of how to compute the delay after transfer.

Table 718. Delay after transfer computation example

f_p	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms



Note: The clock frequency mentioned in Table 718 is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode is not enabled, the delay is fixed at 1 SCK period.

43.4.3.5 Peripheral Chip Select Strobe Enable ($\overline{PCSS}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, $\overline{PCSS}$ provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4] and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. *Figure 663* shows the timing of the $\overline{PCSS}$ signal relative to PCS signals.

Figure 663. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

Equation 26

$$t_{PCSSCK} = \frac{1}{f_P} \times PCSSCK$$

At the end of the transfer the delay between $\overline{PCSS}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

Equation 27

$$t_{PASC} = \frac{1}{f_P} \times PASC$$

Table 719 shows an example of how to compute the t_{PCSSCK} delay.

Table 719. Peripheral Chip Select Strobe Assert Computation Example

f_p	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

Table 720 shows an example of how to compute the t_{PASC} delay.

Table 720. Peripheral Chip Select Strobe Negate Computation Example

f_p	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK is enabled.

Note: The clock frequency mentioned in the preceding Table 719 and Table 720 is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

43.4.4 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

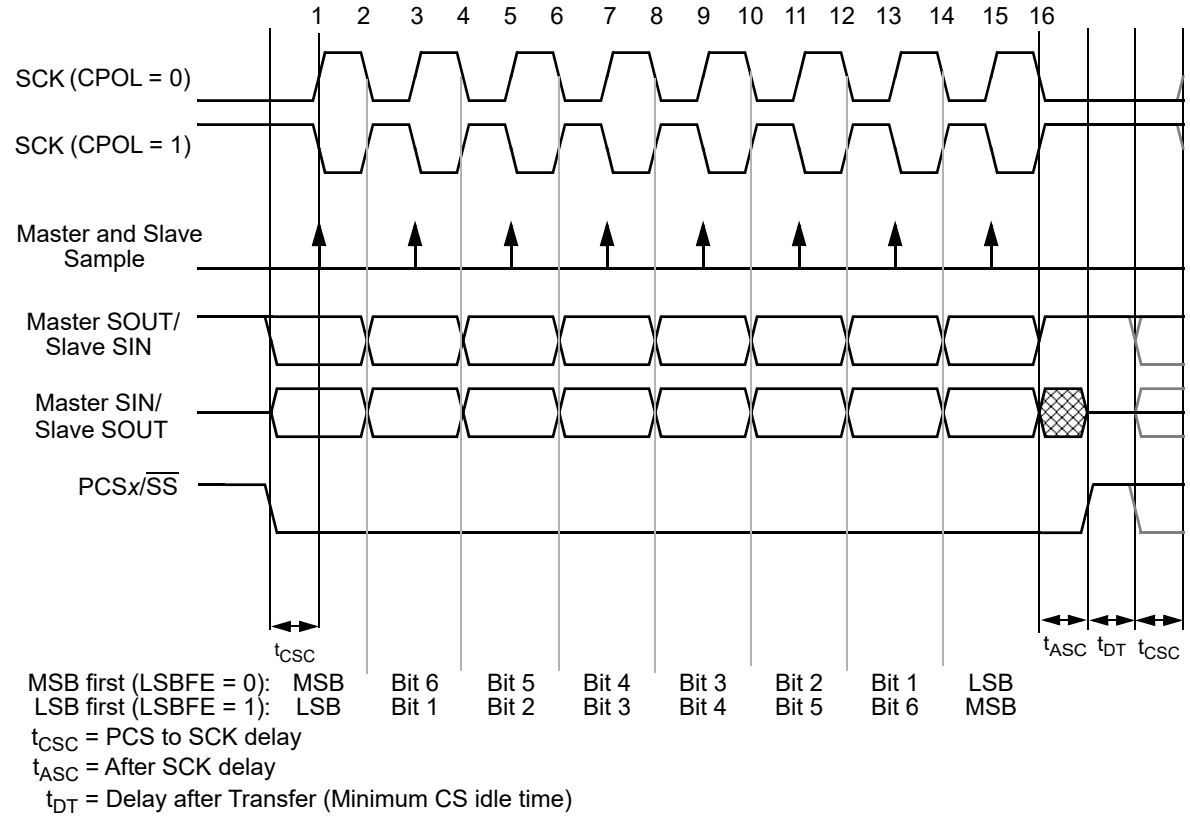
In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTAR*n*) select the polarity and phase of the serial clock, SCK.

- CPOL—Selects the idle state polarity of the SCK
- CPHA—Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0
- Classic SPI with CPHA = 1
- Modified Transfer format with CPHA = 0
- Modified Transfer format with CPHA = 1



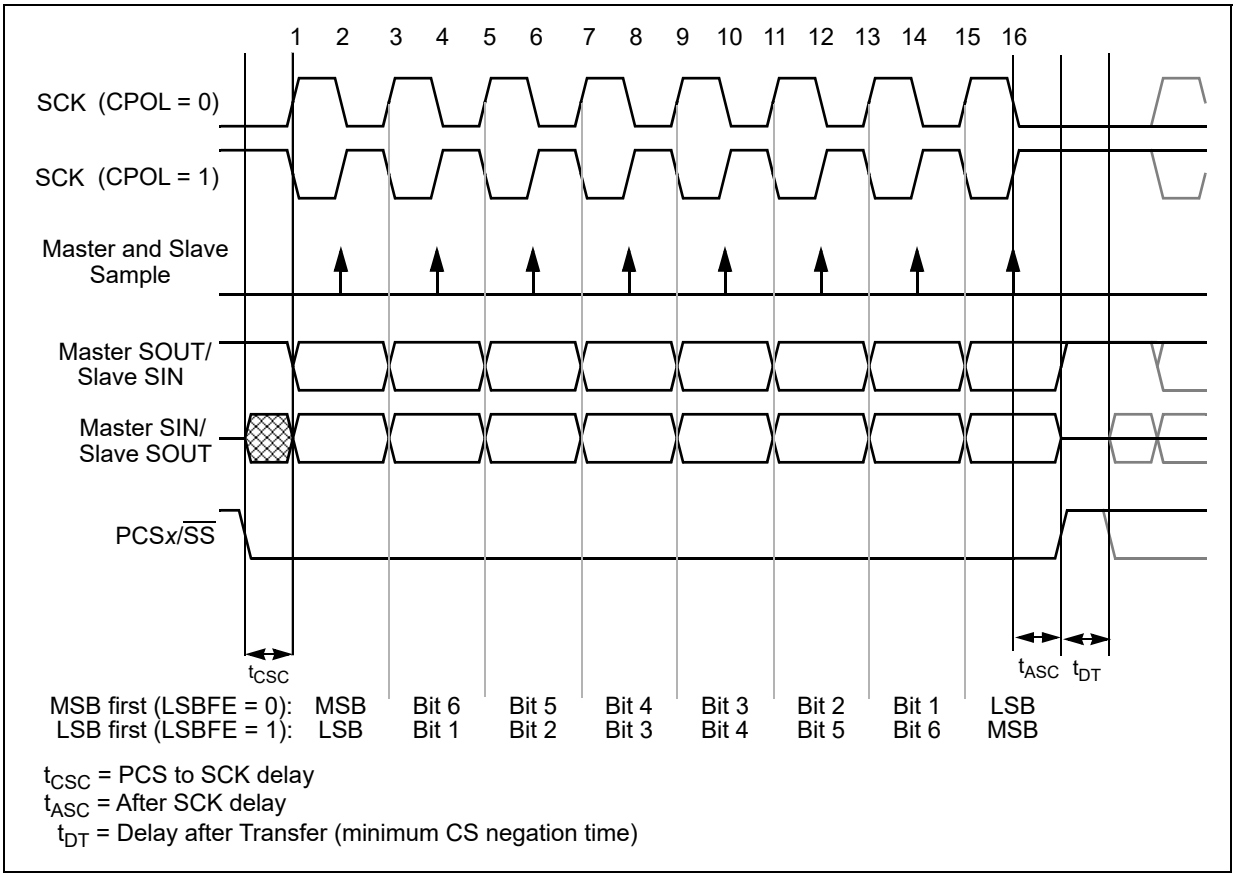
A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI configuration, the DSPI provides the option of keeping the PCS signals asserted between frames. See *Section 43.4.4.5: Continuous Selection Format* for details.

43.4.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in *Figure 664* is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 664. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)



The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

43.4.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in *Figure 665* is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 665. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

43.4.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_sl} – data hold time on slave data input
- t_p – protocol clock period

Figure 666 shows the modified transfer format for CPHA = 0 and f_p/f_{sck} = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked “SOUT of Ext Slave”, presents regular SPI slave serial output.
- Signal, marked “SOUT of DSPI Slave”, presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note: In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

Figure 666. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)

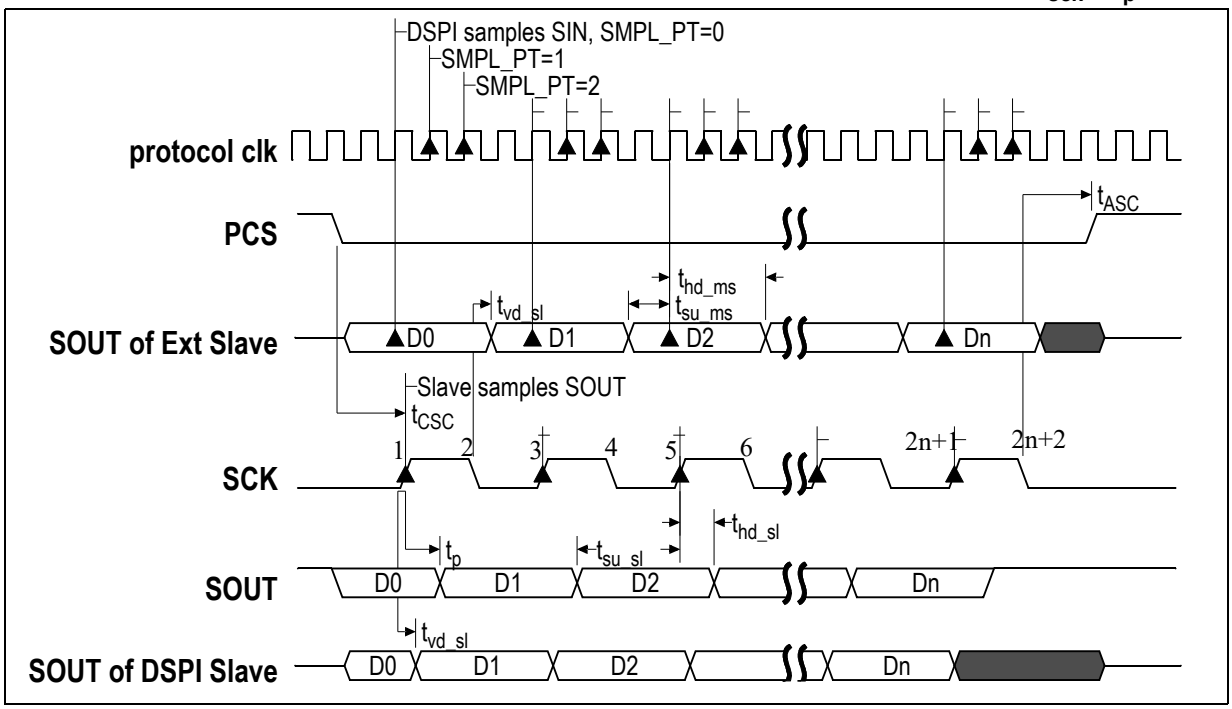


Figure 667. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

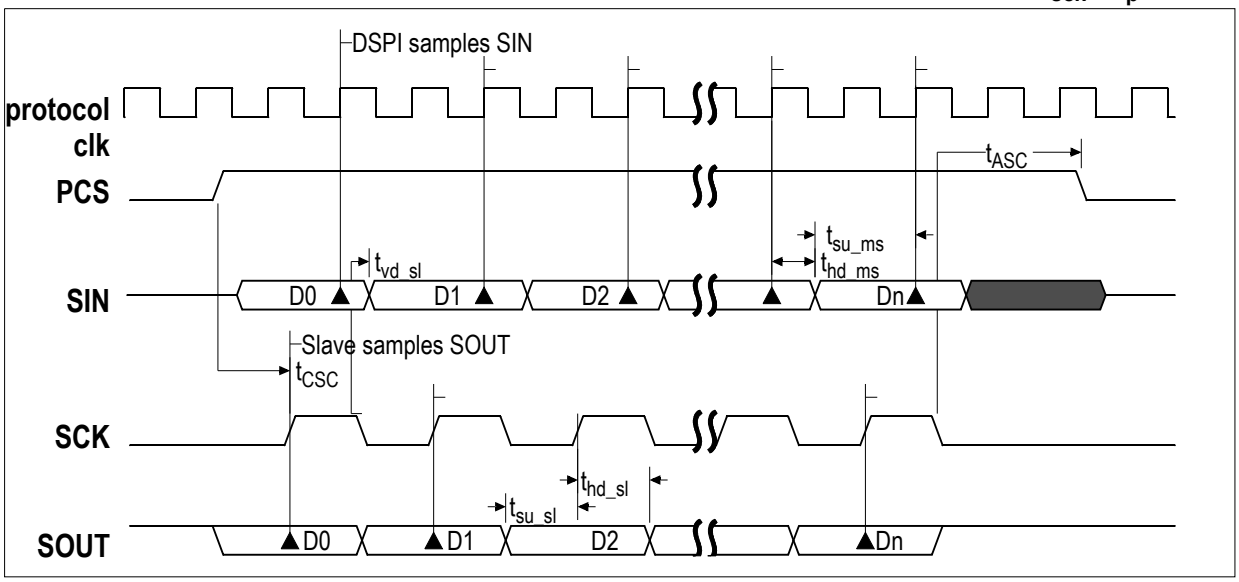

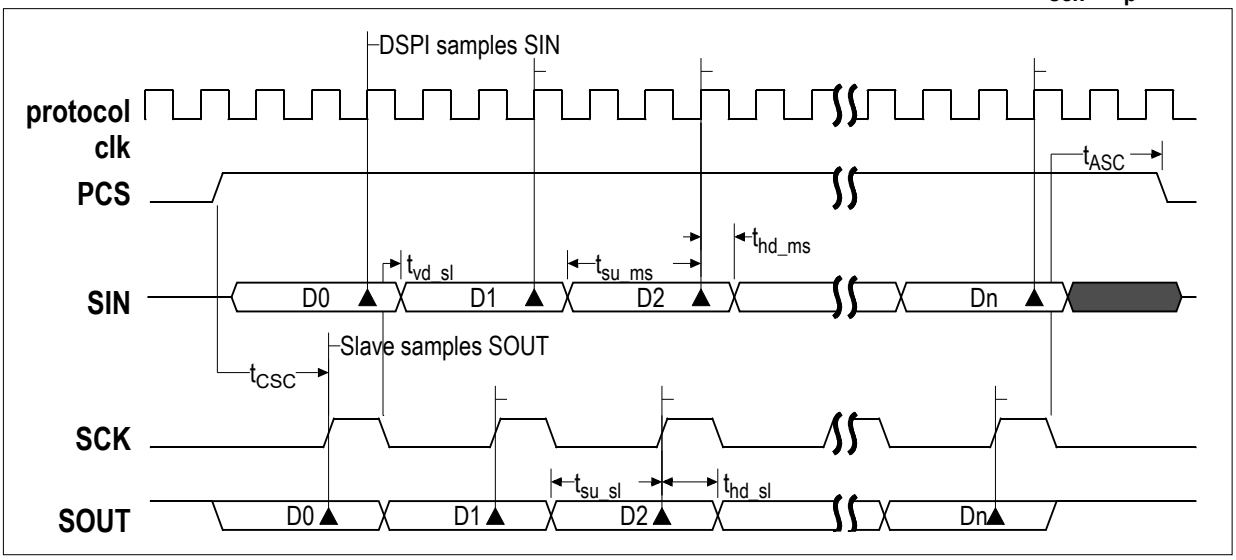

Figure 668. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

43.4.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay must be greater or equal to half of the SCK period.**

Figure 669. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

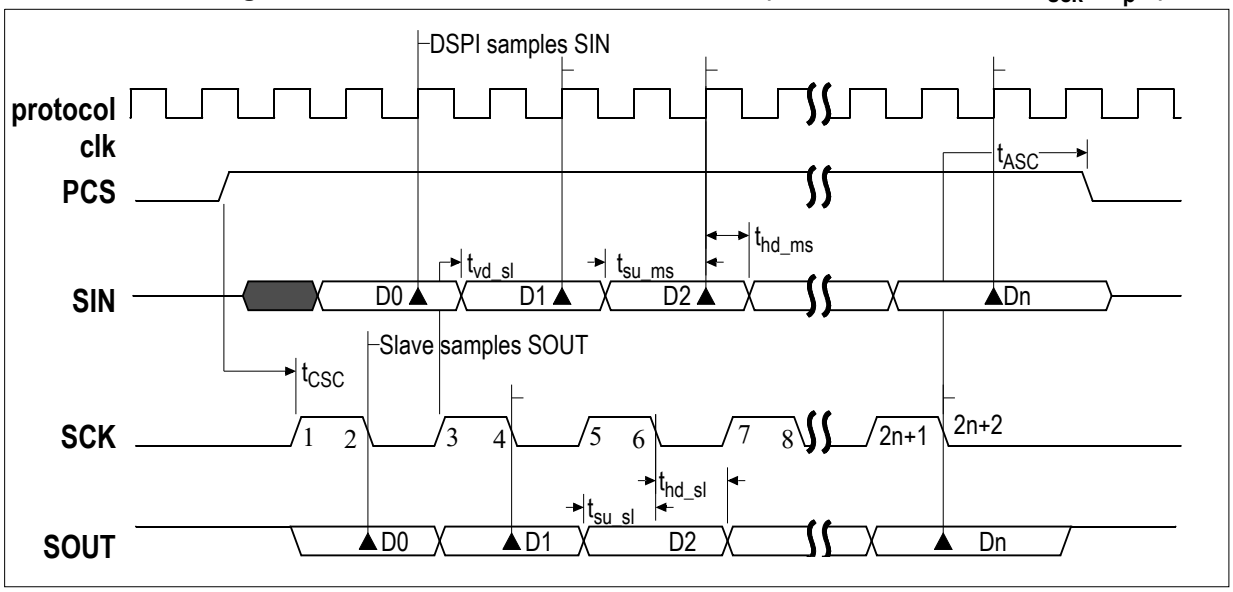

Figure 670. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)

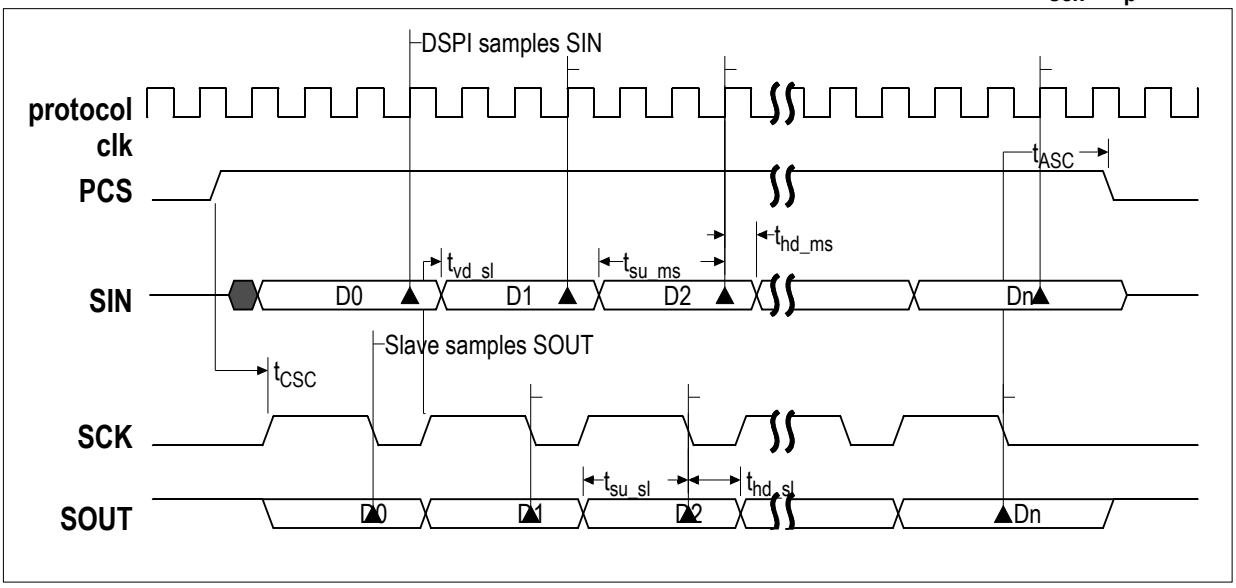

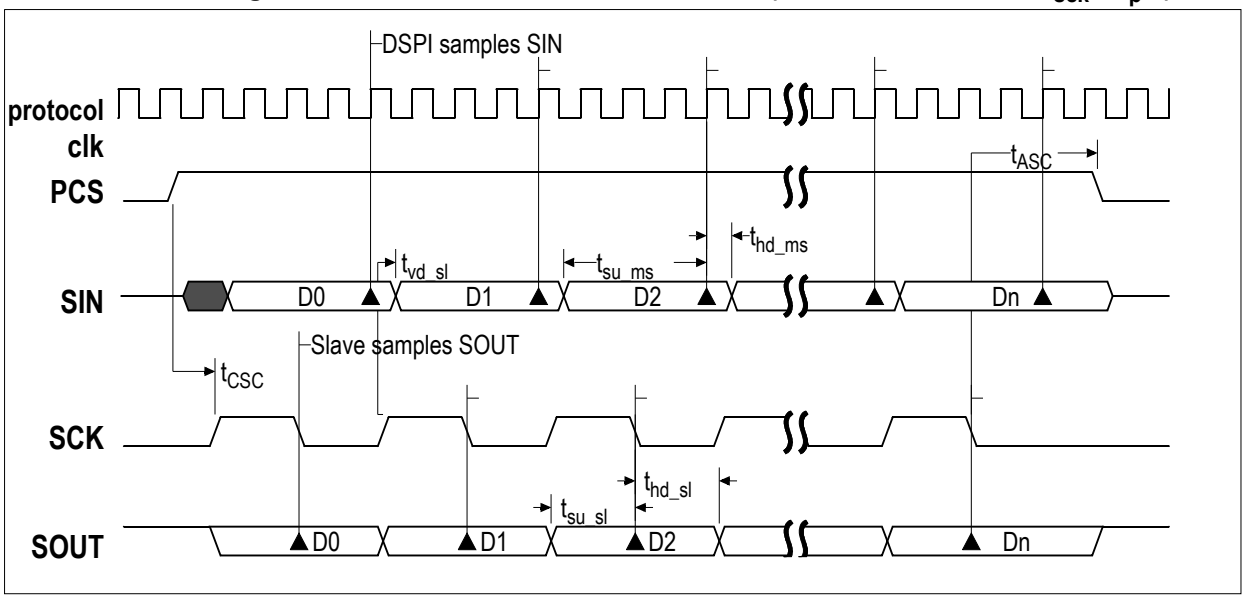

Figure 671. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

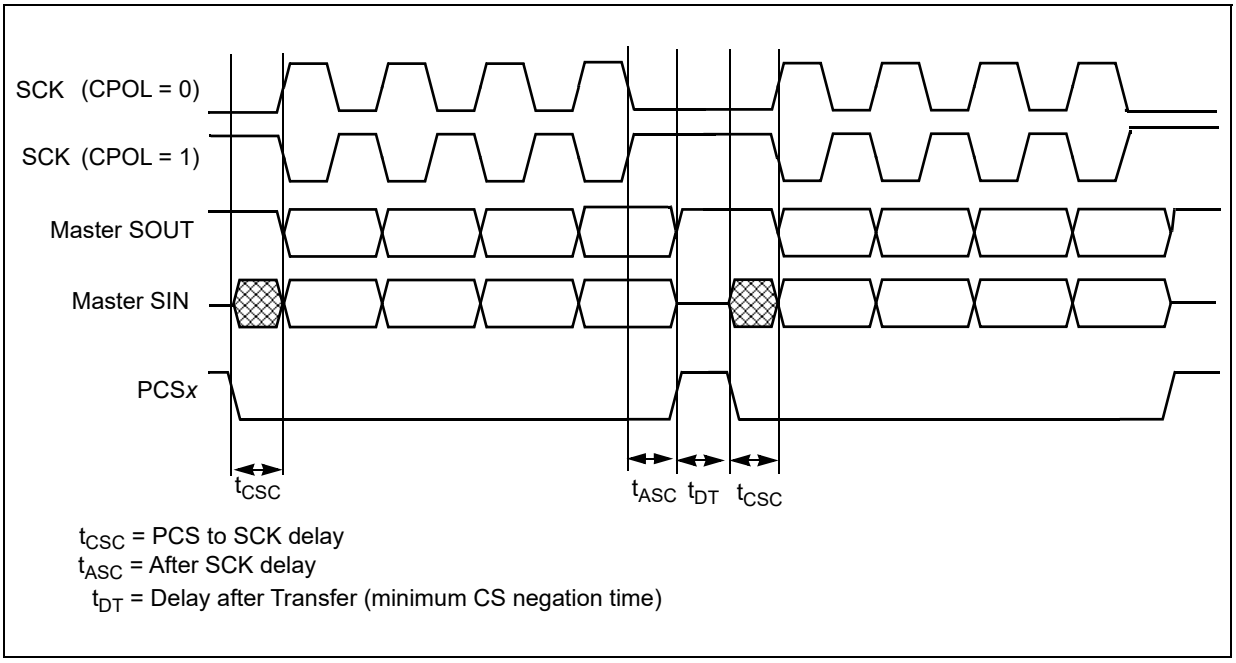
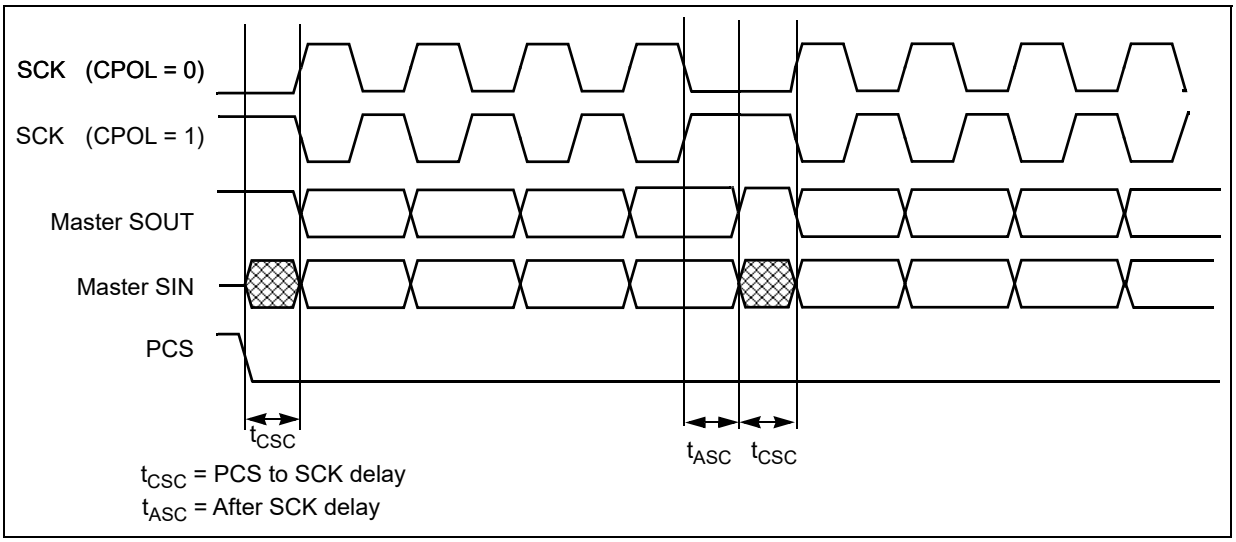


43.4.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.



The behavior of the PCS signals in the two configurations is identical so only SPI configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The timing diagram in *Figure 672* is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 672. Example of non-continuous format (CPHA = 1, CONT = 0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. *Figure 673* shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 673. Example of continuous transfer (CPHA = 1, CONT = 1)

When using DSPI with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.
- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit de-asserted (in master mode) and the user

software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCSn at end of transmission of last frame.

- The PUSHR[CONT] bit must be de-asserted before asserting MCR[HALT] bit (in master mode). This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

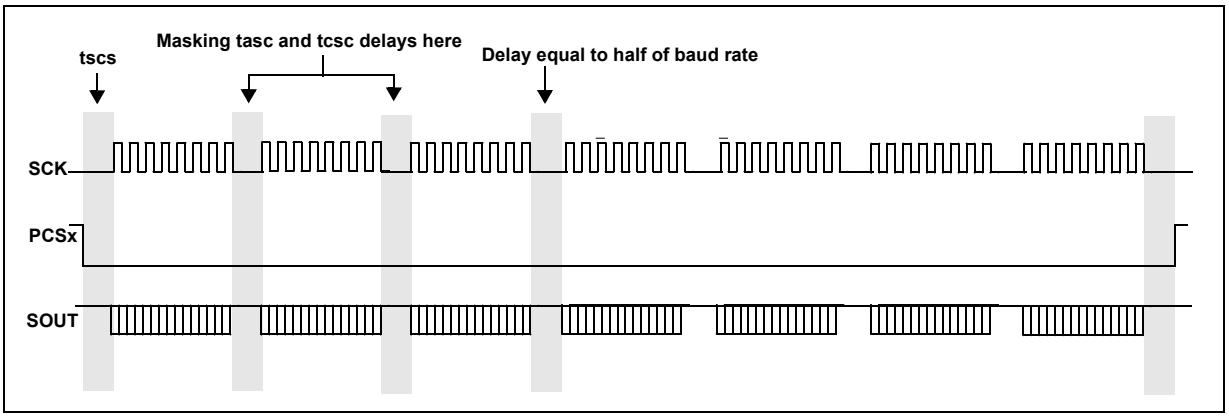
Note: You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

43.4.4.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

Note: The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled.



The Fast Continuous Selection Format is enabled by writing '1' to bit MCR[FCPCS]. When this bit is asserted, MASC and MCSC bits of the PUSHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the "After SCK" delay for the current frame.
- MCSC bit masks the "PCS to SCK" delay for the next frame.
- "After SCK" (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The "PCS to SCK" delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

Figure 674 shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

Figure 674. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

43.4.5 Continuous Serial Communications Clock

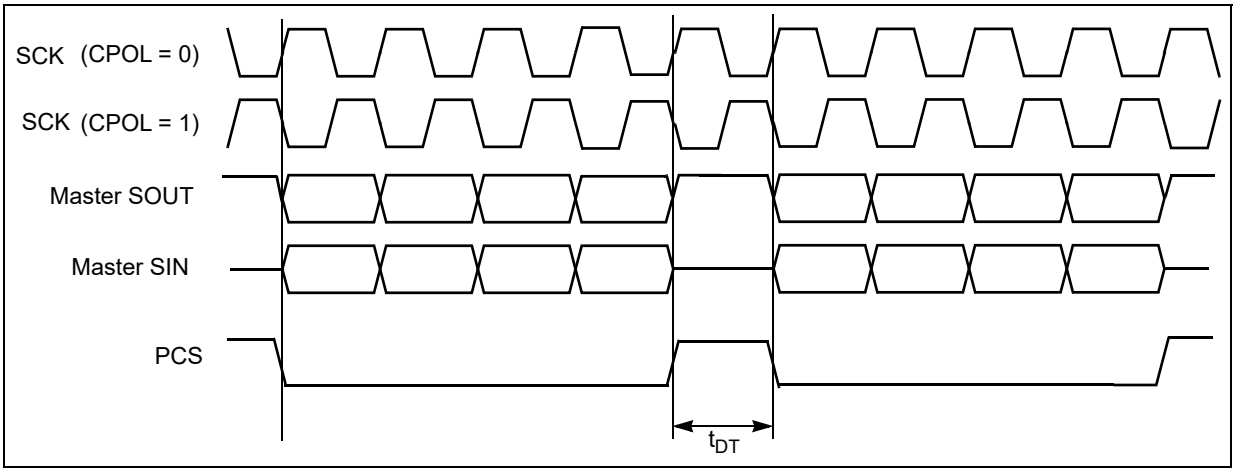
The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting bit MCR[CONT_SCKE]. Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In SPI configuration, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.



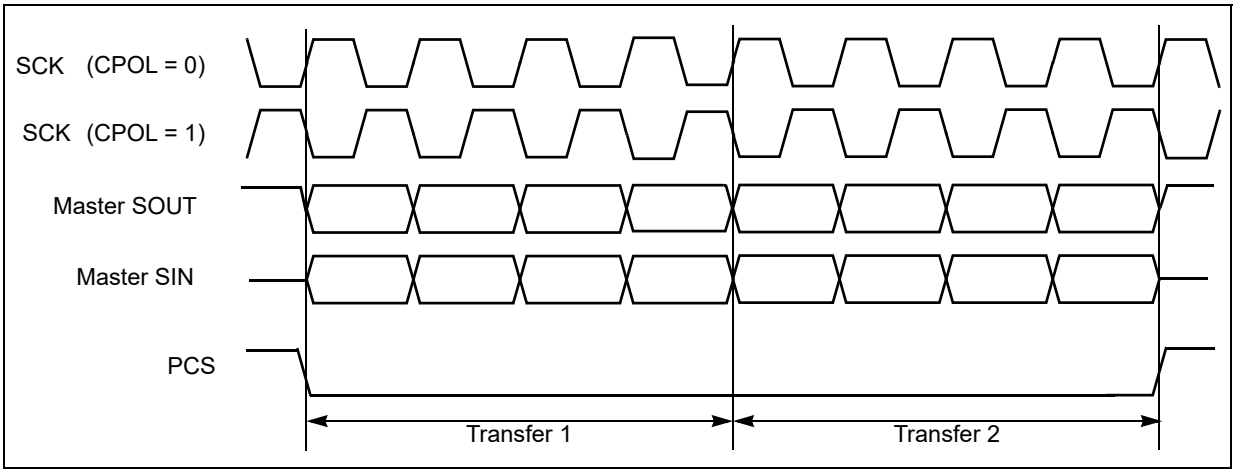
It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle.

Figure 675 is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note: When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 675. Continuous SCK timing diagram (CONT = 0)



If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to *Section 43.4.1*.
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

Figure 676 shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 676. Continuous SCK Timing Diagram (CONT = 1)

43.4.6 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

43.4.7 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programmed to stop SPI frame transmission in case of a frame reception with parity error.

43.4.7.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each subframe separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each subframe set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

43.4.8 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. *Table 721* lists these conditions.

Table 721. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

43.4.8.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and RSER[EOQF_RE] is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note: This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

43.4.8.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: TFFF flag clears automatically when DMA is used to fill TXFIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

- *Wait until TFFF = 1*

- *Write data to PUSHR using CPU.*
- *Clear TFFF by writing a '1' to its location. If TX FIFO is not full, this flag will not clear.*

43.4.8.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note: CMDFFF flag clears automatically when DMA is used to fill CMD FIFO.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

- *Wait until CMDFFF = 1*
- *Write data to Command field of PUSHR using CPU.*
- *Clear CMDFFF by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.*

43.4.8.4 Transmit FIFO Invalid Write interrupt request

The Transfer FIFO Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transfer FIFO Invalid Write Request is generated for the above condition when RSER[TFIWF_RE] is set.

43.4.8.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when RSER[TCF_RE] is set.

43.4.8.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when RSER[CMDTCF_RE] is set.

43.4.8.7 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

43.4.8.8 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The bit RSER[RFDF_DIRS] selects whether a DMA request or an interrupt request is generated.

43.4.8.9 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The bit RSER[RFOF_RE] must be set for the interrupt request to be generated.

Depending on the state of the bit MCR[ROOE], the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

43.4.8.10 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

43.4.9 Power saving features

The DSPI supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

43.4.9.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter external stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

43.4.9.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting MCR[MDIS]. The module disable mode can also be initiated by hardware. A power management block can initiate the module disable mode by asserting the DOZE mode signal while MCR[DOZE] is set.

When MCR[MDIS] is set or the DOZE mode signal is asserted while MCR[DOZE] is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible. Certain read or write operations have a different effect when

the DSPI is in the module disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Likewise, writing to the FIFO Push Register does not change the state of the TX FIFO or CMD FIFO. Clearing of the FIFOs has no effect in the module disable mode. Changes to MCR[DIS_TXF] and MCR[DIS_RXF] have no effect in the module disable mode. In the module disable mode, all status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect. Writing to the TCR during module disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the module disable mode.

43.5 Initialization/application information

This section describes how to initialize the DSPI module.

43.5.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a ‘1’ to MCR[CLR_TXF]. Flush RX FIFO by writing a ‘1’ to MCR[CLR_RXF].
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to TCR[SPI_TCNT].
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

43.5.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a ‘1’ to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

43.5.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

43.5.4 Baud rate settings

Table 722 shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Chapter 24: Clocking for the frequency used to drive this module in the device.

Table 722. Baud rate values (bps)

Baud Rate scaler values (DSPI*n*_CTAR[BR])	Baud rate divider prescaler values (DSPI*n*_CTAR[PBR])				
		2	3	5	7
	2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
	4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
	6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
	8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
	16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
	32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
	64	781 kHz	521 kHz	312 kHz	223 kHz
	128	391 kHz	260 kHz	156 kHz	112 kHz
	256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
	512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
	1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
	2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
	4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
	8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
	16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
	32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

43.5.5 Delay settings

Table 723 shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Chapter 24: Clocking for the frequency used to drive this module in the device.

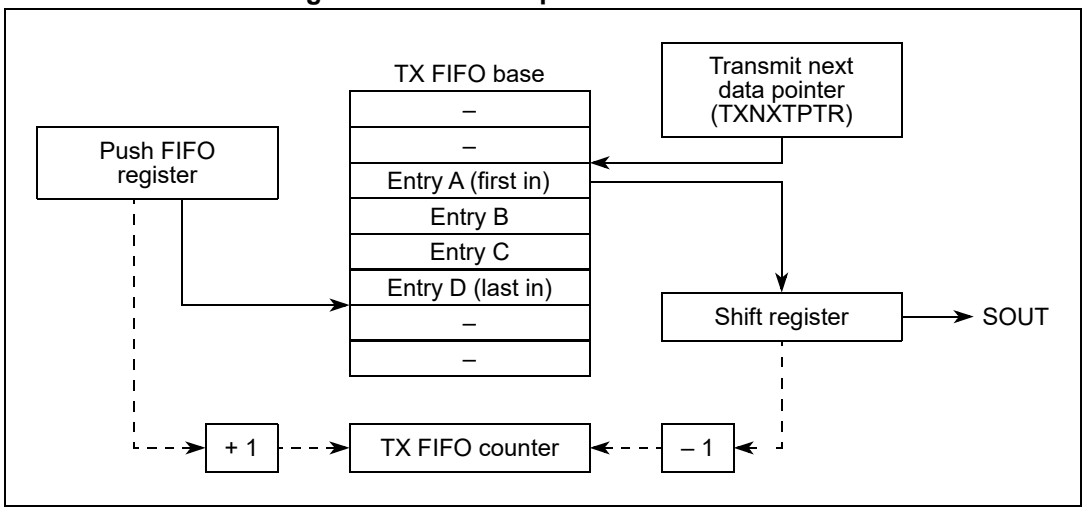


Table 723. Delay values

		Delay prescaler values (DSPI*n*_CTAR[PBR])			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

43.5.6 Calculation of FIFO pointer addresses

Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). *Figure 677* illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over to the CMD FIFO and RX FIFO. See *Section 43.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*, *Section 43.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* and *Section 43.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism* for details on the FIFO operation.

Figure 677. TX FIFO pointers and counter

43.5.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

Equation 28
First-in EntryAddress = TXFIFOBase + (4 × TXNXTPTR)

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

Equation 29
Last-in EntryAddress = TXFIFOBase + 4 × (TXCTR + TXNXTPTR – 1)mod(TXFIFOdepth)

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXTPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

43.5.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

Equation 30
First-in EntryAddress = CMDFIFOBase + (4 × CMDNXTPTR)

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

Equation 31
Last-in EntryAddress = CMDFIFOBase + 4 × (CMDCTR + CMDNXTPTR – 1)mod(CMDFIFOdepth)

CMD FIFO Base – Base address of CMD FIFO

CMDCTR – CMD FIFO Counter

CMDNXTPTR – Command Next Pointer

CMD FIFO Depth – Command FIFO depth, implementation specific

43.5.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

Equation 32
First-in EntryAddress = RX FIFOBase + (4 × POPNXTPTR)

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

Equation 33
Last-in EntryAddress = RX FIFOBase + 4 × (RXCTR + POPNXTPTR – 1)mod(RXFIFOdepth)

RX FIFO Base – Base address of RX FIFO

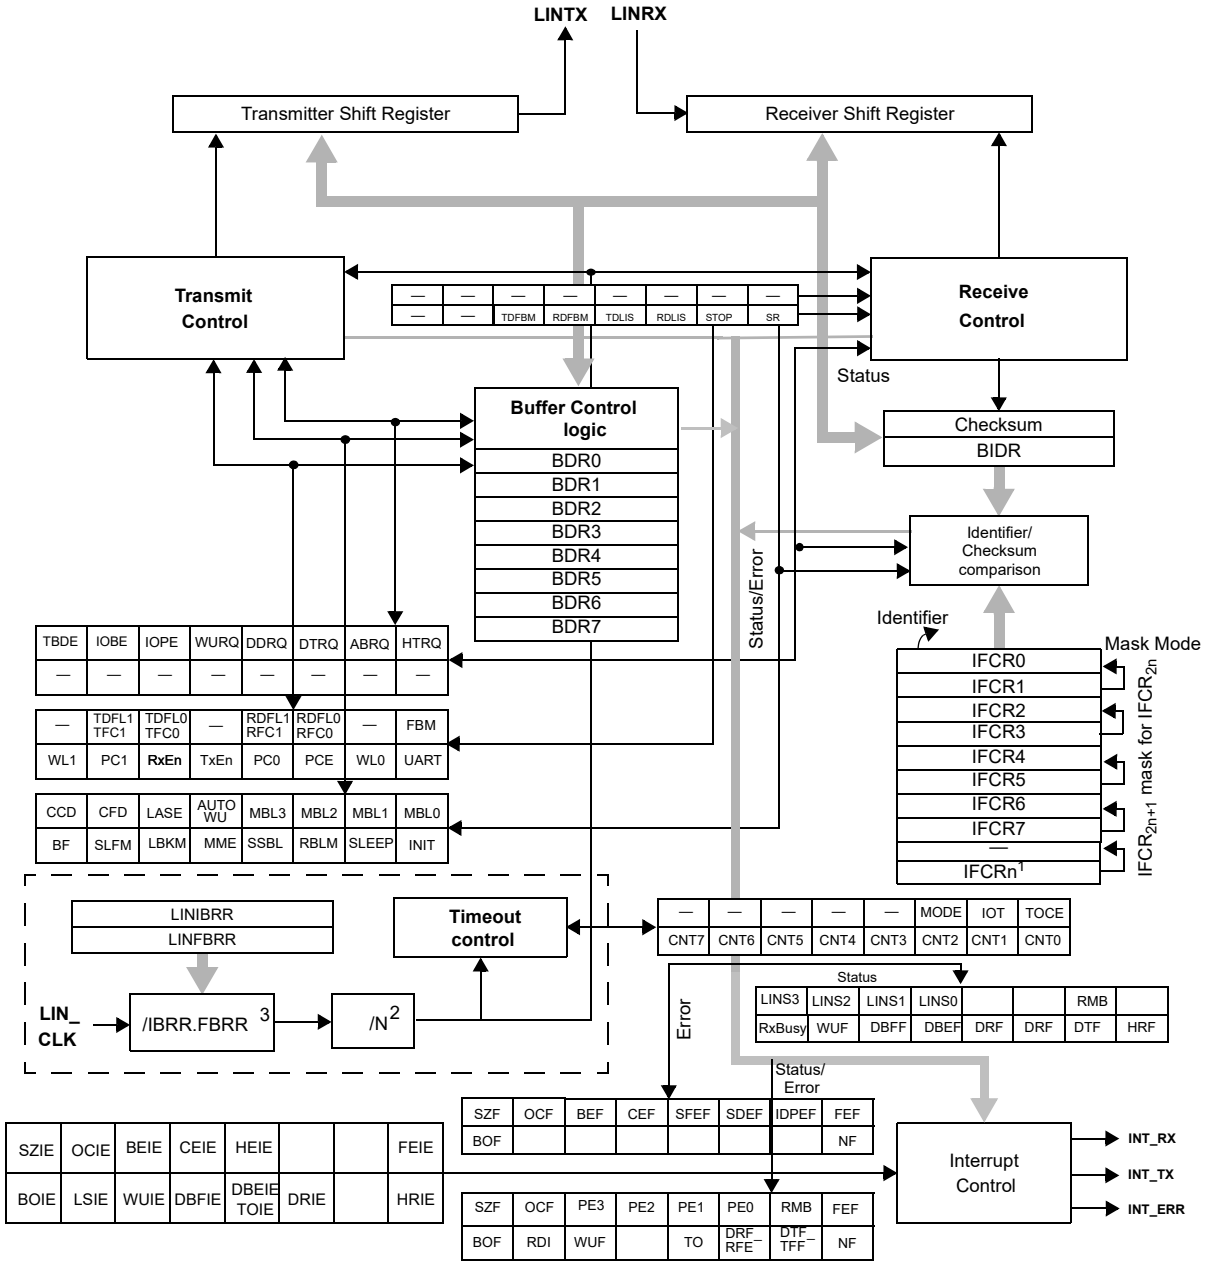
RXCTR – RX FIFO counter

POPNXTPTR – Pop Next Pointer

RX FIFO Depth – Receive FIFO depth, implementation specific

44 LINFlexD

44.1 Introduction



The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 678. Block diagram

Notes:

1. The value of n depends on the no_of_filters. Refer to the *Chapter 7: Device configuration* to see the number of filters used in this device.
2. For LIN mode N = 16 and N is programmable by user in UART mode.
3. FBRR is not usable when reduced over-sampling is enabled in UART mode.

44.2 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

44.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK $\geq$ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)

44.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers (see *Section 44.3.2.8: Baud rate generation*)
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s
  - Reduced over sampling programmable by the user
  - 3:1 majority voting for reduced over sampling of 8
- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

44.2.3 Standard features

DMA2x bus interface

44.3 Functional description

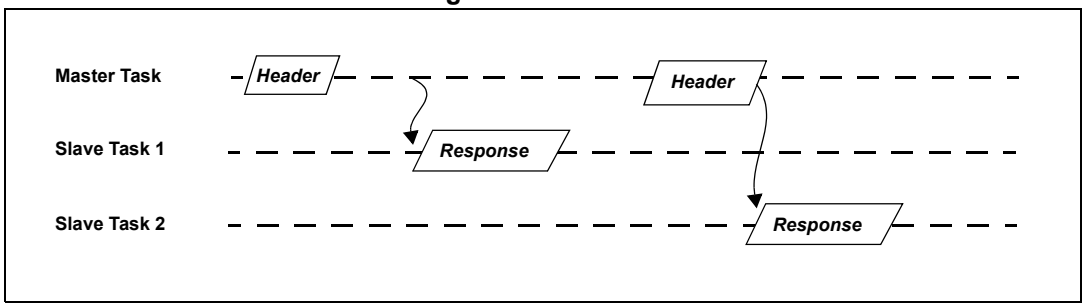
44.3.1 LIN protocol

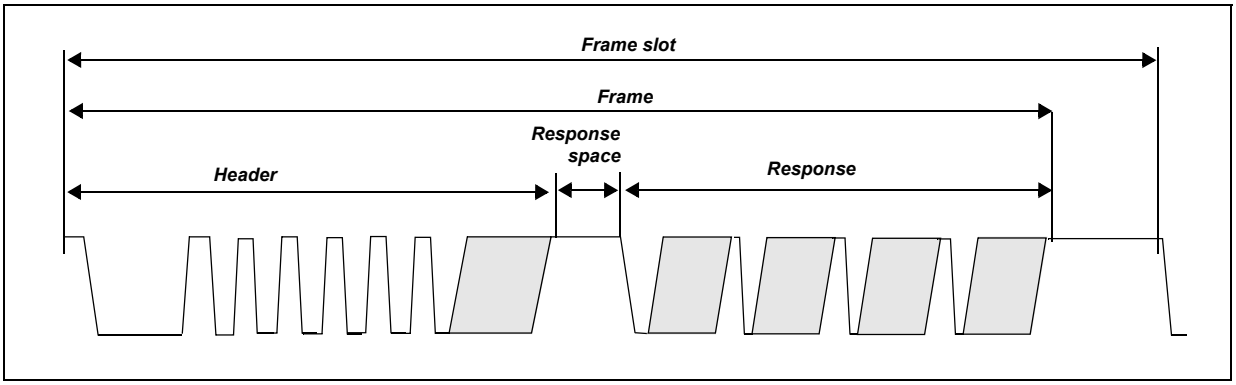
The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task - all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

44.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 679. Frames





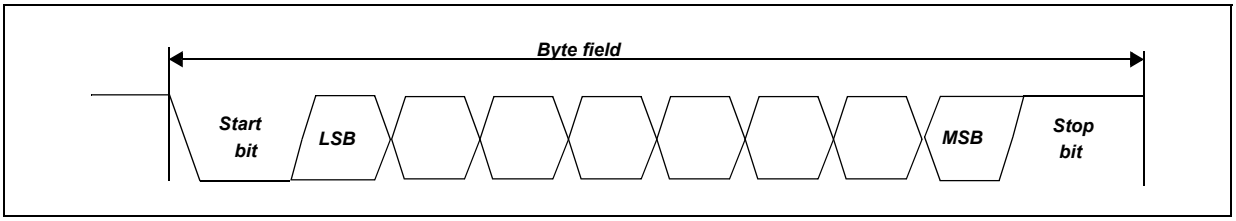


Figure 680. Structure of LIN frame

44.3.1.2 Data field

Each byte is transmitted as shown in *Figure 681*. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

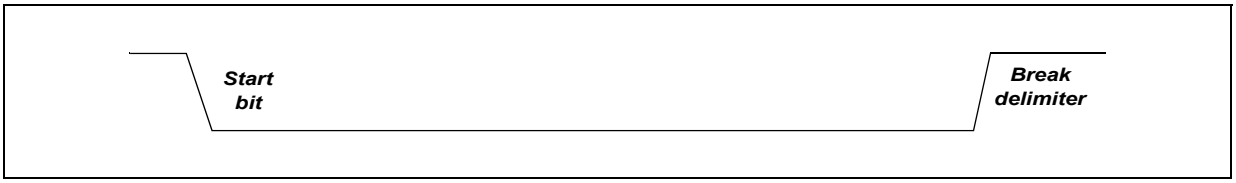

Figure 681. Structure of byte field

44.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in *Figure 682*. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

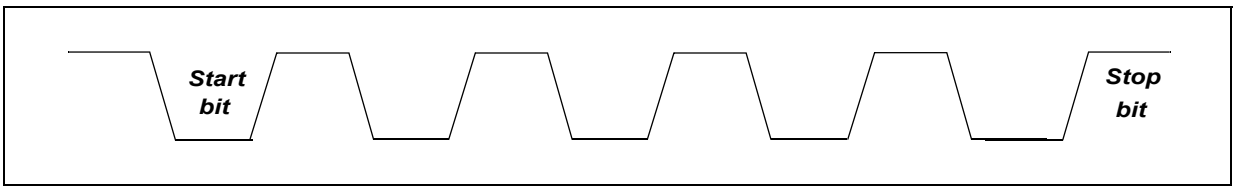

Figure 682. Break field

44.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

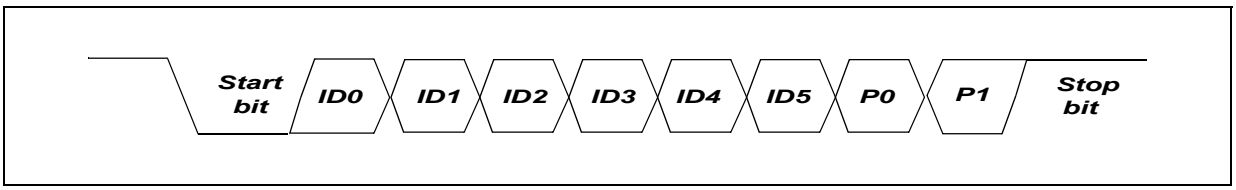

Figure 683. Sync byte field

44.3.1.5 Identifier

The Identifier field consists of two sub fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 684. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

44.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it used for communication with LIN 2.0 slaves.

44.3.2 LINFlexD features

44.3.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal,** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

44.3.2.1.1 Initialization mode (INIT)

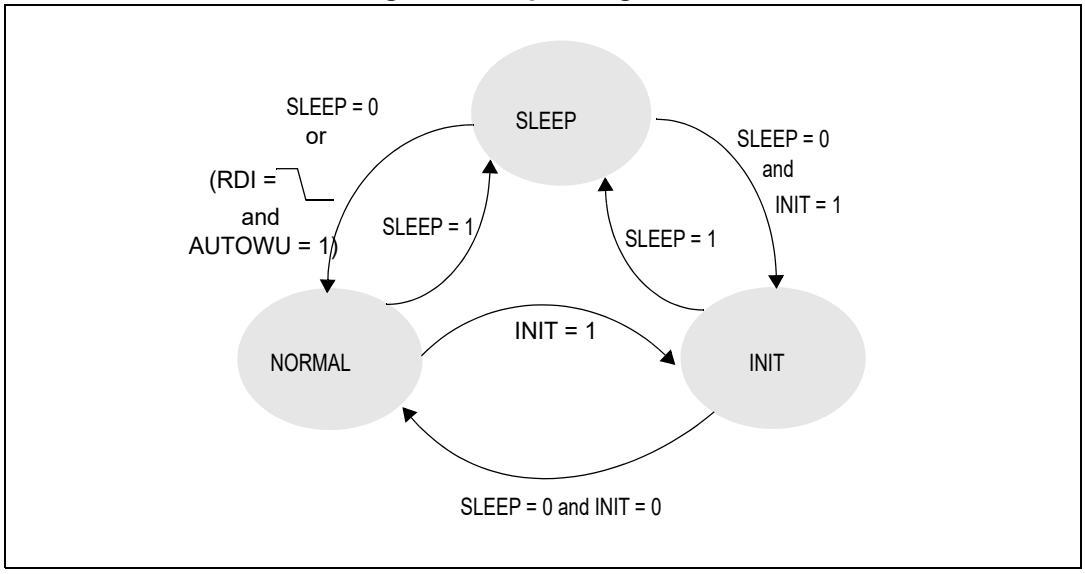
To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. Set up the baud rate registers
2. Reset the UART bit
3. Select the mode (Master or Slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

44.3.2.1.2 Normal mode (NM)



Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

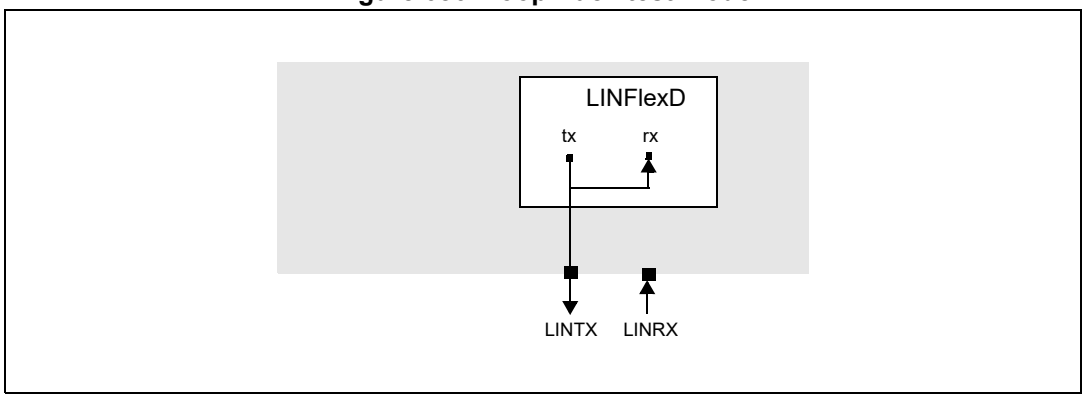
44.3.2.1.3 Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to *Section 44.3.2.10: Wakeup management*.

Figure 685. Operating modes

44.3.2.2 Test mode



44.3.2.2.1 Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and

Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

Figure 686. Loop Back test mode

44.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

44.3.2.3.1 Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

44.3.2.3.2 Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

44.3.2.3.3 Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

44.3.2.3.4 Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

44.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

44.3.2.4.1 Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

44.3.2.4.2 Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

44.3.2.5 Errors

44.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- That the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,

  or

- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

   If there is an inconsistent Sync Field error, it means that:

   D > 14.0625%

   If there is no error, it means that:

   D < 14.84375%

   If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 0)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

1. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

44.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles. Bit error is not checked during break field transmission.

Example 1

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In

this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

44.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

44.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINIER.

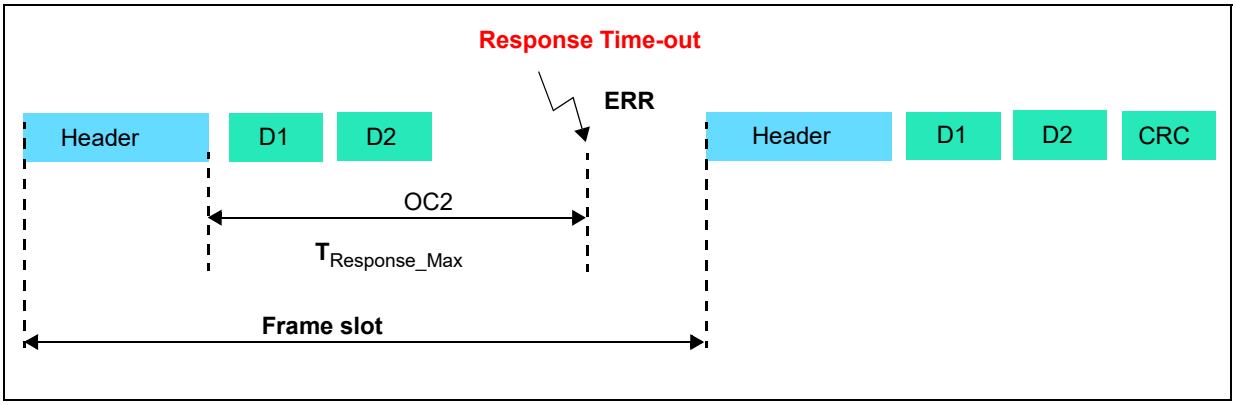
44.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

44.3.2.5.6 Timeout error

Figure 687. Incomplete response (for example, missing checksum)



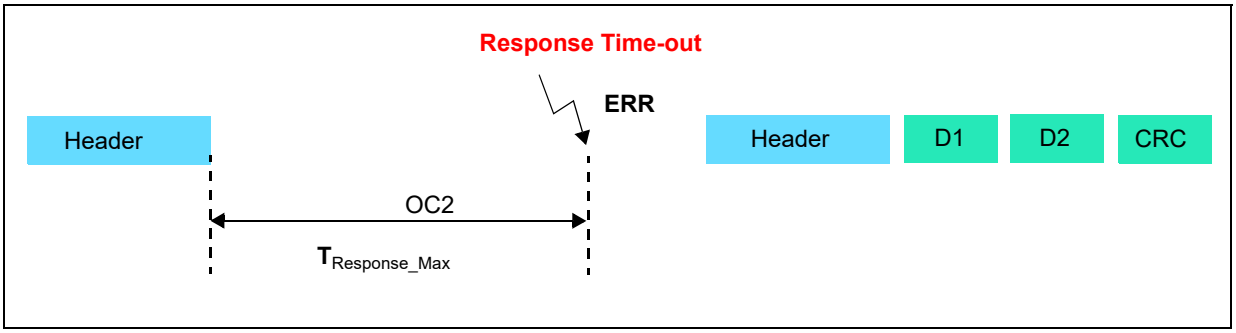


Figure 688. No response

Header timeout mechanism

- Master mode
  - ocr_2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further ocr_2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the ocr_2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the ocr_2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, ocr_2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = 1.4 × (9 × 10 bit time) and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:

    At the end of the ID, ocr_2 is loaded with 36 (maximum possible response space)

    At the end of the first_data_byte it is reloaded again according to DFL

    Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - No error on the bus and timing is correct (nominal header length).
  - An error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

    Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - Header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - Header_max = 1.4 × Header_nominal = 49 Tbit
  - Taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit.
  - If the counter starts after 11 Tbit, the HTO value is 56 – 11 = 45 Tbit

    The reset value of HTO is 45 and this register can only be programmed in slave mode.

    As response space is now included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

    The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

44.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th, and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see *Section 44.4.2.4: LIN Error Status Register (LINESR)*).

44.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

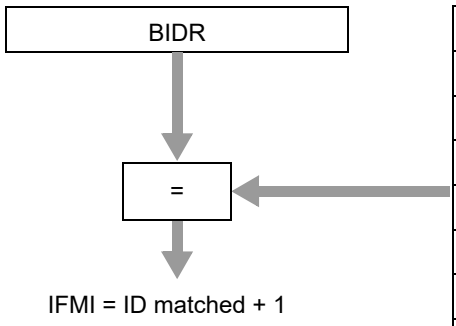
There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

44.3.2.6.1 Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2*n* and 2*n*+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2*n* or IFCR2*n*+1 (if the corresponding FACT bit is set).

44.3.2.6.2 Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2*n* is the filter and 2*n*+1 acts as a mask for it. The FACT bit for filter 2*n*+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.



If there is a match of identifier with the *m*th filter in any mode, then *m*+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note: If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.

44.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 724. 10-bit-shift-register sample register

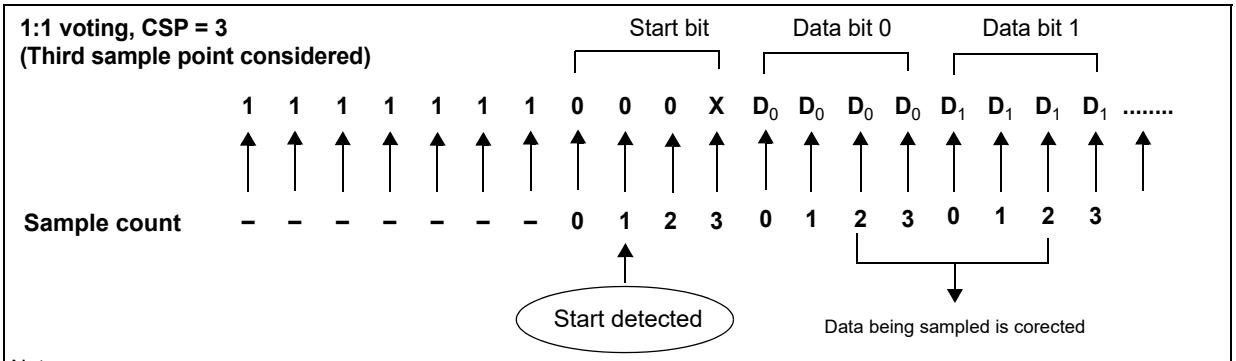
Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x(1)	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: due to sampling during transition of the bit, the bit value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. So ‘x’ refers to an indeterministic value.

44.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to *Table 724* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘0’ (2 or more), then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.



44.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to *Table 724* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘1’ (2 or more), then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

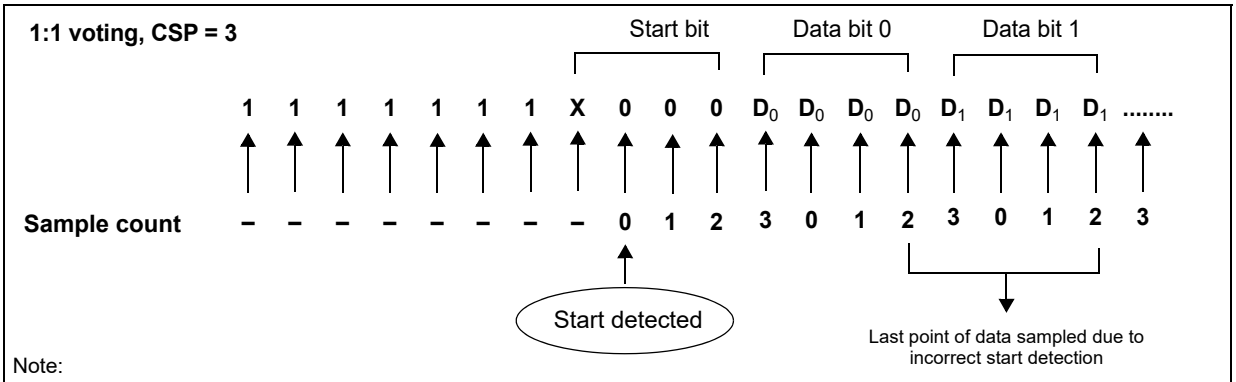


Figure 691. Start detection and sampling for over sampling rate = 4 (Case 1)

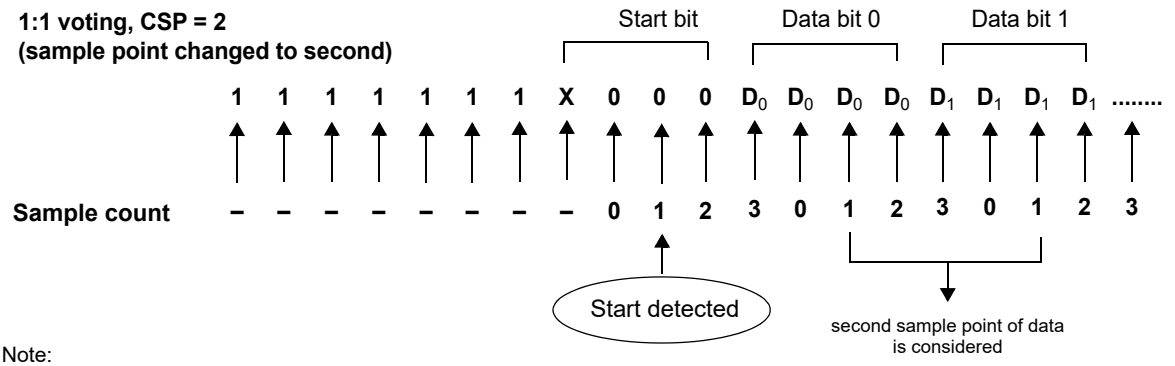
Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.Therefore ‘X’ refers to a indeterministic value.

Figure 692. Start detection and sampling for over sampling rate = 4 (Case 2a)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

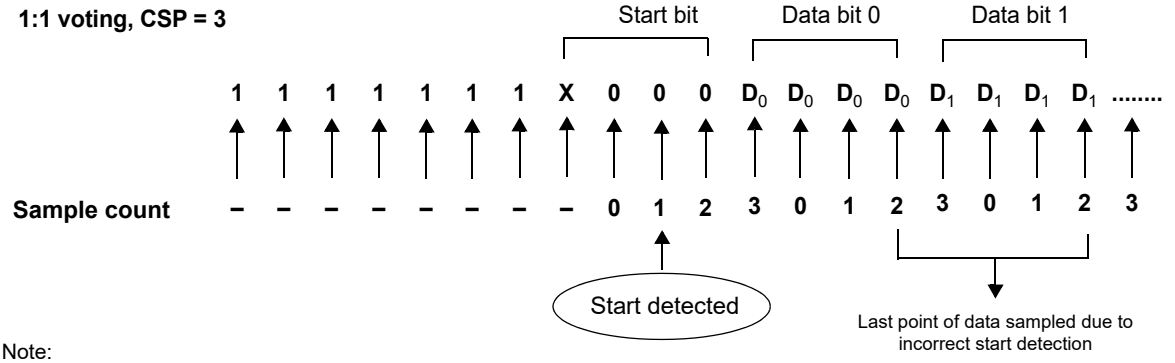


Figure 693. Start detection and sampling for over sampling rate = 4 (Case 2b)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.

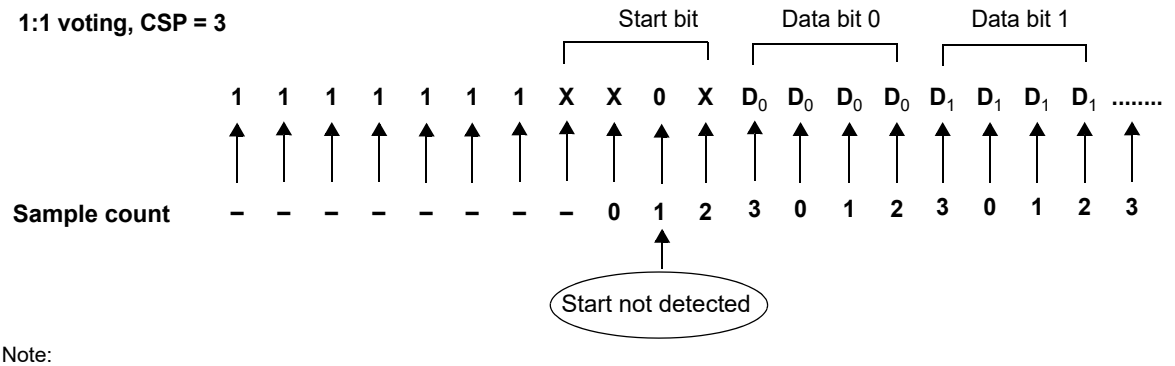

Figure 694. Start detection and sampling for over sampling rate = 4 (Case 3)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.
3. Therefore ‘X’ refers to a non deterministic value.

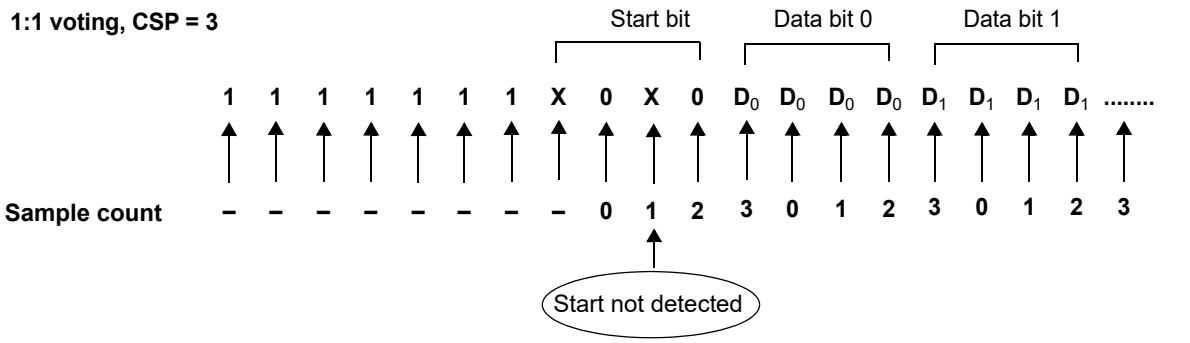

Figure 695. Start detection and sampling for over sampling rate = 4 (Case 4)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.
3. Therefore ‘X’ refers to a non deterministic value.

Figure 696. Start detection and sampling for over sampling rate = 4 (Case 5)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time.
3. Therefore 'X' refers to a non deterministic value.

44.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Equation 34 Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled LINFBRR is not used and LDIV contains only the integer part of LINIBRR.

Example 2

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Baud rate = 80 MHz/(16 x 1041,67) = 4.8 Kbit/s

Example 3

When ROSE = 1 (Only for UART mode):

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, OSR = 4

Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

Note: Due to design constraints the maximum baud rate achievable is 25 Mbit/s.

The relationship "(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK" should be maintained)

44.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

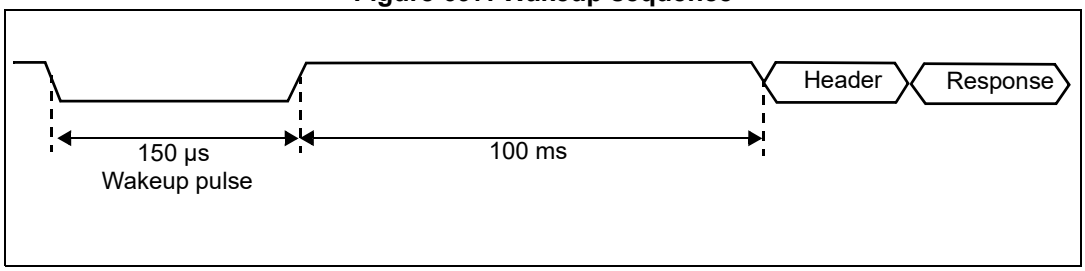
When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

44.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.



1. AUTOWU = 1

   On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.

2. AUTOWU = 0

   On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 697. Wakeup sequence

44.3.2.11 Use case and limitations

In LIN mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

44.3.3 Timer

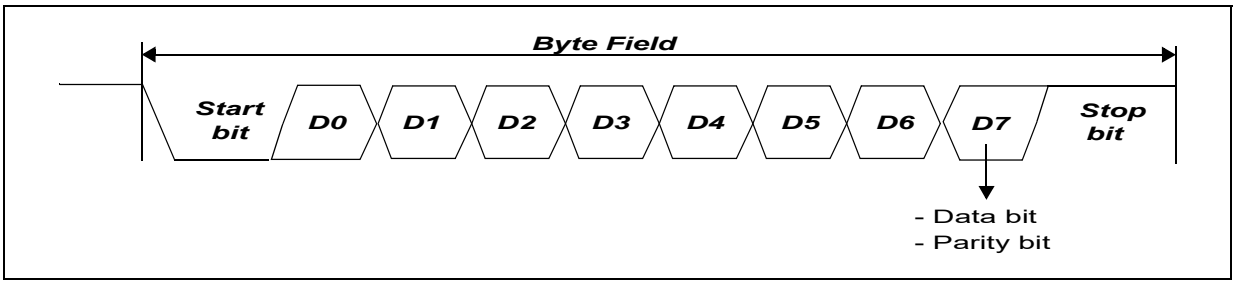
There is an 8 bit counter which has different behavior in different modes.

In Output Compare Mode (LINTCSR[MODE]= 1) : This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable

output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has soft reset the LIN IP through GCR [SR] bit to get reset the output compare flag (LINESR[OCF]).

In LIN Mode: The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

44.3.4 UART mode



The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames,16-bit frames,17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

44.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

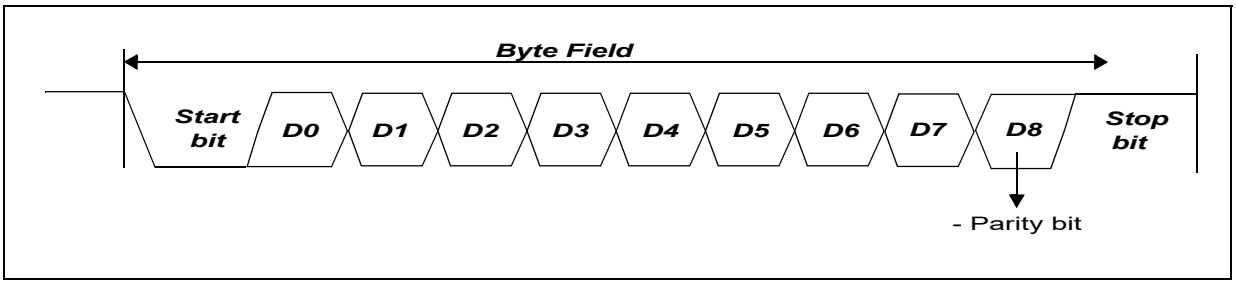


Figure 698. UART mode 8-bit data frame

44.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

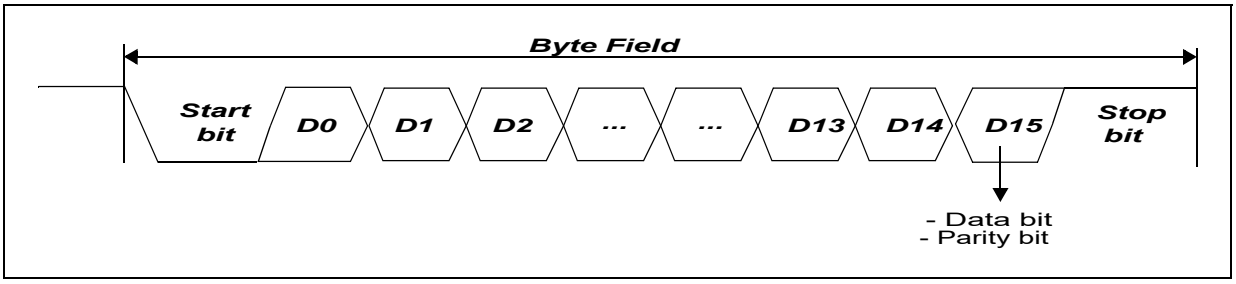

Figure 699. UART mode 9-bit data frame

44.3.4.3 16-bit data frames

The 16th bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

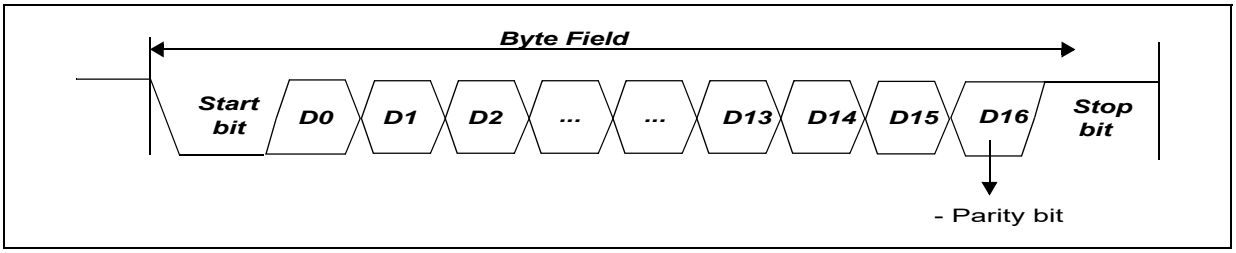

Figure 700. UART mode 16-bit data frame

44.3.4.4 17-bit frames

The 17th bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

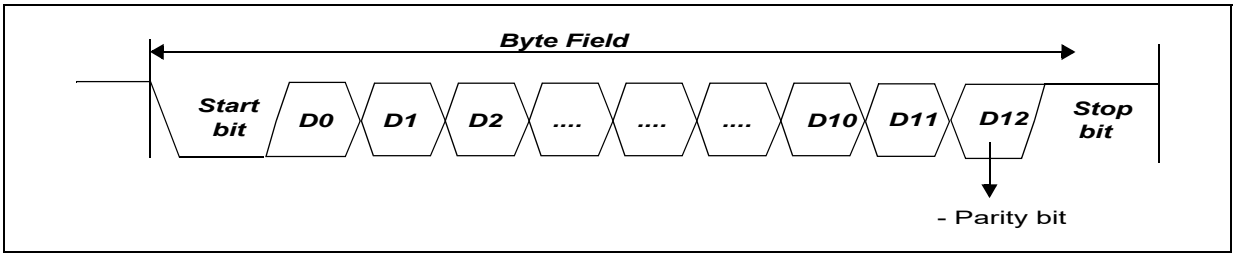

Figure 701. UART mode 17-bit data frame

44.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

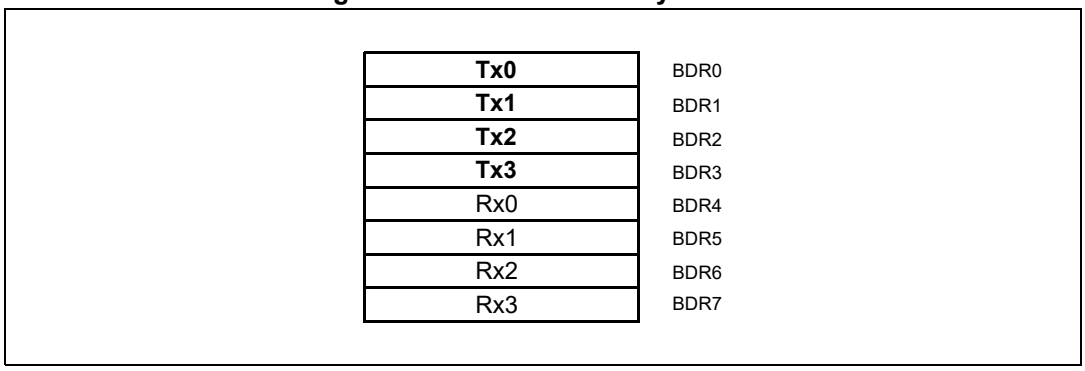

Figure 702. UART mode 13-bit data frame

44.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in *Figure 703*.

Figure 703. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1.

The same applies for reception.

44.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Invalid writes to BDRL which generates IPS transfer error, also triggers data transmission at the same time.

When the FIFO is full, a read to DATA0 of BDRM reflects the content of DATA3 in BDRL. Proper functionality of the IP is not affected by this.

Table 725. BDRL access in UART mode (1)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error

Table 725. BDRL access in UART mode (continued)(1)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register. Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

44.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 726. BDRM access in UART mode(1),(2)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error

Table 726. BDRM access in UART mode(1),(2) (continued)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.
2. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
   Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

Note: If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.

If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.

If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.

If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.

If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.

When WLS bit = 1, BDRM access depends on WL bit setting.

When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.

In UART FIFO mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

44.3.5 DMA interface

44.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

44.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in *Table 727* and *Table 728*.

Table 727. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: 1 8 bytes: normal frames 1 64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier

Table 727. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full

DMATXE[2**TX_CH_NUM](1)		High	DMA Tx channel enable (read/write)
			In UART or LIN master mode only channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1.
			DMATXE[x] = 0b → TX channel x disabled
			DMATXE[x] = 1b → TX channel x enabled

DMARXE[2**RX_CH_NUM](1)		High	DMA Rx channel enable (read/write)
			In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1.
			DMARXE[x] = 0b → RX channel x disabled
			DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation

Table 728. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the Tranfer Control Descriptors (TCDs) referred to in this document are described in *Table 729*.

Table 729. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)

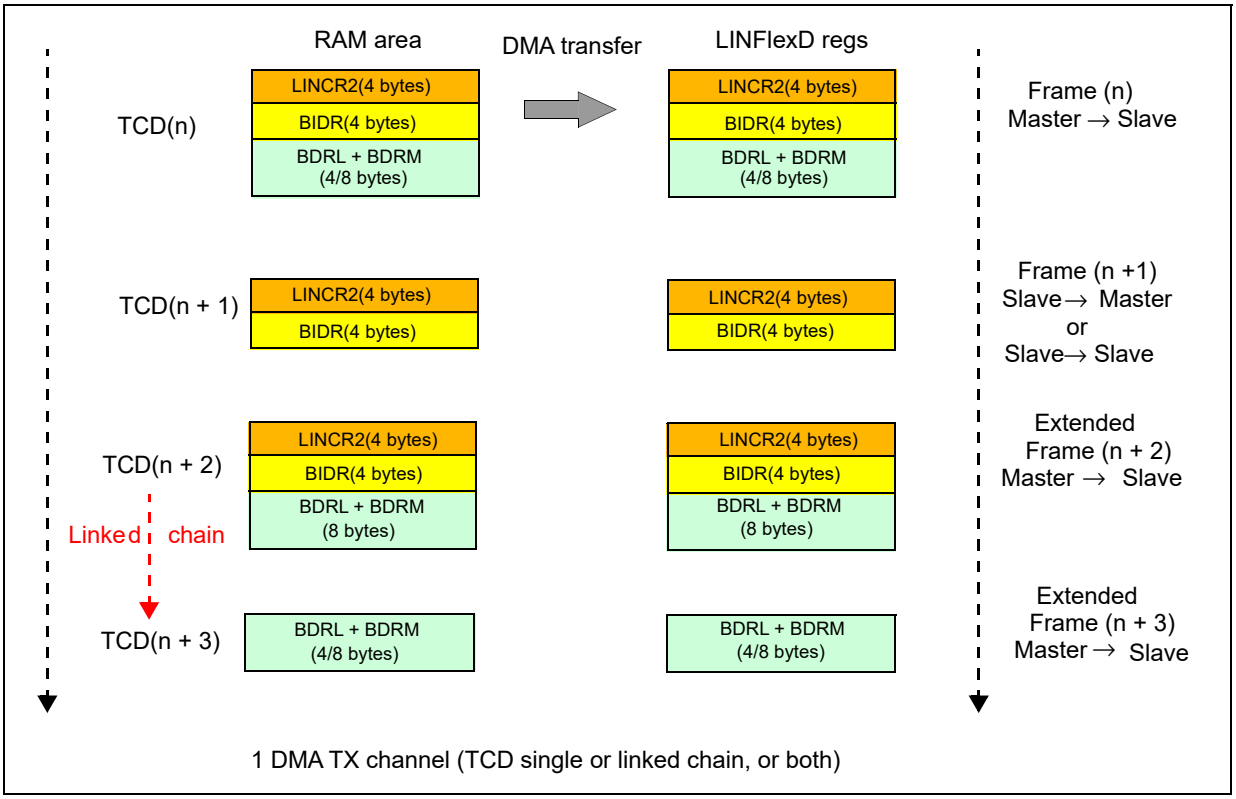

Table 729. TCD control fields description (continued)

TCD field	Level	Description
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

44.3.5.3 Master node: TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 704*.

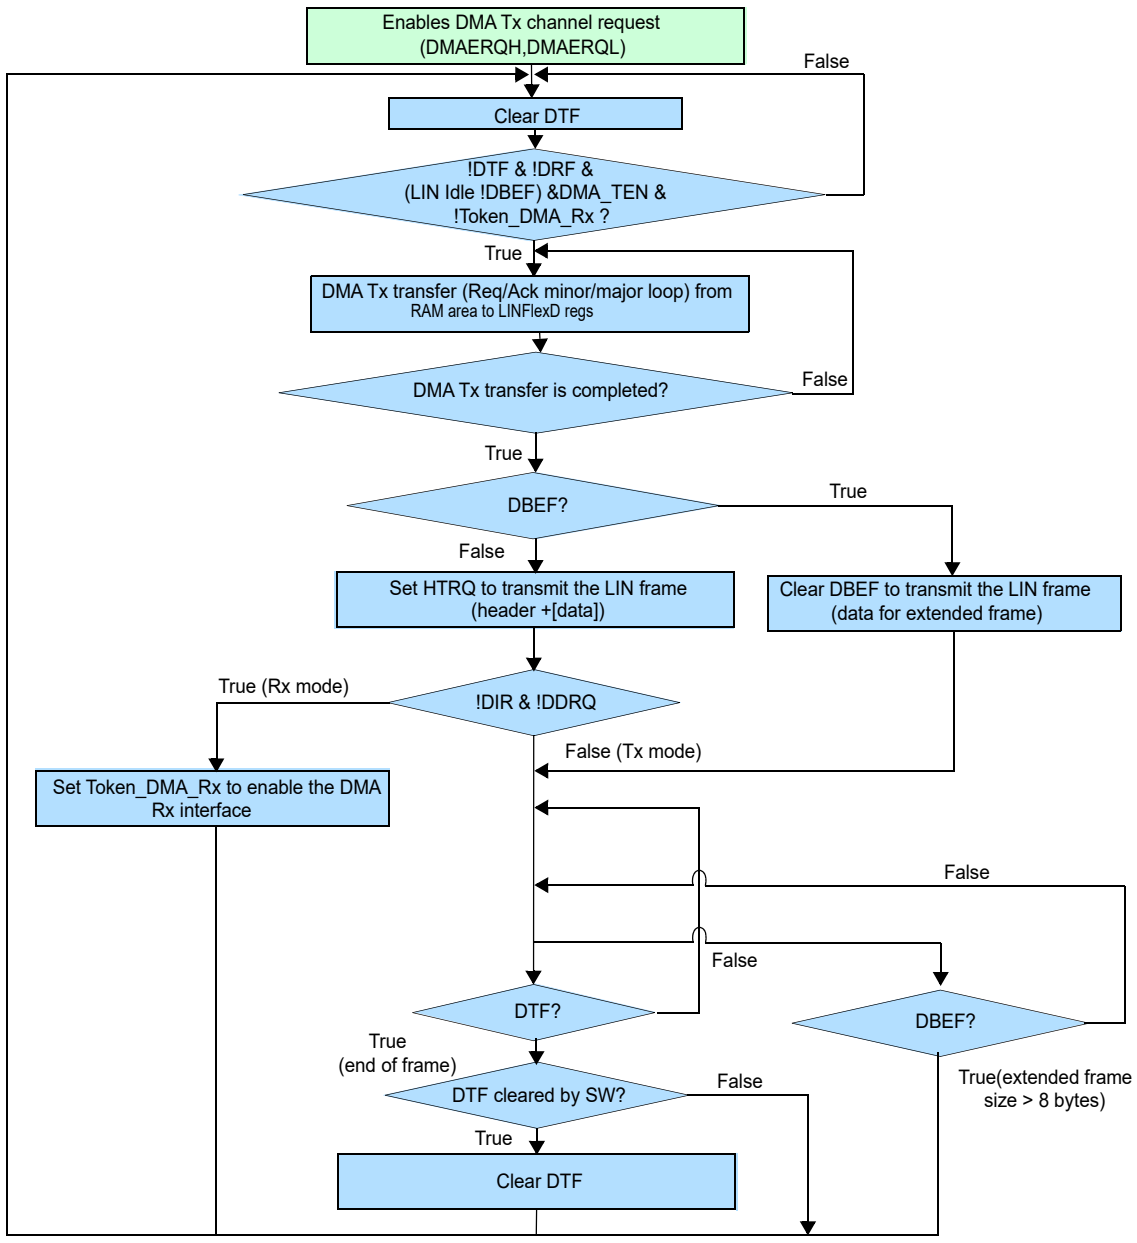
Figure 704. Master node: TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

Table 730 provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 730. Master node: Tx mode - Register setting



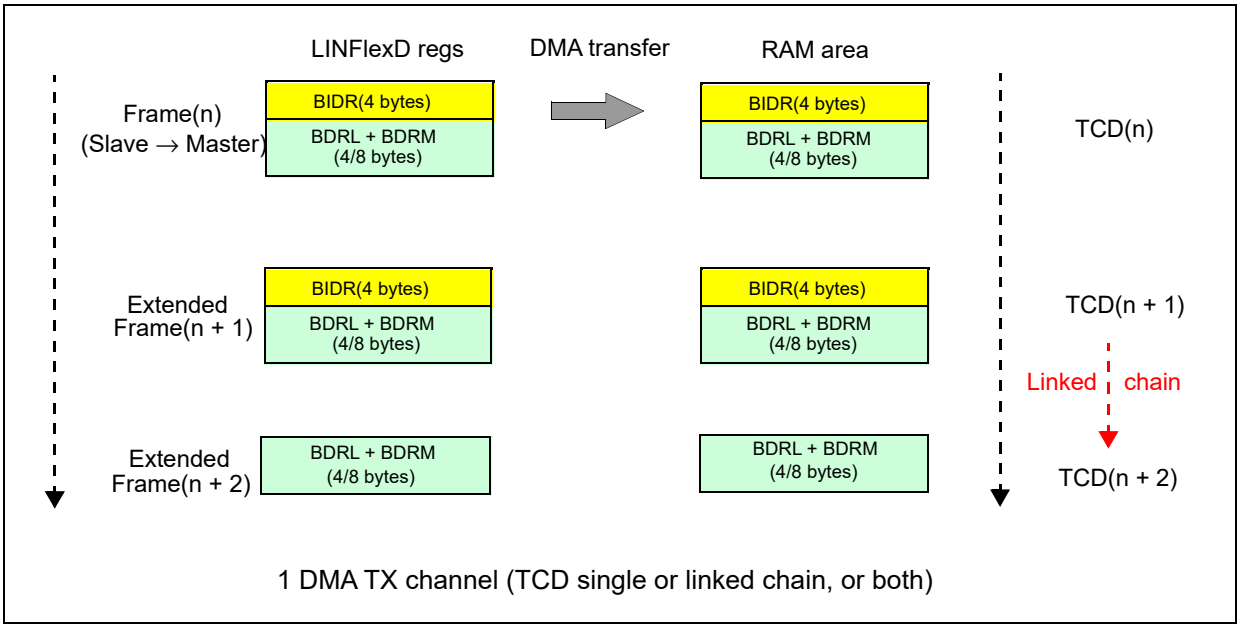
LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in *Figure 705*. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in *Table 731*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 731. TCD setting: Master node -Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 705. Master node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

44.3.5.4 Master node: RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 706*.

Figure 706. Master node: RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in *Figure 707*. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in *Table 732*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

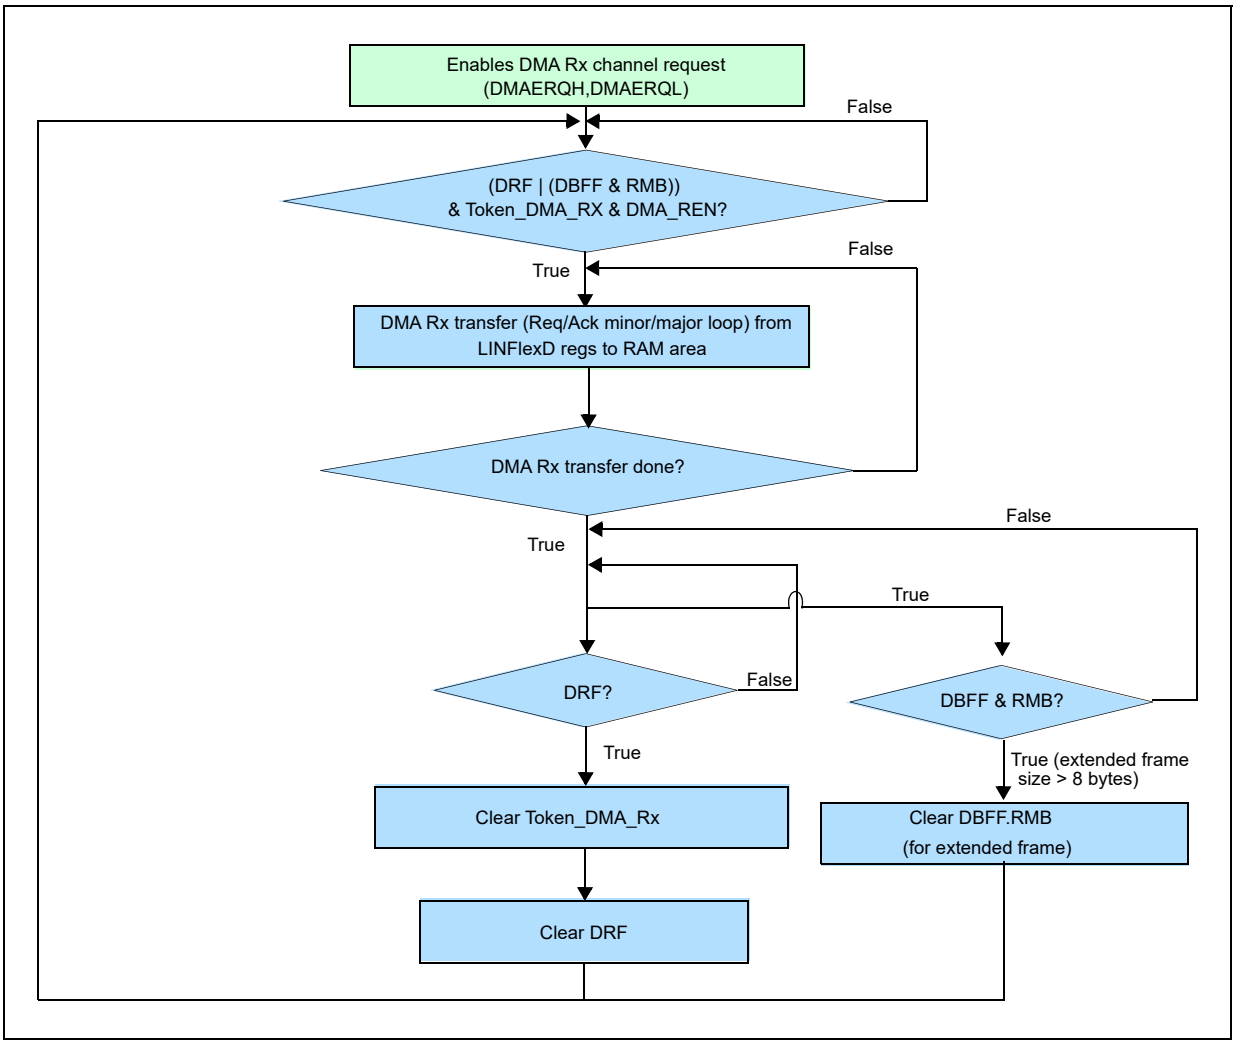


Table 732. TCD setting: Master node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 732. TCD setting: Master node - Rx mode (continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

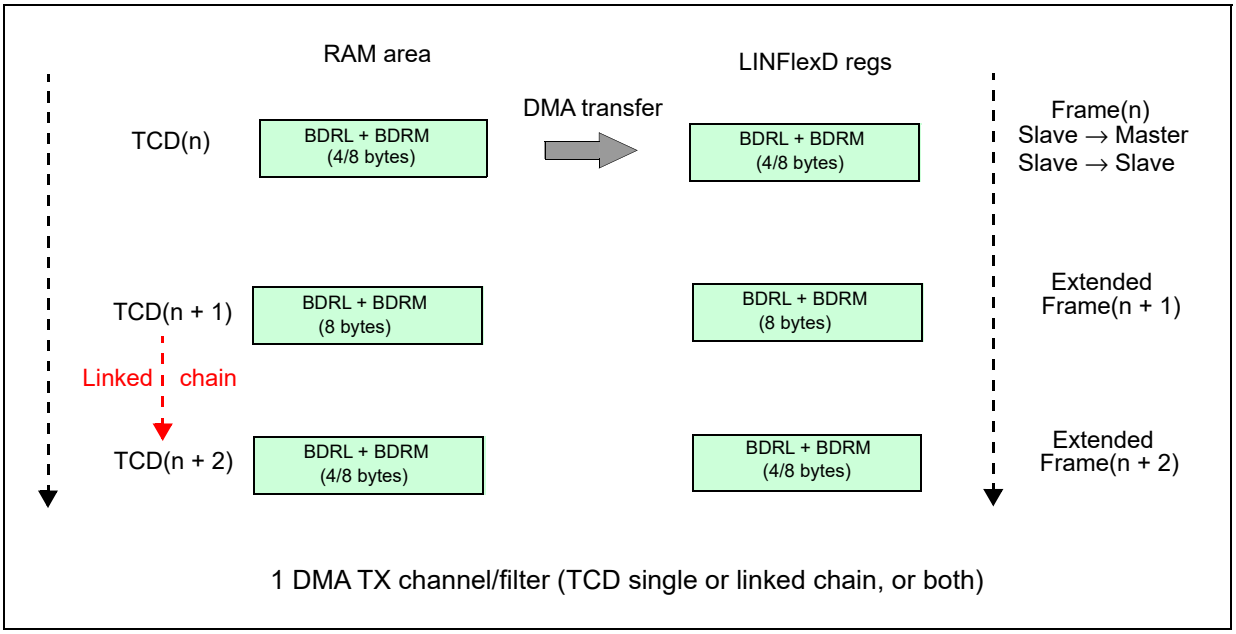

Figure 707. Master node — DMA Rx FSM (concept scheme)

44.3.5.5 Slave node: TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 708*.

Figure 708. Slave node — TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 733*.

Table 733. Slave node: Tx mode - Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in *Figure 709*. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 734*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

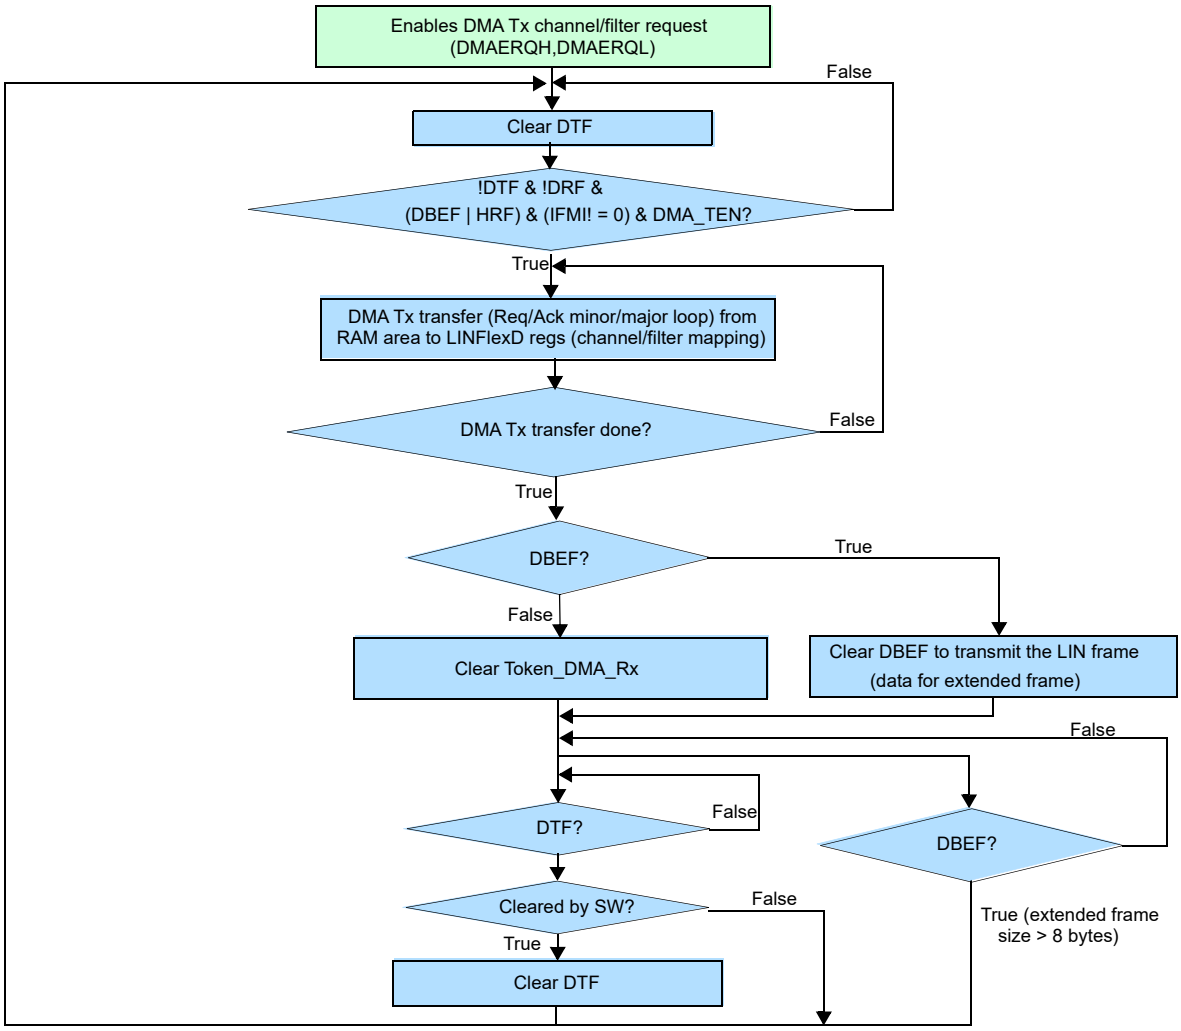

Table 734. TCD setting: Slave node - Tx mode

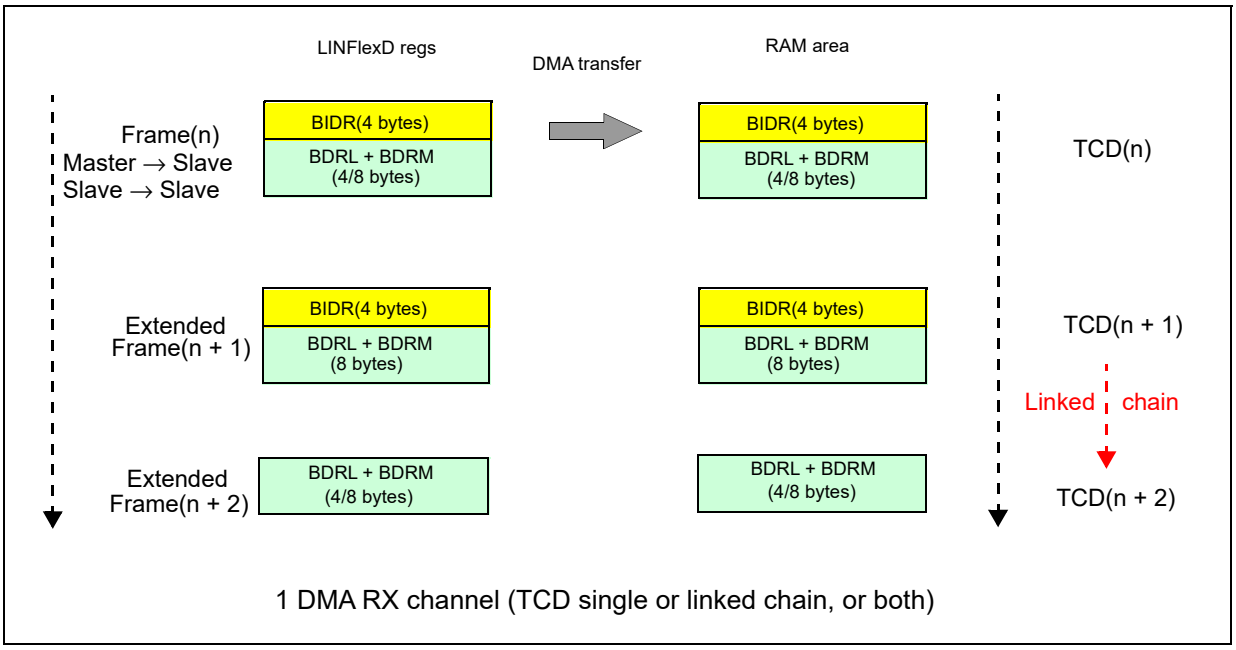
TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 734. TCD setting: Slave node - Tx mode (continued)

TCD field	Value	Description
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 709. Slave node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

44.3.5.6 Slave node: RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 710*.

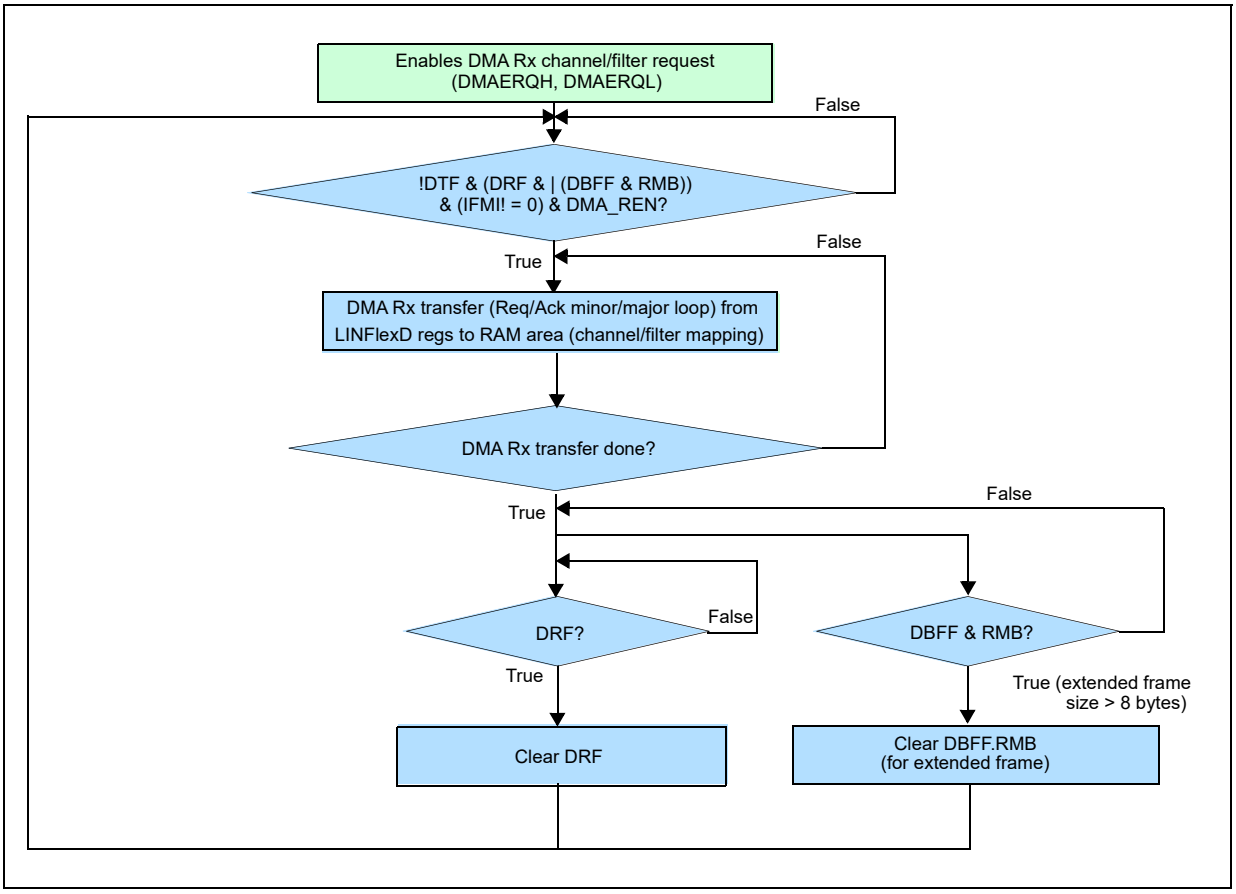
Figure 710. Slave node: RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 735*.

Table 735. Slave node: Rx mode - Register setting



LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in *Figure 711*. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 736*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 736. TCD setting: Slave node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer

DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

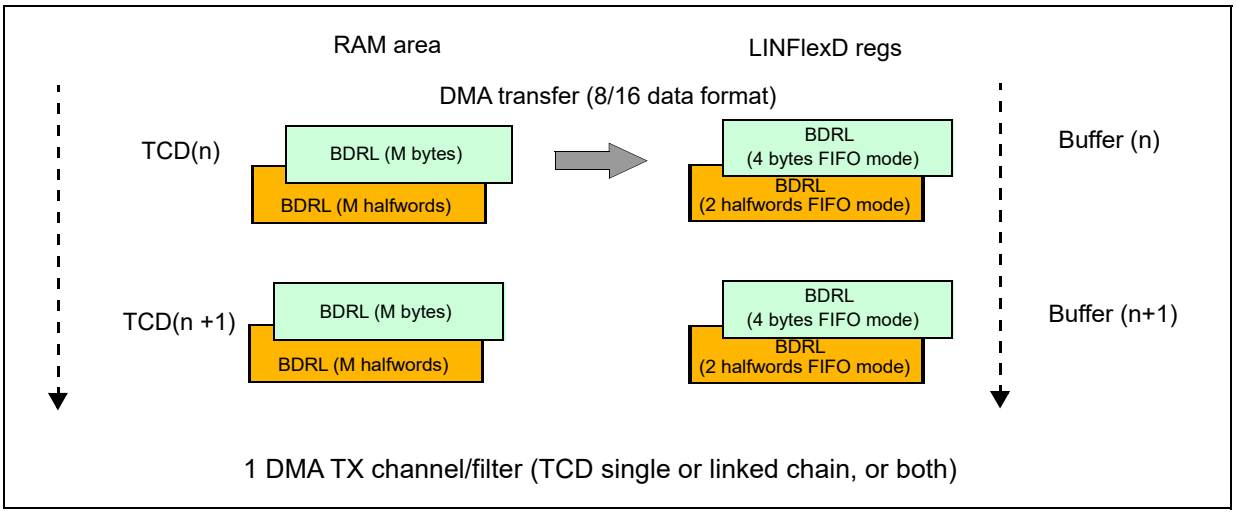

Figure 711. Slave node — DMA Rx FSM (concept scheme)

44.3.5.7 UART: TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 712*.

Figure 712. UART: TX memory map

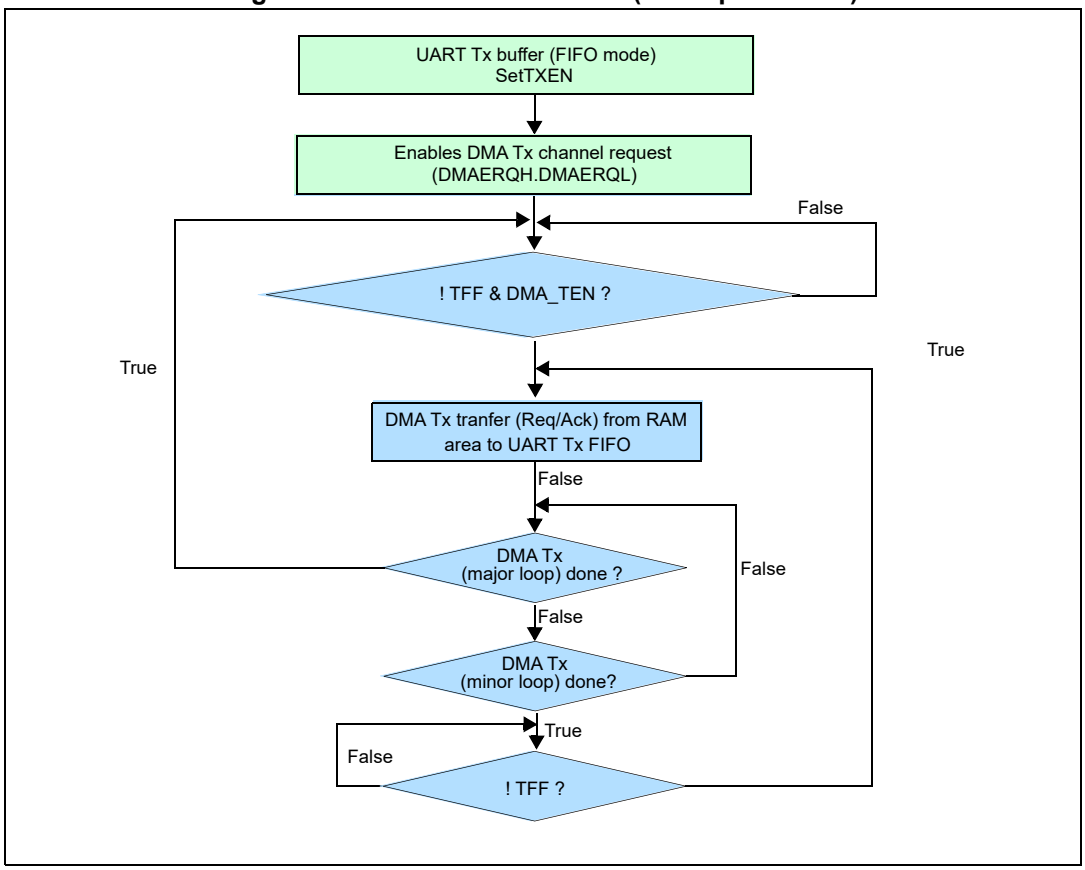
The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.



The concept FSM to control the DMA Tx interface is given in *Figure 713*. DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in *Table 737*. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 737. TCD setting: UART - Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	-M	-M × 2	—
DADDR[31:0](1)	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

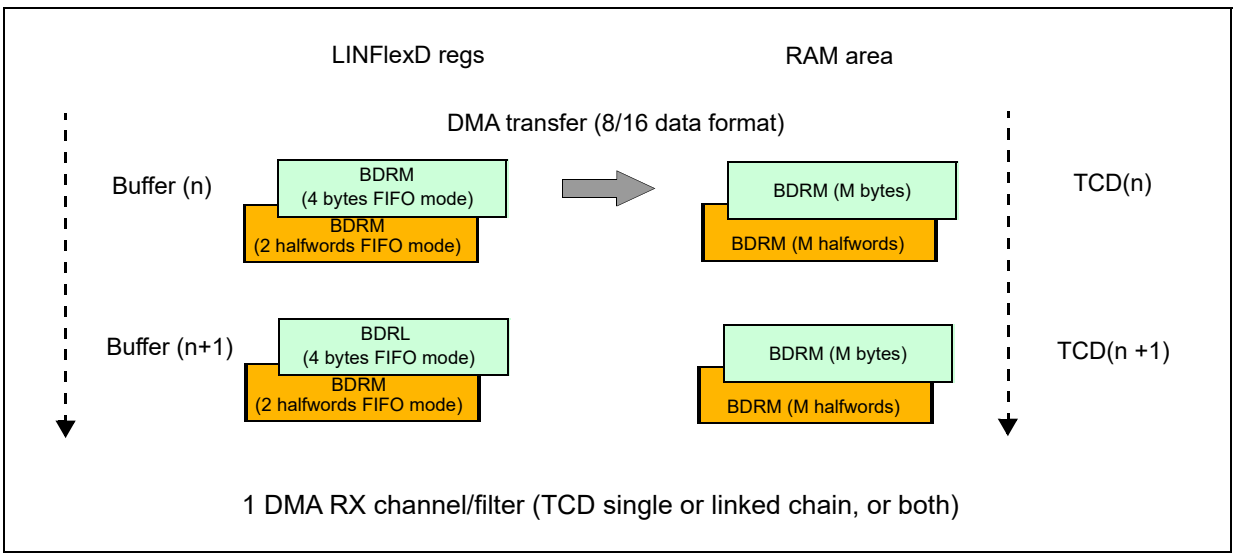


Figure 713. UART: DMA Tx FSM (concept scheme)

44.3.5.8 UART: RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Table 738*.

Figure 714. UART: RX memory map

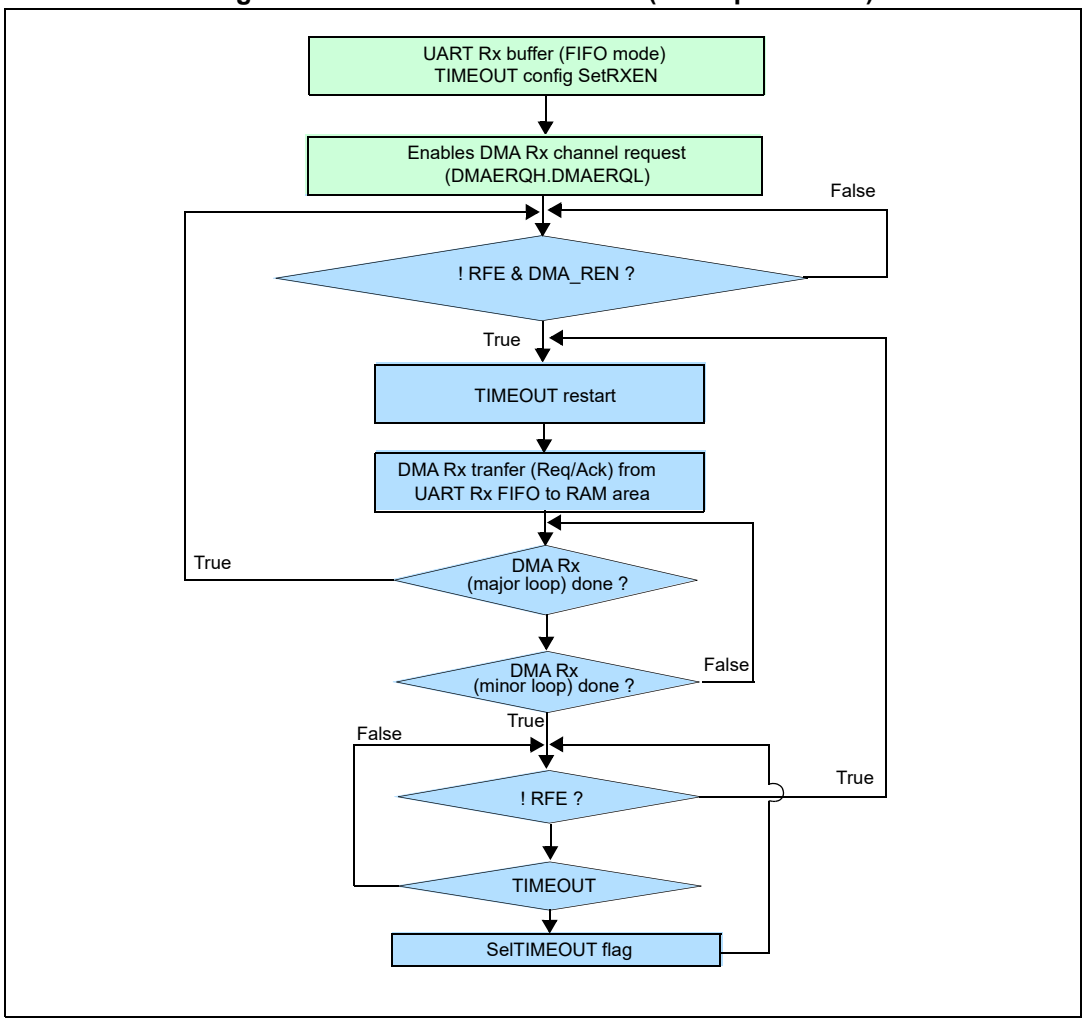
The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.



The concept FSM to control the DMA Rx interface is given in *Figure 715*. DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 738. TCD setting: UART - Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0](1)	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	-M	-M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 715. UART — DMA Rx FSM (concept scheme)

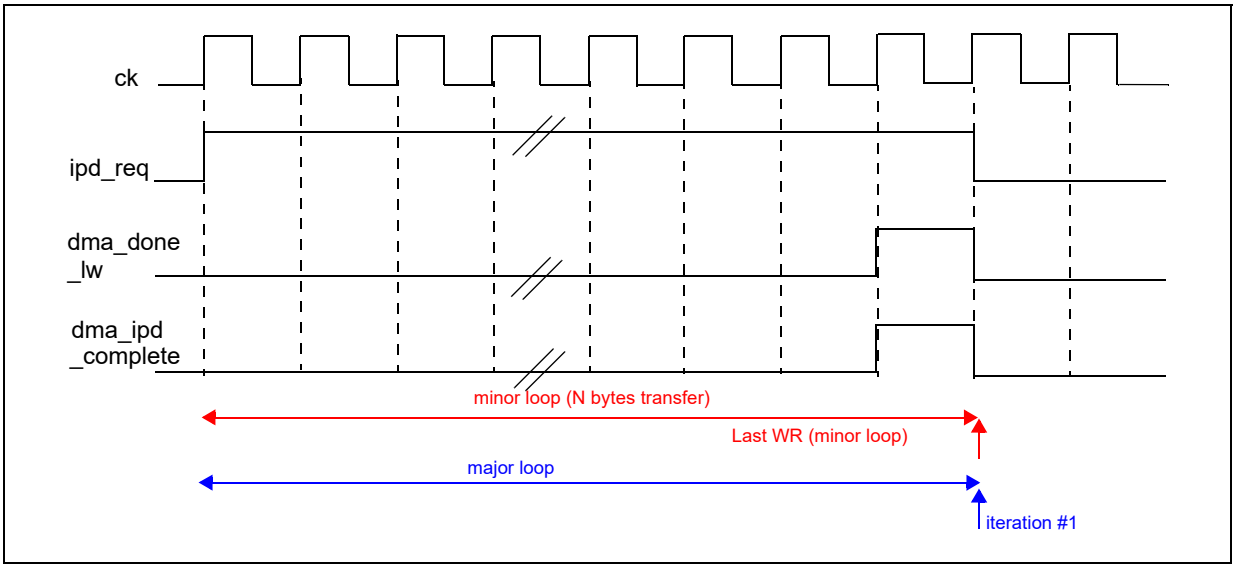
44.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- ipd_req
  - DMA peripheral request, asserted until the DMA transfer has been completed
- dma_done_lw
  - DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected
- dma_ipd_complete
  - DMA major loop finished. It is asserted for one cycle after the data phase of the last write
- dma_ipd_ack, dma_ipd_done
  - Unused in this implementation

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 716. DMA interface (major loop — single iteration)



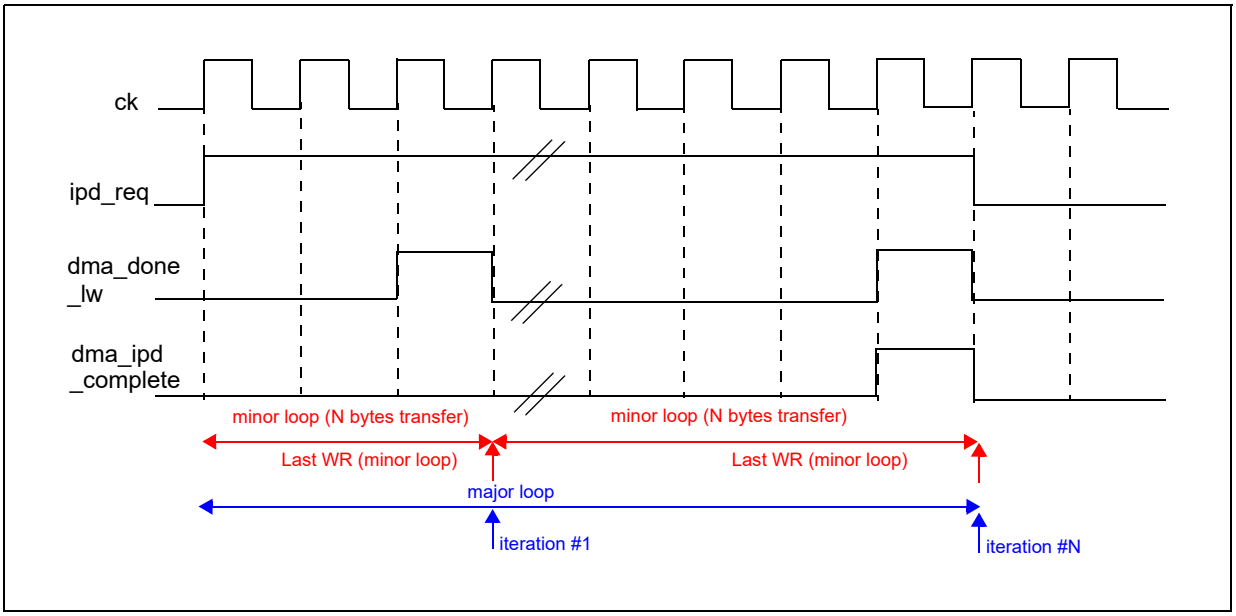


Figure 717. DMA interface (major loop — N iteration)

44.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA

channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

44.4 Memory map and register description

44.4.1 Memory map

Table 739 shows the LINFlexD memory/register map.

Note: In Master mode, the registers IFCR0 – IFCR15 are not present.

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in bus transfer error.

Table 739. LINFlexD memory map

1. No-Saf = Not safety relevant, Saf-Lat = Safety Latent, Saf-Relv = Safety Relevant, Saf-Crit = Safety Critical.
2. Refer to the *Chapter 7: Device configuration* for the number of filters used in each instance of LINFlexD in this device.

44.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format.
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

44.4.2.1 LIN Control Register 1 (LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

Address: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CCD(1)	CFD(1)	LASE(1)	AUTOWU(1)	MBL(1)				BF(1)	0	LBKM(1)	MME(1)	SSBL(1)	RBLM(1)	SLEEP	INIT
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1(2)	0	0	1	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When slave = 0, this field reads '1' and cannot be programmed.

Figure 718. LIN Control Register 1 (LINCR1)

Table 740. LINCR1 field descriptions

Field	Description
16 CCD	Calculation disable 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read-only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).

Table 740. LINCR1 field descriptions (continued)

Field	Description
19 AUTOWU	Auto Wakeup 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.
20:23 MBL[3:0]	Master Break Length These bits choose the length of the Sync break to be generated by the master. 0x0 10-bit break length 0x1 11-bit break length 0x2 12-bit break length 0x3 13-bit break length 0x4 14-bit break length 0x5 15-bit break length 0x6 16-bit break length 0x7 17-bit break length 0x8 18-bit break length 0x9 19-bit break length 0xA 20-bit break length 0xB 21-bit break length 0xC 22-bit break length 0xD 23-bit break length 0xE 36-bit (cooling) break length 0xF 50-bit break length These bits can be programmed in Initialization mode only. They are read-only in Normal mode.
24 BF	By-pass filter 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter This bit can be programmed during Initialization mode only. Note: If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.
25	Reserved
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to *Section 44.3.2.2*. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. If generic *slave* = 0, then this bit will read a ‘1’ always, and cannot be programmed.

Table 740. LINCR1 field descriptions (continued)

Field	Description
28 SSBL	Slave Mode Sync Break Length 0 11-bit break length 1 10-bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

Figure 719. LIN Interrupt enable register (LINIER)

Table 741. LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **Note:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.

Table 741. LINIER field descriptions (continued)

Field	Description
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE_TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

44.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0x0008 Access: User read/write

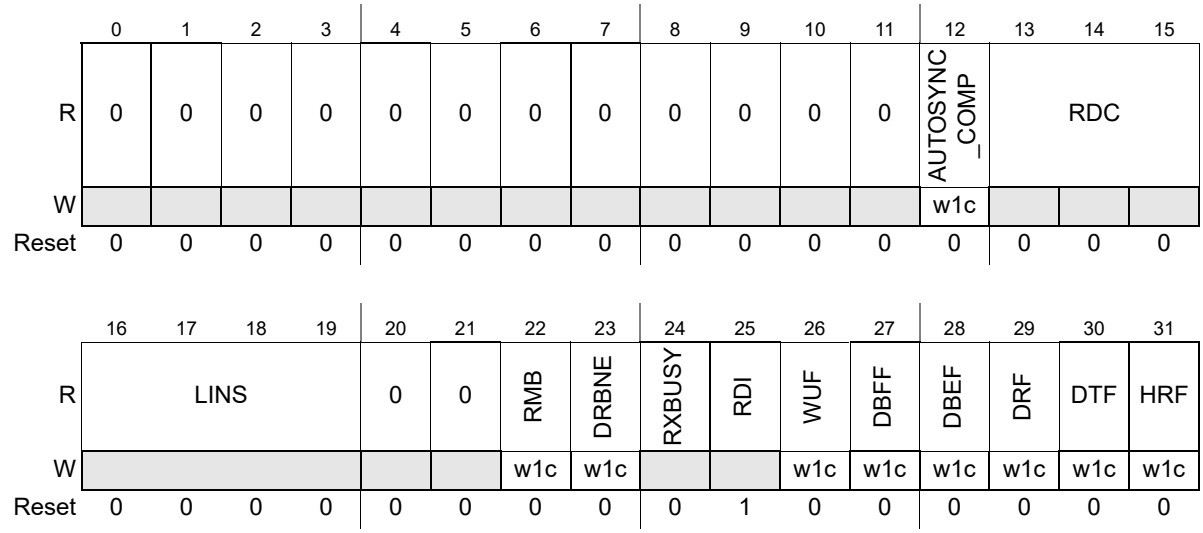

Figure 720. LIN Status Register (LINSR)

Table 742. LINSR field descriptions

Field	Description
12 AUTOSYNC_COMP	Autosynchronization Completed This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers should be read in autosynchronization mode.
13:15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 742. LINSR field descriptions (continued)

Field	Description
16:19 LINS	LIN state 0x0 Sleep mode LINFlexD is in Sleep mode to save power consumption. 0x1 Init 0x2 Idle This mode is entered when: SLEEP bit and INIT bit are reset by software, Wakeup pulse has been received on RX pin (AUTOWU set), Previous frame transmission/reception has been completed/aborted. 0x3 Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0x4 Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0x5 Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0x6 Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0x7 Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 0x8 Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 0x9 Checksum Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.

Table 742. LINSR field descriptions (continued)

Field	Description
24 RXBUSY	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **Note:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin and when: The slave is in Sleep mode The master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next eight bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: All filters are inactive and Bypass filter (BF) bit is set No match in any filter and Bypass filter (BF) bit is set TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

44.4.2.4 LIN Error Status Register (LINESR)

Address: 0x000C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 721. LIN error status register (LINESR)

Refer to *Section 44.3.2.5* for detailed description of all errors.

Table 743. LINESR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

Table 743. LINESR field descriptions (continued)

Field	Description
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **Note:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

44.4.2.5 UART Mode Control Register (UARTCR)

Address: 0x0010 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS(1)	CSP(1)			OSR(1)				ROSE(1)	NEF(1)(2)			DTU_PCETX(1)	SBUR(1)		WLS(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TDFL_TFC(2)			RDFL_RFC(3)			RFBM(1)	TFBM(1)	WL1(1)	PC1(1)	RXEN	TXEN	PC0(1)	PCE(1)	WL0(1)	UART(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When TFBM = 0, the field is read/write; when TFBM = 1, the field is read-only.
3. When RFBM = 0, the field is read/write; when RFBM = 1, the field is read-only.

Figure 722. UART Mode Control Register (UARTCR)

Table 744. UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 1 UARTCTO monitors the idle state of the reception line. 0 UARTCTO monitors the number of bits to be received. The default value of this bit is 0.
1:3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: – OSR 4: CSP 2, 3 – OSR 5: CSP 2, 3, 4 – OSR 6: CSP 3, 4, 5 – OSR 8: CSP NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received (num_of_frames). When num_of_frames equals NEF, Disable Timeout is set and num_of_frames gets reset to zero, restarting the timer and enabling the timeout again.
13:14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.

Table 744. UARTCR field descriptions (continued)

Field	Description
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.
16:18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL_TFC defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL_TFC is a read/write field. TDFL_TFC[2] is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL_TFC = x01 or TDFL_TFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes TDFL_TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TDFL_TFCx is a read-only field available for debug purposes. 000 empty 001 1-byte 010 2-bytes 011 3-bytes 100 4-bytes Others: Reserved **Note:** TDFL_TFC can be programmed and are significative only when the UART bit is set.
19:21 RDFL_RFC	Reception Data Field Length/RX FIFO Counter RDFL_RFC defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL_RFC is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL_RFC = x01 or RDFL_RFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes RDFL_RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RDFL_RFCx is a read-only field available for debug purposes. 000 Empty 001 1-byte 010 2-bytes/1.5 byte in case of WLS bit setting 011 3-bytes 100 4-bytes/2×1.5 byte in case of WLS bit setting Others: Reserved RDFL_RFC can be programmed and are significative only when the UART bit is set. **Note:** In buffer mode, RDFL_RFC should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.

Table 744. UARTCR field descriptions (continued)

Field	Description
22 RFBM	RFBM Rx FIFO/Buffer mode 0 Rx Buffer mode enabled 1 Rx FIFO mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx FIFO/Buffer mode 0 Tx Buffer mode enabled 1 Tx FIFO mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
26 RXEN	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TXEN	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
29 PCE	Parity Control Enable 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.

Table 744. UARTCR field descriptions (continued)

Field	Description
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

44.4.2.6 UART Mode Status Register (UARTSR)

1. When RFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when RFBM = 1, the field is read-only.
2. When TFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when TFBM = 1, the field is read-only.

Figure 723. UART Mode Status Register (UARTSR)

Table 745. UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. For Baud rate above 1 Mbit/s, this flag is not usable.
18:21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. PE[i] (where i = 0,1,2 or 3) can be equal to: 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **Note:** Parity is checked only after a complete frame is received. When WL bits = 10 or 11, either PE[0] or PE[2] is only set. – When PE[0] is set, it indicates Parity error in either first or second byte received. – When PE[2] is set, it indicates Parity error in either third or fourth byte received.
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table 745. UARTSR field descriptions (continued)

Field	Description
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software.The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF_RFE	Data Reception Completed Flag/Rx FIFO Empty Flag DRF_RFE is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF_RFE should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF_RFE bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF_RFE is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DRF_RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. DRF_RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF_TFF	Data Transmission Completed Flag/TX FIFO Full Flag DTF_TFF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF_TFF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DTF_TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. DTF_TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

44.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Address: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.

Figure 724. LIN Time-Out Control Status Register (LINTCSR)

Table 746. LINTCSR field descriptions

Field	Description
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event This feature is applicable only when MODE bit in LINTCSR is cleared.
23 TOCE	Time-out counter enable 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24:31 CNT[7:0]	Counter Value These bits reflect the value of a free-running counter used for timeout. **Note:** For proper functionality of this counter, LINIBRR should be greater than or equal to 5. This counter increments once in every bit duration, as per the programmed bit rate. The counter starts as soon as the IP comes out of reset and increments based on the slowest baud rate possible (LINIBRR = FFFFFh), until the user programs LINIBRR and LINFBRR with the desired values.

44.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the count value in LINTOCR register. This register is writable by software only in Output Compare Mode.

Address: 0x001C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	1	1	1	0	0	0	0(1)/1	1(1)/0	1	1	0	0

1. This reset value is valid only in Master mode.

Figure 726. LIN Time-Out Control Register (LINTOCR)

Table 748. LINTOCR field descriptions

Field	Description
20:23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0xE = 14, corresponding to $T_{Response_Maximum} = 1.4 * T_{Response_Nominal}$
25:31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is 0x2C = 45, corresponding to $T_{Header_Maximum}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 0x1C = 28 (1.4 × 10 bits of sync + 1.4 × 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

44.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0x0024 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

44.4.2.11 LIN Integer Baud Rate Register (LINIBRR)

This register consists of control bits that decide the baud rate along with the LINFBRR. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Address: 0x0028 Access: User read/write

Reset	0	1	0(3)/1	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in Initialization mode.
2. This field can be read/set by software.
3. When slave = 0, reset value is '0' and the this field cannot be programmed.

Figure 730. LIN Control Register 2 (LINCR2)

Table 752. LINCR2 field descriptions

Field	Description
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **Note:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.

44.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0x0034 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 731. Buffer Identifier Register (BIDR)

Table 753. BIDR field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1 **Note:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copies them in the BDRs 1 LINFlexD transmits the data from the BDRs
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = ‘1’).

44.4.2.15 Buffer Data Register Least Significant (BDRL)

This register is a part of an 8-byte data buffer.

Address: 0x0038 Access: User read/write

Figure 737. Identifier Filter Control Register (IFCR2n)

Table 759. IFCR2*n* field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes - 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity.

44.4.2.21 Identifier Filter Control Register (IFCR2*n*+1)

This register is read-only in normal mode and can be programmed only in Initialization mode. This register acts as a filter in Identifier list mode but acts as a mask for IFCR2*n* in Identifier mask mode.

Address: 0x50+ *n**0x8 (*n* = 0 to (no_of_filters(2)/2–1)) Access: User read/write

Figure 740. UART Preset Timeout Register (UARTPTO)

Table 762. UARTPTO field descriptions

Field	Description
20:31 PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A value of 0, 1 or 2 is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer to the UARTCTO register.

44.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see *Section 44.4.2.23*) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

*Note: Due to this synchronisation, UARTCTO reflects the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) which was present on it, before 4 to 6 clock cycles of PBRIDGEx_CLK.*

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO-1
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

Figure 770. Interrupt diagram

45 SENT Receiver (SRX)

45.1 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled “SENT - Single Edge Nibble Transmission for Automotive Applications” and released on January 27, 2010 (SAE web site), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

45.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See *Section 7.9.4: SENT Receiver (SRX) configuration* for details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
  - Programmable option per channel to support reading of messages via DMA or Interrupt
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
  - Separate buffers for storing Fast and Slow Serial Messages
  - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
  - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 1.27 µs to 90 µs
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (such as, without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See *Section 45.5: Clocks and resets* for more details on the clocks.

45.1.2 Modes of operation

45.1.2.1 Debug mode

In debug mode, message reception will be halted and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

45.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

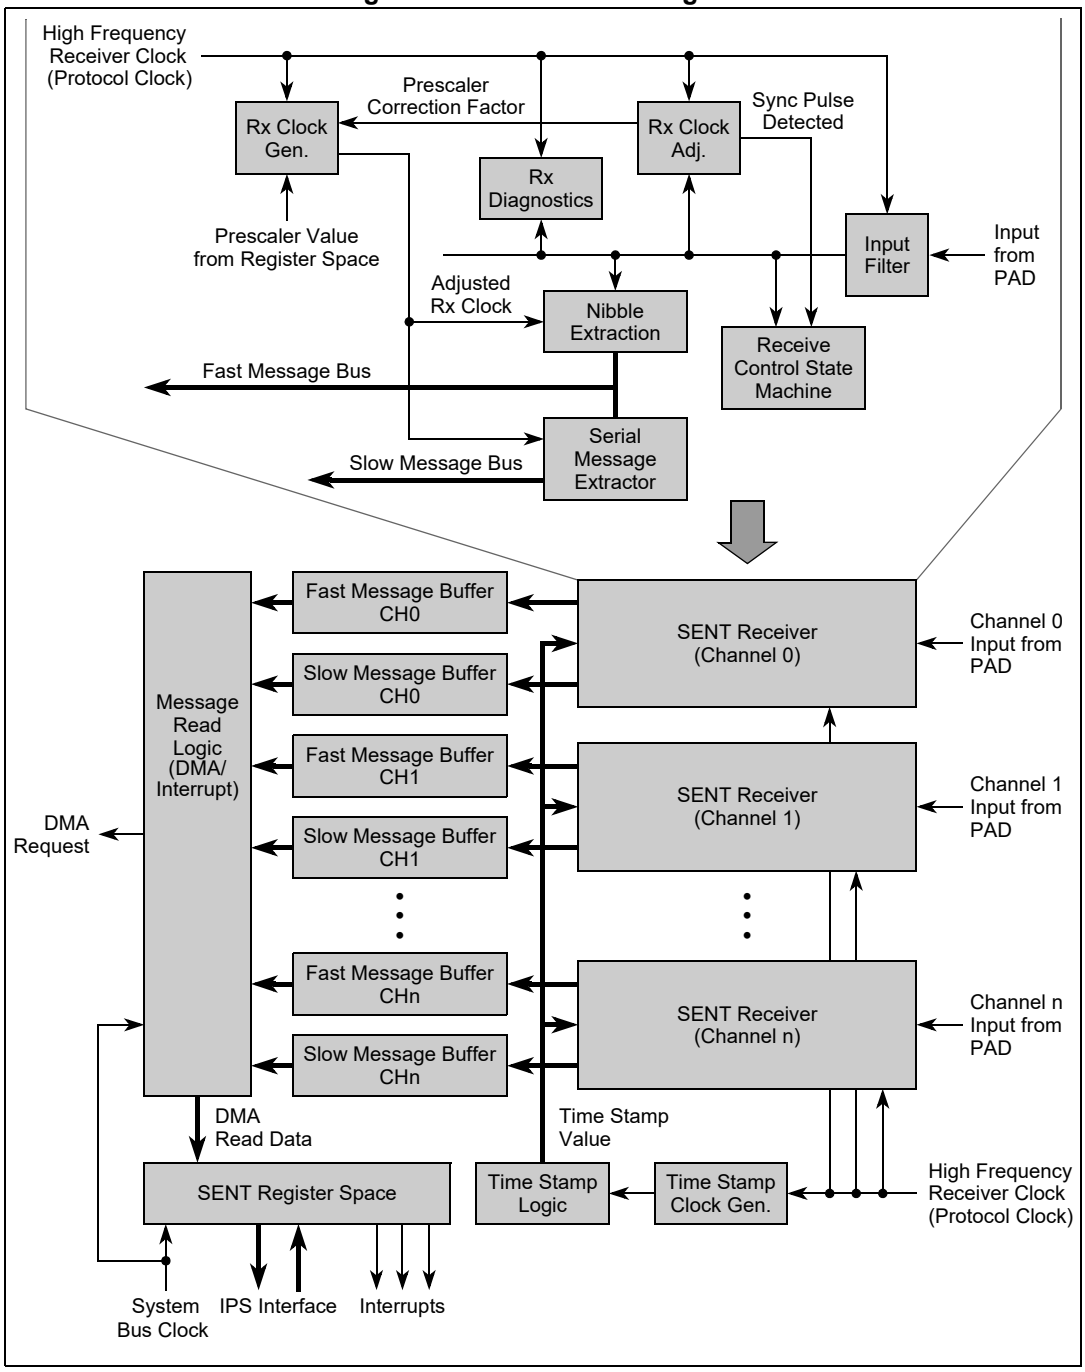
Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See *Section 45.5.2: System bus clock requirements*) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See *Section 45.5.3: High frequency receiver clock (protocol clock) requirements*) for accurate receive operations.

Note: Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

Note: If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

Note: The message read registers [Channel ‘n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA), Channel ‘n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC), Channel ‘n’ Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS), Channel ‘n’ Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3), Channel ‘n’ Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2), Channel ‘n’ Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS), DMA Fast Message Data Read Register (DMA_FMSG_DATA), DMA Fast Message CRC Read Register (DMA_FMSG_CRC), DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS), DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)] will appear to lose their contents in the following conditions:



- *The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros*

- *Auto clear functionality is enabled (GBL_CTRL[FAST_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.*

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL_CTRL[FAST_CLR] = 0), to allow messages to be read in debug or stop mode.

45.1.3 Block diagram

Figure 771. SENT block diagram

45.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. *Figure 771* shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages.A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

45.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel’s status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the buffers on high frequency receiver clock. The module’s message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the

global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see *Section 45.4: Functional description*.

45.2 External signal description

This section lists all inputs to the SENT block.

45.2.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note: The value of the CH is device-specific. See Section 7.9.4: SENT Receiver (SRX) configuration for details.

45.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT block.

45.3.1 Memory map

Table 767 gives an overview on all SENT registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

Note: Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the Device Configuration chapter for details.

The value of the CH is device-specific. See the Chapter 7: Device configuration for details.

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Global Control Register (GBL_CTRL)*

45.3.2 Register descriptions

This section describes in address order all the SENT registers and their individual bits.

45.3.2.1 Global Control Register (GBL_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT_EN bit must be programmed after all other modules settings and control bits have been written to.

Offset: 0x0000 Access: Read/Write

Figure 772. Global Control Register (GBL_CTRL)

Table 768. GBL_CTRL field descriptions

Field	Description
0:7 TSPRSC	Time Stamp Prescaler Value Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. (0 to 255) Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 µs. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1µs clock. **Note:** Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
16 NIB_LEN_VAR _LIMIT	Decides the allowable jitter/clock drift limit for nibble length measurement. 0 Allows a jitter/clock drift of approx upto 12.5% of transmitter clock tick period. This actual allowed jitter/drift value is dependent on the transmitter clock tick period and HF receiver clock period. 1 Allows a jitter/clock drift as per SAE spec (50%). **Note:** This bit should be set to 1 for proper functioning of SRX.
18	Reserved. Read returns zero.
21	Reserved. Read returns zero.
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable Enables interrupt assertion when there is an underflow condition on Slow Message DMA registers. Default value is 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 FAST_CLR	Fast Clearing Enable bit Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See *Fast Message Ready Status Register (FMSG_RDY)* and *Slow Serial Message Ready Status Register (SMSG_RDY)* for details on the ready status bits. 0 Fast Clearing is disabled. Bits will be cleared by writing 1. 1 Fast Clearing is enabled.

Table 768. GBL_CTRL field descriptions (continued)

Field	Description
29 DBG_FRZ	Debug Freeze This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 No effect in debug mode 1 Freeze in debug mode
31 SENT_EN	SENT Receiver Global Enable This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 Entire module is disabled 1 Module is enabled

45.3.2.2 Channel Enable Register (CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and these bits must be written to 0.

Figure 774. Global Status Register (GBL_STATUS)

Table 770. GBL_STATUS field descriptions

Field	Description
22 FMDU	Fast Message DMA Underflow Interrupt Status bit that indicates when there is an underflow in Fast Message buffers in any channel which has DMA enabled. This bit is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 No underflow 1 Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 No underflow 1 Underflow occurred

45.3.2.4 Fast Message Ready Status Register (FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via *Fast Message DMA Control Register (FDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Fast Message Ready Interrupt Control Register (FRDY_IE)*) and the channel is enabled, the message ready status bit in this register will get asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Global Control Register (GBL_CTRL)*.

Note: Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits are unadvisable and may cause unexpected behavior.

Note: Under certain conditions, the Single Edge Nibble Transmission (SENT) Receiver (SRX) stalls and the Fast Message Data Ready bit for the SENT channel (FMSG_RDY[F_RDYn]) will no longer get set to indicate that a fast message is available. Reads of any of the fast message registers by the MCU core will stall and not complete. The registers affected are: DMA_FMSG_DATA (Direct Memory Access (DMA) Fast Message Data Read Register), DMA_FMSG_CRC (DMA Fast Message Cyclic Redundancy Check Register), DMA_FMSG_TS (DMA Fast Message Time-stamp Register), CHn_FMSG_DATA (Channel Fast Message Data Read Register), CHn_FMSG_CRC (Channel Cyclic Redundancy Check Register), CHn_FMSG_TS (Channel Fast Message Time-stamp Register).

This condition occurs when the SENT Receiver is configured as follows:

- *SENT high frequency clock is set higher than the Peripheral Bridge clock;*
- *Polling of ready status bit (FMSG_RDY[F_RDYn]) is used to detect a new message reception instead of interrupt or DMA request;*
- *The fast clear mechanism is used (GBL_CTRL[FAST_CLR] = 1) or the Software Clear (GBL_CTRL[FAST_CLR] = 0) is used for clearing the ready status bits (FMSG_RDY[F_RDYn]); and*
- *an overflow status condition is detected in the SENT Receiver Channel Status register (CHn_STATUS[FMSG_OFLW] = 1).*

The overflow occurs when two messages are allowed to queue in the internal buffers of the SENT Receiver.

Program the clock dividers in MCU for peripheral bridge clock and SENT clock such that SENT clock is always less than or equal to the peripheral bridge clock. In this case, the stall does not occur and MCU transactions to SENT registers will complete.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Global Control Register (GBL_CTRL)*.

Figure 775. Fast Message Ready Status Register (FMSG_RDY)

Table 771. FMSG_RDY field descriptions

Field	Description
16:31 F_RDY[15:0]	Fast Message Data Ready Status Bit Indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). **Note:** These bits are either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL). 0 No Fast Message is available to be read out via Interrupt 1 Fast Message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Global Control Register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. **Note:** When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

45.3.2.5 Slow Serial Message Ready Status Register (SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via *Fast Message DMA Control Register (FDMA_CTRL)* and *Slow Serial Message DMA Control Register (SDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Fast Message Ready Interrupt Control Register (FRDY_IE)* and *Slow Serial Message Ready Interrupt Enable Register (SRDY_IE)*) and the channel is enabled, the message

ready status bit in this register will get asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Global Status Register (GBL_STATUS)*.

Note: Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits are unadvisable and may cause unexpected behavior.

Figure 776. Slow Serial Message Ready Status Register (SMSG_RDY)

Table 772. SMSG_RDY field descriptions

Field	Description
16:31 S_RDY[15:0]	Slow Serial Message Data Ready Status Bit Indicates that a Slow Serial Message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Serial Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). 0 No Slow Serial Message is available to be read out via Interrupt 1 Slow Serial Message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Global Control Register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 Fast Message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

Field	Description
0:31 TS	Time Stamp for received message Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

45.3.2.15 DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

The DMA_SMSG_BIT3 is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in *Figure 801*, *Figure 802* and *Figure 803*. *Figure 801* and *Figure 802* shows the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 803* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Offset: 0x0050 Access: User read only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 786. DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

Table 782. DMA_SMSG_BIT3 Field Descriptions

Field	Description
0:3 CHNUM	Channel Number Indicates the channel number of the received message being read by DMA. Valid values are 0 to ‘15’
4 TYPE	Serial Message Type Indicates the type of Serial Message received 0 Short Serial Message 1 Enhanced Serial Message
20	Placed as 0 by Specification
21 CFG	Configuration bit ‘C’ Indicates the type of Enhanced Serial message. 0 Enhanced Serial Message with 8-bit ID field 1 Enhanced Serial Message with 4-bit ID field
22:23 ID7_6/ID3_2	ID Field Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[7:6] and if the ‘C’ bit is 1, this field is ID[3:2].
24:25 ID5_4/ID1_0	ID Field Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[5:4] and if the ‘C’ bit is 1, this field is ID[1:0].

Table 782. DMA_SMSG_BIT3 Field Descriptions (continued)

Field	Description
26	0 as per SAE Specification
27:30 ID3_0/DATA15_12	ID or Data Field Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12].
31	0 as per SAE Specification

Note: If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID & DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID & DATA fields.

45.3.2.16 DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in *Figure 801*, *Figure 802* and *Figure 803*. *Figure 801* and *Figure 802* shows the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 803* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Offset: 0x0054 Access: User read only

Figure 788. DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)

Table 784. DMA_SMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for the received message Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

45.3.2.18 Channel *n* Clock Control Register (CH*n*_CLK_CTRL)

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

The SENT module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock. See *Section 45.4.5: Adjustment for variation in sensor (Tx) clock* for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (CHNL_EN).

Offset: 0x0060 + *n**0x10 (*n* = 0 to (CH-1)) Access: Read/Write

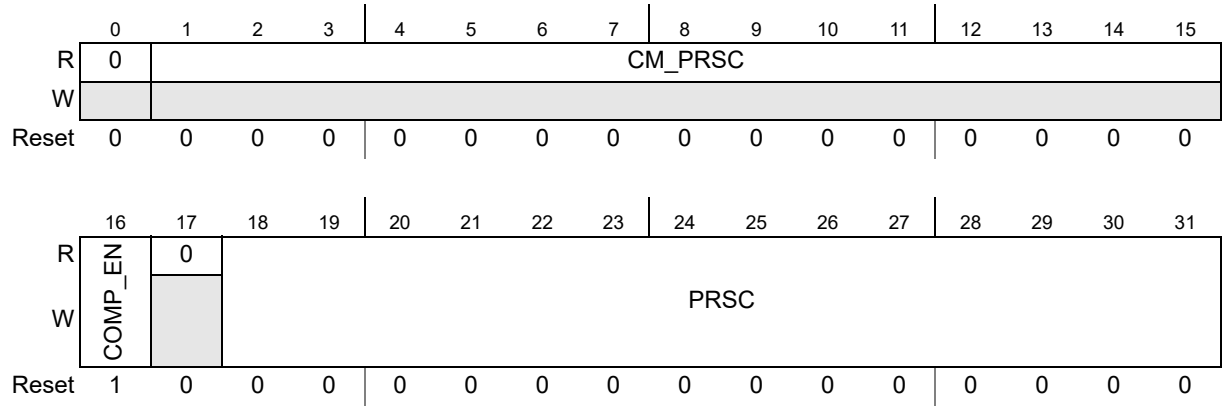

Figure 789. Channel *n* Clock Control Register (CH*n*_CLK_CTRL))

Table 785. CH*n*_CLK_CTRL field descriptions

Field	Description
1:15 CM_PRSC	Compensated Prescaler Value This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' – No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' – Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' – Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as Compensated Prescaler Value × High Frequency Receiver Clock Period **Note:** The value provided in this field is ceiling value of actual tick period as measured by the Receiver.

Table 785. CH*n*_CLK_CTRL field descriptions (continued)

Field	Description
16 COMP_EN	Compensation Enable To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 Compensation is disabled. 1 Compensation is enabled.
18:31 PRSC	Rx Prescaler Value This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (T_{rx_clk}) is not divisible by the high frequency receiver clock (protocol clock) period (T_{hf_clk}), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 Prescaler is bypassed. Should not be used. Non-Zero Value Enables Prescaler The required value is computed by software as follows: **Equation 35 Prescaler_value = floor (Trx_clk / Thf_clk)** (both clock periods taken in µs). Please see *Section 45.5.3: High frequency receiver clock (protocol clock) requirements* before setting this value. For example, if the required receiver clock tick period is 43 µs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 µs) then, Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

45.3.2.19 Channel *n* Status Register (CH*n*_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the bit for the corresponding channel.

Note: The value of the CH is device-specific. See the Chapter 7: Device configuration for details.

Table 786. CH*n*_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value (in *Channel n Configuration Register (CHn_CONFIG)*). CPU should write 1 to this clear this bit once it is read. 0 Bus is not idle. 1 Channel has been idle for more than the allowed value.
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 No interrupt 1 Interrupt Status condition has occurred.
5 CAL_20_25	Calibration Variation 20–25% Interrupt Status This bit indicates that the calibration pulse received on this channel has variation in between ±20% to ±25% from 56 ticks. 0 No Interrupt 1 Interrupt Status condition has occurred.
6 SMSG_OFLW	Slow Serial Message Overflow Status This bit indicates overflow occurred on this channel. Overflow will cause the older messages (which are not read out) to be overwritten with newly received messages. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt 1 Interrupt Status condition has occurred.

Table 786. CH*n*_STATUS field descriptions (continued)

Field	Description
7 FMSG_OFLW	Fast Message Overflow Status This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt 1 Interrupt Status condition has occurred
9 PP_DIAG_ERR	This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than ±1.5625% between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
10 CAL_LEN_ERR	This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks ±25%. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
11 CAL_DIAG_ERR	Successive Calibration pulses differ by ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (see *Section 45.5.3: High frequency receiver clock (protocol clock) requirements*). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
12 NIB_VAL_ERR	Any nibble data value <0 or >15. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
13 SMSG_CRC_ERR	Checksum error in Slow Serial Message This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.

Table 786. CH*n*_STATUS field descriptions (continued)

Field	Description
14 FMSG_CRC_ERR	Checksum error in Fast Message This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
15 NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of “Option 2” for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.

45.3.2.20 Channel *n* Configuration Register (CH*n*_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in *Channel n Status Register (CHn_STATUS)* and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (CHNL_EN).

Note: The value of the CH is device-specific. See the Chapter 7: Device configuration for details.

Figure 791. Channel *n* Configuration Register (CH*n*_CONFIG)

Table 787. CH*n*_CONFIG field descriptions

Field	Description
0:3 BUS_IDLE_CNT	Bus Idle Count This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000 Disabled 0001 127*2 Receiver Clock Tick Counts 0010 127*4 Receiver Clock Tick Counts 0100 127*8 Receiver Clock Tick Counts 1000 127*16 Receiver Clock Tick Counts
4 IE_CAL_RESYNC	Successive Calibration Check Resynchronized Interrupt Enable This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of “Option 2” being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled. 1 Interrupt is enabled.
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 Interrupt is disabled. 1 Interrupt is enabled.
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 FCRC_CHK_OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 Check is enabled. 1 Check is disabled/off.
9 IE_PP_DIAG_ERR	Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_CAL_LEN_ERR	Calibration pulse is wider than 56 ticks ±25%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 787. CH*n*_CONFIG field descriptions (continued)

Field	Description
11 IE_CAL_DIAG_ERR	Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_NIB_VAL_ERR	Any nibble data value <0 or >15 This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_SMSG_CRC_ERR	Checksum error in Slow Serial Message This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_FMSG_CRC_ERR	Checksum error in Fast Message This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast Messages will be received even if data nibbles are same. 1 Only Fast Messages with differing values of data nibbles will be received.
17 CAL_RNG	Valid Calibration Pulse Range Selection This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable. 1 25% variation is acceptable.

Table 787. CH*n*_CONFIG field descriptions (continued)

Field	Description
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run. 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 XOR based implementation (Recommended by SAE Specification) 1 Legacy LUT based implementation
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 Status and Communication Nibble not included in CRC calculation 1 Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 XOR based implementation (Recommended by SAE Specification) 1 Legacy LUT based implementation
22 PAUSE_EN	Pause Pulse Enable Enables the channel receiver to detect a pause pulse. 0 Detection of Pause Pulse is disabled. 1 Detection of Pause Pulse enabled.
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 such as Low Latency Option as per SAE Specification 1 Option 1 such as Preferred but High Latency Option as per SAE Specification
24:31 FIL_CNT	Input Filter Sample Count This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0x00: No filtering. Input from device's pad is only synchronized. Non-Zero: Filtering is enabled

Figure 797. Channel *n* Slow Serial Message Time Stamp Read Register (CH*n*_SMSG_TS)

Table 793. CH*n*_SMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for the received message Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

45.3.3 Register Classification for Safety

The registers of this module are classified as per Safety Requirements as follows:

Safety Critical: There are no safety critical registers in this module.

Safety Relevant: The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU/DMA. The registers containing these bits must be protected by periodic CRC or equivalent check implemented at SoC Level. The following register bits/fields are classified in this category:

- *Global Control Register (GBL_CTRL)*
- *Channel Enable Register (CHNL_EN)*
- *Fast Message Ready Status Register (FMSG_RDY)*
- *Slow Serial Message Ready Status Register (SMSG_RDY)*
- *Data Control Register 1 (DATA_CTRL1)* and *Data Control Register 2 (DATA_CTRL2)*
- *Fast Message DMA Control Register (FDMA_CTRL)*
- *Slow Serial Message DMA Control Register (SDMA_CTRL)*
- *Fast Message Ready Interrupt Control Register (FRDY_IE)*
- *Slow Serial Message Ready Interrupt Enable Register (SRDY_IE)*
- Fast Message DMA Read Register Set and Slow Message DMA Read Register Set

Safety Latent: The register bits/fields in this category should be protected by LBIST at SoC level. The following register bits/fields are classified in this category:

- *Global Status Register (GBL_STATUS)*
- *Channel n Status Register (CHn_STATUS)*
- *Channel n Configuration Register (CHn_CONFIG)*

Non-Safety: The following register bits are classified in this category:

- All other registers and bits fall in this category

45.4 Functional description

45.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the Channel Enable Register (CHNL_EN). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then

reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in *Global Control Register (GBL_CTRL)* to generate the time stamping clock
- Rx Prescaler Value in *Channel n Clock Control Register (CHn_CLK_CTRL)* to generate the channel's receiver clock
- Compensation enable in *Channel n Clock Control Register (CHn_CLK_CTRL)*
- Channel Configuration settings in the *Channel n Configuration Register (CHn_CONFIG)*
- Number of Data Nibbles in Channel in the *Data Control Register 1 (DATA_CTRL1)* and *Data Control Register 2 (DATA_CTRL2)*
- Control bits that control whether messages received in channel are to read by interrupt or DMA in *Fast Message DMA Control Register (FDMA_CTRL)*, *Slow Serial Message DMA Control Register (SDMA_CTRL)*, *Fast Message Ready Interrupt Control Register (FRDY_IE)* and *Slow Serial Message DMA Control Register (SDMA_CTRL)*

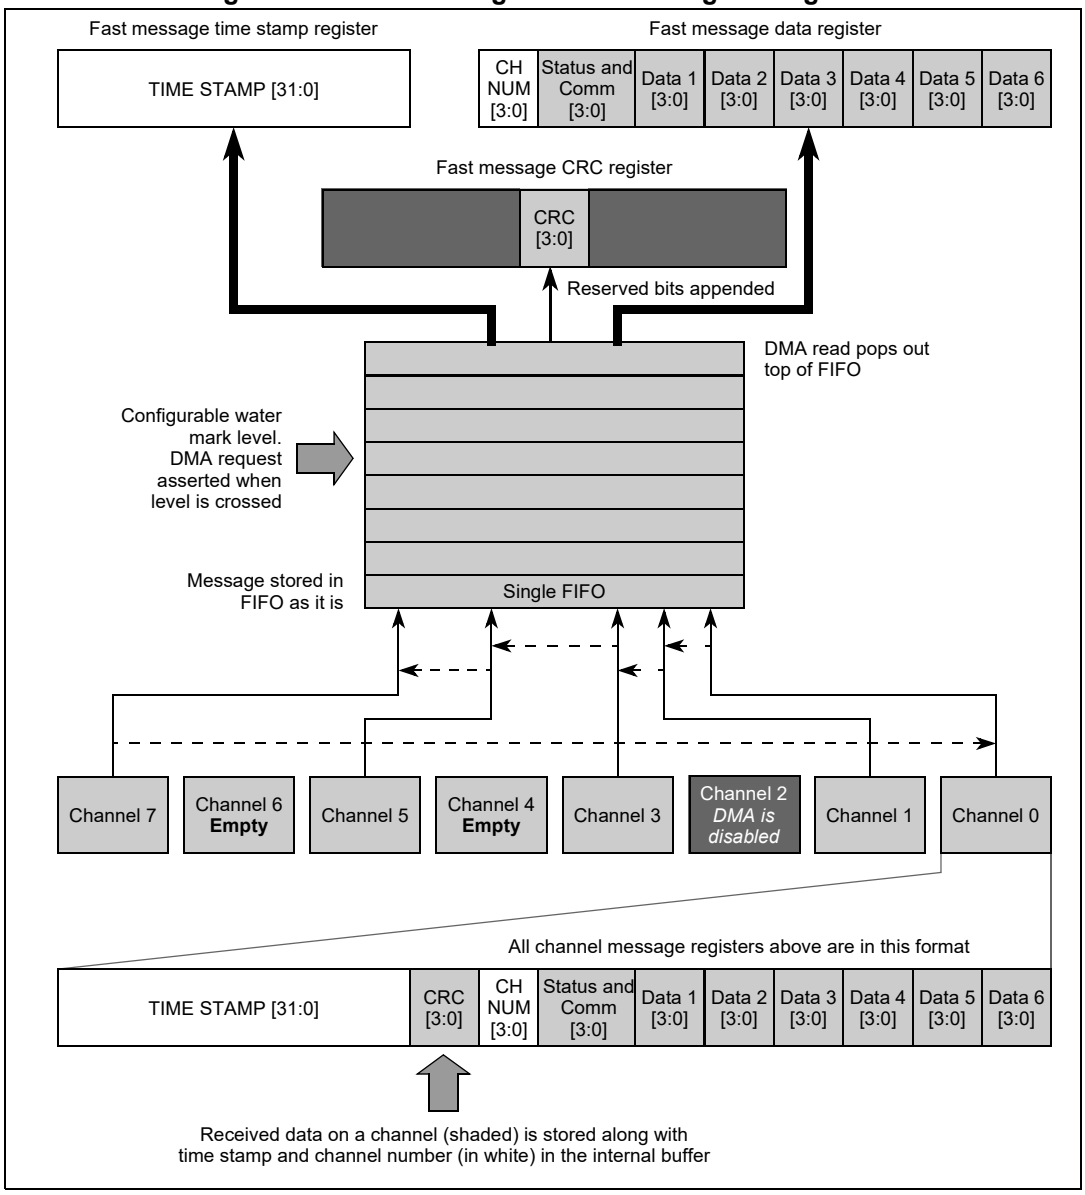
Note: When configuring the Single Edge Nibble Transmission (SENT) Receiver (SRX) to receive message with the Option 1 of the successive calibration pulse check method (CHn_CONFIG[SUCC_CAL_CHK] = 1), the number of expected edges error (CHn_STATUS[NUM[EDGES_ERR]) gets randomly asserted. Option 2 is not affected as the number of expected edges are not checked in this mode.

The error occurs randomly when the channel input (on the MCU pin) goes from idle to toggling of the calibration pulse.

Note: The Successive Calibration Pulse Check Method Option 1 and Option 2 are defined as follows:

- *Option 1 : Preferred but High Latency Option per SAE specification*
- *Option 2 : Low Latency Option per SAE specification*

To avoid getting the error, the sensor should be enabled first (by the MCU software) and when it starts sending messages, the SENT module should be enabled in the SENT Global Control register (by making GBL_CTRL[SENT_EN] = 1). The delay in start of the two can be controlled by counting a fixed delay in software between enabling the sensor and enabling the SENT module. The first message will not be received but subsequent messages will get received and there will be no false assertions of the number of expected edges error status bit (CHn_STATUS[NUM[EDGES_ERR]).



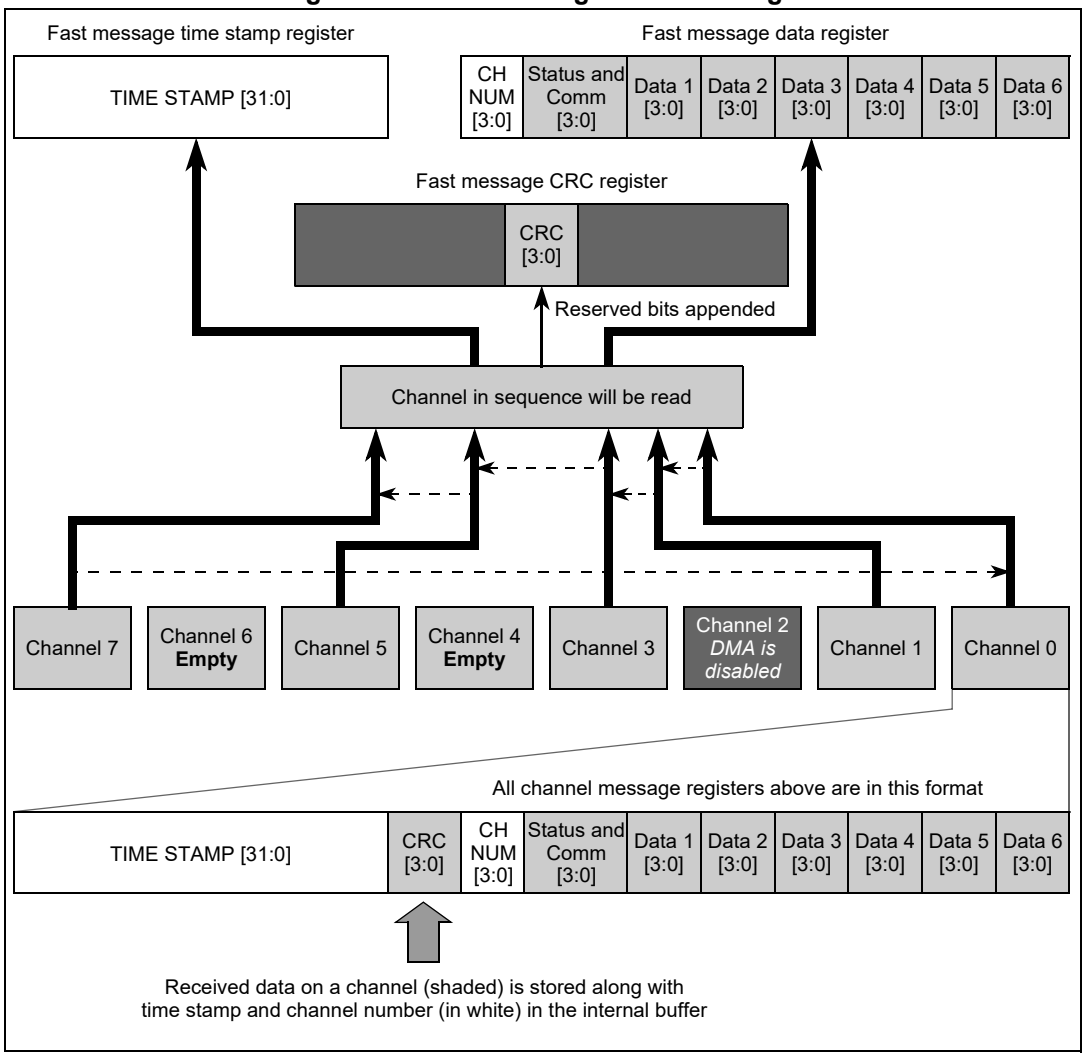
Alternatively, software can count the period from SENT enable (GBL_CTRL[SENT_EN] = 1) to the first expected calibration pulse. If the number of expected edges error status bit (CHn_STATUS[NUM[EDGES_ERR]) is asserted, software can simply clear it as there have no messages which have been completely received.

Alternatively, the software can clear this bit at the start and move ahead. When pause pulse is enabled, then NUM_EDGES will not assert spuriously for subsequent messages which do not have errors in them or cause overflows.

45.4.2 DMA read logic

The SENT module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in *Section 45.4.8: Time stamp logic*.

Figure 798. Fast Message DMA Read Logic using FIFO



45.4.2.1 DMA request for Fast Message reading

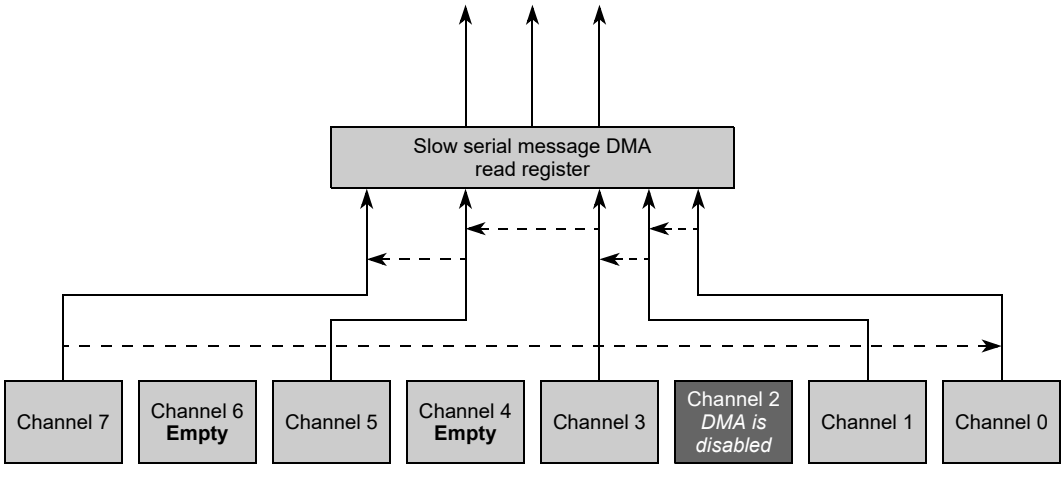
Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note that the DMA Controller must read all 3 DMA Read Registers to obtain the complete message.

The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - *DMA Fast Message Data Read Register (DMA_FMSG_DATA)*
  - *DMA Fast Message CRC Read Register (DMA_FMSG_CRC)*
  - *DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)*
- A fixed round robin sequencing runs, as shown in *Figure 799*, and this logic checks for messages in sequence 0→1→3 →5→7 and back to channel 0 and so on. Channel 2 is skipped as it's not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (such as, 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (such as,12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

Figure 799. Fast Message DMA read logic

Note: The data buffer related to the SENT data transferred by the DMA in the system memory is in the following order DMA_FMSG_TS, then DMA_FMSG_CRC and then DMA_FMSG_DATA.



45.4.2.2 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers.
- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - *DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)*
  - *DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*
  - *DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)*
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (such as, 3 DMA read accesses to the above mentioned registers).
- The channel number and time stamp will also be appended for every message.
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages.
- The DMA controller should be programmed to read only one message in one DMA transfer (such as, 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur.
- Since serial messages receive rate is very slow, user software should ensure there is no overflow.
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see *DMA request for Fast Message reading*).

Figure 800 shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

Figure 800. Slow Serial Message DMA read logic

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in one transfer.

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

Figure 801. Enhanced Serial Message with 8-bit ID field

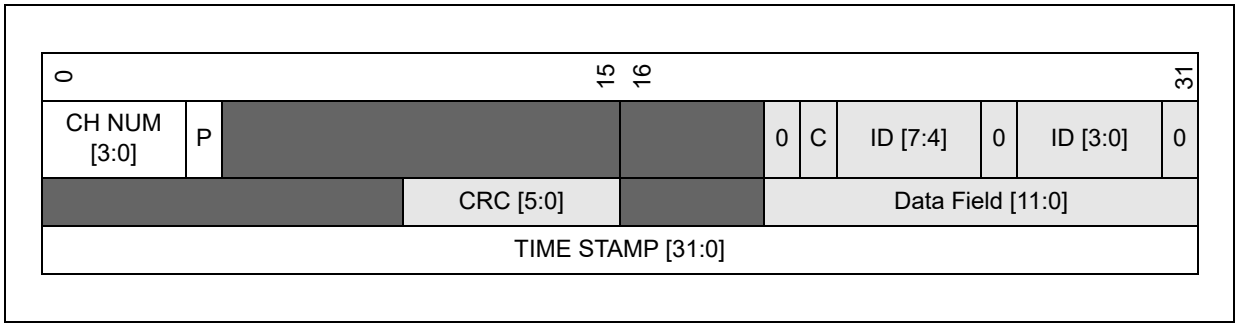


Figure 802. Enhanced Serial Message with 4-bit ID field

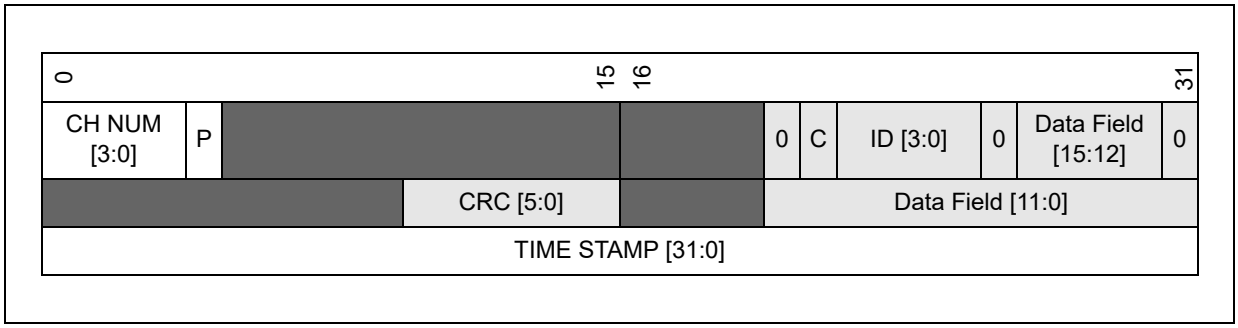

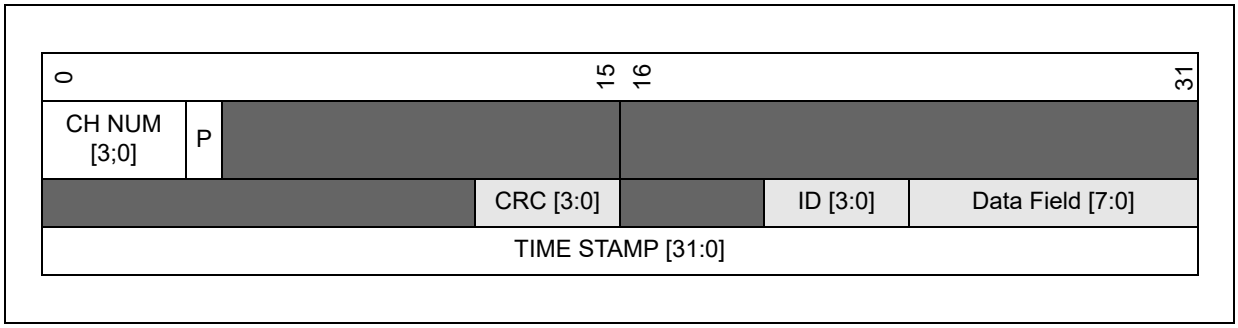

Figure 801 and *Figure 802* shows the enhanced serial messages. Bit C (shown in figure) or bit CFG (as shown in *DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)* description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in *DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)* description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Figure 803 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

Figure 803. Short serial message

Three 32-bit accesses to be made by DMA to get one complete message with time stamp.

45.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

45.4.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be:

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be:

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Threeread accesses will fetch complete message . Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable
- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

45.4.4 Overflow behavior

This section describes the overflow behavior.

45.4.4.1 Fast messages buffers

Overflow in Fast Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (such as, all **3** read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

45.4.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

45.4.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter

which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register (*Channel n Clock Control Register (CHn_CLK_CTRL)*). Software can use this value to determine the variation in Tx Clock.

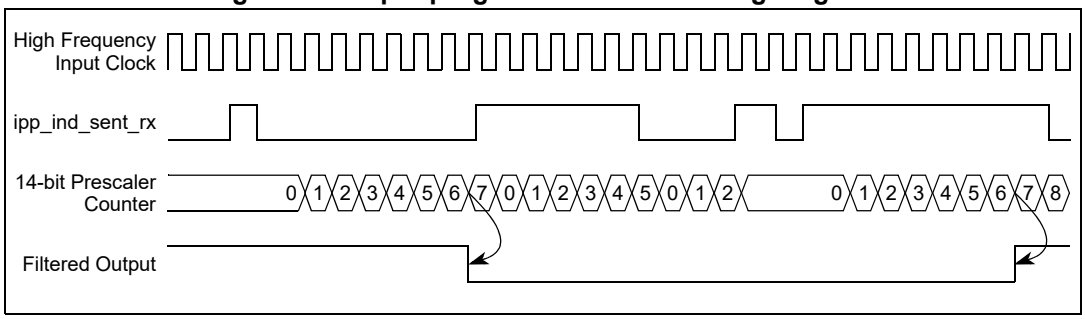
Note: A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

Note: At ambient temperatures above 114 degree C, Single Edge Nibble Transmission (SENT) Receiver (SRX) generates CAL_LEN_ERR and NUM_EDGES error when calibration pulse length from sensor is 25% higher than normal length. As temperature is increased, the frequency of occurrence of these errors also increases.

By configuring the SENT high frequency clock in the SRX module to run at a slower frequency (40 MHz) will help to reduce the occurrence of these errors.

45.4.5.1 Adjustment for nibble length variation



Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

45.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (such as, sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (such as, overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter

output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register (*Channel n Configuration Register (CHn_CONFIG)*). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (*Channel n Configuration Register (CHn_CONFIG)*). A timing diagram of the input filter when FIL_CNT is 4, is shown in *Figure 804*.

Figure 804. Input programmable filter timing diagram

45.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel.

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%
- Not the expected number of falling edges between calibration pulses (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use such as, Legacy or XOR-based.
- Any nibble data values measured as < 0 or > 15
- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (*Channel n Status Register (CHn_STATUS)*). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

45.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic

detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

45.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is T_{HF_CLK} and channel tick period is T_{TX_CLK} then the check will be of 1.5625% ± {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. So it won't allow variance in clock of a channel by 1.5625% - {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

45.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

45.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:

- Status and Communication nibble
- All Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

45.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using

either the legacy CRC implementation method or the new XOR-based CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

Note: The Single Edge Nibble Transmitter (SENT) Receiver does not properly round off incoming data to nearest nibble. For example, if the data nibble input to the SENT receiver is 3.5 to 3.87, it is rounded off to 3 instead of 4 as the jitter tolerance is 12.5% instead of 50%. As a result, the Channel n Fast Message Data Read Register (CHn_FMSG_DATA), or Channel n Fast Message Cyclic Redundancy Check (CRC) register (CHn_FMSG_CRC) register values may not match the expected values or the Message is not received at all because of the CRC mismatch.

Disable the CRC check by setting (to 0b1) the Fast Message CRC Check Off bit in the Channel Configuration register (CHn_CONFIG) and perform the CRC check of messages in software.

45.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per specification). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel 'n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel 'n' Status Register - CHn_STATUS(NUM_EDGES_ERR] = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion

of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. *Table 794* contains information due to erratum behavior and *Table 795* below contains clarification of normal NUM_EDGES_ERR behavior.

Table 794. Behavior of NUM_EDGES_ERR

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error
FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR errors
CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error
FMSG_OFLW	NUM_EDGES_ERR asserted once (random occurrence)	A message buffer overflow may lead the state machine to enter a state where it waits for a calibration pulse (behavior also seen in ERR007404). When in this state, the state machine can detect both a Pause pulse and a Calibration pulse as back to back calibration pulses and no edges in between. Then, the NUM_EDGES_ERR can get asserted. Since entry into this state is random, the error can be seen occasionally.	Ignore NUM_EDGES_ERR error

Table 795. Expected behavior, clarification of NUM_EDGES_ERR cases

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.	Ignore the NIB_VAL_ERR
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

45.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in *Global Control Register (GBL_CTRL)*) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 µs. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value to generate a time stamp clock of 1 µs resolution is 59.

Note: The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

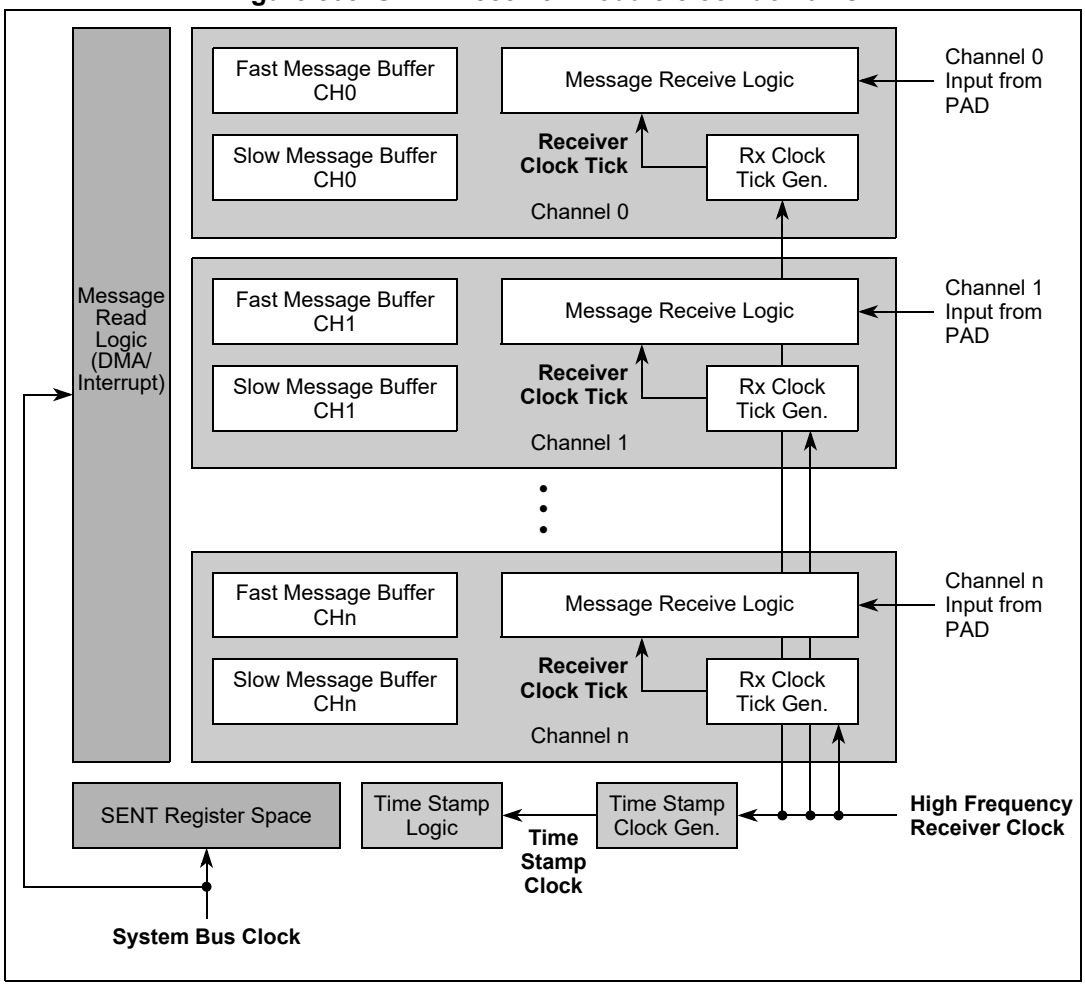
The time stamp for a serial message is sampled at the end of the message such as when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

45.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

45.4.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in *Channel n Configuration Register (CHn_CONFIG)*). Status bit (bus_idle in *Channel n Status Register (CHn_STATUS)*) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.



45.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

45.5.1 Clocking strategy

Figure 805 shows the clock domain in which each module is functioning.

Figure 805. SENT Receiver module clock domains

45.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 µs receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 µs (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as 154 $\times$ 2.4 = 369.6 µs. Now since messages are arriving in parallel, 369.6 µs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that 'N_{CHNL}' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be $369.6/N_{CHNL}$ µs or ~$370/N_{CHNL}$ µs. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as 'T_{RD}' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

Equation 36 $$3 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370/N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

Equation 37 $$3 \times T_{RD} + T_{WAKUP} < 370/N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get

For CPU,

Equation 38 $$(3 \times N_{RD} + N_{ISR}) \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(All units is µs)

For DMA,

Equation 39 $$3 \times N_{RD} \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(All units is µs)

45.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula below.

Equation 40 $F_{HF_CLK} > 332 / (3 \times T_{Tx_CLK})$

where F_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in MHz and T_{Tx_CLK} is the Transmitter or Sensor Clock Frequency in µs.

Note: T_{TX_CLK} in the above equation should be chosen based on the fastest sensor clock among all channels in the device.

46 FlexRay Communication Controller (FlexRay)

46.1 Introduction

46.1.1 Reference

The following documents are referenced in this chapter. They may be consulted for further information on the FlexRay Communication Controller's operation.

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A[n]
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0

46.1.2 Color coding

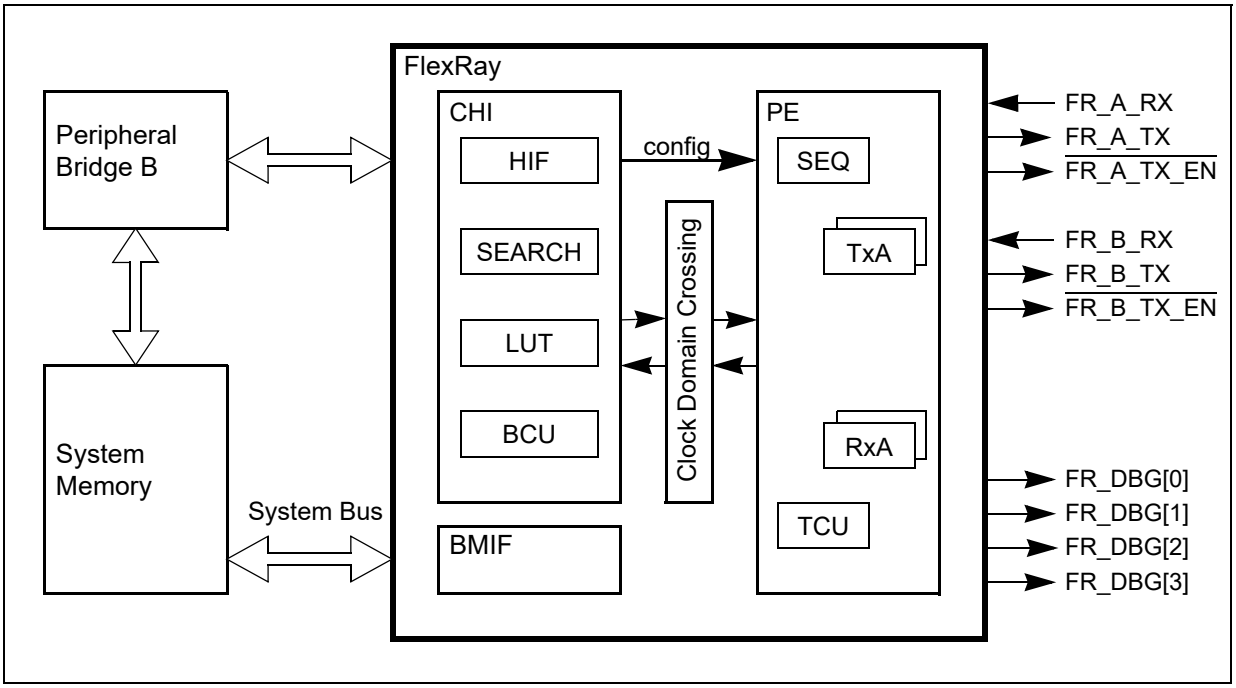
Throughout this chapter, some items are displayed in an italicized, colored font.

FlexRay protocol parameters, constants, and variables are highlighted with *blue italics*. An example is the parameter *gdActionPointOffset*.

FlexRay protocol states are highlighted in *green italics*. An example is the state *POC:normal active*.

46.1.3 Overview

The communication controller (CC) is a FlexRay communication controller that implements the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*



The CC has three main components:

- Controller host interface (CHI)
- Protocol engine (PE)
- Clock domain crossing unit (CDC)

A block diagram of the CC with its surrounding modules is given in *Figure 806*.

n. The FlexRay Specifications have been developed for automotive applications. The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Figure 806. FlexRay block diagram

The protocol engine has two transmitter units, TxA and TxB, and two receiver units, RxA and RxB, for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the protocol engine (PE) is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, as well as the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the controller host interface (CHI) clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the *Section 46.5.2.5: System Memory Base Address Register (FR_SYMBADR)*. All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note: The CC does not provide a memory protection scheme for the FlexRay memory area.

46.1.4 Features

The CC provides the following features:

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A-compliant protocol implementation
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0-compliant bus driver interface
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 64 configurable message buffers with
  - Individual frame ID filtering
  - Individual channel ID filtering
  - Individual cycle counter filtering
- Message buffer header, status, and payload data stored in dedicated FlexRay memory area
  - Allows for flexible and efficient message buffer implementation
  - Ensures consistent data access by means of a buffer-locking scheme
  - Application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0–254 bytes
- Two independent message buffer segments with configurable size of payload data section
  - Each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
  - Applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
  - Receive message buffer
  - Transmit message buffer
- Individual message buffers can be reconfigured
  - Individual message buffers can be disabled safely
  - Disabled message buffers can be reconfigured
- Two independent receive FIFOs
  - One receive FIFO per channel
  - Up to 255 entries for each FIFO
  - Global frame ID filtering, based on both value/mask filters and range filters
  - Global channel ID filtering
  - Global message ID filtering for the dynamic segment
- Four configurable slot error counters
- Four dedicated slot status indicators
  - Used to observe slots without using receive message buffers

- Measured value indicators for clock synchronization
  - Internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- One absolute timer
- One timer that can be configured as absolute or relative
- SECDED for protocol engine data RAM
- SEDDED for CHI lookup table RAM

46.1.5 Modes of operation

This section describes the basic operational power modes of the CC.

46.1.5.1 Disabled mode

The CC enters Disabled mode during hard reset or when the host clears the 'MEN' field in the Module Configuration Register (FR_MCR). The host can clear this field by writing '0' and only when the module is in *POC:default config* mode. The Disabled mode can be checked by reading the module enable field, MEN, in the Module Configuration Register (FR_MCR).

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled mode* can be accessed for writing as stated in *Section 46.5: Memory map and register description*.

The application configures the CC by accessing the configuration fields in the Module Configuration Register (FR_MCR) as described in *Section 46.7.2.1: Module initialization*.

46.1.5.1.1 Leave Disabled mode

The CC leaves Disabled mode and enters Normal mode, when the application writes 1 to FR_MCR[MEN].

Note: Once the CC is enabled, it cannot be disabled later.

46.1.5.2 Normal mode

In this mode, the CC is fully functional. The CC indicates that it is in Normal mode by asserting FR_MCR[EN].

46.1.5.2.1 Enter Normal mode

This mode is entered when the application requests that the CC leave Disabled mode. If Normal mode is entered after leaving Disabled mode, the application has to perform the protocol initialization described in *Section 46.7.2.2: Protocol initialization* to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB fields in the Module Configuration Register (FR_MCR), the corresponding FlexRay bus driver ports are enabled and driven.

46.1.5.3 System memory test

46.1.5.3.1 Bus Master Interface Functional Test for AMBA/AHB Bus

This section describes the test access to test the AMBA/AHB Bus Master Interface.

46.1.5.3.1.1 AMBA Read Access

This describes the sequence to initiate a AMBA read access

1. write word offset of address to read from into FR_PEDRAR[SYSMEMADDR]
2. and set the read/write indicator FR_PEDRAR[RW] to 1

The module clears the FR_PEDRAR[DAD] bit while access is running

The BMIF initiates a read from 64 bit-aligned byte address:
readaddr = ({SYSMEMADDR,0} + SMBA) & 64'hFFFFFFF8

The module sets the FR_PEDRAR[DAD] bit when access has finished

3. the data read and corresponds to {SYSMEMADDR,0} + SMBA are provided in the FR_PEDRDR register

46.1.5.3.1.2 AMBA Write Access (Prepare)

This describes how to provide data for the AMBA write access.

1. write 16-bit data to be written into FR_PEDRDR register
2. write 16-bit offset of address to be written to into FR_PEDRAR[SYSMEMADDR]
3. and set the read/write indicator FR_PEDRAR[RW] to 0

The module clears the FR_PEDRAR[DAD] bit.

The BMIF buffers this write request,

4. the module sets the FR_PEDRAR[DAD] bit when data are buffered

46.1.5.3.1.3 AMBA Write Access (Initiate)

The BMIF initiates the AMBA write access if any of sequences listed above was executed.
writeaddr = ({SYSMEMADDR,0} + SMBA) & 64'hFFFFFFF8.

Note: The read access to force the buffer write is not necessary in all cases, but suggested to have similar test sequences.

46.1.5.3.1.4 16 bit write initiate

A 16-bit write can be initiated as follows

- write to byte 0 and byte 1:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
  initiate read from any address, to force buffer write
- write to byte 2 and byte 3:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
  initiate read from any address, to force buffer write
- write to byte 4 and byte 5:
  initiate read from any address, to empty the buffer

write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
initiate read from any address, to force buffer write

- write to byte 6 and byte 7:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
  initiate read from any address, to force buffer write

46.1.5.3.1.5 32 bit write

- write to byte 0,1,2,3:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
  initiate read from any address, to force buffer write
- write to byte 4,5,6,7:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
  initiate read from any address, to force buffer write

46.1.5.3.1.6 64 bit write

- write to byte 0,1,2,3,4,5,6,7:
  initiate read from any address, to empty the buffer
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
  write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
  initiate read from any address, to force buffer write

46.2 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in *Table 796* and described in detail in *Section 46.2.1: Detailed signal description*.

Note: The off-chip FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ signals are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 796. External Signal Properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR_A_TX_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR_B_TX_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

46.2.1 Detailed signal description

This section provides a detailed description of the CC signals connected to external pins.

46.2.1.1 FR_A_RX – Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

46.2.1.2 FR_A_TX – Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

46.2.1.3 $\overline{\text{FR_A_TX_EN}}$ – Transmit Enable Channel A

The $\overline{\text{FR_A_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

46.2.1.4 FR_B_RX – Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

46.2.1.5 FR_B_TX – Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

46.2.1.6 $\overline{\text{FR_B_TX_EN}}$ – Transmit Enable Channel B

The $\overline{\text{FR_B_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

46.2.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] – Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection, refer to *Section 46.6.16: Strobe signal support*.

46.3 Controller Host Interface clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

- The first constraint corresponds to the number of utilized message buffers and is specified in *Section 46.7.5: Number of usable message buffers*.
- The second constraint corresponds to the value of the TIMEOUT field in the *Section 46.5.2.32: System Memory Access Timeout Register (FR_SYMATOR)* and is specified in *Section 46.7.1.1: Configure System Memory Access Timeout Register (FR_SYMATOR)*.

46.4 Protocol engine clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select field, CLKSEL, in the *Section 46.5.2.4: Module Configuration Register (FR_MCR)*

Note: See the device clocking details for the exact clock sources used.

46.4.1 Oscillator clocking

If the protocol engine is clocked by the internal crystal oscillator, a 40 MHz crystal or CMOS-compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*

46.4.2 PLL clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately to generate the 40 MHz and 180 degree phase-shifted 40 MHz clocks and provide them to the PE. For more details, see the clocking chapter of the device reference manual.

46.5 Memory map and register description

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU.

Note: The following registers are 16-bit write accessible only:

- *Strobe Signal Control Register (FR_STBSCR)*
- *PE DRAM Access Register (FR_PEDRAR)*
- *PE DRAM Data Register (FR_PEDRDR)*

- *Sync Frame ID Rejection Filter Register (FR_SFIDRFR)*
- *Slot Status Selection Register (FR_SSSR)*
- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Index Register (FR_RSBIR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*
- *Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)*
- *Message Buffer Frame ID Register (FR_MBFIDRn)*
- *Message Buffer Index Register (FR_MBIDXRn)*
- *Message Buffer Data Field Offset Register (FR_MBDORn)*
- *LRAM ECC Error Test Register (FR_LEETRn)*

46.5.1 Memory map

The complete memory map of the CC is shown in *Table 797*. The addresses presented here are the offsets relative to the CC base address, which is defined by the MCU address map.

Table 797. FlexRay memory map

Address Offset	Register Name	Location
Module Configuration and Control		
0x0000	Module Version Register (FR_MVR)	*Section 46.5.2.3*

46.5.2 Register descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities

46.5.2.1 Register Reset

All registers except the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), and Message Buffer Index Registers (FR_MBIDXRn) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are described in the detailed description of the register. The additional reset conditions are explained in *Table 798*.

Table 798. Additional register reset conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes RUN command “0101” to the POCCMD field in the *Section 46.5.2.11: Protocol Operation Control Register (FR_POCR)*.
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants a disable to the application by clearing the FR_MBCCSRn[EDS] bit.

46.5.2.2 Register write access

This section describes the write access restriction terms that apply to all registers.

46.5.2.2.1 Register write access restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in *Table 799*. If, for a specific register field, none of the given write access conditions is fulfilled, any write attempt to this register field is ignored without any notification. The values of the fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 799. Register Write Access Restrictions

Condition	Indication	Description
Anytime	—	No write access restriction.
Disabled mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled mode.
Normal mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal mode.

Table 799. Register Write Access Restrictions (continued)

Condition	Indication	Description
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSRn[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.
Functional Test Mode	FR_MCR[TMODE] = 1	Write access only when CC is in Functional Test Mode.

46.5.2.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

46.5.2.2.3 Internal Register Access

The following memory-mapped registers are used to access multiple internal registers.

- Strobe Signal Control Register (FR_STBSCR)
- Slot Status Selection Register (FR_SSSR)
- Slot Status Counter Condition Register (FR_SSCCR)
- Receive Shadow Buffer Configuration Data

Each of these memory-mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If WMD is set to 0 during the write access, all fields of the internal register are updated. If WMD is set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

46.5.2.3 Module Version Register (FR_MVR)

Offset: 0x0000 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CHIVER								PEVER							
W																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

Figure 807. Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Table 800. FR_MVR field descriptions

Field	Description
0:7 CHIVER	**CHI Version Number** This field provides the version number of the controller host interface.
8:15 PEVER	**PE Version Number** This field provides the version number of the protocol engine.

46.5.2.4 Module Configuration Register (FR_MCR)

Access: Read/Write
Write: SBFF, SCM, CHB, CHA, ECCE, TMODE, FUM, FAM, CLKSEL, BITRATE: Disabled mode
Offset: 0x0002
Write: MEN: Disabled or *POC:default config*
SFFE: Disabled Mode or *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 808. Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Table 801. FR_MCR field descriptions

Field	Description
0 MEN	**Module Enable** This bit indicates whether or not the CC is in Disabled mode. The application requests that the CC leave Disabled mode by writing 1 to this bit Before leaving Disabled mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, and BITRATE values. For details, see *Section 46.1.5: Modes of operation*. 0 Write: only during *POC:default config*, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled **Note:** If the CC is enabled, it can only be disabled during mode: POC:default config
1 SBFF	**System Bus Failure Freeze** This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to Freeze mode
2 SCM	**Single Channel Device Mode** This control bit defines the channel device mode of the CC as described in *Section 46.6.10: Channel device modes*. 0 CC works in Dual-Channel Device mode 1 CC works in Single-Channel Device mode

Table 801. FR_MCR field descriptions (continued)

Field	Description
3 CHB	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 802*.
4 CHA	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 802*.
5 SFFE	**Synchronization Frame Filter Enable** This bit controls the filtering for received synchronization frames. For details see *Section 46.6.15: Sync frame filtering*. 0 Synchronization frame filtering disabled 1 Synchronization frame filtering enabled
6 ECCE	**ECC Functionality Enable** This bit controls the ECC memory error detection functionality. For details see *Section 46.6.24: Memory content error detection*. 0 ECC functionality (injection, detection, reporting, response) disabled 1 ECC functionality enabled
7 TMODE	**Test Mode** This control bit is used to enable and disable the functional test mode. For details see *Section 1.2.6.5: Functional Test Mode*. 0 Functional Test Mode disabled 1 Functional Test Mode enabled
8 FUM	**FIFO Update Mode** This bit controls the FIFO update behavior when the interrupt flags FR_GIFER[FAFAIF] and FR_GIFER[FAFBIF] are written by the application (see *Section 46.6.9.8: FIFO update*) 0 FIFOA/FIFOB is updated on writing 1 to FR_GIFER[FAFAIF] /FR_GIFER[FAFBIF] 1 FIFOA/FIFOB) is *not* updated on writing 1 to FR_GIFER[FAFAIF]/FR_GIFER[FAFBIF]
9 FAM	**FIFO Address Mode** This bit controls the location of the system memory base address for the FIFOs (see *Section 46.6.9.2: FIFO configuration*). 0 FIFO Base Address located in *Section 46.5.2.5: System Memory Base Address Register (FR_SYMBADR))* 1 FIFO Base Address located in *Section 46.5.2.70: Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)*

Table 801. FR_MCR field descriptions (continued)

Field	Description
11 CLKSEL	**Protocol Engine Clock Source Select** This bit is used to select the clock source for the protocol engine. 0 PE clock source is generated by on-chip crystal oscillator. 1 PE clock source is generated by on-chip PLL.
12:14 BITRATE	**FlexRay Bus Bit Rate** This field defines the FlexRay bus bit rate. 000 10.0 Mbit/s 001 5.0 Mbit/s 010 2.5 Mbit/s 011 8.0 Mbit/s 100 Reserved 101 Reserved 110 Reserved 111 Reserved

Figure 810. System Memory Base Address Low Register (FR_SYMBADLR)

Note: The system memory base address must be set before the CC is enabled.

The system memory base address registers define the base address of the FlexRay memory area within the system memory. The base address is used by the bus master interface (BMIF) to calculate the physical memory address for system memory accesses.

Table 803. FR_SYMBADR field descriptions

Field	Description
SMBA	**System Memory Base Address** This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if FR_MCR[FAM] is set to 1. It is defined as a byte address.

46.5.2.6 Strobe Signal Control Register (FR_STBSCR)

Offset: 0x0008

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	SEL				0	0	0	ENB	0	0	STBPSEL	
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 811. Strobe Signal Control Register (FR_STBSCR)

This register is used to assign the individual protocol timing-related strobe signals given in *Table 805* to the external strobe ports. Each strobe signal can be assigned to at most one strobe port. Each write access to registers overwrites the previously-written ENB and STBPSEL values for the signal indicated by SEL. If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port. If no strobe signal is assigned to a strobe port, the strobe

port carries logic 0. For more detailed and timing information refer to *Section 46.6.16: Strobe signal support*.

Note: In Single-Channel Device mode, channel B-related strobe signals are undefined and should not be assigned to the strobe ports.

Table 804. FR_STBSCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
4:7 SEL	**Strobe Signal Select** This control field selects one of the strobe signals given in *Table 805* to be enabled or disabled and assigned to one of the four strobe ports.
11 ENB	**Strobe Signal Enable** The control bit is used to enable and disable the strobe signal selected by STBSSEL. 0 Strobe signal is disabled and not assigned to any strobe port. 1 Strobe signal is enabled and assigned to the strobe port selected by STBPSEL.
14:15 STBPSEL	**Strobe Port Select** This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 Assign selected signal to FR_DBG[0]. 01 Assign selected signal to FR_DBG[1]. 10 Assign selected signal to FR_DBG[2]. 11 Assign selected signal to FR_DBG[3].

Table 805. Strobe signal mapping

46.5.2.7 Message Buffer Data Size Register (FR_MBDSR)

Offset: 0x000C

Access: Read/Write
Write: *POC:config*

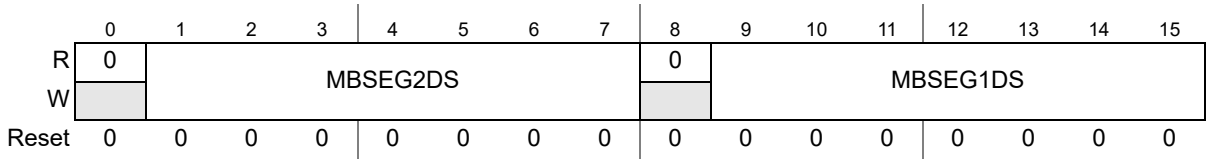

Figure 812. Message Buffer Data Size Register (FR_MBDSR)

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Table 806. FR_MBDSR field descriptions

Field	Description
1:7 MBSEG2DS	**Message Buffer Segment 2 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *second* message buffer segment.
9:15 MBSEG1DS	**Message Buffer Segment 1 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *first* message buffer segment.

46.5.2.8 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Offset: 0x000E

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	LAST_MB_SEG1						0	0	LAST_MB_UTIL

Reset	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

Figure 813. Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

This register defines the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Table 807. FR_MBSSUTR Field Descriptions

Field	Description
2:7 LAST_MB_SEG1	**Last Message Buffer In Segment 1** This field defines the message buffer number of the last individual message buffer that is assigned to the *first* message buffer segment. The individual message buffers in the *first* segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn with n ≤ LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1 + 1 individual message buffers. **Note:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the *second* message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 64. **Note:** If LAST_MB_SEG1 = 63, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
10:15 LAST_MB_UTIL	**Last Message Buffer Utilized** This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n ≤ LAST_MB_UTIL. **Note:** If LAST_MB_UTIL=LAST_MB_SEG1, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

46.5.2.9 PE DRAM Access Register (FR_PEDRAR)

Offset: 0x0010

Access: Read/Write(1)
Write: Normal mode or Functional Test mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SYSMEMADDR															DAD
W																RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 814. PE DRAM Access Register (FR_PEDRAR)

In Functional Test mode this register is used to setup read and write operations to the system memory.

The FR_PEDRAR is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this register initiates a read or write operation on the PE DRAM. The access done status bit, DAD, is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR is written into the PE DRAM, read back from the PE DRAM, and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data is read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description, refer to *Section 46.6.24: Memory content error detection*

Table 808. FR_PEDRAR field descriptions

Field	Description
15 DAD	**PE DRAM Access Done** This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done
0:14 SYSMEMADDR	Functional Test Mode Only **System Memory Address** This field defines the system memory address to be written to or read from.
15 RW	Functional Test Mode Only **Debug Read Write Selector** This control bit defines the access direction for the system memory access. 0 system memory write access 1 system memory read access

46.5.2.10 PE DRAM Data Register (FR_PEDRDR)

Offset: 0x0012

Access: Read/Write(1)

W	WME															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 816. Protocol Operation Control Register (FR_POCR)

The application uses this register to issue:

- Protocol control commands
- External clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see *Section 46.7.6: Protocol Control Command Execution*.

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to *Section 46.6.11: External clock synchronization*.

Table 810. FR_POCR Field Descriptions

Field	Description
0 WME	**Write Mode External Correction** This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write 1 No write to EOC_AP and ERC_AP fields on register write
4:5 EOC_AP	**External Offset Correction Application** This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 Do not apply external offset correction value 01 Reserved 10 Subtract external offset correction value 11 Add external offset correction value
6:7 ERC_AP	**External Rate Correction Application** This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21). 00 Do not apply external rate correction value 01 Reserved 10 Subtract external rate correction value 11 Add external rate correction value

Table 810. FR_POCR Field Descriptions (continued)

Field	Description
8 BSY_WMC	**Protocol Control Command Write Busy (BSY)** This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR), and will not change the value of the POCCMD field. (0) Command write idle, command accepted and ready to receive new protocol command (1) Command write busy, command not yet accepted, not ready to receive new protocol command **Write Mode Command (WMC)** This bit controls the write mode of the POCCMD field. (0) Write to POCCMD field on register write (1) Do not write to POCCMD field on register write
12:15 POCCMD	**Protocol Control Command** The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTAR: Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS: Delayed(1) transition to the All Slots Transmission mode. 0010 CONFIG: Immediately transition to the *POC:config* state. 0011 FREEZE: Immediately transition to the *POC:halt* state. 0100 READY, CONFIG_COMPLETE: Immediately transition to the *POC:ready* state. 0101 RUN: Immediately transition to the *POC:startup start* state. 0110 DEFAULT_CONFIG: Immediately transition to the *POC:default config* state. 0111 HALT: Delayed transition to the *POC:halt* state 1000 WAKEUP: Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

W				w1c	w1c	w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. In Functional Test Mode writing 1 toggles the interrupt flags.

Figure 817. Global Interrupt Flag and Enable Register (FR_GIFER)

This register controls some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation scheme for these flags is depicted in *Figure 965*. For more details on interrupt generation, see *Section 46.6.20: Interrupt support*. These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Table 811. FR_GIFER field descriptions

Field	Description
0 MIF	**Module Interrupt Flag** This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set
1 PRIF	**Protocol Interrupt Flag** This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set
2 CHIF	**CHI Interrupt Flag** This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the CHI error interrupt enable bit FR_GIFER[CHIE] are set. 0 All CHI error flags are equal to 0 or the CHI error interrupt is disabled 1 At least one CHI error flag and the CHI error interrupt enable are is set
3 WUPIF	**Wakeup Interrupt Flag** This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus

Table 811. FR_GIFER field descriptions (continued)

Field	Description
4 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or b) The current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO B almost full event has occurred **Note:** If the bit MCR[FUM] is set to 0, to clear FAFAIF or FAFBIF will also remove one element from the FIFO.
5 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) The current number of FIFO A entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO A almost full event has occurred
6 RBIF	**Receive Message Buffer Interrupt Flag** This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly; instead, it is cleared by the CC when all of the MBIF interrupt flags of the individual receive message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual receive message buffers has the MBIF and MBIE flag set 1 At least one individual receive message buffer has the MBIF and MBIE flag set
7 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application cannot clear this interrupt flag directly; instead, this interrupt flag is cleared by the CC when all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set 1 At least one individual transmit message buffer has the MBIF and MBIE flag set
8 MIE	**Module Interrupt Enable** This bit controls whether the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	**Protocol Interrupt Enable** This bit controls whether the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table 811. FR_GIFER field descriptions (continued)

Field	Description
10 CHIE	**CHI Interrupt Enable** This bit controls whether the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	**Wakeup Interrupt Enable** This bit controls whether the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
12 FAFBIE	**Receive FIFO Channel B Almost Full Interrupt Enable** This bit controls whether the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	**Receive FIFO Channel A Almost Full Interrupt Enable** This bit controls whether the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	**Receive Message Buffer Interrupt Enable** This bit controls whether the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 TBIE	**Transmit Message Buffer Interrupt Enable** This bit controls whether the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Figure 818. Protocol Interrupt Flag Register 0 (FR_PIFR0)

This register holds one set of the protocol-related individual interrupt flags.

Table 812. FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	**Fatal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. The fatal protocol errors are: – *pLatestTx* violation, as described in the MAC process of the FlexRay protocol – Transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event 1 Fatal protocol error detected
1 INTL_IF	**Internal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event 1 Internal protocol error detected
2 ILCF_IF	**Illegal Protocol Configuration Interrupt Flag** This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the *POC:halt* state immediately. The protocol engine checks the *listen_timeout* value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of *listen_timeout* is equal to 0, the protocol configuration setting is considered as illegal. 0 No such event 1 Illegal protocol configuration detected
3 CSA_IF	**Cold Start Abort Interrupt Flag** This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event 1 Cold start aborted and no more coldstart attempts allowed
4 MRC_IF	**Missing Rate Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	**Missing Offset Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event 1 Insufficient number of measurements for offset correction detected

Table 812. FR_PIFR0 field descriptions (continued)

Field	Description
6 CCL_IF	**Clock Correction Limit Reached Interrupt Flag** This flag is set when the internal calculated offset or rate calculation values have reached or exceeded their configured thresholds as given by the *offset_coorection_out* field in the Protocol Configuration Register 9 (FR_PCR9) and the *rate_correction_out* field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event 1 Offset or rate correction limit reached
7 MXS_IF	**Max Sync Frames Detected Interrupt Flag** This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the *node_sync_max* field in the Protocol Configuration Register 30 (FR_PCR30). 0 No such event 1 More than *node_sync_max* sync frames detected **Note:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account
8 MTX_IF	**Media Access Test Symbol Received Interrupt Flag** This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event 1 MTS symbol received
9 LTXB_IF	*pLatestTx* **Violation on Channel B Interrupt Flag** This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation, as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel B
10 LTXA_IF	*pLatestTx* **Violation on Channel A Interrupt Flag** This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel A
11 TBVB_IF	**Transmission across boundary on channel B Interrupt Flag** This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel B
12 TBVA_IF	**Transmission across boundary on channel A Interrupt Flag** his flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel A
13 TI2_IF	**Timer 2 Expired Interrupt Flag** This flag is set whenever timer 2 expires. 0 No such event 1 Timer 2 has reached its time limit

Table 812. FR_PIFR0 field descriptions (continued)

Field	Description
14 TI1_IF	**Timer 1 Expired Interrupt Flag** This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	**Cycle Start Interrupt Flag** This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started

Figure 819. Protocol Interrupt Flag Register 1 (FR_PIFR1)

The register holds one set of the protocol-related individual interrupt flags.

Table 813. FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	**Error Mode Changed Interrupt Flag** This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event 1 ERRMODE field changed
1 IPC_IF	**Illegal Protocol Control Command Interrupt Flag** This flag is set when the PE tries to execute a protocol control command that was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case, the command is not executed. For more details, see *Section 46.7.6: Protocol Control Command Execution*. 0 No such event 1 Illegal protocol control command detected
2 PECF_IF	**Protocol Engine Communication Failure Interrupt Flag** This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event 1 Protocol Engine Communication Failure detected

Table 813. FR_PIFR1 field descriptions (continued)

Field	Description
3 PSC_IF	**Protocol State Changed Interrupt Flag** This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event 1 Protocol state changed
4 SSI3_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR3) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
5 SSI2_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR2) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
6 SSI1_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR1) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
7 SSI0_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR0) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
10 EVT_IF	**Even Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the even cycle. 0 No such event 1 Sync frame measurement table written
11 ODT_IF	**Odd Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the odd cycle. 0 No such event 1 Sync frame measurement table written

1. In Functional Test Mode writing 1 toggles the interrupt flags.

Figure 822. CHI Error Flag Register (FR_CHIERFR)

This register holds the CHI-related error flags. The interrupt generation for each of these error flags is controlled by the CHI interrupt enable bit, CHIE, in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 816. FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	**Frame Lost Channel B Error Flag** This flag is set if a complete frame was received on channel B but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	**Frame Lost Channel A Error Flag** This flag is set if a complete frame was received on channel A but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected

Table 816. FR_CHIERFR field descriptions (continued)

Field	Description
2 PCMI_EF	**Protocol Command Ignored Error Flag** This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case, the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	**Receive FIFO Overrun Channel B Error Flag** This flag is set when an overrun of the FIFO for channel B has occurred. This error occurs if a semantically valid frame was received on channel B and matches all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	**Receive FIFO Overrun Channel A Error Flag** This flag is set when an overrun of the FIFO for channel A has occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	**Message Buffer Search Error Flag** This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 67 is detected in the FR_MBIDXR[MBIDX] field of a found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to *Section 46.6.7.4: Message buffer search error* for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
6 MBU_EF	**Message Buffer Utilization Error Flag** This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	**Lock Error Flag** This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected

Table 816. FR_CHIERFR field descriptions (continued)

Field	Description
9 SBCF_EF	**System Bus Communication Failure Error Flag** This flag is set if a system bus access was not finished within the required amount of time (see *Section 46.6.19.1.2: System bus access timeout*). 0 No such event 1 System bus access not finished in time
10 FID_EF	**Frame ID Error Flag** This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register. 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	**Dynamic Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	**Static Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	**Network Management Length Error Flag** This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case, the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
14 NMF_EF	**Network Management Frame Error Flag** This flag is set if a received message in the static segment with a Preamble Indicator flag (PP) asserted has its Null Frame indicator flag (NF) asserted as well. In this case, the Global Network Management Registers (see *Section 46.5.2.39: Network Management Vector Registers (FR_NMVRn)*) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	**Illegal System Bus Address Error Flag** This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see *Section 46.6.19.1.1: System bus illegal address access*). 0 No such event 1 Illegal system bus address accessed

46.5.2.18 Message Buffer Interrupt Vector Register (FR_MBIVEC)

Figure 823. Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their MBIF interrupt status flag and MBIE interrupt enable bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Table 817. FR_MBIVEC field descriptions

Field	Description
2:7 TBIVEC	**Transmit Buffer Interrupt Vector** This field provides the number of the lowest numbered enabled transmit message buffer that has its MBIF interrupt status flag and its MBIE interrupt enable bit set. If there is no transmit message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.
10:15 RBIVEC	**Receive Buffer Interrupt Vector** This field provides the message buffer number of the lowest numbered receive message buffer that has its MBIF interrupt flag and its MBIE interrupt enable bit asserted. If there is no receive message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.

46.5.2.19 Channel A Status Error Counter Register (FR_CASERCR)

1. **A**dditional Reset: RUN Command

Figure 824. Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits *vSS!SyntaxError, vSS!ContentError, vSS!BViolation*, and *vSS!TxConflict*. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see *Section 46.6.18: Slot status monitoring*.

Table 818. FR_CASERCR Field Descriptions

Field	Description
0:15 CHAERSCNT	**Channel Status Error Counter** This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

46.5.2.20 Channel B Status Error Counter Register (FR_CBSERCR)

1. **A**dditional Reset: RUN Command

Figure 825. Channel B Status Error Counter Register (FR_CBSERCR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the network idle time (NIT). The slot status vector contains the four protocol-related error indicator bits *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, and *vSS!TxConflict*. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see *Section 46.6.18: Slot status monitoring*.

Table 819. FR_CBSERCR field descriptions

Field	Description
0:15 CHBERSCNT	**Channel Status Error Counter** This field provides the current channel status error count. The counter value is updated within the first macrotick of the following slot or segment.

Figure 827. Protocol Status Register 1 (FR_PSR1)

Table 821. FR_PSR1 field descriptions

Field	Description
0 CSAA	**Cold Start Attempt Aborted Flag** protocol-related event: 'set coldstart abort indicator in CHI.' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	**Leading Cold Start Path** This status bit is set when the CC has reached the *POC:normal active* state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 *POC:normal active* reached from *POC:startup* state via leading cold start path
3:7 REMCSAT	**Remaining Coldstart Attempts** protocol-related variable: *vRemainingColdstartAttempts.* This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	**Leading Cold Start Path Noise**—protocol-related variable: *vPOC!ColdstartNoise.* This status bit is set if the CC has reached the *POC:normal active* state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 *POC:normal active* state was reached from *POC:startup* state via noisy leading cold start path
9 HHR	**Host Halt Request Pending** protocol related variable: *vPOC!CHIHaltRequest.* This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 HALT command received
10 FRZ	**Freeze Occurred** protocol related variable: *vPOC!Freeze.* This status bit is set when the CC has reached the *POC:halt* state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11:15 APTAC	**Allow Passive to Active Counter** protocol-related variable: *vPOC!vAllowPassivetoActive.* This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the *POC:normal passive* state due to an application-configured delay to enter *POC:normal active* state. This delay is defined by the allow_passive_to_active field in Protocol Configuration Register 12 (FR_PCR12).

46.5.2.23 Protocol Status Register 2 (FR_PSR2)

1. Additional Reset: RUN Command

Figure 828. Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the network idle time (NIT), the symbol window, and the clock synchronization. The NIT-related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The symbol-window-related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol-window-related status bits remain in their reset state. The clock synchronization-related CKCORFCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Table 822. FR_PSR2 field descriptions

Field	Description
0 NBVB	**NIT Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for NIT on channel B. This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	**NIT Syntax Error on Channel B** protocol-related variable: *vSS!SyntaxError* for NIT on channel B. This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	**Symbol Window Transmit Conflict on Channel B** protocol-related variable: *vSS!TxConflict* for symbol window on channel B. This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	**Symbol Window Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for symbol window on channel B. This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected

Table 822. FR_PSR2 field descriptions (continued)

Field	Description
4 SSEB	**Symbol Window Syntax Error on Channel B** protocol related variable: *vSS!SyntaxError* for symbol window on channel B. This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	**Media Access Test Symbol MTS Received on Channel B** protocol-related variable: *vSS!ValidMTS* for Symbol Window on channel B. This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	**NIT Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for NIT on channel A. This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	**NIT Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected
8 STCA	**Symbol Window Transmit Conflict on Channel A** protocol related variable: *vSS!TxConflict* for symbol window on channel A. This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	**Symbol Window Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for symbol window on channel A. This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	**Symbol Window Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for symbol window on channel A. This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected

Table 822. FR_PSR2 field descriptions (continued)

Field	Description
11 MTA	**Media Access Test Symbol MTS Received on Channel A** protocol-related variable: *vSS!ValidMTS* for symbol window on channel A. This status bit is set if the Media Access Test Symbol (MTS) was received in the symbol window on channel A. 0 No such event 1 MTS symbol received
12:15 CKCORFCNT	**Clock Correction Failed Counter** protocol -elated variable: *vClockCorrectionFailed.* This field provides the number of consecutive even/odd communication cycle pairs that have passed without a clock synchronization offset or rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the *POC:normal active* state, or when both the rate and offset correction terms have been calculated successfully.

1. Additional Reset: RUN Command

Figure 834. Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Table 828. FR_RTCORVR Field Descriptions

Field	Description
0:15 RATECORR	**Rate Correction Value** protocol-related variable: *vRateCorrection* (before value limitation and external rate correction). This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag (CCL_IF) is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

46.5.2.30 Offset Correction Value Register (FR_OFCORVR)

1. Additional Reset: RUN Command

Figure 835. Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Table 829. FR_OFCORVR Field Descriptions

Field	Description
0:15 OFFSETCORR	**Offset Correction Value** protocol-related variable: *vOffsetCorrection* (before value limitation and external offset correction). This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

46.5.2.31 Combined Interrupt Flag Register (FR_CIFR)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 836. Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in *Figure 967*. The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

Note: The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 830. FR_CIFR field descriptions

Field	Description
8 MIF	**Module Interrupt Flag** This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	**Protocol Interrupt Flag** This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	**CHI Interrupt Flag** This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1. 0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	**Wakeup Interrupt Flag** Provides the same value as FR_GIFER[WUPIF].
12 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFBIF].
13 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFAIF].
14 RBIF	**Receive Message Buffer Interrupt Flag** This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted 1 At least one individual receive message buffers has the MBIF flag asserted
15 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted 1 At least one individual transmit message buffers has the MBIF flag asserted

Figure 838. Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 macroticks after offset correction start.

Note: If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the SFODB and SFODA values.

Table 832. FR_SFCNTR field descriptions

Field	Description
0:3 SFEVB	Sync Frames Channel B, even cycle protocol-related variable: size of (*vsSyncIdListB* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4:7 SFEVA	Sync Frames Channel A, even cycle protocol related variable: size of (*vsSyncIdListA* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8:11 SFODB	Sync Frames Channel B, odd cycle protocol-related variable: size of (*vsSyncIdListB* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
12:15 SFODA	Sync Frames Channel A, odd cycle protocol-related variable: size of (*vsSyncIdListA* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.

Figure 840. Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see *Section 46.6.12: Sync frame ID and sync frame deviation tables*.

Table 834. FR_SFTCCSR field descriptions

Field	Description
0 ELKT	**Even Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables
1 OLKT	**Odd Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables

Table 834. FR_SFTCCSR field descriptions (continued)

Field	Description
2:7 CYCNUM	**Cycle Number** This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	**Even Cycle Tables Lock Status** This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables 1 Application has locked the even cycle tables
9 OLKS	**Odd Cycle Tables Lock Status** This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables 1 Application has locked the odd cycle tables
10 EVAL	**Even Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
11 OVAL	**Odd Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
13 OPT	**One Pair Trigger** This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.

Table 834. FR_SFTCCSR field descriptions (continued)

Field	Description
14 SDVEN	**Sync Frame Deviation Table Enable** This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area **Note:** If SDVEN is set to 1, then SIDEN must also be set to 1.
15 SIDEN	**Sync Frame ID Table Enable** This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 844. Network Management Vector Registers (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0–FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Table 838. NMVR*n* field descriptions

Field	Description
0:15 NMVP	**Network Management Vector Part** The mapping between the Network Management Vector Registers (FR_NMVR0–FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in *Table 839*.

Table 839. Mapping of NMVRn to the Received Payload Bytes NMV*x*

1. It is read as 0. Application must not write 1 to this bit.

Figure 849. Timer 2 Configuration Register 0 (FR_TI2CR0)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to *Section 46.6.17.2: Absolute/relative timer T2*.

Table 844. FR_TI2CR0 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
2:7 T2_CYC_VAL	**Timer T2 Cycle Filter Value** This field defines the cycle filter value for timer T2.
10:15 T2_CYC_MSK	**Timer T2 Cycle Filter Mask** This field defines the cycle filter mask for timer T2.
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
0:15 T2_MTCNT[31:16]	**Timer T2 Macrotick High Word** This field defines the high word of the macrotick count for timer T2.

Note: If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

46.5.2.45 Timer 2 Configuration Register 1 (FR_TI2CR1)

Offset: 0x0062

Access: Read/Write
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved(1)				T2_MTOFFSET											
R W	T2_MTCNT[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. It is read as 0. Application must not write 1 to this bit.

Figure 850. Timer 2 Configuration Register 1 (FR_TI2CR1)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to *Section 46.6.17.2: Absolute/relative timer T2*.

Table 845. FR_TI2CR1 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
2:15 T2_MTOFFSET	**Timer T2 Macrotick Offset** This field holds the macrotick offset value for timer T2.

Table 845. FR_TI2CR1 field descriptions

Field	Description
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
0:15 T2_MTCNT[15:0]	**Timer T2 Macrotick Low Word** This field defines the low word of the macrotick value for timer T2.

Note: If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

46.5.2.46 Slot Status Selection Register (FR_SSSR)

Offset: 0x0064

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	SEL		0	SLOTNUMBER										
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 851. Slot Status Selection Register (FR_SSSR)

This register is used to access the four internal non-memory-mapped Slot Status Selection Registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR_SSR0–FR_SSR7) according to *Table 847*. For a detailed description of slot status monitoring, refer to *Section 46.6.18: Slot status monitoring*.

Table 846. FR_SSSR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL field only on write access

Table 846. FR_SSSR field descriptions

Field	Description
2:3 SEL	**Selector** This field selects one of the four internal slot status selection registers for access. 00 Select FR_SSSR0 01 Select FR_SSSR1 10 Select FR_SSSR2 11 Select FR_SSSR3
5:15 SLOTNUMBER	**Slot Number** This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. **Note:** If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.

Table 847. Mapping between FR_SSSRn and FR_SSRn

Internal Slot Status Selection Register	Write the Slot Status of the Slot Selected by FR_SSSRn for each			
	Even Communication Cycle		Odd Communication Cycle	
	For Channel B to	For Channel A to	For Channel B to	For Channel A to
FR_SSSR0	FR_SSR0[0:7]	FR_SSR0[8:15]	FR_SSR1[0:7]	FR_SSR1[8:15]
FR_SSSR1	FR_SSR2[0:7]	FR_SSR2[8:15]	FR_SSR3[0:7]	FR_SSR3[8:15]
FR_SSSR2	FR_SSR4[0:7]	FR_SSR4[8:15]	FR_SSR5[0:7]	FR_SSR5[8:15]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 852. Slot Status Counter Condition Register (FR_SSCCR)

This register is used to access and program the four internal non-memory-mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal Slot Status Counter Condition Registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). The correspondence is given in *Table 849*. For a detailed description of slot status counters, refer to *Section 46.6.18.4: Slot Status Counter Registers*.

Table 848. FR_SSCCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
2:3 SEL	**Selector** This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0 01 select FR_SSCCR1 10 select FR_SSCCR2 11 select FR_SSCCR3
5:6 CNTCFG	**Counter Configuration** These bit field controls the channel related incrementing of the slot status counter. 00 Increment by 1 if condition is fulfilled on channel A 01 Increment by 1 if condition is fulfilled on channel B 10 Increment by 1 if condition is fulfilled on at least one channel 11 Increment by 2 if condition is fulfilled on both channels Increment by 1 if condition is fulfilled on only one channel.
7 MCY	**Multi Cycle Selection** This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	**Valid Frame Restriction** This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	**Sync Frame Restriction** This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	**Null Frame Restriction** This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.

Table 848. FR_SSCCR field descriptions (continued)

Field	Description
11 SUF	**Startup Frame Restriction** This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12:15 STATUSMASK	**Slot Status Mask** This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3]: This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2]: This bit enables the counting for slots with the content error indicator bit set to 1. STATUSMASK[1]: This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0]: This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

46.5.2.49 Slot Status Counter Registers (FR_SSCR*n*)

Offset: 0x0078 +*n**0x2 (*n* = 0 to 3) Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SLOTSTATUSCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 854. Slot Status Counter Registers (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal Slot Status Counter Condition Register (FR_SSCCRn), which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, see *Section 46.6.18.4: Slot Status Counter Registers*.

Note: If the counter has reached its maximum value 0xFFFF and is in Multicycle mode (that is, FR_SSCCRn[MCY] = 1), the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be put into Multicycle mode again.

Table 851. FR_SSCR*n* field descriptions

Field	Description
0:15 SLOTSTATUSCNT	**Slot Status Counter** This field provides the current value of the Slot Status Counter.

46.5.2.50 MTS A Configuration Register (FR_MTSACFR)

Figure 903. Stop Watch Count Low Register (FR_STPWLR)

Table 871. FR_STPWR field descriptions

Field	Description
0:15 STPW	Stop Watch Count Register This is the value of the stop watch counter running on system clock. This starts on cycle start even and stops on an external event “OS_tick”. For details see *Section 46.6.26*. This is a read reset type register, which means that when all the 32 bits are read, it automatically clears.

46.5.2.68 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Offset: 0x00E2

Figure 905. Receive FIFO Start Data Offset Register (FR_RFSDOR)

Table 873. FR_RFSDOR field descriptions

Field	Description
0:15 SDO_A/SDO_B	Start Data Field Offset This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO’s first message buffer header field. For configuration constraints, see *Section 46.7.1.2: Configure data field offsets*.

Note: Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses, the content of the FR_RFSDOR register corresponds to the start address of the payload area of the selected FIFO.

46.5.2.70 Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)

Figure 907. Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Table 874. FR_RFSYMBADR field descriptions

Field	Description
SMBA	System Memory Base Address This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defined as a byte address.

46.5.2.71 Receive FIFO Periodic Timer Register (FR_RFPTR)

Offset: 0x00EC

Access: Read/Write
Write: *POC:config*

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 908. Receive FIFO Periodic Timer Register (FR_RFPTR)

This register holds the periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see *Section 46.6.9.3: FIFO periodic timer*).

Table 875. FR_RFPTR field descriptions

Field	Description
2:15 PTD	Periodic Timer Duration This value defines the periodic timer duration in terms of macroticks. 0000 Timer stays expired 3FFF Timer never expires other Timer expires after specified number of macroticks, expires and is restarted at each cycle start

46.5.2.72 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

Offset: 0x00EE Access: Read/Write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 909. Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs.

Table 876. FR_RFFLPCR field descriptions

Field	Description
0:7 FLB_PCB	Fill Level FIFO B (FLB) This field provides the current number of entries in the FIFO B. Pop Count FIFO B (PCB) This field defines the number of entries to be removed from FIFO B.
8:15 FLA_PCA	Fill Level FIFO A (FLA) This field provides the current number of entries in the FIFO A. Pop Count FIFO A (PCA) This field defines the number of entries to be removed from FIFO A.

Note: If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, then the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

1. In Functional Test Mode writing 1 toggles the _OF and _IF flags.

Figure 910. ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC-related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description, see *Section 46.6.24.2*.

Table 877. FR_EEIFER field descriptions

Field	Description
Error Overflow Flags	
0 LRNE_OF	LRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *but not corrected* on CHI LRAM and interrupt flag LRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of CHI LRAM. 0 No such event 1 Non-Corrected Error overflow detected on CHI LRAM
1 LRCE_OF	LRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *and corrected* on CHI LRAM and interrupt flag LRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of CHI LRAM. 0 No such event 1 Corrected Error overflow detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
2 DRNE_OF	DRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *but not corrected* on PE DRAM and interrupt flag DRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of the PE DRAM. 0 No such event 1 Non-Corrected Error overflow detected on PE DRAM
3 DRCE_OF	DRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *and corrected* on PE DRAM and interrupt flag DRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of PE DRAM. 0 No such event 1 Corrected Error overflow detected on PE DRAM

Table 877. FR_EEIFER field descriptions (continued)

Field	Description
Error Interrupt Flags	
4 LRNE_IF	LRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on the CHI LRAM. 0 No such event 1 Non-Corrected Error detected on CHI LRAM
5 LRCE_IF	LRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on the CHI LRAM. 0 No such event 1 Corrected Error detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
6 DRNE_IF	DRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on PE DRAM. 0 No such event 1 Non-Corrected Error detected on PE DRAM
7 DRCE_IF	DRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on PE DRAM. 0 No such event 1 Corrected Error detected on PE DRAM
Error Interrupt Enables	
12 LRNE_IE	**LRAM Non-Corrected Error Interrupt Enable** This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 LRCE_IE	**LRAM Corrected Error Interrupt Enable** This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 DRNE_IE	**DRAM Non-Corrected Error Interrupt Enable** This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 DRCE_IE	**DRAM Corrected Error Interrupt Enable** This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

46.5.2.74 ECC Error Report and Injection Control Register (FR_EERICR)

Offset: 0x00F2

Access: Read/Write
Write: ERS: Anytime
ERM, EIM, EIE: IDL

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: CMT, DUP, DVAL, MBIF: Message Buffer Disable

Figure 918. Message Buffer Configuration, Control and Status Registers (FR_MBCCSR*n*)

The content of these registers comprises message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in *Section 46.6.6: Individual message buffer functional description*.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Table 887. FR_MBCCSR*n* field descriptions

Field	Description
Message Buffer Configuration	
3 MTD	Message Buffer Transfer Direction This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
Message Buffer Control	
4 CMT	Commit for Transmission This bit indicates if the transmit message buffer data are ready for transmission. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
Message Buffer Status	
11 DUP	Data Updated This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and message buffer data field not updated 1 Frame Header and message buffer data field updated
12 DVAL	Data Valid For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers, the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 Receive message buffer contains no valid frame data / message is transmitted for the first time. 1 Receive message buffer contains valid frame data / message will be transferred again.
13 EDS	Enable/Disable Status This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled 1 Message buffer is enabled

Table 887. FR_MBCCSR*n* field descriptions (continued)

Field	Description
14 LCKS	Lock Status This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application 1 Message buffer is locked by the application
15 MBIF	Message Buffer Interrupt Flag This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled In Functional Test Mode writing a 1 toggles the interrupt flag

46.5.2.82 Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

Offset: 0x0802 +*n**0x8 (*n* = 0 to 63)

Access: Read/Write(1)
Write: *POC:config* or MB_DIS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. 16-bit write access required

Figure 919. Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to *Section 46.6.7.1: Message buffer cycle counter filtering*.

Table 888. FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event Transmission mode 1 State Transmission mode
1 CHA	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 889*.
2 CHB	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 889*.
3 CCFE	Cycle Counter Filtering Enable This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled

Table 888. FR_MBCCFR*n* field descriptions (continued)

Field	Description
4:9 CCFMSK	Cycle Counter Filtering Mask This field defines the filter mask for the cycle counter filtering.
10:15 CCFVAL	Cycle Counter Filtering Value This field defines the filter value for the cycle counter filtering.

Table 889. Channel assignment description

CHA	CHB	Transmit message buffer		Receive message buffer	
		Static segment	Dynamic segment	Static segment	Dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Note: If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.

46.5.2.83 Message Buffer Frame ID Registers (FR_MBFIDR*n*)

Offset: 0x0804 +*n**0x8 (*n* = 0 to 63)

Access: Read/Write(1)

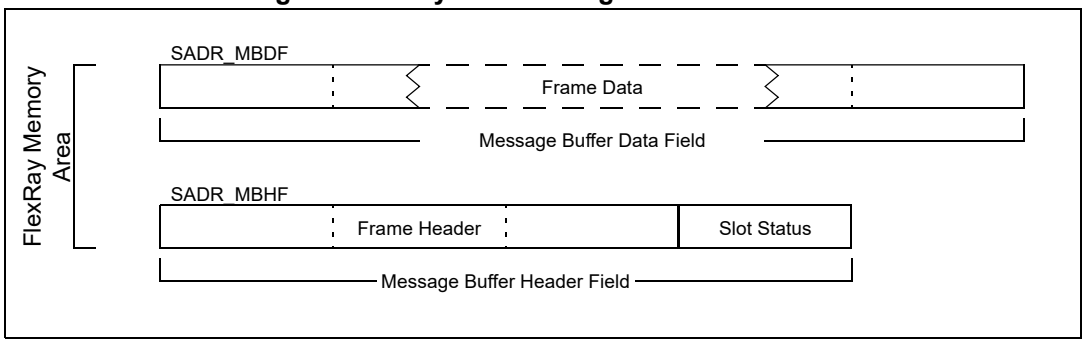
0:15 LEETD	LRAM ECC Error Test Data This field contains the LRAM data belonging to the test register located in LRAM Bank n.

46.6 Functional description

This section provides a detailed description of the functionality implemented in the CC.

46.6.1 Message buffer concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts: the *message buffer control data* and the *physical message buffer.* The message buffer control data is located in dedicated registers. The structure of the message buffer control data depends on the message buffer type, described in *Section 46.6.3: Message Buffer Types*. The physical message buffer is located in the FlexRay memory area and is described in *Section 46.6.2: Physical message buffer*.



46.6.2 Physical message buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area.The structure of a physical message buffer is depicted in *Figure 923*.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

Figure 924. Physical message buffer structure

46.6.2.1 Message buffer header field

The message buffer header field is a contiguous region in the FlexRay memory area that occupies eight bytes. It contains the frame header and the slot status. Its structure is shown in *Figure 924*. The physical start address SADR_MBHF of the message buffer header field must be 16-bit aligned.

46.6.2.1.1 Frame header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the usage and the content of the frame header is provided in *Section 46.6.5.2.1: Frame header description*.

46.6.2.1.2 Slot status

The slot status occupies the last 2 bytes of the message buffer header field. It provides the slot and frame status-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in *Section 46.6.5.2.2: Slot status description*.

46.6.2.2 Message buffer data field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in *Section 46.6.3: Message Buffer Types*.

46.6.3 Message Buffer Types

The CC provides three different types of message buffers.

- Individual Message Buffers
- Receive Shadow Buffers
- Receive FIFO Buffers

For each message buffer type, the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

46.6.3.1 Individual Message Buffers

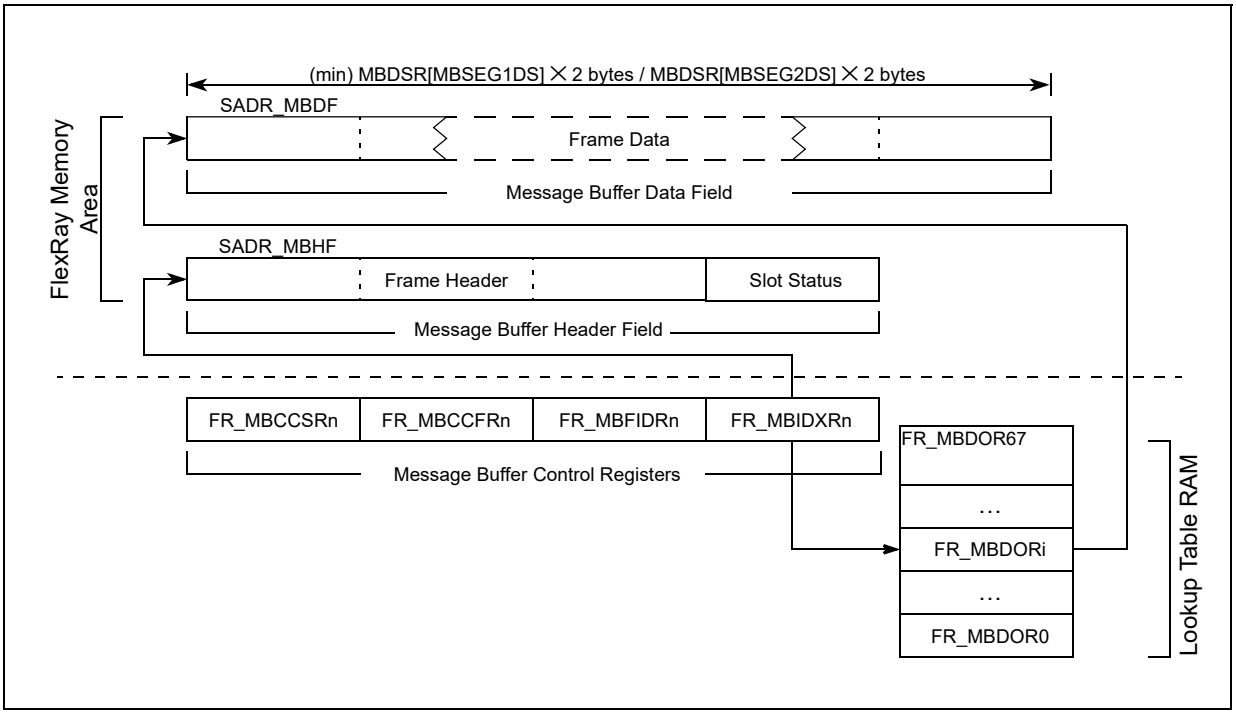
The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in *Section 46.6.6: Individual message buffer functional description*.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in *Figure 925*.

Each individual message buffer has a message buffer number *n* assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n* and FR_MBIDXR*n*.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field, MBIDX, in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 41*.

Equation 41 **SADR_MBHF = (FR_MBIDXR*n*[MBIDX] × 8) + SMBA**



The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i, the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to *Equation 42*.

Equation 42 **SADR_MBDF = [Data Field Offset] + SMBA**

The FR_MBDOR*n* are stored in the module internal memory LRAM. Refer to *Section 46.7.2.3: CHI LRAM initialization* for the setup of the data field offset values.

Figure 925. Individual message buffer structure

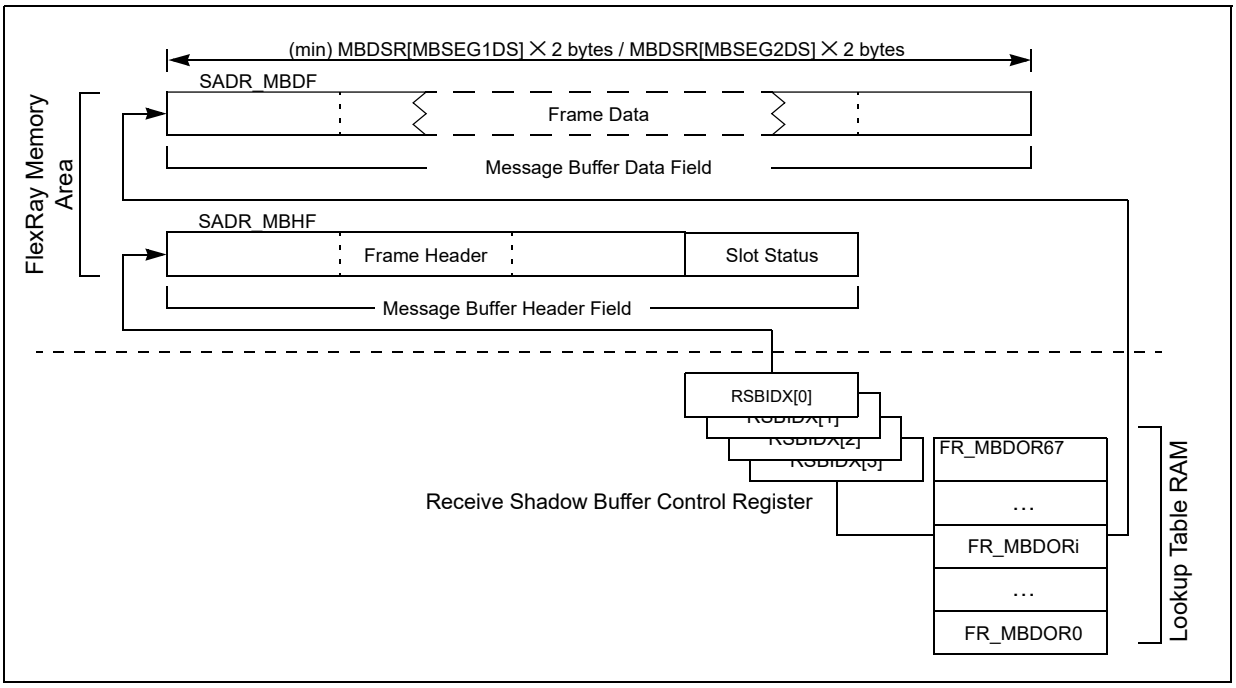
46.6.3.1.1 Individual message buffer segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- All physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length.
- The minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes.
- The minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.

46.6.3.2 Receive shadow buffers

The receive shadow buffers are required for the individual message buffers' frame reception process. The CC provides four receive shadow buffers: one receive shadow buffer per channel and per message buffer segment.



Each receive shadow buffer consists of two parts: the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in *Figure 926*. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 43*.

Equation 43 $$SADR_MBHF = (FR_RSBIR[RSBIDX] \times 8) + SMBA$$

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

Figure 926. Receive shadow buffer structure

46.6.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in *Figure 927*.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR)/Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM], refer to *Section 46.5.2.4: Module Configuration Register (FR_MCR)*.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to *Equation 44*.

Equation 44 SADR_MBHF[1] = (8 × FR_RFSIR[SIDX]) + SMBA

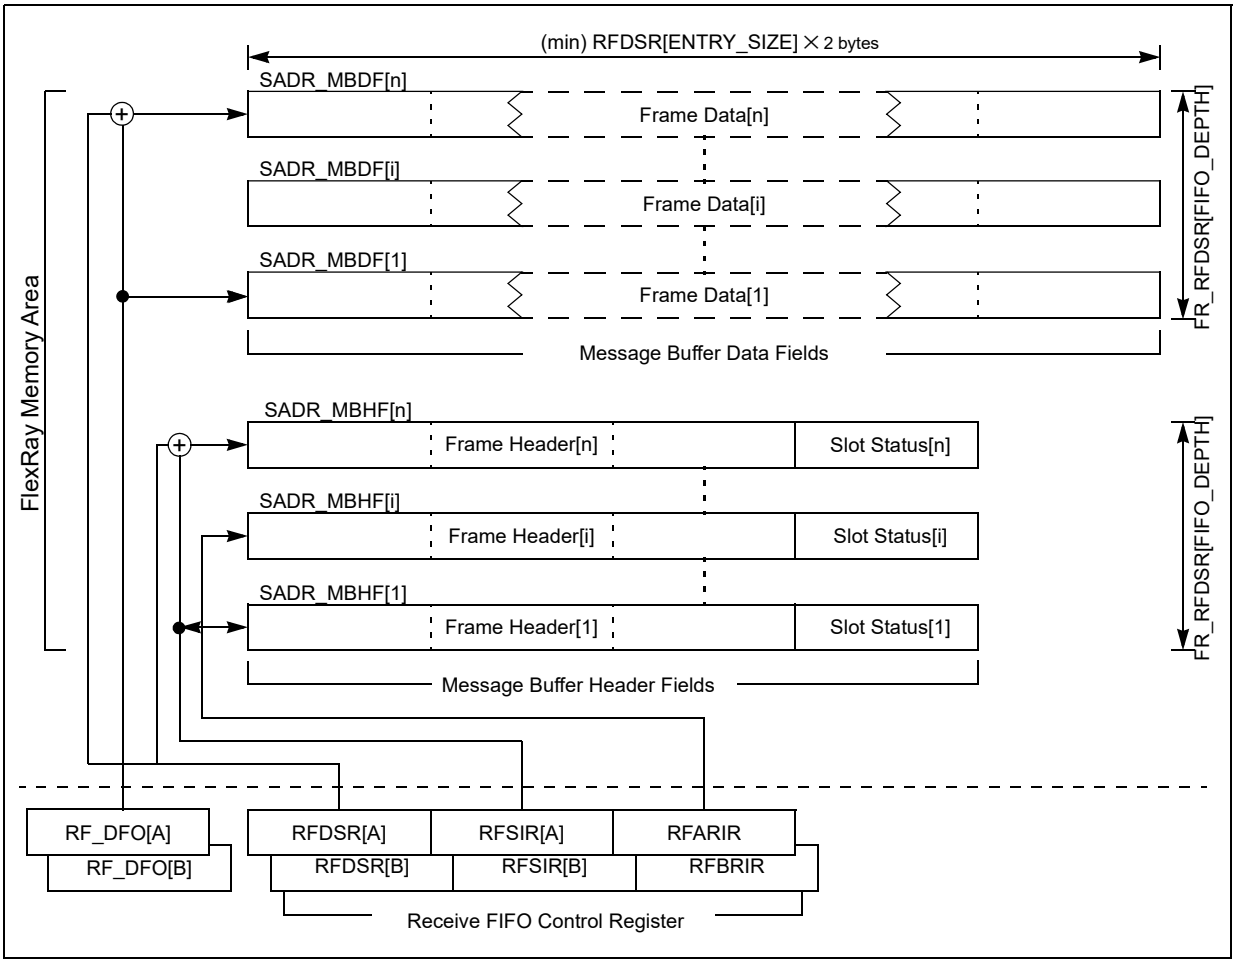
The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according to *Equation 45*.

Equation 45 SADR_MBHF[n] =
(8 × (FR_RFSIR[SIDX] + FR_RFDSR[FIFO_DEPTH])) + SMBA

The required information to access the current entry of the FIFO is given in the following registers:

- The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.
- The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

Equation 46 RF_DFO[X] =
FR_RFSDOR[X] + (FR_RFDSR[X][ENTRY_SIZE] × 2) × (i - R_RFSIR[SIDX])



Note: The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to Section 46.6.9.8: FIFO update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

Figure 927. Receive FIFO structure

Note: The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 46. They are not stored in a register.

46.6.3.4 Message buffer configuration and control data

This section describes the configuration and control data for each message buffer type.

46.6.3.4.1 Individual message buffer configuration data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

46.6.3.4.2 Common configuration data

The set of common configuration data for individual message buffers is located in the following registers.

- Message Buffer Data Size Register (FR_MBDSR)
  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.
- Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)
  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, see *Section 46.6.3.1.1: Individual message buffer segments*.

46.6.3.4.3 Specific configuration data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*)
  The MTD bit configures the message buffer type.
- Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)
  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.
- Message Buffer Frame ID Registers (FR_MBFIDR*n*)
  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.
- Message Buffer Index Registers (FR_MBIDXR*n*)
  This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.

46.6.3.5 Individual message buffer control data

During normal operation, each individual message buffer can be controlled by the CMT, LCKT, EDT, and MBIE control and trigger bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*).

46.6.3.6 Receive shadow buffer configuration data

Before the individual message buffers can receive frames, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

46.6.3.7 Receive FIFO control and configuration data

This section describes the configuration and control data for the two receive FIFOs.

46.6.3.7.1 Receive FIFO configuration data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- Receive FIFO Periodic Timer Register (FR_RFPTR)

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- Receive FIFO Watermark and Selection Register (FR_RFWMSR)
- Receive FIFO Start Index Register (FR_RFSIR)
- Receive FIFO Start Data Offset Register (FR_RFSDOR)
- Receive FIFO Depth and Size Register (FR_RFDSR)
- Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
- Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
- Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
- Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
- Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

46.6.3.7.2 Receive FIFO control data

The application can access the FIFOs at any time using the control bits in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

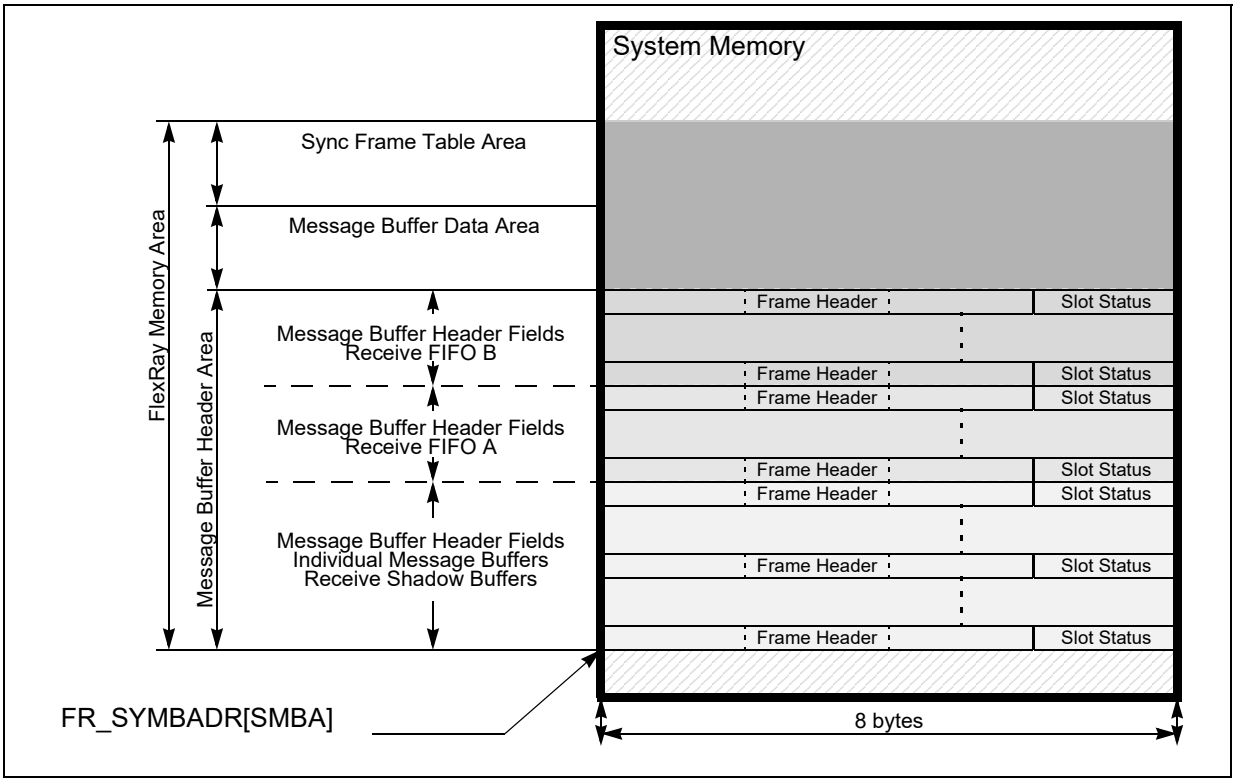
46.6.3.7.3 Receive FIFO status data

The current status of the receive FIFO is provided in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO A Read Index Register (FR_RFARIR)
- Receive FIFO B Read Index Register (FR_RFBRIR)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

46.6.4 FlexRay memory area layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].



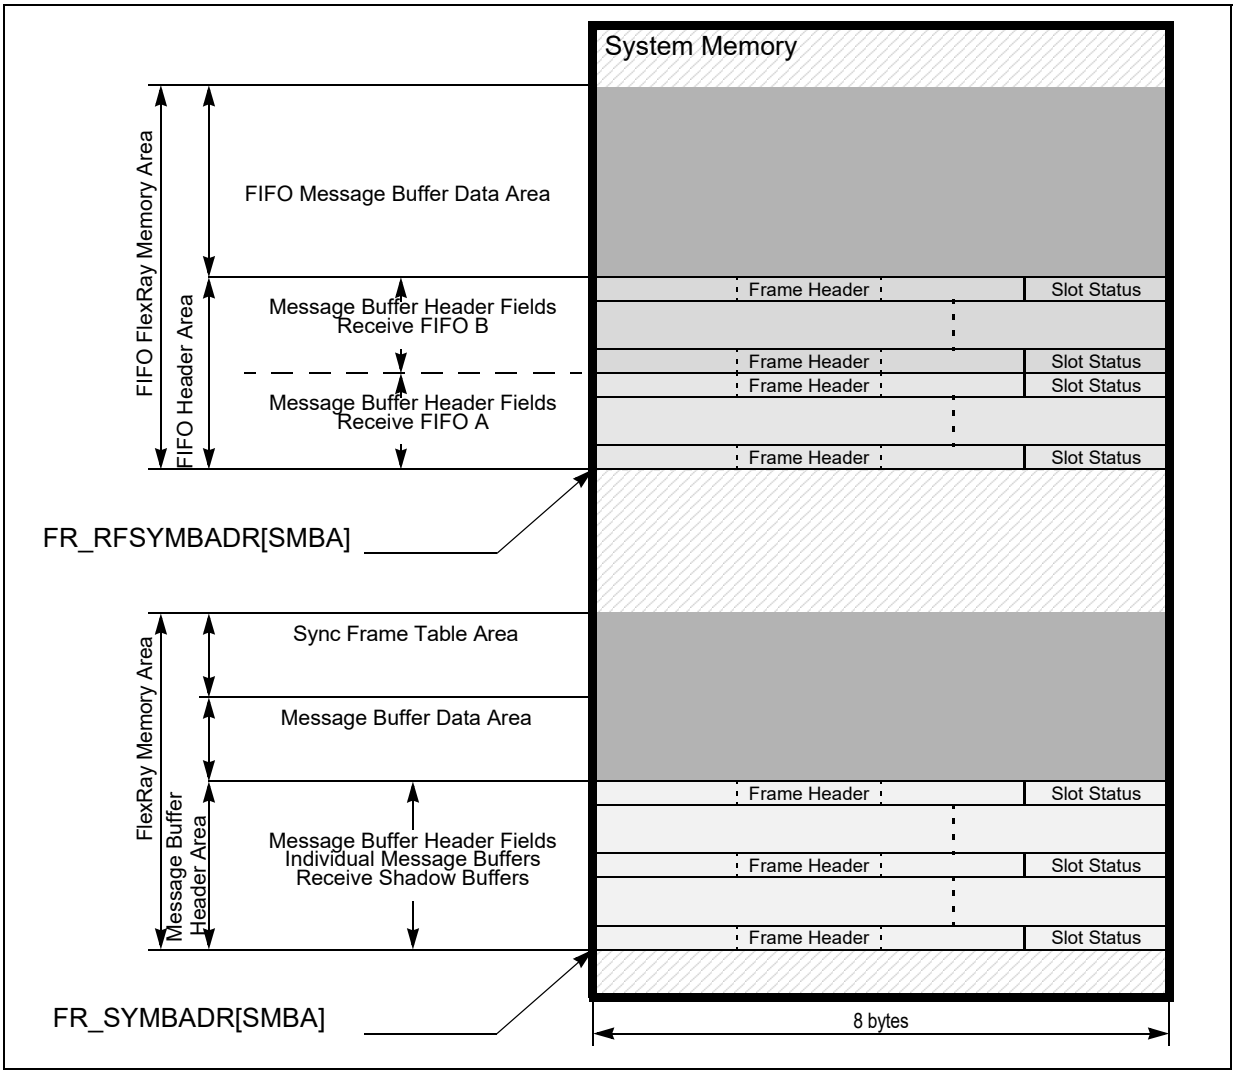
46.6.4.1 FlexRay memory area layout (FR_MCR[FAM] = 0)

Figure 928 shows an example layout for the FIFO address mode FR_MCR[FAM] = 0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is a maximum of 64 KB.
- The FlexRay memory area starts at a 16 byte boundary.

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

Figure 928. Example of FlexRay memory area layout (FR_MCR[FAM] = 0)



46.6.4.2 FlexRay memory area layout (FR_MCR[FAM] = 1)

Figure 929 shows an example layout for the FIFO address mode FR_MCR[FAM] = 1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

Figure 929. AreaExample of FlexRay memory area layout (FR_MCR[FAM] = 1)

46.6.4.3 Message buffer header area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rules apply to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 47*.

Equation 47 $\quad SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 67)$

2. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill *Equation 48*.

Equation 48 $\quad SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 1023)$

3. The message buffer header fields for each FIFO must be a contiguous area.

46.6.4.4 Message buffer header area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 49*.

Equation 49 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 67)$$

46.6.4.5 FIFO message buffer header area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill .

$$SADR_MBHF = (i \times 8) + FR_RFSYMBADR[SMBA];\ (0 \leq i \leq 1023)$$

2. The message buffer header fields for each FIFO have to be a contiguous area.

46.6.4.6 Message buffer data area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

46.6.4.7 Sync frame table area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to *Section 46.6.12: Sync frame ID and sync frame deviation tables* for the description of the sync frame table area.

46.6.5 Physical message buffer description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer: the message buffer header field and the message buffer data field.

46.6.5.1 Message buffer protection and data consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

46.6.5.2 Message buffer header field description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in *Section 46.6.2.1: Message buffer header field*. Each message buffer header field consists of two sections: the frame header section and the slot status section.

46.6.5.2.1 Frame header description

46.6.5.2.1.1 Frame header content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in *Figure 930*. A detailed description is given in *Table 895*.

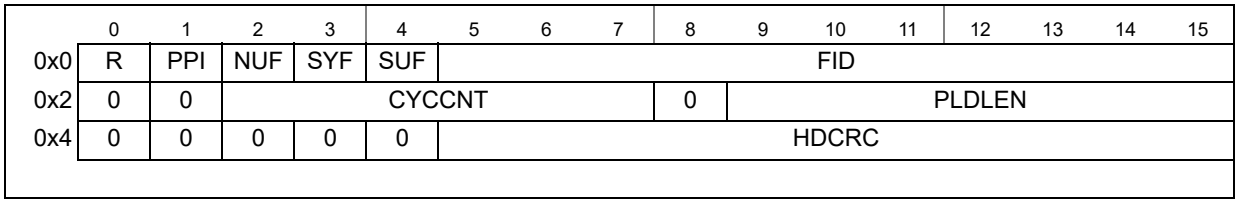


Figure 930. Frame header structure (receive message buffer and receive FIFO)

The structure of the frame header in the message buffer header field for transmit message buffers is given in *Figure 931*. A detailed description is given in *Table 896*. The checks that will be performed are described in Frame Header Checks.

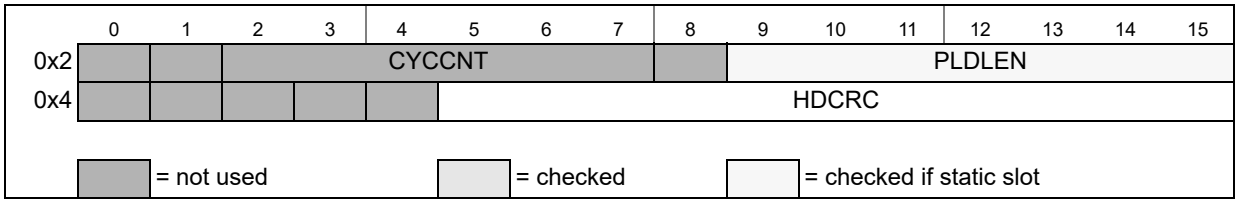

Figure 931. Frame header structure (transmit message buffer)

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in *Figure 932*.

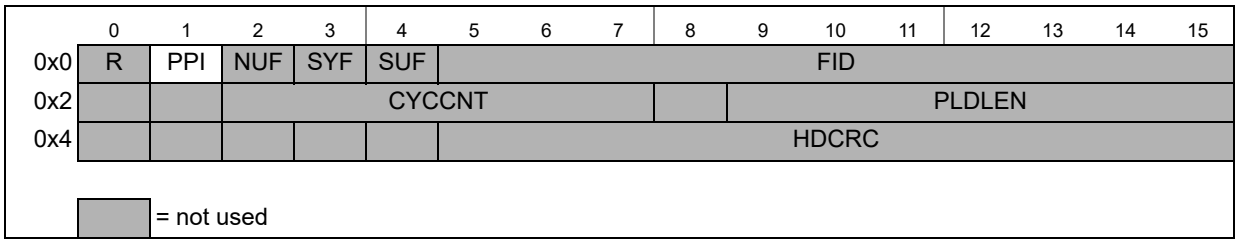

Figure 932. Frame header structure (transmit message buffer for key slot)

46.6.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 894*. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 894. Frame header write access constraints (transmit message buffer)

Field	Static segment	Dynamic segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	
		MB_LCK

46.6.5.2.1.3 Frame Header Checks

As shown in *Figure 931* and *Figure 932*, not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDR*n*). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag, FID_EF, in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDR*n*).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 895. Frame header field descriptions (receive message buffer and receive FIFO)

Field	Description
R	Reserved Bit This is the value of the *Reserved bit* of the received frame stored in the message buffer.
PPI	Payload Preamble Indicator This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	Null Frame Indicator This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	Sync Frame Indicator This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	Startup Frame Indicator This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	Frame ID This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	Cycle Count This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	Payload Length This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	Header CRC This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 896. Frame header field descriptions (transmit message buffer)

Field	Description
R	Reserved Bit This bit is not used. The value of the Reserved bit is generated internally according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
PPI	Payload Preamble Indicator This bit provides the value of the Payload Preamble Indicator for the frame transmitted from the message buffer.
NUF	Null Frame Indicator This bit is not used, the value of the Null Frame Indicator is generated internally according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

Table 896. Frame header field descriptions (transmit message buffer) (continued)

Field	Description
SYF	Sync Frame Indicator This bit is not used. The value of the Sync Frame Indicator is generated internally according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
SUF	Startup Frame Indicator This bit is not used. The value of the Startup Frame Indicator is generated internally according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
FID	Frame ID This field is checked as described in Frame Header Checks.
CYCCNT	Cycle Count This field is not used, the value of the transmitted Cycle Count field is taken from the internal communication cycle counter.
PLDLEN	Payload Length This field is checked and used as described in Frame Header Checks.
HDCRC	Header CRC This field provides the value of the Header CRC field for the frame transmitted from the message buffer.

46.6.5.2.2 Slot status description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

46.6.5.2.2.1 Receive message buffer and receive FIFO slot status description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given by *Table 897*.

Table 897. Receive message buffer slot status content

Receive message buffer type	Slot status content
Individual Receive Message Buffer assigned to both channels FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 1	See *Figure 933*
Individual Receive Message Buffer assigned to channel A FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 0	See *Figure 934*
Individual Receive Message Buffer assigned to channel B FR_MBCCFR*n*[CHA] = 0 and FR_MBCCFR*n*[CHB] = 1	See *Figure 935*
Receive FIFO Channel A Message Buffer	See *Figure 934*
Receive FIFO Channel B Message Buffer	See *Figure 935*

The meaning of the bits in the slot status structure is explained in *Table 898*.

46.6.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given by *Table 899*.

Table 899. Transmit message buffer slot status content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=1	See *Figure 936*
Individual Transmit Message Buffer assigned to channel A FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=0	See *Figure 937*
Individual Transmit Message Buffer assigned to channel B FR_MBCCFR*n*[CHA]=0 and FR_MBCCFR*n*[CHB]=1	See *Figure 938*

The meaning of the bits in the slot status structure is described in *Table 900*.

46.6.5.3 Message buffer data field description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in *Table 901*. The structure of the message buffer data field is given in *Figure 939*.

Table 901. Message buffer data field minimum length

Physical message buffer assigned to	Minimum length defined by
Individual message buffer in segment 1	FR_MBDSR[MBSEG1DS]
Receive shadow buffer in segment 1	FR_MBDSR[MBSEG1DS]
Individual message buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive shadow buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note: The CC will not access any locations outside the message buffer data field boundaries given by Table 901.

	0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15
0x0	DATA0 / MID0 / NMV0		DATA1 / MID1 / NMV1	
0x2	DATA2 / NMV2		DATA3 / NMV3	
…	…		…	
0xN-2	DATA N-2		DATA N-1	

Figure 939. Message buffer data field structure

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

46.6.5.3.1 Message buffer data field read access

For transmit message buffers, the CC will not modify the content of the message buffer data field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXR*n*). While the message buffer is locked, the CC will not update the message buffer data field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

46.6.5.3.2 Message buffer data field write access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 902*.

Table 902. Frame data write access constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 903. Frame data field descriptions

Field	Description
DATA 0, DATA 1, … DATA N–1	Message Data Provides the message data received or to be transmitted. For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	Message Identifier If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0, NMV 1, … NMV 11	Network Management Vector If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

46.6.6 Individual message buffer functional description

The CC provides the following basic types of individual message buffers:

- Transmit message buffers
- Receive message buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in *Section 46.6.3.4.1: Individual message buffer configuration data*.

46.6.6.1 Individual message buffer configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

46.6.6.1.1 Common configuration data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. This data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

46.6.6.1.2 Specific configuration data

The second part of the message buffer configuration data is specific for each message buffer.

This data can be changed only when either

- The protocol is in the POC:config state, or
- The message buffer is disabled (that is, FR_MBCCSR*n*[EDS] = 0)

The individual message buffer type is defined by the MTD bit in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*) as given in *Table 904*.

Table 904. Individual message buffer types

FR_MBCCSRn[MTD]	Individual message buffer description
0	Receive message buffer
1	Transmit message buffer

The message-buffer-specific configuration data includes the following:

1. MTD bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*)
2. All fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)
3. All fields in the Message Buffer Frame ID Registers (FR_MBFIDR*n*)
4. All fields in the Message Buffer Index Registers (FR_MBIDXR*n*)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions. See *Section 46.6.6.2: Transmit message buffers* and *Section 46.6.6.3: Receive message buffers* for further information.

46.6.6.2 Transmit message buffers

The section provides a detailed description of the functionality of single-buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number *n* is configured to be a transmit message buffer by the following setting:

- FR_MBCCSR*n*[MTD] = 1 (transmit message buffer)

46.6.6.2.1 Access regions

For certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in *Figure 940*. A description of the regions is given in *Table 906*. If a region is active as indicated in *Table 907*, the access scheme given for that region applies to the message buffer.

Figure 940. Transmit message buffer access regions

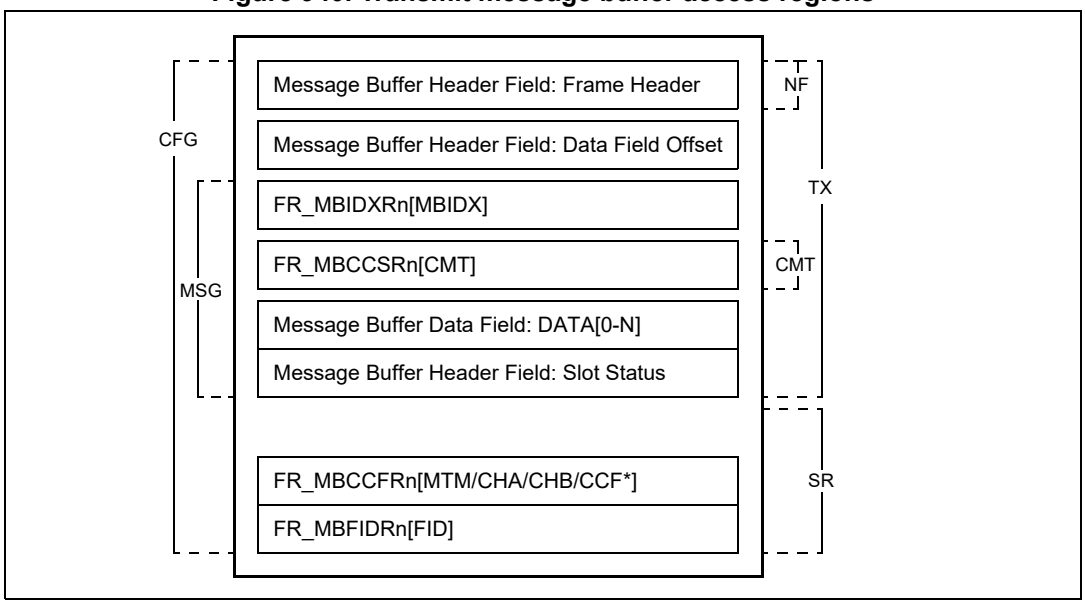

Table 905. Transmit message buffer access regions description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration
MSG	Read/write	—	Message data and slot status access
NF	—	Read-only	Message header access for null frame transmission
TX	—	Read/write	Message transmission and slot status update
CMT	—	Read-only	Message buffer validation
SR	—	Read-only	Message buffer search

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT], and the interrupt enable bit FR_MBCCSR*n*[MBIE], are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in *Figure 941*. A description of the states is given in *Table 906*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

46.6.6.2.2 Message buffer states

This section describes the transmit message buffer states and provides a state diagram.

Figure 941. Transmit message buffer states

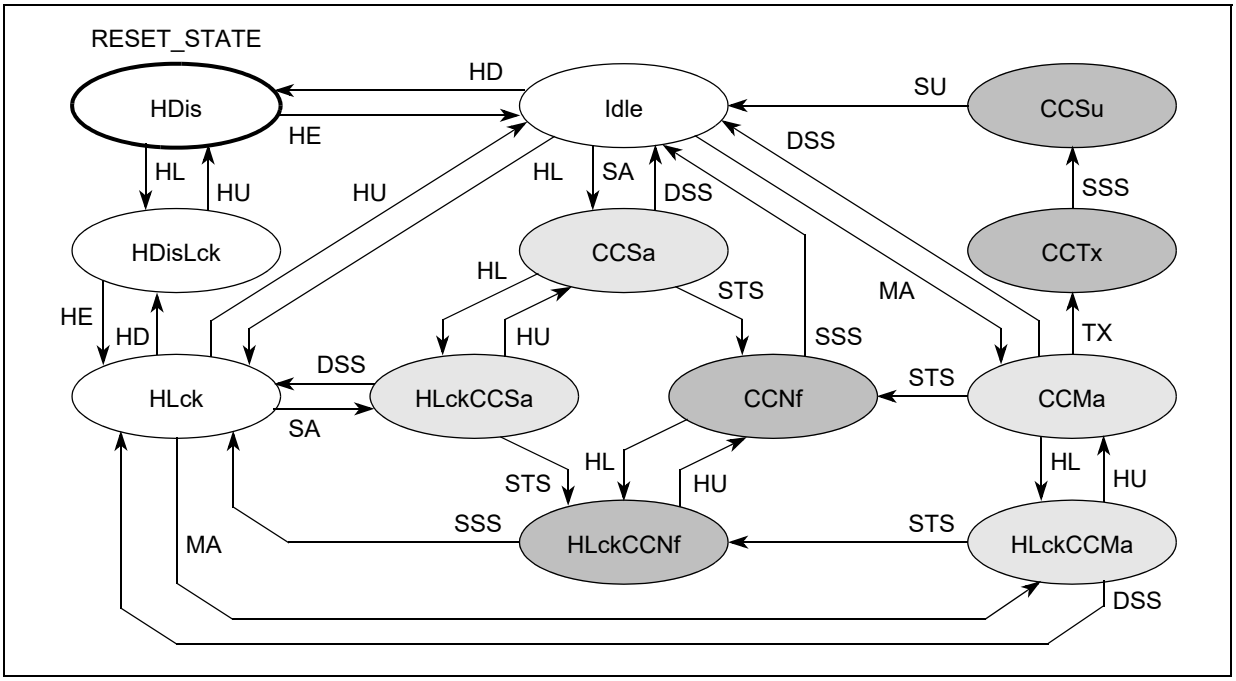

Table 906. Transmit message buffer state description

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	CMT, SR	Idle – Message Buffer is idle. Included in message buffer search
HDis	0	0	CFG	—	Disabled – Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message Buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	SR	Locked – Application access to data, control, and status. Included in message buffer search.
CCSa	1	0	—	—	Slot Assigned – Message buffer assigned to next static slot. Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	—	Locked and Slot Assigned – Application access to data, control, and status.Message buffer assigned to next static slot.
CCNf	1	0	—	NF	Null Frame Transmission – Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	Locked and Null Frame Transmission – Application access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	—	CMT	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.

Table 906. Transmit message buffer state description (continued)

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
HLckCCMa	1	1	MSG	—	Locked and Message Available – Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	—	TX	Message Transmission – Message buffer data transmit. Payload data from buffer transmitted.
CCSu	1	0	—	TX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

46.6.6.2.3 Message buffer transitions

46.6.6.2.3.1 Application transitions

The application transitions can be triggered by the application using the commands described in *Table 912*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

- Message Buffer Enable and Disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

- Message Buffer Lock and Unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 907. Transmit message buffer application transitions

Transition	Command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable.

Table 907. Transmit message buffer application transitions (continued)

Transition	Command	Condition	Description
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock.

46.6.6.2.3.2 Module transitions

The module transitions that can be triggered by the CC are described in *Table 908*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 908. Transmit message buffer module transitions

Transition	Condition	Description
SA	Slot match and static slot	Slot Assigned – Message buffer is assigned to next static slot.
MA	Slot match and CycleCounter match	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.
TX	Slot start and FR_MBCCSR*n*[CMT] = 1	Transmission Slot Start – Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	Status updated	Status Updated – Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	Static slot start	Static Slot Start – Start of static slot.
DSS	Dynamic slot start or symbol window start or NIT start	Dynamic Slot or Segment Start – Start of dynamic slot or symbol window or NIT.
SSS	Slot start or symbol window start or NIT start	Slot or Segment Start – Start of static slot or dynamic slot or symbol window or NIT.

46.6.6.2.3.3 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of *Table 909*, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and, subsequently, the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions are given in the second part of *Table 909*.

Table 909. Transmit message buffer transition priorities

State	Priorities	Description
Module vs. application		
Idle, HLck	SA > HD MA > HD	Slot Assigned > Message Buffer Disable Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
Module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS TX > DSS	Transmission Slot Start > Static Slot Start Transmission Slot Start > Dynamic Slot Start

46.6.6.2.4 Transmit message setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit, CMT, in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*). The physical access to the message buffer data field is described in *Section 46.6.3.1: Individual Message Buffers*.

As indicated by *Table 900*, the application will write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the following states: HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in *Table 900*. The state change is indicated through the FR_MBCCSR*n*[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters the HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa state, the FR_MBCCSR*n*[DVAL] flag is negated.

46.6.6.2.5 Message transmission

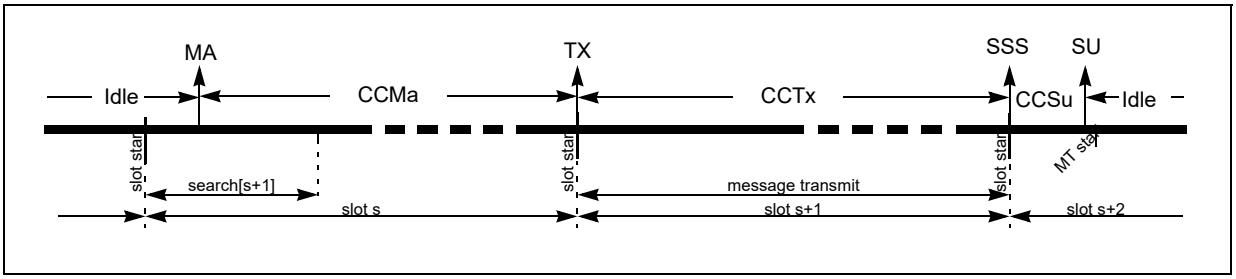
As a result of the message buffer search described in *Section 46.6.7: Individual message buffer search*, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. The message buffer is in the message available state CCMa
2. The message data is still valid (that is, FR_MBCCSR*n*[CMT] = 1)

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in *Figure 942*. In this example, the message buffer with message buffer number *n* is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid (that is, FR_MBCCSR*n*[CMT] = 1).

Figure 942. Message transmission timing



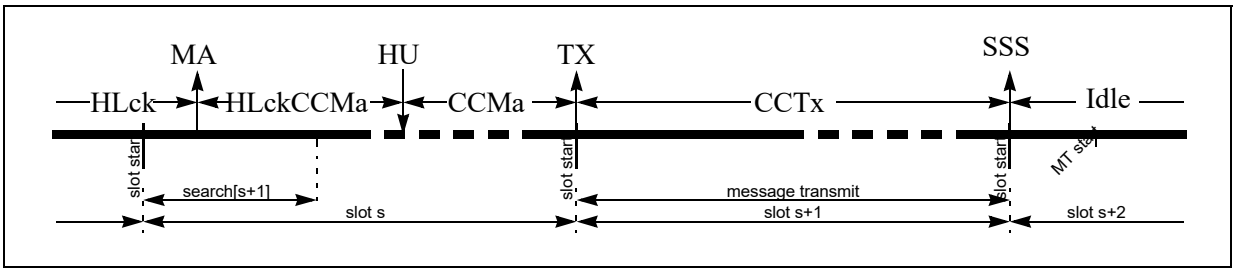


Figure 943. Message transmission from HLck state with unlock

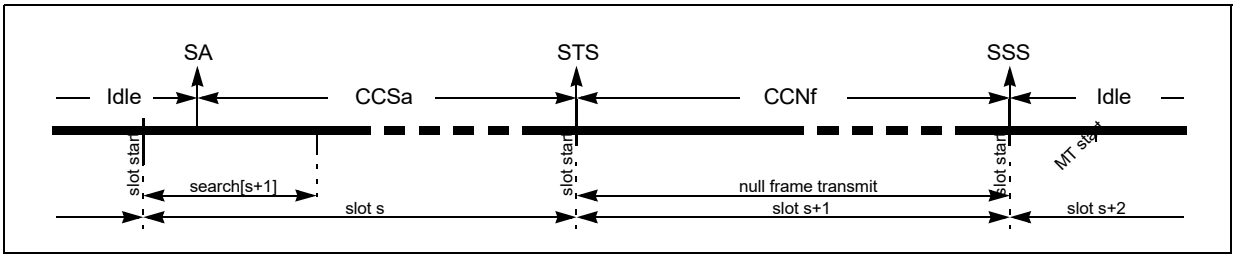
The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. The value of the PLDLEN field in the message buffer header field, as described in *Section 46.6.5.2.1: Frame header description*

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN ≤ MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

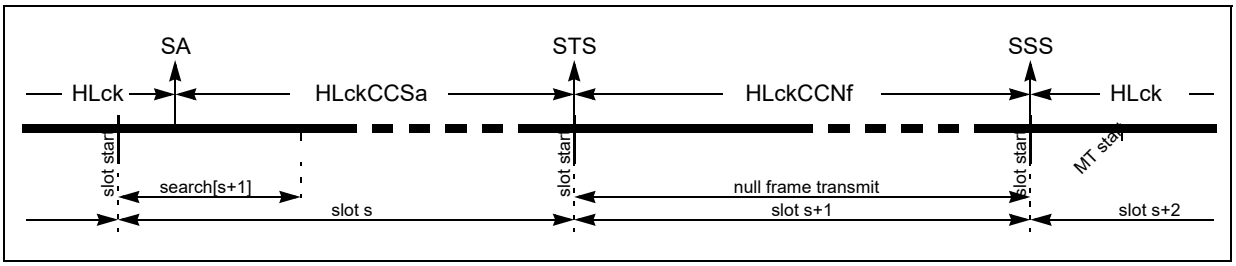
46.6.6.2.6 Null frame transmission



A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDR*n*[FID] set to S and FR_MBCCFR*n*[CHA] set to 1. A null frame is transmitted in the static slot *s* on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDR*n*[FID] = S and FR_MBCCFR*n*[CHA] = 1 are either not committed (that is FR_MBCCSR*n*[CMT] = 0), or are locked by the application (that is, FR_MBCCSR*n*[LCKS] = 1), or the cycle counter filter is enabled and does not match.

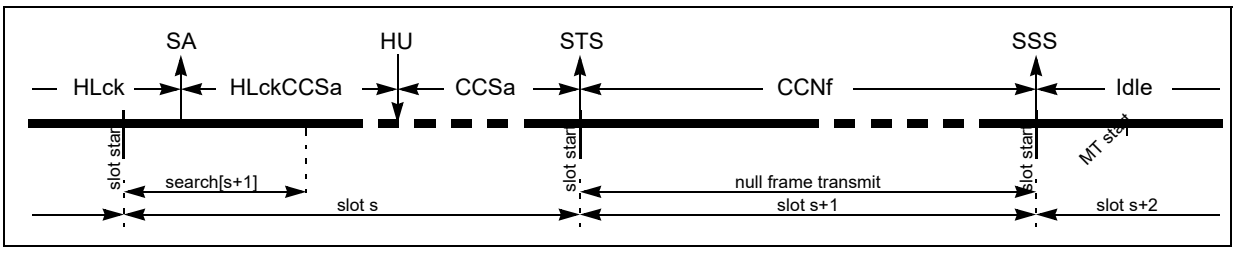
Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in *Section 46.6.7: Individual message buffer search*, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or



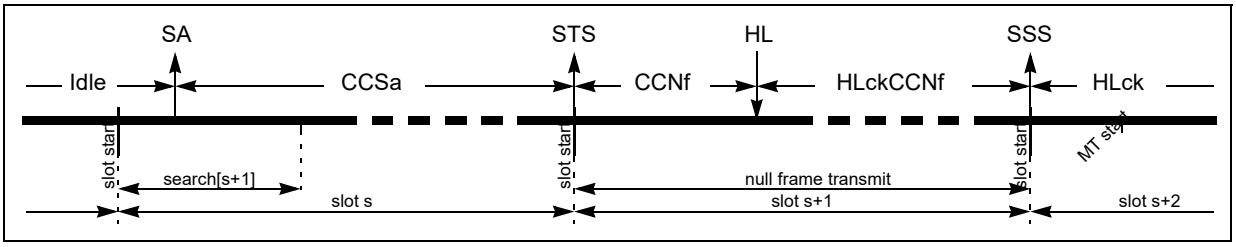
from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in *Figure 944*.

Figure 944. Null frame transmission from Idle state



A message buffer timing and state change diagram for null frame transmission from HLck state is given in *Figure 945*.

Figure 945. Null frame transmission from HLck state



If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 946*.

Figure 946. Null frame transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 947*.

Figure 947. Null frame transmission from Idle state with locking

46.6.6.2.7 Message buffer status update

After the end of each slot, the PE generates the slot status vector. Depending on the status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

46.6.6.2.7.1 Message buffer status update after complete message transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer was sent to the FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSR*n*[MBIF] to indicate the successful message transmission.

Depending on the Transmission Mode flag FR_MBCCFR*n*[MTM], the CC changes the commit flag FR_MBCCSR*n*[CMT] and the valid flag FR_MBCCSR*n*[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in *Event Transmission mode.* In this case, each committed message is transmitted only once. The commit flag FR_MBCCSR*n*[CMT] is cleared with the SU transition. If the FR_MBCCFR*n*[MTM] flag is asserted, the message buffer is in the *State Transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSR*n*[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSR*n*[DVAL] to indicate that the message will be transmitted again.

46.6.6.2.7.2 Message buffer status update after incomplete message transmission

The term *incomplete message transmission* refers to the fact that not all payload data that should be transmitted was sent to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those error occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

In either of these two cases, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

46.6.6.2.7.3 Message buffer status update after null frame transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

46.6.6.3 Receive message buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used, the related receive shadow buffer must be configured as described in *Section 46.6.3.2: Receive shadow buffers*.

A receive message buffer is used to receive a message from the FlexRay bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application:

- Message data received
- Information about the reception process
- Status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration settings:

- FR_MBCCSR*n*[MTD] = 0 (receive message buffer)

Both the application and the CC have access to certain message buffers. To ensure data consistency, a message buffer locking scheme controls the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in *Figure 948*. A description of the regions is given in *Table 910*. If an region is active as indicated in *Table 911*, the access scheme given for that region applies to the message buffer.

Figure 948. Receive message buffer access regions

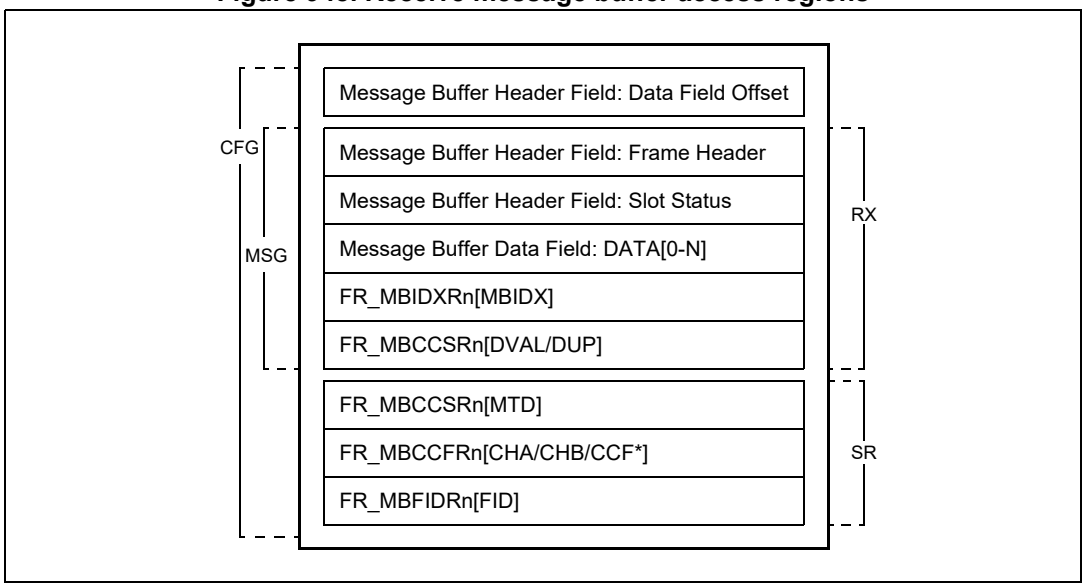


Table 910. Receive message buffer access region description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration, message data, and status access
MSG	Read/write	—	Message data, header, and status access
RX	—	Write-only	Message reception and status update
SR	—	Read-only	Message buffer search data

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT] and the interrupt enable bit FR_MBCCSR*n*[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in *Figure 949*. A description of the message buffer states is given in *Table 906*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

Figure 949. Receive message buffer states

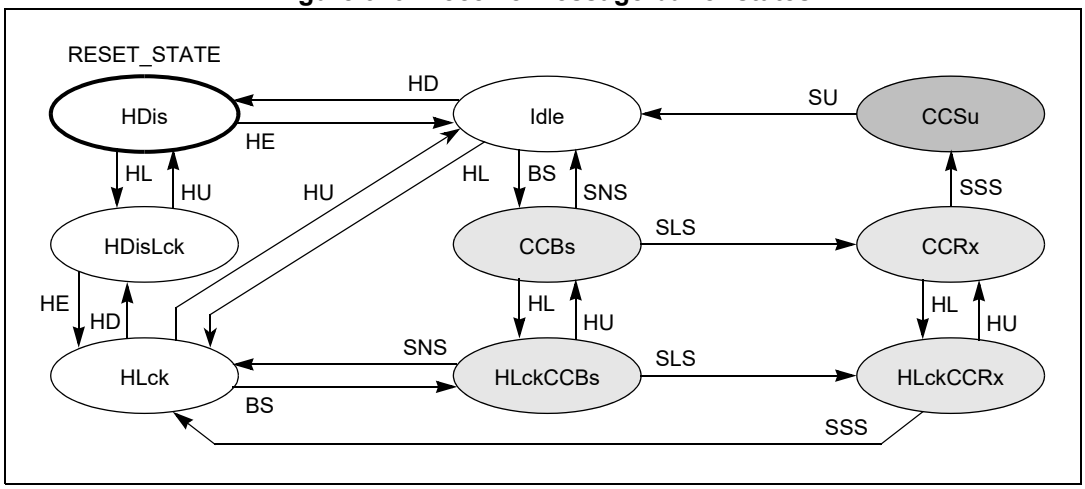

Table 911. Receive message buffer states and access

State	FR_MBCCSR*n*		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	SR	Idle – Message buffer is idle. Included in message buffer search.
HDis	0	0	CFG	—	Disabled – Message buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	—	Locked – Application access to data, control, and status. Included in message buffer search.
CCBs	1	0	—	—	Buffer Subscribed – Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	—	Locked and Buffer Subscribed – Application access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	—	—	Message Receive – Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	—	Locked and Message Receive – Application access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	—	RX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

46.6.6.3.1 Message buffer transitions

46.6.6.3.1.1 Application transitions

The application transitions that can be triggered by the application using the commands are described in *Table 907*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

Message buffer enable and disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCBs, HLckCCBs, or CCRx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

Message buffer lock and unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSR*n*[LCKS]. If the command triggers the lock transition HL while the message buffer is in the CCRx state, the lock transition has no effect (command is ignored) and the message buffer state is not changed.

In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 912. Receive message buffer application transitions

Transition	Host command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS = 0	Application triggers message buffer lock
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock

Module Transitions

The module transitions that can be triggered by the CC are described in *Table 913*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 913. Receive message buffer module transitions

Transition	Condition	Description
BS	Slot match and cyclecounter match	Buffer Subscribed – The message buffer filter matches next slot and cycle.
SLS	Slot start	Slot Start – Start of either Static Slot or Dynamic Slot.
SNS	Symbol window start or NIT start	Symbol Window or NIT Start – Start of either Symbol Window or NIT.
SSS	Slot start, symbol window start, or NIT start	Slot or Segment Start – Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	Status updated	Status Updated – Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

46.6.6.3.1.2 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in *Table 914*, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the CCBs buffer subscribed state and the module triggers the SLS slot start transition at the same time that the application locks the message buffer through the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state, HLckCCRx.

Table 914. Receive message buffer transition priorities

State	Priorities	Description
Module vs. Application		
Idle	BS > HD	Buffer subscribed > Message buffer disable

Table 914. Receive message buffer transition priorities (continued)

State	Priorities	Description
HLck	BS > HD	Buffer subscribed > Message buffer disable
CCRx	SSS > HL	Slot or segment start > Message buffer lock

46.6.6.3.2 Message reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffer is assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot, the module triggers the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data is written into the shadow buffers. For details on receive shadow buffers, see *Section 46.6.6.3.5: Receive shadow buffer concept*. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

46.6.6.3.3 Message buffer update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer is in the locked state HLckCCRx, no update will be performed. The received data is lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state, it is now in the CCSu state. After the evaluation of the slot status provided by the PE, the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to, as described in *Table 915*.

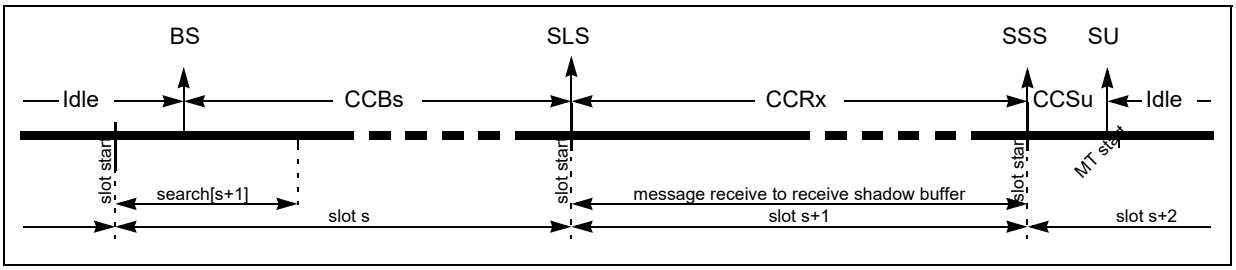

Table 915. Receive message buffer update

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
1	1	Valid non-null frame received. – Message Buffer Data field updated. – Frame Header field updated. – Slot Status field updated. – DUP = 1 – DVAL = 1 – MBIF = 1
1	0	Valid null frame received. – Message Buffer Data field *not* updated. – Frame Header field *not* updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed – MBIF = 1
0	x	No valid frame received. – Message Buffer Data field not updated. – Frame Header field not updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed. – MBIF = 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: vSS!ValidFrame = 0 and vSS!SyntaxError = 0 and vSS!ContentError = 0 and vSS!BViolation = 0.

Note: If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > n will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in *Figure 950*.

Figure 950. Message Reception timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following items:

- The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
- The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR).
- The number of bytes received over the FlexRay bus.

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

46.6.6.3.4 Received message access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in *Section 46.6.3.1: Individual Message Buffers*.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

46.6.6.3.5 Receive shadow buffer concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in *Section 46.6.3.2: Receive shadow buffers*.

The receive shadow buffers temporarily store the received frame header and message data. The slot status information is generated after the slot boundary. If the slot status information indicates the reception of the valid non-null frame (see *Table 915*), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXR*n*) with the content of the corresponding internal shadow buffer index register. In all cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXR*n*). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXR*n*).

46.6.7 Individual message buffer search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel whether a slot *s* in a communication cycle *c* is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm invoked at the following protocol-related events:

- NIT start
- Slot start in the static segment
- Minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *s* searches for message buffers assigned or subscribed to slot *s* + *1*.

In general, the message buffer search for the next slot *s* considers only message buffers that

1. Are enabled (that is, FR_MBCCSR*n*[EDS] = 1), and
2. Match the next slot *s*, (that is, FR_MBFIDR*n*[FID] = *s*)

On top of that, for the static segment, only those message buffers are considered that match the condition of at least one row of *Table 916*. For the dynamic segment, only those message buffers are considered that match the condition of at least one row of *Table 917*. These message buffers are called *matching* message buffers.

For each enabled channel, the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers, the message buffers with highest priority according to *Table 916* for the static segment and according to *Table 917* for the dynamic segment are selected.

Table 916. Message buffer search priority (static segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	1	—	0	1	Transmit buffer, matches cycle count, not committed	SA
	1	1	—	1	Transmit buffer, matches cycle count, locked	SA
2	1	—	—	—	Transmit buffer	SA
3	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(lowest) 4	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, see *Section 46.6.7.1: Message buffer cycle counter filtering*.

Table 917. Message buffer search priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(lowest) 2	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, see *Section 46.6.7.1: Message buffer cycle counter filtering*

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffers that have the highest priority must have a consistent channel assignment as specified in *Section 46.6.7.2: Message buffer channel assignment consistency*.

Depending on the message buffer channel assignment, the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in *Section 46.6.3.1: Individual Message Buffers*.

46.6.7.1 Message buffer cycle counter filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled (CCFE = 0), this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

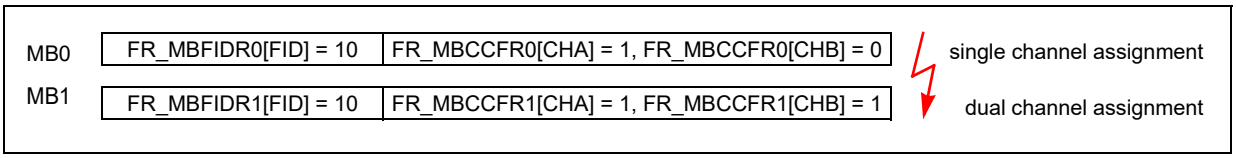
The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

Equation 50

$$MBCCFRn[CCFE] = 0$$

Equation 51

$$CYCCNT \& MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \& MBCCFRn[CCFMSK]$$



46.6.7.2 Message buffer channel assignment consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFR*n*[CHA] = 1 and transmits or receives on channel B if FR_MBCCFR*n*[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they

must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in *Figure 951*.

Figure 951. Inconsistent channel assignment

46.6.7.3 Node-related slot multiplexing

The term *node-related slot multiplexing* applies to the dynamic segment only and refers to the functionality if transmit as well as receive message buffers are configured for the same slot.

According to *Table 917* the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

46.6.7.4 Message buffer search error

There are two kinds of errors that may occur during message buffer search[o].

46.6.7.4.1 Message buffer search start while running

If the message buffer search is running in slot *s – 1* and the next message buffer search start event appears due to the start of slot *s*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *s*. Additionally, the search engine will not be started in slot *s*, and consequently no individual message buffer is identified for transmission or reception in slot *s + 1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see *Section 46.7.5: Number of usable message buffers*.

46.6.7.4.2 Illegal message buffer index found

If the message buffer search has finished the message buffer search in slot *s – 1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) and no individual message buffer is identified for transmission or reception in slot *s*. The legal message buffer index values for the individual and receive shadow

o. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

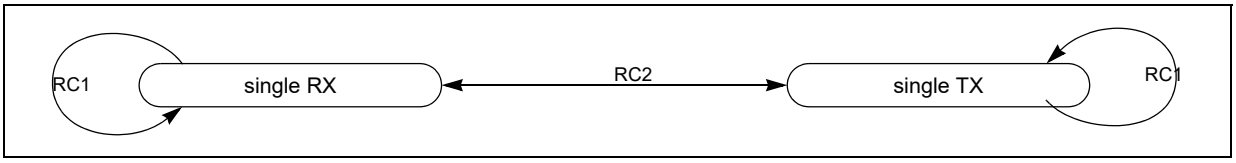
buffers are specified in *Section 46.5.2.52: Receive Shadow Buffer Index Register (FR_RSBIR)* and *Section 46.5.2.84: Message Buffer Index Registers (FR_MBIDXRn)*.

46.6.8 Individual message buffer reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data can not be reconfigured when the protocol is out of the *POC:config* state.

46.6.8.1 Reconfiguration schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.



46.6.8.1.1 Basic type not changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSR*n*[MTD] is not changed. This type of reconfiguration is denoted by RC1 in *Figure 952*. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

46.6.8.1.2 Buffer type not changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in *Figure 952*. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

Figure 952. Message buffer reconfiguration scheme

46.6.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

46.6.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.* One FIFO is assigned to channel A, and the other FIFO is assigned to channel B. Both FIFOs work independently from each other.

The message buffer structure of each FIFO is described in *Section 46.6.3.3: Receive FIFO*. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- The FIFO system memory base address
- The index of the first FIFO entry given by the Receive FIFO Start Index Register (FR_RFSIR)
- The data field offset of the data field belonging to the first FIFO entry given by the Receive FIFO Start Data Offset Register (FR_RFSDOR)
- The number of FIFO entries and the length of each FIFO entry as given by the Receive FIFO Depth and Size Register (FR_RFDSR)

46.6.9.2 FIFO configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO Address Mode bit FAM in the Module Configuration Register (FR_MCR).

46.6.9.2.1 Single System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is the System Memory Base Address Register (FR_SYMBADR).

46.6.9.2.2 Dual System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is the Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data is given in *Section 46.6.3.7: Receive FIFO control and configuration data*. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details, see *Section 46.6.4: FlexRay memory area layout*.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

1. Configure the FIFO update and address modes in Module Configuration Register (FR_MCR).
2. Configure the FIFO system memory base address.
3. Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO.
4. Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO.
5. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size.
6. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth.
7. Configure the FIFO filters.

46.6.9.3 FIFO periodic timer

The FIFO periodic timer is used to generate a FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached but the FIFO is not empty. This can be used to prevent frames from getting stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd,* greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

46.6.9.4 FIFO reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case, the FIFO filter path shown in *Figure 953* is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented.If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

46.6.9.5 FIFO almost-full interrupt generation

If the FIFO fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM (that is, FLA > WM_A (FLB > WM_B)), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.If the periodic timer expires, and FIFOA (FIFOB) is not empty (that is, FLA > 0 (FLB > 0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

46.6.9.6 FIFO overflow error generation

If the FIFOA (FIFOB) is full (that is, FLA = $FIFO_DEPTH_A$ (FLB=$FIFO_DEPTH_B$)) and the conditions for a FIFO reception as described in *Section 46.6.9.4: FIFO reception* are fulfilled, then the FIFO overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

46.6.9.7 FIFO message access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the (Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to *Equation 46*.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, then the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case, the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to *Equation 46*. The application can access the message data as described in *Section 46.6.3.3: Receive FIFO*. When the application has read the message buffer data and status information, it can update the FIFO as described in *Section 46.6.9.8: FIFO update*.

46.6.9.8 FIFO update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

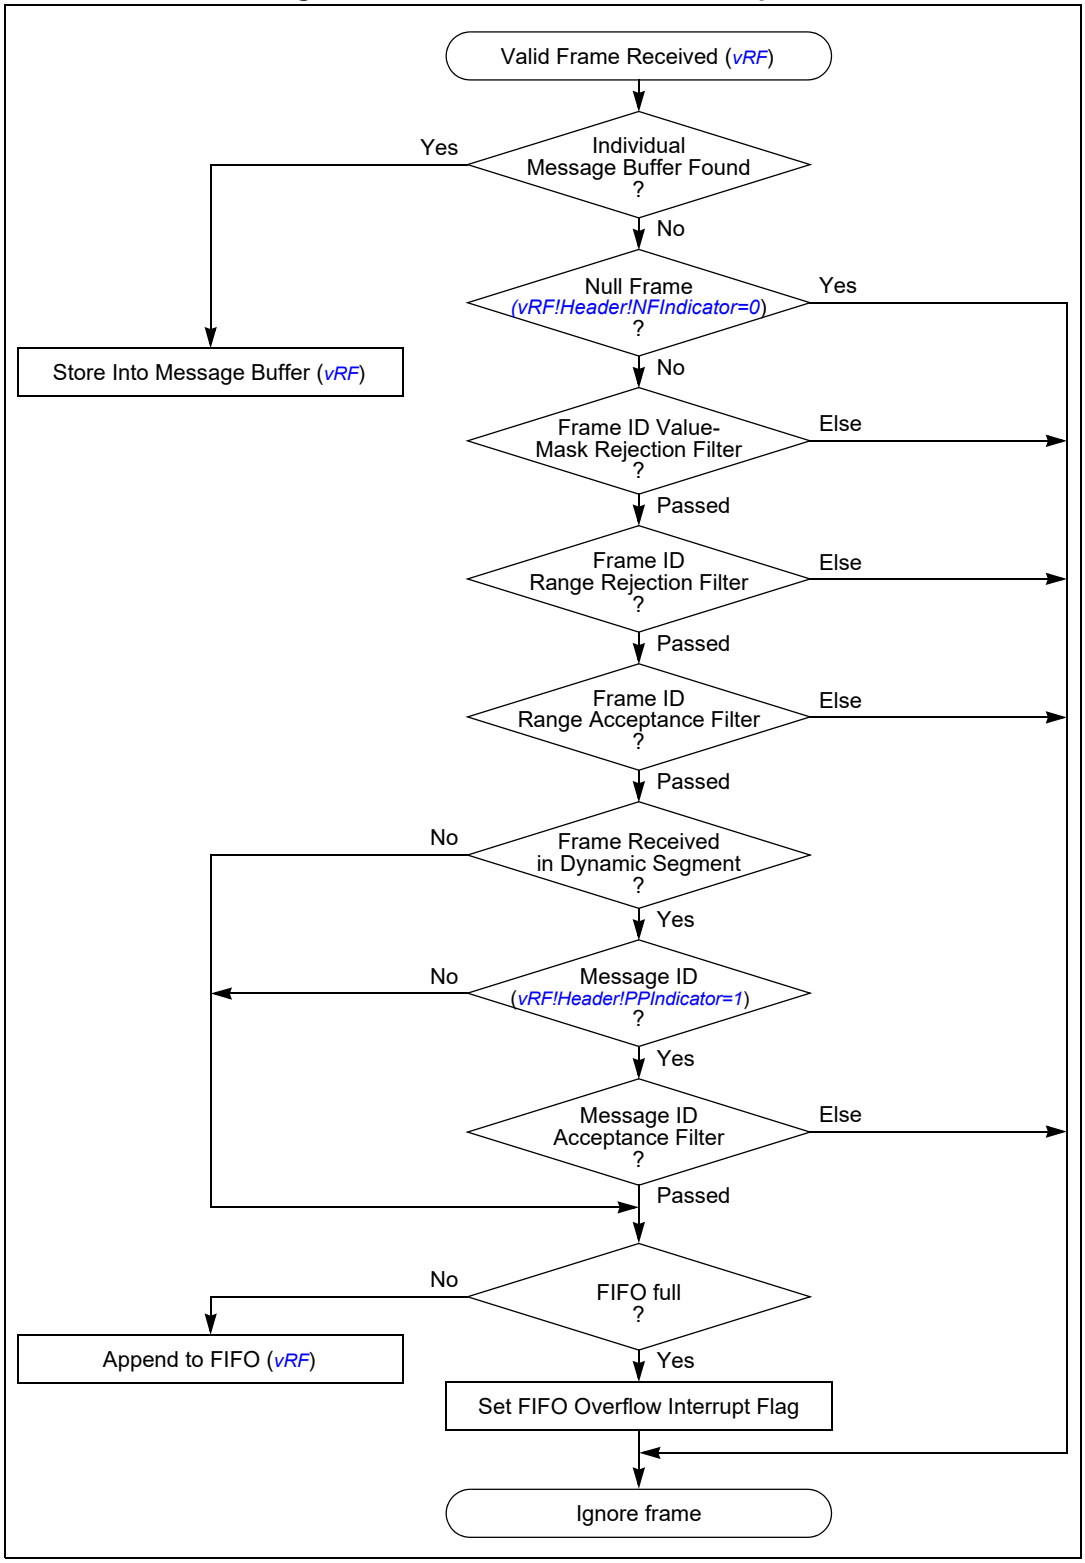
The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

46.6.9.8.1 FIFO interrupt flag update

The FIFO Interrupt Flag Update mode is configured when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode, FIFOA (FIFOB) will be updated by one entry when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1 if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.



46.6.9.9 FIFO filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides four sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass

criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in *Figure 953*.

Figure 953. Received frame FIFO filter path

A received frame passes the FIFO filtering if it has passed all four type of filter.

46.6.9.9.1 RX FIFO Frame ID Value-mask Rejection filter

The Frame ID Value-mask Rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter (that is, it is not rejected).

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-mask Rejection filter if *Equation 52* is fulfilled.

Equation 52

$$FID \,\&\, FR_RFFIDRFMR[FIDRFMSK] \neq FR_RFFIDRFVR[FIDRFVAL] \,\&\, FR_RFFIDRFMR[FIDRFMSK]$$

The RX FIFO Frame ID Value-mask Rejection filter can be configured to pass all frames by using the following settings:

- FR_RFFIDRFVR[FIDRFVAL] = 0x000 and FR_RFFIDRFMR[FIDRFMSK] = 0x7FF

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-mask Rejection filter can be configured to reject all frames by using the following settings:

- FR_RFFIDRFMR[FIDRFMSK] = 0x000

Using the settings above, *Equation 52* can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

46.6.9.9.2 RX FIFO Frame ID Range Rejection filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range Rejection filters if either no rejection filter is enabled, or, if for all of the enabled RX FIFO Frame ID Range Rejection filters (that is, FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1), *Equation 53* is fulfilled.

Equation 53

$$(FID < FR_RFRFCFR_{SEL}[SID_{IBD=0}]) \text{ or } (FR_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Consequently, all frames with a frame ID that fulfills *Equation 54* for at least one of the enabled rejection filters will be rejected and thus not pass.

Equation 54

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

46.6.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, if for at least one of the enabled RX FIFO Frame ID Range acceptance filters (that is, FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1), *Equation 55* is fulfilled.

Equation 55

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

46.6.9.9.4 RX FIFO Message ID Acceptance filter

The RX FIFO Message ID Acceptance filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance filter if *Equation 56* is fulfilled.

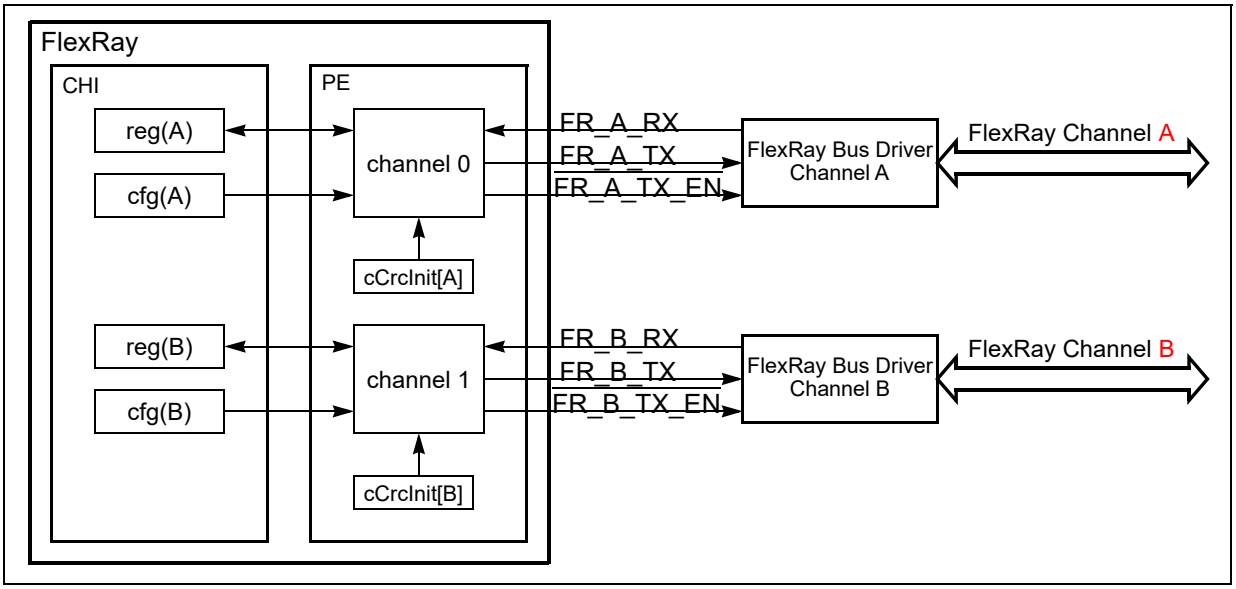
Equation 56

$$MID \,\&\, FR_RFMIDAFMR[MIDAFMSK] = FR_RFMIDAFMR[MIDAFVAL] \,\&\, FR_RFMIDAFMR[MIDAFMSK]$$

The RX FIFO Message ID Acceptance filter can be configured to accept all frames by setting

- FR_RFMIDAFMR[MIDAFMSK]:= 0x000

Using the settings above, *Equation 56* is always fulfilled and all frames will pass.



46.6.10 Channel device modes

This section describes the two FlexRay channel device modes that are supported by the CC.

46.6.10.1 Dual-Channel Device mode

In Dual-Channel Device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and FR_A_TX_EN is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and FR_B_TX_EN is connected to the physical bus channel B. The dual-channel system is shown in *Figure 954*.

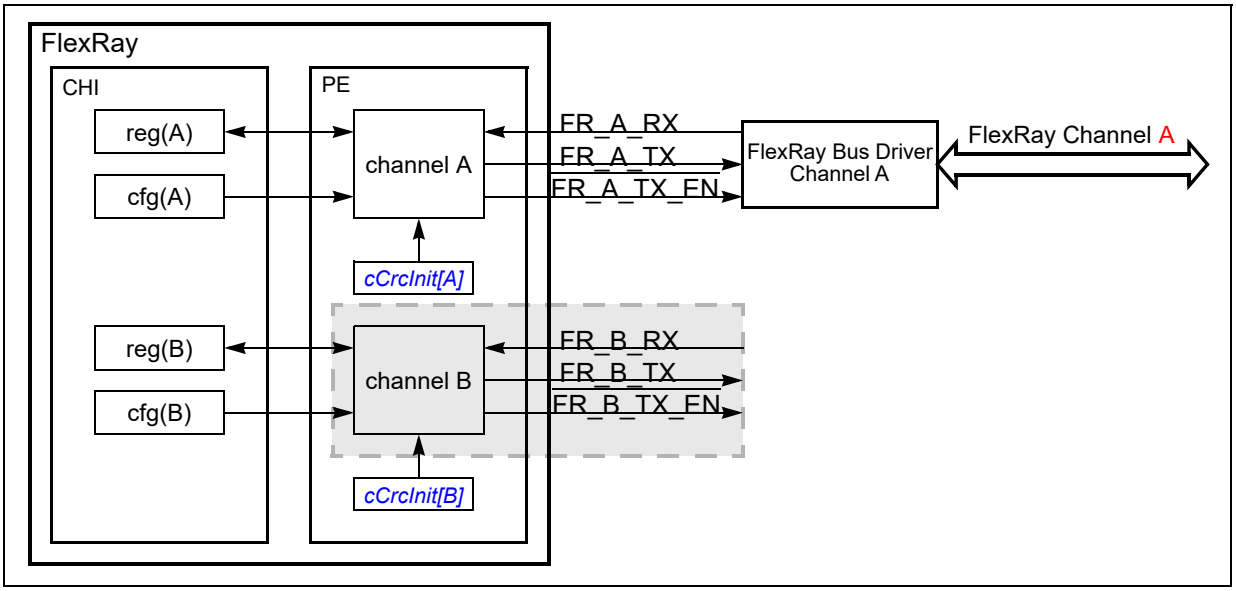
Figure 954. Dual-Channel Device mode

46.6.10.2 Single-Channel Device mode

Single-Channel Device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and FR_A_TX_EN and can be connected to either the physical bus channel A (shown in *Figure 955*) or the physical bus channel B (shown in *Figure 956*).

If the device is configured as a single-channel device by setting FR_MCR[SCM] to 1, only the internal channel A and FlexRay port A are used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay channel A or FlexRay channel B. The bit FR_MCR[CHA] must be set, if FlexRay port A is connected to FlexRay channel A. The bit FR_MCR[CHB] must be set if FlexRay port B is connected to FlexRay channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single-channel device, the application can access and configure only the registers related to internal channel A.

Figure 955. Single-Channel Device mode (channel A)



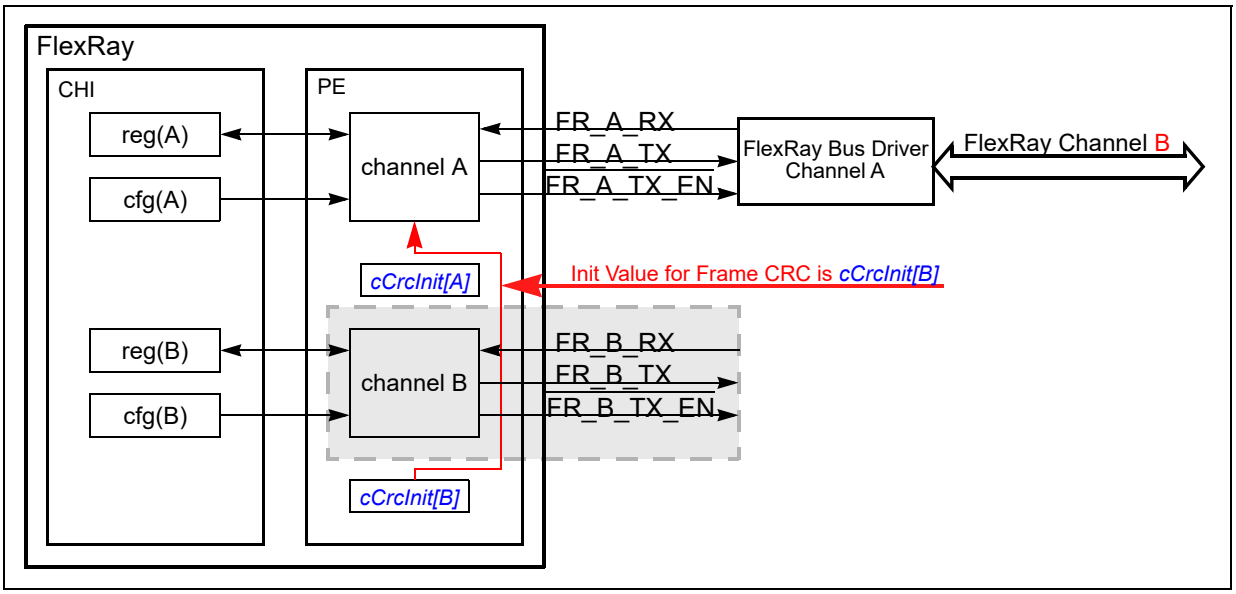


Figure 956. Single-Channel Device mode (channel B)

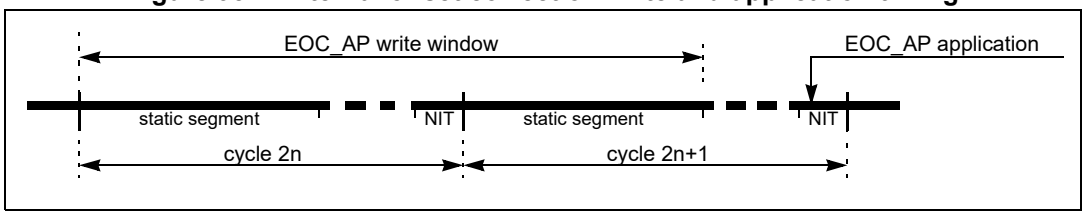
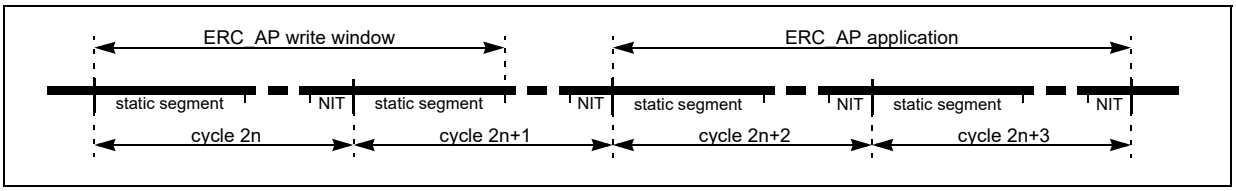
46.6.11 External clock synchronization



The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in *Figure 957* and *Figure 958*.

Note: The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n + 1 will be affected by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end



of the static segment of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle 2n + 1. If the value is not applied in cycle 2n + 1, then the value will be applied in the cycle 2n+3. Refer to *Figure 957* for timing details.

Figure 957. External offset correction write and application timing

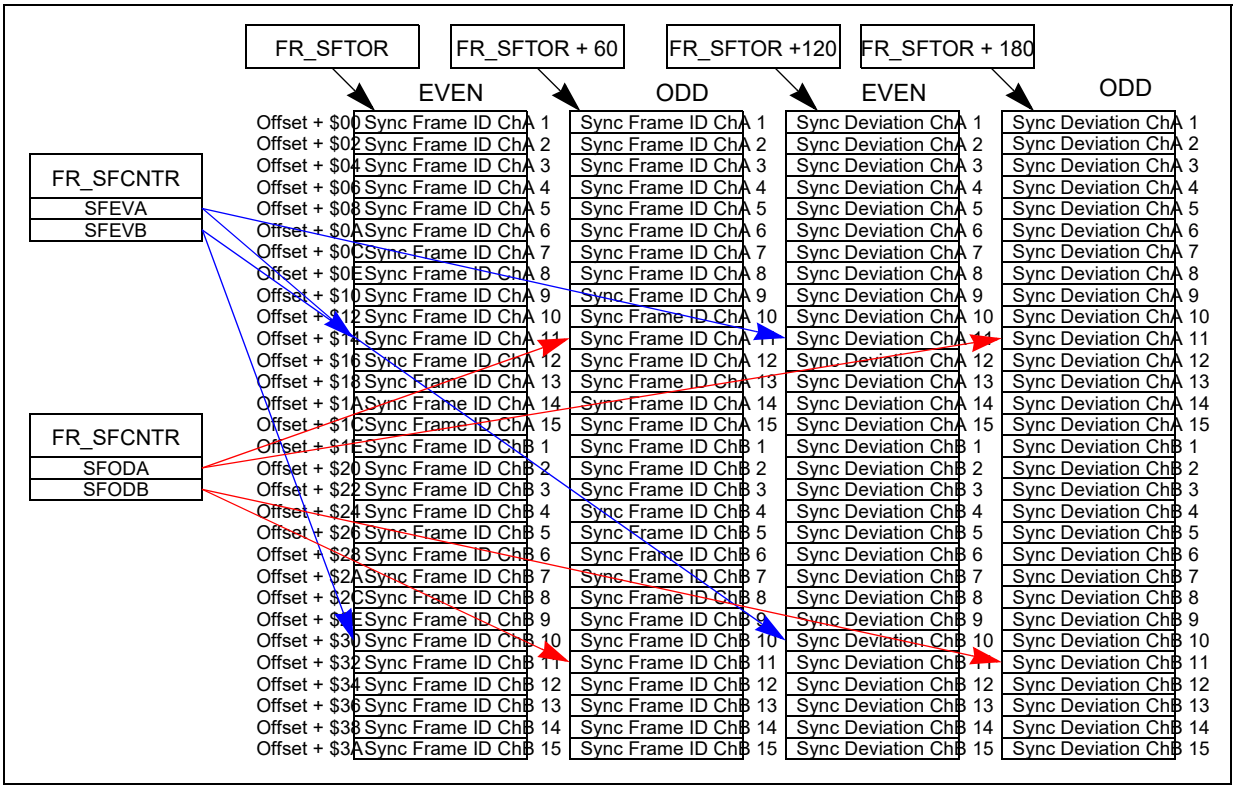
If the rate correction for the cycle pair [2n + 2, 2n + 3] will be affected by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle pair [2n + 2, 2n + 3]. If the value is not applied for cycle pair [2n + 2, 2n + 3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to *Figure 958* for details.

Figure 958. External rate correction write and application timing

46.6.12 Sync frame ID and sync frame deviation tables

The FlexRay protocol requires the provision of a snapshot of the synchronization frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note: Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.



46.6.12.1 Sync frame ID table content

The sync frame ID table is a snapshot of the protocol-related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

46.6.12.2 Sync frame deviation table content

The sync frame deviation table is a snapshot of the protocol-related variable zsDev(id)(oe)(ch)!Value. Each sync frame deviation table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the sync frame ID table.

Figure 959. Sync table memory layout

46.6.12.3 Sync frame ID and sync frame deviation table setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in *Figure 959*. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

46.6.12.4 Sync frame ID and sync frame deviation table generation

The application controls the generation process of the sync frame ID and sync frame deviation tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in *Table 918*.

Table 918. Sync frame table generation modes

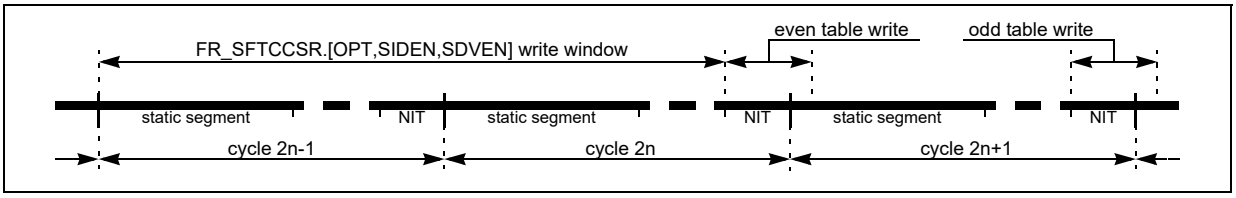
FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No sync frame table copy
0	0	1	Sync frame ID tables will be copied continuously
0	1	0	Reserved

Table 918. Sync frame table generation modes (continued)

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	1	1	Sync frame ID tables and sync frame deviation tables will be copied continuously
1	0	0	No sync frame table copy
1	0	1	Sync frame ID tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync frame ID tables and sync frame deviation tables for next even-odd-cycle pair will be copied

The sync frame table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even-cycle-related tables after the start of the NIT of the next even cycle. The CC checks whether the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. When all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.



To read the generated tables, the application must lock the tables to prevent the CC from updating them. The locking is initiated by writing a 1 to the Even Table Lock trigger, FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding status information fields, SFRA and SFRB, in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in *Figure 959*.

After reading all the data from the locked tables, the application must unlock the table by writing to the Even Table Lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

Figure 960. Sync frame table trigger and generation timing

46.6.12.5 Sync frame table access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in *Figure 959*. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

46.6.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

46.6.13 MTS generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol (MTS) in the symbol window on channel A or channel B.

The application can configure the set of communication cycles that transmit the MTS over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT if *Equation 57*, *Equation 58*, and *Equation 59* are fulfilled.

Equation 57

FR_PSR0[PROTSTATE] = *POC:normal active*

Equation 58

FR_MTSACRF[MTE] = 1

Equation 59

CYCCNT & FR_MTSACFR[CYCCNTMSK] = FR_MTSACFR[CYCCNTVAL] & FR_MTSACFR[CYCCNTMSK]

The MTS is transmitted over channel B in the communication cycle with number CYCCNT if *Equation 57*, *Equation 60* and *Equation 61* are fulfilled.

Equation 60

$$FR_MTSBCRF[MTE] = 1$$

Equation 61

$$CYCCNT \& FR_MTSBCFR[CYCCNTMSK] = FR_MTSBCFR[CYCCNTVAL] \& FR_MTSBCFR[CYCCNTMSK]$$

46.6.14 Key slot transmission

46.6.14.1 Key slot assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less than or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2); otherwise no key slot is assigned.

46.6.14.2 Key slot transmission in *POC:startup*

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version *2.1 Rev A*.

46.6.14.3 Key slot transmission in *POC:normal active*

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in *Table 919* is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see *Section 46.6.6.2.5*). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see *Section 46.6.6.2.6*).

Table 919. Key slot frame type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	Normal frame
0	1	Normal frame(1)
1	0	Sync frame
1	1	Startup frame

1. The frame transmitted has a semantically incorrect header and will be detected as an invalid frame at the receiver.

46.6.15 Sync frame filtering

Each received synchronization frame must pass the Sync Frame Acceptance filter and the Sync Frame Rejection filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled (that is, the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared), all received synchronization frames are considered for clock synchronization. If a received synchronization frame did not pass at

least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

46.6.15.1 Sync frame acceptance filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if *Equation 62* or *Equation 63* evaluates to true.

Equation 62

$$FR_MCR[SFFE] = 0$$

Equation 63

$$FID \,\&\, FR_SFIDAFMR[FMSK] = FR_SFIDAFVR[FVAL] \,\&\, FR_SFIDAFMR[FMSK]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

46.6.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if *Equation 64* or *Equation 65* evaluates to true.

Equation 64

$$FR_MCR[SFFE] = 0$$

Equation 65

$$FID \neq FR_SFIDRFR[SYNFRID]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

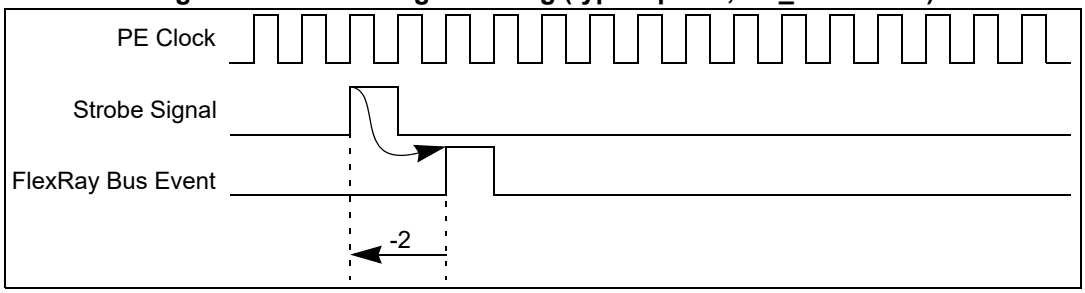
46.6.16 Strobe signal support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in *Table 805*.

46.6.16.1 Strobe signal assignment

Each of the strobe signals listed in *Table 805* can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

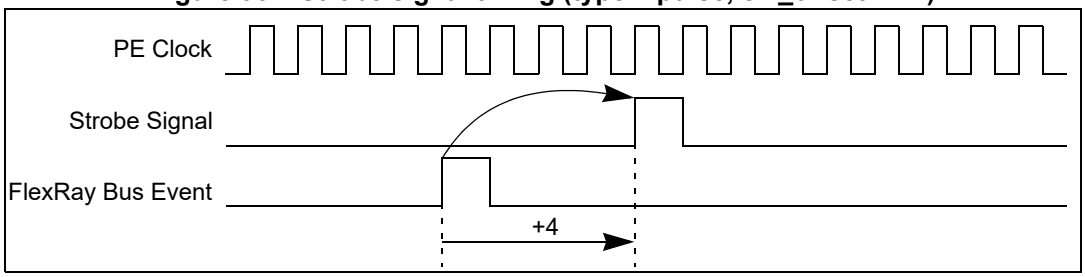
To read out the current settings for a strobe signal with number *n*, the application must execute the following sequence.



1. Write to FR_STBSCR with WMD = 1 and SEL = *n*. (Updates the SEL field only.)
2. Read STBCSR.
   The SEL field provides *n* and the ENB and STBPSEL fields provides the settings for signal *n*.

46.6.16.2 Strobe signal timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.



The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay bus. These signals are listed in *Table 805* with a negative clock offset. An example waveform is given in *Figure 961*.

Figure 961. Strobe signal timing (type = pulse, clk_offset = –2)

Other signals refer to events that occurred on the FlexRay bus some cycles before the strobe signal is changed. These signals are listed in *Table 805* with a positive clock offset. An example waveform is given in *Figure 962*.

Figure 962. Strobe signal timing (type = pulse, clk_offset = +4)

46.6.17 Timer support

The CC provides two timers that run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In Non-repetitive mode, the timer stops if it expires. In Repetitive mode, the timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

46.6.17.1 Absolute timer T1

Absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if *Equation 66* and *Equation 67* are fulfilled.

Equation 66

$$CYCTR[CTCCNT] \& FR_TI1CYSR[T1_CYC_MSK] = FR_TI1CYSR[T1_CYC_VAL] \& FR_TI1CYSR[T1_CYC_MSK]$$

Equation 67

$$FR_MTCTR[MTCT] = FR_TI1MTOR[T1_MTOFFSET]$$

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding interrupt condition (that is, when *Equation 66* and *Equation 67* are fulfilled) also leads to an event-out indication on an output port (*fr_evt_tim1*) based on the FR_PEOER[TIM1_EE].

46.6.17.2 Absolute/relative timer T2

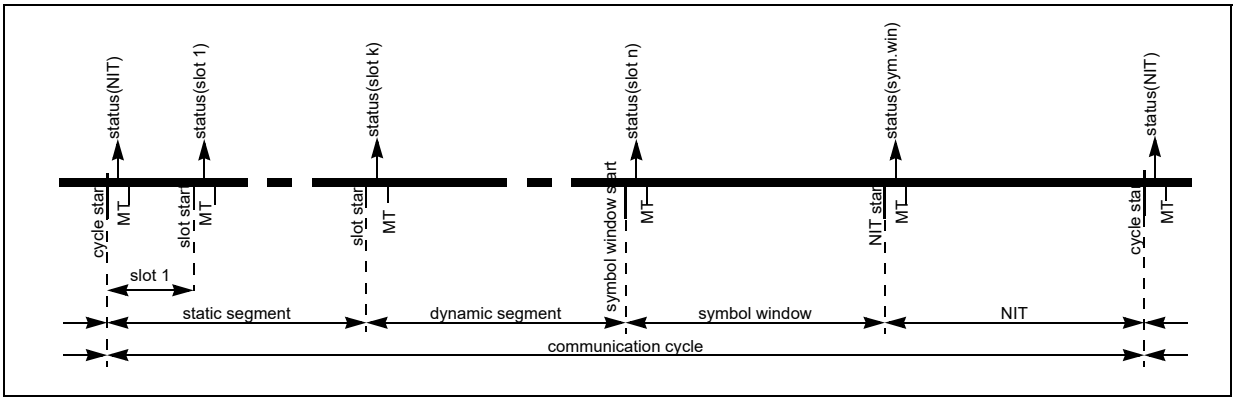
Timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

46.6.17.2.1 Absolute timer T2

If timer T2 is configured as an absolute timer, it has the same functionality as timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. When timer T2 expires, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

46.6.17.2.2 Relative Timer T2



If timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set when the programmed amount of macroticks MT[31:0] – defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) – has elapsed since the trigger or restart of timer T2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

46.6.18 Slot status monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per-channel base. The content of the slot status vector is described in *Table 920*. The PE provides the

slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in *Figure 963*.

Figure 963. Slot status vector update

Note: The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 920. Slot status content

Slot	Status content

static/dynamic Slot	Slot-related status
	vSS!ValidFrame: valid frame received
	vSS!SyntaxError: syntax error occurred while receiving
	vSS!ContentError: content error occurred while receiving
	vSS!BViolation: boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict: reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict: reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	Received-frame-related status
	extracted from
	a) header of valid frame, if vSS!ValidFrame = 1
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator: null frame indicator (0 for null frame)
	vRF!Header!SuFIndicator: startup frame indicator
	vRF!Header!SyFIndicator: sync frame indicator

Symbol window	Window-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: reception ongoing while transmission starts Received-symbol-related status *vSS!ValidMTS*: valid Media Test Access Symbol received Received-frame-related status see static/dynamic slot

Table 920. Slot status content (continued)

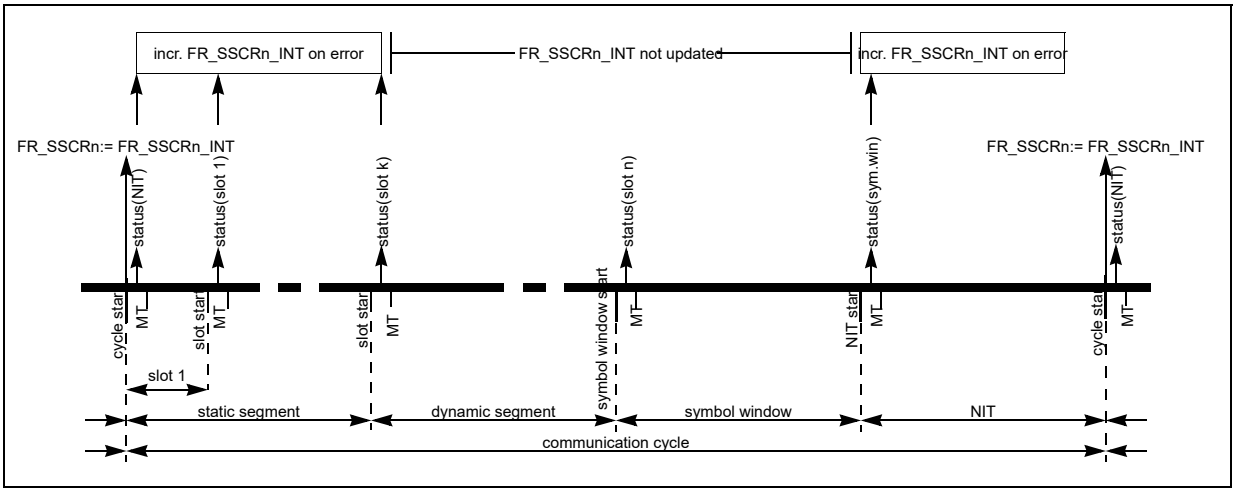
Slot	Status content
NIT	NIT-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: always 0 Received-frame-related status see static/dynamic slot

46.6.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR) are incremented by one if at least one of four slot status error bits, *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap around after they have reached the maximum value.

46.6.18.2 Protocol Status Registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the NIT and the symbol window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.



46.6.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status-related and received frame/symbol-related status information, as given in *Table 920*, except for the *first valid* indicator for non-transmission slots.

46.6.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in *Figure 964*.

Figure 964. Slot status counting and FR_SSCR*n* update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCR*n* register reflects, in cycle n, the status of the NIT of cycle n – 2, and the status of all static slots and the symbol window of cycle n – 1.

The increment condition for each slot status counter consists of two parts: the frame-related condition part and the slot-related condition part. The internal slot status counter FR_SSCR*n*_INT is incremented if at least one of the following conditions is fulfilled:

1. Frame-related condition:

- (FR_SSCCR*n*[VFR] | FR_SSCCR*n*[SYF] | FR_SSCCR*n*[NUF] | FR_SSCCR*n*[SUF]) // count on frame condition
  = 1;

and

- ((~FR_SSCCR*n*[VFR] | vSS!ValidFrame) & // valid frame restriction
  (~FR_SSCCR*n*[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction
  (~FR_SSCCR*n*[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction
  (~FR_SSCCR*n*[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction
  = 1;

Note: The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus, the VFR must always be set whenever the count-on-frame condition is used.

2. Slot-related condition:

- ((FR_SSCCR*n*[STATUSMASK[3]] & vSS!ContentError) | // increment on content error
  (FR_SSCCR*n*[STATUSMASK[2]] & vSS!SyntaxError) | // increment on syntax error
  (FR_SSCCR*n*[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation
  (FR_SSCCR*n*[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict
  = 1;

If the slot status counter is in Single-cycle mode (that is, FR_SSCCR*n*[MCY] = 0), the internal slot status counter FR_SSCR*n*_INT is reset at each cycle start. If the slot status counter is in Multicycle mode (that is, FR_SSCCR*n*[MCY] = 1), the counter is not reset and incremented until the maximum value is reached.

46.6.18.5 Message Buffer Slot Status field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in *Table 920* for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update sections in *Section 46.6.3.4.1*.

46.6.19 System bus access

This section provides a description of the system bus access failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in *Section 46.6.19.1*.

The behavior of the CC after the occurrence of a system bus access failure is described in *Section 46.6.19.2*.

46.6.19.1 System bus access failure types

This section describes the two types of system bus access failures.

46.6.19.1.1 System bus illegal address access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions that are treated as a system bus illegal address access:

- The system bus subsystem detects a CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see *Section 46.6.24.3.1*).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

46.6.19.1.2 System bus access timeout

A system bus access timout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see *Section 46.7.1.1*).

If a system bus access timout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

46.6.19.2 System bus access failure response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

46.6.19.2.1 Continue after system bus access failure

If FR_MCR[SBFF] is 0, the CC will continue its operation after the occurrence of the system bus access failure, but it will not generate any system bus accesses until the start of the next communication cycle.Since no data is read from or written to the FlexRay memory

area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated in which the remaining header and frame data are replaced by all zeros. Depending on the point in time, this can affect the PPI bit, the header CRC, the payload length in the case of a dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted or received, except for the key slot; a sync or startup null-frame is transmitted if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

46.6.19.2.2 Freeze after system bus access failure

If FR_MCR[SBFF] is set to 1, the CC will go into Freeze mode immediately after the occurrence of one of the system bus access failures.

46.6.20 Interrupt support

The CC provides 108 individual interrupt sources and five combined interrupt sources.

46.6.20.1 Individual interrupt sources

46.6.20.1.1 Message buffer interrupts

The CC provides 64 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSR*n*[MBIF] and an interrupt enable bit FR_MBCCSR*n*[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

46.6.20.1.2 FIFO interrupts

The CC provides two FIFO interrupt sources.

Each of the two FIFOs provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding receive FIFO fill level exceeds the defined watermark.

46.6.20.1.2.1 Wakeup interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

46.6.20.1.2.2 Protocol interrupts

The CC provides 25 interrupt sources for protocol-related events. For details, see the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

46.6.20.1.2.3 CHI interrupts

The CC provides 16 interrupt sources for CHI-related error events. For details, see the CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

46.6.20.2 Combined interrupt sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

46.6.20.2.1 Receive message buffer interrupt

The receive message buffer interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

46.6.20.2.2 Transmit message buffer interrupt

The transmit message buffer interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

46.6.20.2.3 Protocol interrupt

The protocol interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set..

46.6.20.2.4 CHI interrupt

The CHI interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

46.6.20.2.5 Module interrupt

The module interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

Figure 965. Scheme of FR_GIFER interrupt signal generation

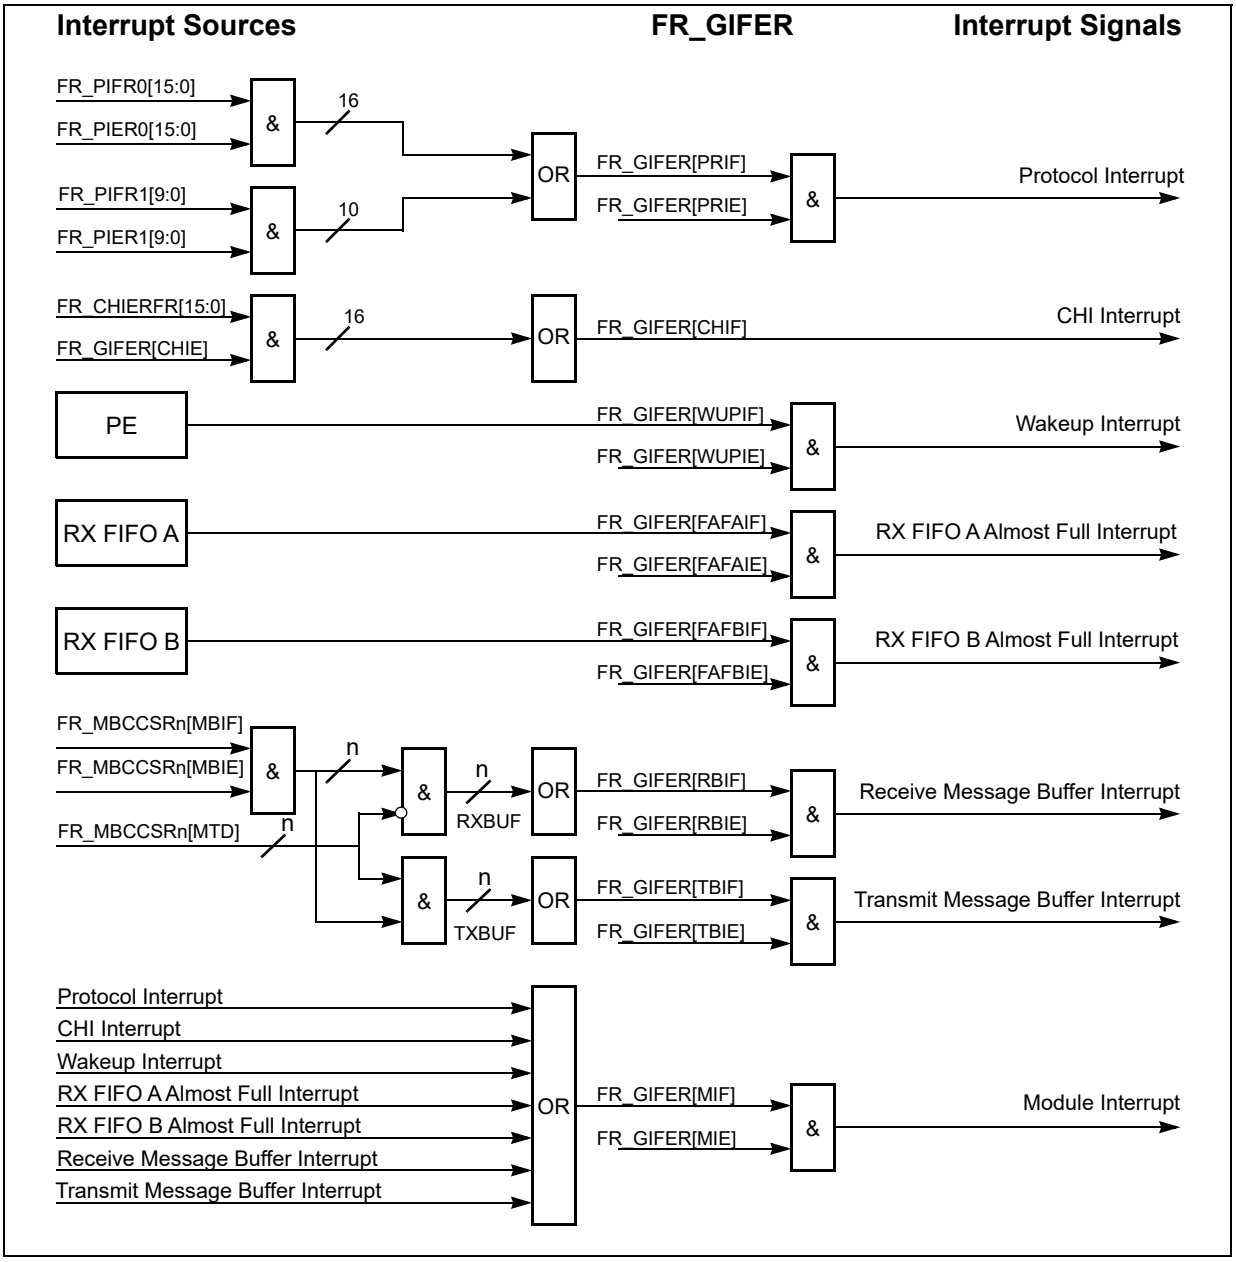


Figure 966. FR_EEIFER interrupt signal generation scheme

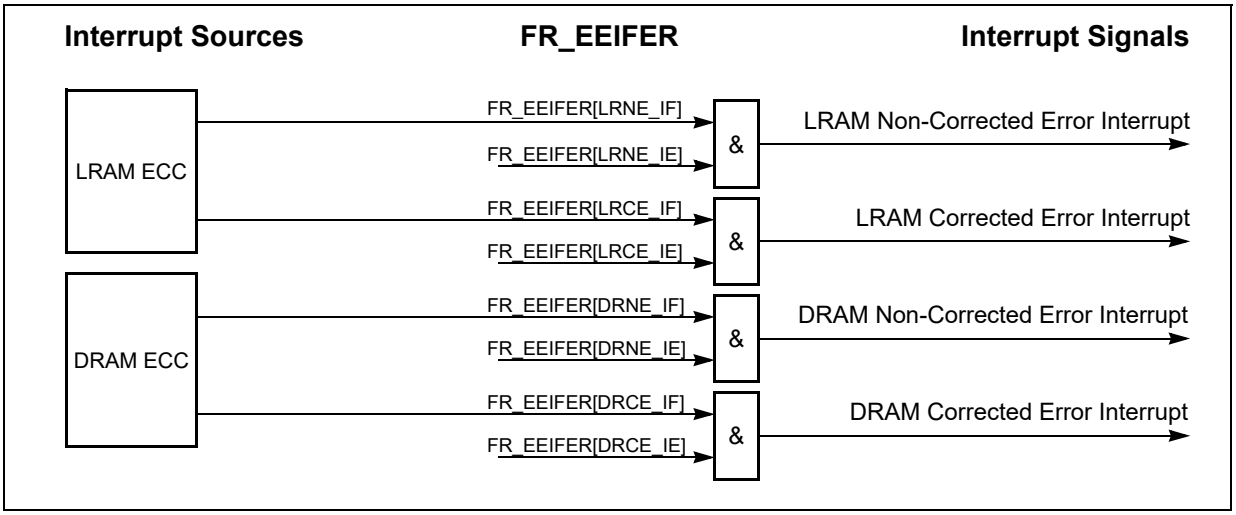

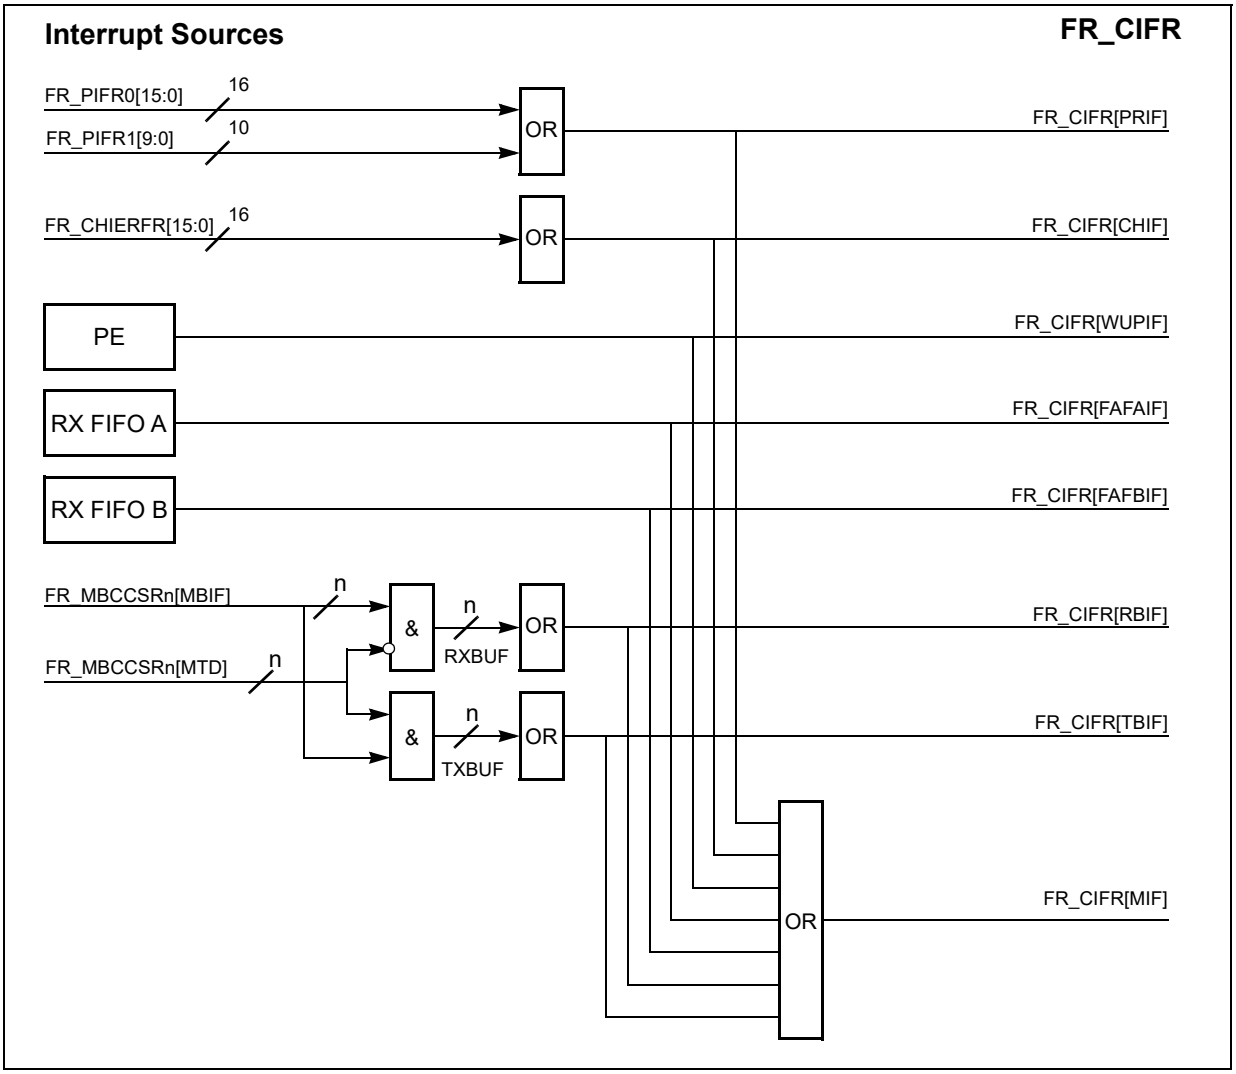

Figure 967. FR_CIFR flag generation scheme

46.6.21 Lower bit rate support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset.* The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings, and the related protocol parameter values are shown in *Table 921*.

Table 921. FlexRay channel bit rate control

FlexRay channel bit rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick* [ns]	*gdSampleClockPeriod* [ns]	pSamplesPerMicrotick	cSamplesPerBit	cStrobeOffset
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note: The bit rate of 8 Mbit/s is not defined by the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

46.6.22 PE data memory (PE DRAM)

The PE data memory (PE DRAM) is 128 word, 16-bit wide memory with byte access that contains the program data of the PE internal CPU. The PE DRAM is divided into two banks of 8 bits each. The memory data [7:0] is assigned to BANK0 and the memory data [15:8] is assigned to BANK1.

Table 922. PE DRAM layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via *Section 46.5.2.9: PE DRAM Access Register (FR_PEDRAR)* and *Section 46.5.2.9: PE DRAM Access Register (FR_PEDRAR)*. This functionality is used to check the memory error detection.

46.6.22.1 PE DRAM read access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;
   // INST=0x5; ADDR=070
2. Wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA];
   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

46.6.22.2 PE DRAM write access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;
   // write value to be written into data register
2. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
3. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
4. val = FR_PEDRDR[DATA];
   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25 µs).

If the conditions given in *Section 46.6.22.3: PE DRAM write access limitations* are fulfilled, the data provided in PE DRAM Access Register (FR_PEDRAR) is written into the PE DRAM, read back in the next clock cycle, and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data is not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

46.6.22.3 PE DRAM write access limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not in *POC:default config* state, only PE DRAM address 0x70 is writable.

46.6.23 CHI lookup-table memory (CHI LRAM)

The CHI lookup-table memory (CHI LRAM) is an CHI-internal memory that contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or six data field offsets are contained in one memory row. The CHI LRAM is divided into six memory banks.

Table 923. CHI LRAM layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x1F	FR_MBIDXR63	FR_MBFIDR63	MBCCF63	FR_MBIDXR62	MBFID62	FR_MBCCFR62
0x20	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0x2B	-	-	-	-	FR_MBDOR67	FR_MBDOR66
0x2C	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

46.6.23.1 CHI LRAM read and write access

The CHI LRAM is accessed by the application via regular register read and write accesses.

46.6.24 Memory content error detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses a standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED). The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

46.6.24.1 Memory error types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as a special case. The FlexRay module detects and indicates the memory errors as shown in *Table 924*. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error-free bank has been read.

Table 924. Detected memory error types

Memory	Priority	Memory data	Indication
CHI LRAM	0 (highest)	All zeros	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM		All ones	Non-corrected error
PE DRAM			
CHI LRAM	1 (lowest)	One bit flipped	Non-corrected error
PE DRAM			Corrected error
CHI LRAM		Two bits flipped	Non-corrected error
PE DRAM			
CHI LRAM		Three or more bits flipped	One out of {no error, non-corrected error}, defined by coding given in *Section 46.6.24.2.3* and *Section 46.6.24.2.4*
PE DRAM			One out of {no error, corrected error, non-corrected error}, defined by coding given in *Section 46.6.24.2.1* and *Section 46.6.24.2.2*

46.6.24.2 Memory error reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories, there are two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.
- If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to the above, the error indications (corrected/non-corrected) along with the failing address are sent out from the module for external error logging and corrective actions by the software.

46.6.24.2.1 PE DRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 924*. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 925. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4(1)	X	X	X	X	X	X	X	X	X	X	X	X
3(2)	—	—	—	—	X	X	X	X	—	—	—	—
2	—	—	—	—	X	—	—	—	X	X	X	—
1	—	—	—	—	—	X	X	—	X	X	—	X
0	—	—	—	—	—	X	—	X	X	—	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is an even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is an odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words written into the memory.

46.6.24.2.2 PE DRAM syndrome

The coding of the syndrome reported in the ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 926*.

Table 926. FR_EERCR[CODE] PE DRAM syndrome coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected error (parity bit 0)
0x0	0x2	Corrected error (parity bit 1)
0x0	0x3	Corrected error (data bit 0)
0x0	0x4	Corrected error (parity bit 2)
0x0	0x5	Corrected error (data bit 1)
0x0	0x6	Corrected error (data bit 2)
0x0	0x7	Corrected error (data bit 3)
0x0	0x8	Corrected error (parity bit 3)
0x0	0x9	Corrected error (data bit 4)
0x0	0xA	Corrected error (data bit 5)
0x0	0xB	Corrected error (data bit 6)
0x0	0xC	Corrected error (data bit 7)
0x0	0xD–0xF	Non-corrected error
0x1	0x1–0xF	Non-corrected error

46.6.24.2.3 CHI LRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 927*. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 927. CHI LRAM checkbits coding

CODE(1)	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	—	—	—	—	—	—	—	—	—	—	—
3	—	—	—	—	—	X	X	X	X	X	X	X	—	—	—	—
2	X	X	—	—	—	X	X	X	X	—	—	—	X	X	X	—
1	—	—	X	X	—	X	X	—	—	X	X	—	X	X	—	X
0	X	—	X	—	X	X	—	X	—	X	—	X	X	—	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is an odd number of 1's in all columns with X.

46.6.24.2.4 CHI LRAM syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 928*.

Table 928. FR_EERCR[CODE] CHI LRAM syndrome coding

FR_EERCR[CODE]	Description
0x00	No Error (never appears in error report registers)
0x01–0x1F	Non-corrected error

46.6.24.3 Memory error response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case a *corrected* memory error is detected, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

46.6.24.3.1 CHI LRAM error response after CC read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access, the error response of the module depends from LRAM location where the error occurred.

- If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current

search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.

  – If the affected message buffer is a Tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is an Rx message buffer, no frame will be received to this message buffer in the next slot.

- If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx, the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs with respect to payload access for the complete frame.

46.6.24.3.2 CHI LRAM error response after application read

The application can read the content of the CHI LRAM by reading the FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBIDXR*n*, FR_MBDOR*n* and FR_LEETR*n* registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read, and continues its normal operation.

46.6.24.3.3 PE DRAM error response after CC read

If the CC detects a non-corrected memory error during an internal read of program data contained in PE DRAM, this is considered a fatal protocol error and the module enters the protocol freeze state immediately.

46.6.24.3.4 PE DRAM error response after application read in *POC:default config* state

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered a fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

46.6.24.3.5 PE DRAM error response after application read out of *POC:default config*

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is not in the *POC:default config* state, this error is not considered a fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

46.6.25 Memory error injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

Error Injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).When error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

46.6.25.1 CHI LRAM error injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in *Table 923*.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see *Section 46.7.3*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 1;
   // select CHI LRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // select address for error injection; I_ADDR ≤ 0x2C
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application Write Access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;
If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;
If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;
If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;
If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;
If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;
// write DATA to the defined injection bank and injection address (see *Table 923*).

46.6.25.2 PE DRAM error injection

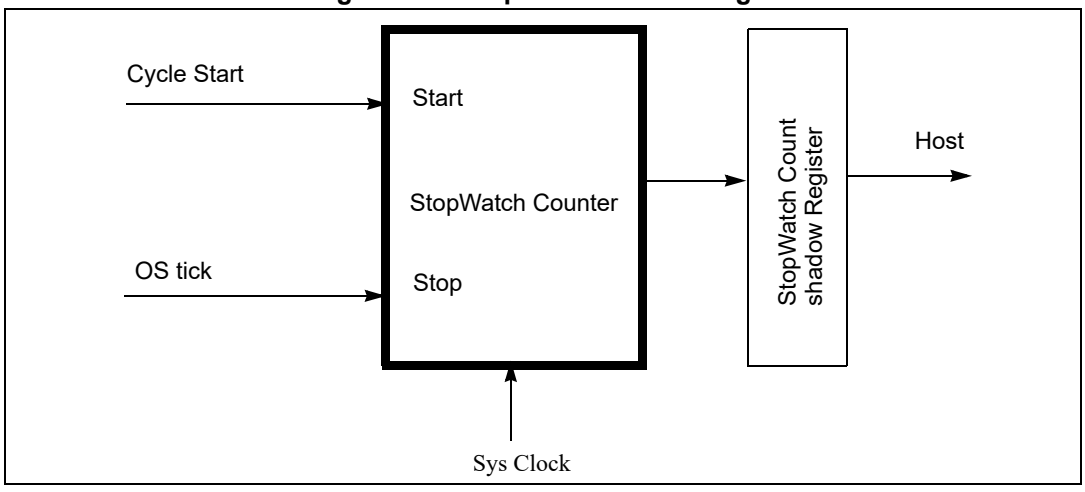
The following sequence describes a memory error injection sequence for the PE DRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see *Section 46.7.3.2*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 0;
   // select PE DRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // define bank for error injection; I_BANK = {0,1}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // define address for error injection; I_ADDR ≤ 0x7F
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application write access (for example, I_ADDR=0x70):



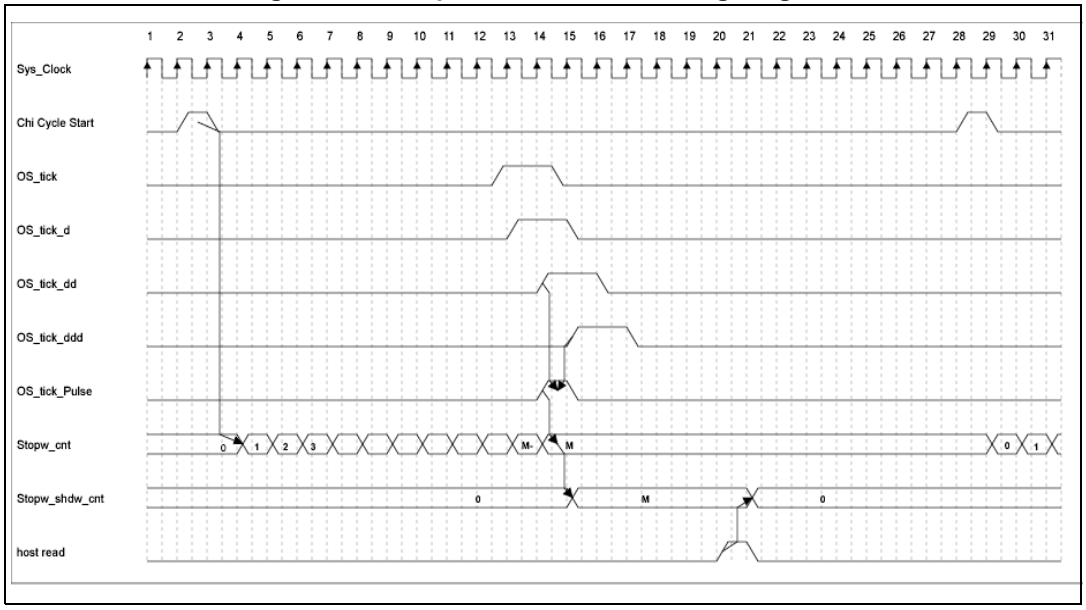
1. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
2. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA]; |
   // get read back PE DRAM data

Note: The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

46.6.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick.

Figure 968. StopWatch counter logic



As shown here, there is a 32 bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (*Section 46.5.2.67: Stop Watch Count Register (FR_STPWR)*) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared.

The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (*Section* : . The counter runs only when this bit is set.

Figure 969 shows the actual timing of the stopwatch counter logic operation.

Figure 969. StopWatch function timing diagram

1. ‘Host read’ implies that all 32 bits have been read out completely. Any partial read (that is for 8/16 bits access) will not clear the StopWatch count register.
2. “If cycle start and OS tick occurs simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and cycle_start has a single stage synchronizer into chi clock domain. So simultaneously here means OS_tick_pulse and chi_cycle_start occurring at the same cycle."

46.7 Application information

46.7.1 Module configuration

This section describes essential parts of the module configuration.

46.7.1.1 Configure System Memory Access Timeout Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in the System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill *Equation 68*[p].

p. See *Section 46.3: Controller Host Interface clocking* for all constraints of minimum CHI clock frequency.

Equation 68

$$0 \leq \text{SYMATOR[TIMEOUT]} \leq \lfloor 0.45 \cdot f_{CHI} - 8 \rfloor$$

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in *Table 929*.

Table 929. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
≥ 18 MHz	0	≥ 100 MHz	≤ 37
≥ 23 MHz	≤ 2	≥ 120 MHz	≤ 46
≥ 27 MHz	≤ 4	≥ 140 MHz	≤ 55
≥ 32 MHz	≤ 6	≥ 160 MHz	≤ 64
≥ 60 MHz	≤ 19	≥ 180 MHz	≤ 73
≥ 80 MHz	≤ 28	≥ 200 MHz	≤ 82

46.7.1.1.1 System bus wait state constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single-channel configurations and situations in which the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0), no timeout will be detected if fewer than 2 × SYMATOR[TIMEOUT] + 1 wait states will be seen on the system bus for each system bus access.

For dual-channel configurations, or situations in which the sync frame table generation functionality is used, no timeout will be detected if fewer than SYMATOR[TIMEOUT] – 1 wait states will be seen on the system bus for each system bus access.

46.7.1.2 Configure data field offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDOR*n*) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers that are used.

When the module is enabled, the initilization value of the FR_MBDOR*n*[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (see *Section 46.6.19.1.1*).

46.7.2 Initialization sequence

This section describes the steps required to initialize the CC. The first subsection describes the steps required after a system reset; the second section describes the steps required after preceding shutdown of the CC.

46.7.2.1 Module initialization

This section describes the module-related initialization steps after a system reset.

1. Configure the CC.
   a) Configure the control bits in the Module Configuration Register (FR_MCR).
   b) Configure the system memory base address in the System Memory Base Address Register (FR_SYMBADR).
2. Enable the CC.
   a) Write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR).

The CC now enters Normal mode. The application can commence with the protocol initialization described in *Section 46.7.2.2*.

46.7.2.2 Protocol initialization

This section describes the protocol-related initialization steps.

1. Configure the Protocol Engine.
   a) Issue CONFIG command via the Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:config* in the Protocol Status Register 0 (FR_PSR0).
   c) Configure the FR_PCR0,..., FR_PCR30 registers to set all protocol parameters.
2. Configure the message buffers and FIFOs.
   a) Set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
   b) Define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR)
   c) Configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSR*n*), Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*), Message Buffer Frame ID Registers (FR_MBFIDR*n*), and Message Buffer Index Registers (FR_MBIDXR*n*)
   d) Configure the FIFOs.
   e) Issue CONFIG_COMPLETE command via the Protocol Operation Control Register (FR_POCR).
   f) Wait for *POC:ready* in the Protocol Status Register 0 (FR_PSR0).

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

46.7.2.3 CHI LRAM initialization

The CHI LRAM initialization is performed by the CC when it leaves Disabled mode. The unitization runs for 45 CHI clock cycles. All fields in the FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBDOR*n* and LEETR*n* registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

46.7.2.4 PE DRAM initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs and will delay the state transition from *POC:default config* into *POC:config*.

46.7.3 Memory error injection out of *POC:default config*

This section provides information for application-driven memory error injection out if *POC:default config.* The CC provides means to inject memory errors from the application without any impacts to the internal protocol operation of the CC.

46.7.3.1 CHI LRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETR*n*). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in *Section 46.6.25.1*.

46.7.3.2 PE DRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM locations to inject memory errors into the PE DRAM. The injection sequence is described in *Section 46.6.25.2*.

46.7.4 Shutdown sequence

This section describes a secure shutdown sequence to stop the CC gracefully. The main targets of this sequence are

- Finish all ongoing reception and transmission
- Do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication

For a graceful shutdown, the application should perform the following tasks:

1. Disable all enabled message buffers.
   a) Repeatedly write 1 to FR_MBCCSR*n*[EDT] until FR_MBCCSR*n*[EDS] == 0.
2. Stop the Protocol Engine.
   a) Issue HALT command via Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0).

46.7.5 Number of usable message buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[q].

Additional constraints for the minimum CHI clock frequency are given in *Section 46.3*.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of the slot and must be finished before the start of the next slot.

q. see *Section 46.3: Controller Host Interface clocking* for all constraints of minimum CHI clock frequency.

The shortest FlexRay slot is a corrected empty dynamic slot. A corrected empty dynamic slot is a mini-slot and consists of *gdMinislot* corrected macroticks with a duration of *gdMacrotick*. The minimum duration of an corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of an correct slot.

Equation 69

$$\Delta_{slotmin} = 39 \cdot pdMicrotick \cdot gdMinislot$$

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

Equation 70

$$\Delta_{search} = \frac{1}{f_{chi}} \cdot (FR_MBSSUTR[LAST_MB_UTIL]+27)$$

The message buffer search must be finished within one slot which requires that *Equation 71* must be fulfilled:

Equation 71

$$\Delta_{search} \leq \Delta_{slotmin}$$

This results in the formula given in *Equation 72* which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

Equation 72

$$f_{chi} \geq \frac{(FR_MBSSUTR[LAST_MB_UTIL]+27)}{39 \cdot pdMicrotick \cdot gdMinislot}$$

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 63 is given in *Table 930*.

Table 930. Minimum CHI clock frequency[MHz] examples (64 message buffers used)

pdMicrotick [ns]	gdMinislot					
	2	3	4	5	6	7
25.0	46.7	31.2	23.4	18.7	15.6	13.4
50.0	23.4	15.6	11.7	9.4	7.8	6.7

Note: If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to Section 46.5.2.17: CHI Error Flag Register (FR_CHIERFR) for details.

46.7.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of *Table 810* by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in *Table 931*. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by *Table 931*. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 931. Protocol control command priorities

Protocol command	Priority	Interrupted by	Cleared and terminated by
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLET, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE, fatal protocol error

46.7.7 Message buffer search on simple message buffer configuration

This section describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

46.7.7.1 Simple message buffer configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *s*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has following configuration.

Table 932. Transmit buffer configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	Transmit buffer
FR_MBCCFR*t*	MTM	0	Event Transition mode
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000011	Cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	S	Assigned to slot s

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number *r* and has following configuration.

Table 933. Receive buffer configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	Receive buffer
FR_MBCCFR*r*	MTM	—	n/a
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000001	Cycle set = {2n} = {0,2,4,6,…}
	CCFVAL	000000	
FR_MBFIDR*r*	FID	S	Subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSR*t*[EDS] = 1 and FR_MBCCSR*r*[EDS] = 1).

Note: The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

46.7.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *s* in the *static* segment.

The configuration of a transmit buffer for a static slot *s* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *s*. In any case, the result of the message buffer search will be the transmit message buffer *t*. The receive message buffer *r* will not be found, no reception is possible.

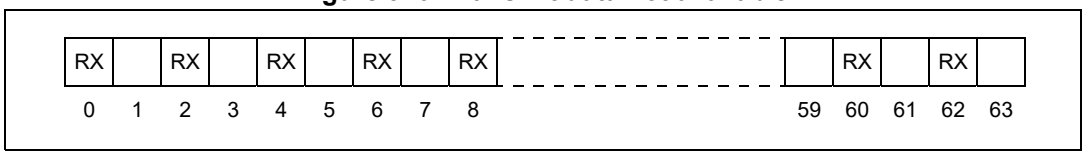
46.7.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *s* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

46.7.7.3.1 Transmit Data Not Available



If transmit data are not available, that is the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 or locked FR_MBCCSR*t*[LCKS]=1, or both.

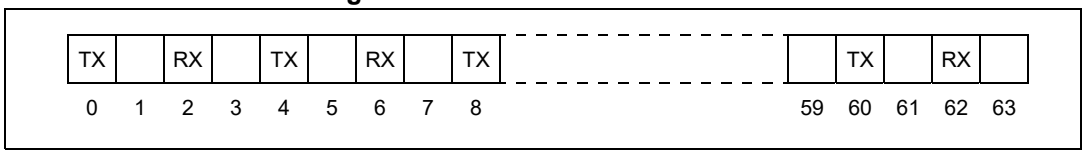
a) For the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and,

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in *Figure 970*.

Figure 970. Transmit data not available

46.7.7.3.2 Transmit data available



If transmit data are *available,* that is, the transmit buffer is committed FR_MBCCSR*t*[CMT] = 1 and not locked FR_MBCCSR*t*[LCKS] = 0,

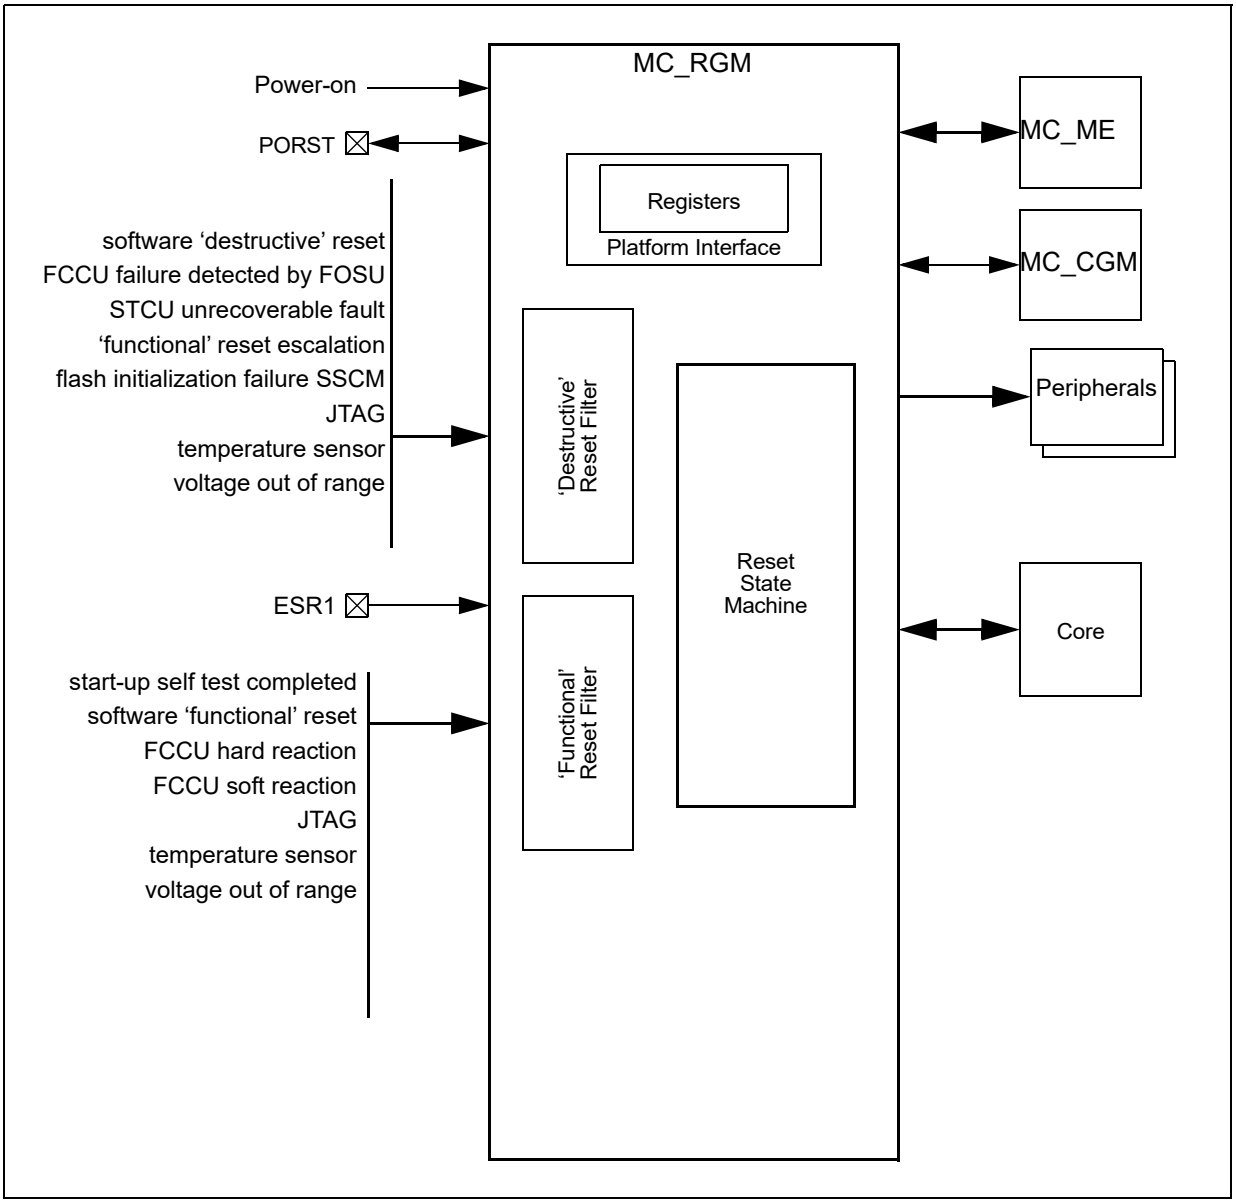
a) For the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in *Figure 971*.

Figure 971. Transmit data available

47 Reset Generation Module (MC_RGM)



47.1 Introduction

47.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

Figure 972 shows the MC_RGM block diagram.

Figure 972. MC_RGM block diagram

47.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'Destructive' resets management
- 'Functional' resets management
- Signalling of reset events after each reset sequence (reset status flags)
- Conversion of reset events to SAFE mode or interrupt request events
- Short reset sequence configuration
- Configurable escalation of recurring 'functional' resets to 'destructive' reset
- Configurable escalation of recurring 'destructive' resets to keep chip in reset state until next power-on reset

47.1.3 Reset sources

The different reset sources are organized into two families: ‘destructive’ and ‘functional’.

- A ‘destructive’ reset source is associated with an event related to a critical, usually hardware, error or dysfunction. When a ‘destructive’ reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software ‘destructive’ reset and external power-on reset cases, which do preserve the system memory content if the chip is not configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Destructive’ resets are:
  - Power-on reset
  - External power-on reset
  - Software ‘destructive’ reset
  - FCCU failure to react reset
  - STCU2 unrecoverable fault
  - ‘Functional’ reset escalation
  - Flash initialization failure
  - SSCM ’destructive’ reset request
  - JTAG ‘destructive’ reset request
  - Temperature sensor ‘destructive’ reset
  - Voltage out of range ‘destructive’ reset
- A ‘functional’ reset source is associated with an event related to a less-critical, usually non-hardware, error or dysfunction. When a ‘functional’ reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example, debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Functional’ resets are:
  - ESR1 external reset
  - Start-up self test completed
  - Software ‘functional’ reset
  - FCCU hard reaction
  - FCCU soft reaction
  - JTAG ‘functional’ reset
  - Temperature sensor ‘functional’ reset
  - Voltage out of range ‘functional’ reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (see *Section 47.3.2.2: Destructive Event Reset Disable Register (RGM_DERD)* and *Section 47.3.2.3: Destructive Event Alternate Request Register (RGM_DEAR)* for 'destructive' resets. See *Section 47.3.2.6: Functional Event Reset Disable Register (RGM_FERD)* and *Section 47.3.2.7: Functional Event Alternate Request Register (RGM_FEAR)* for 'functional' resets).

47.2 External signal description

The MC_RGM has no external interface signal.

47.3 Memory map and register definition

1. individual bits cleared on writing '1'
2. write once: '0' = enable, '1' = disable.

Note: Any access to unused registers as well as write accesses to read-only registers:
- does not change register content
- causes a transfer error

47.3.2 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

47.3.2.1 Destructive Event Status Register (RGM_DES)

This register contains the status of the 'destructive' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1'. This register is reset only on power-on.

26 F_SUF	Flag for STCU unrecoverable fault 0 No STCU unrecoverable fault event has occurred since either the last clear or the last power-on reset assertion 1 An STCU unrecoverable fault event has occurred
27 F_FFRR	Flag for FCCU failure to react 0 No FCCU failure to react event has occurred since either the last clear or the last power-on reset assertion 1 An FCCU failure to react event has occurred
28 F_SOFT_DEST	Flag for software ’destructive’ reset(1) 0 No software ’destructive’ reset event has occurred since either the last clear or the last power-on reset assertion 1 An software ’destructive’ reset event has occurred
30 F_PORST	Flag for external power-on reset 0 No external power-on reset event has occurred since either the last clear or the last power-on reset assertion 1 An external power-on reset event has occurred
31 F_POR	Flag for power-on reset 0 No power-on reset event has occurred since either the last clear or the last power-on reset assertion 1 A power-on reset event has occurred

1. The software reset is generated by the Mode Entry module (see *Chapter 52: Mode Entry Module (MC_ME)*)

47.3.2.2 Destructive Event Reset Disable Register (RGM_DERD)

This register provides dedicated bits to disable particular ‘destructive’ reset sources. When a ‘destructive’ reset source is disabled, the associated ‘destructive’ event will trigger either a SAFE mode request or an interrupt request (see *Section 47.3.2.3: Destructive Event Alternate Request Register (RGM_DEAR)*). Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Each byte can be written only once after a ‘destructive’ or power-on reset. This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x010 Access: User read, Supervisor read, Test read

Figure 974. Destructive Event Reset Disable Register (RGM_DERD)

Table 936. RGM_DERD register field descriptions

Field	Description
7 D_VOR_DEST	Disable voltage out of range ‘destructive’ reset 0 A voltage out of range ‘destructive’ reset event triggers a reset sequence
8 D_TSR_DEST	Disable temperature sensor ‘destructive’ reset 0 A temperature sensor ‘destructive’ reset event triggers a reset sequence 1 A temperature sensor ‘destructive’ reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_DEAR.AR_TSR_DEST
17 D_SSCM	Disable SSCM ’destructive’ reset request 0 A SSCM ’destructive’ reset request event triggers a reset sequence 1 A SSCM ’destructive’ reset request event generates either a SAFE mode or an interrupt request depending on the value of RGM_DEAR.AR_SSCM
21 D_JTAG_DEST	Disable JTAG ‘destructive’ reset request 0 A JTAG ‘destructive’ reset request event triggers a reset sequence

Table 936. RGM_DERD register field descriptions (continued)

Field	Description
22 D_FIF	Disable flash initialization failure 0 A flash initialization failure event triggers a reset sequence
23 D_EDR	Disable ‘functional’ reset escalation 0 A ‘functional’ reset escalation event triggers a reset sequence
26 D_SUF	Disable STCU unrecoverable fault 0 A STCU unrecoverable fault event triggers a reset sequence
27 D_FFRR	Disable FCCU failure to react 0 A FCCU failure to react event triggers a reset sequence
28 D_SOFT_DEST	Disable software ’destructive’ reset(1) 0 A software ’destructive’ reset event triggers a reset sequence
30 D_PORST	Disable external power-on reset 0 A external power-on reset event triggers a reset sequence 1 A external power-on reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_DEAR.AR_PORST
31 D_POR	Disable power-on reset 0 A power-on reset event triggers a reset sequence

1. The software reset is generated by the Mode Entry module (see Chapter *Mode Entry Module (MC_ME)*)

47.3.2.3 Destructive Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a ‘destructive’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. This register is reset only on power-on.

Address: 0x020 Access: User read, Supervisor read, Test read

31 BE_POR	Bidirectional Reset Enable for power-on reset 0 PAD_47 is asserted on power-on reset event

47.3.2.5 Functional Event Status Register (RGM_FES)

This register contains the status of the 'functional' reset sources, including those configured to not generate a reset sequence. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source. This register is reset only on power-on.

Note: If a 'functional' reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES register has been properly cleared and clear it again if this is not the case.

Figure 977. Functional Event Status Register (RGM_FES)

1. HVD6 occurrence will not raise the F_VOR_FUNC flag

Table 939. Functional Event Status Register (RGM_FES) field descriptions

Field	Description
7 F_VOR_FUNC	Flag for Voltage out of range functional reset 0 No Voltage out of range functional reset event has occurred since either the last clear or the last power-on reset assertion. 1 A Voltage out of range functional reset event has occurred.
8 F_TSR_FUNC	Flag for temperature sensor functional reset 0 No temperature sensor functional reset event has occurred since either the last clear or the last power-on reset assertion. 1 A temperature sensor functional reset event has occurred.
21 F_JTAG_FUNC	Flag for JTAG ‘functional’ reset 0 No JTAG ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion. 1 A JTAG ‘functional’ reset event has occurred.
25 F_FCCU_SOFT	Flag for soft reaction request 0 No soft reaction request event has occurred since either the last clear or the last power-on reset assertion. 1 A soft reaction request event has occurred.

Table 939. Functional Event Status Register (RGM_FES) field descriptions (continued)

Field	Description
26 F_FCCU_HARD	Flag for hard reaction request 0 No hard reaction request event has occurred since either the last clear or the last power-on reset assertion. 1 A hard reaction request event has occurred.
28 F_SOFT_FUNC	Flag for Software 'functional' reset(1) or online selftest completion 0 No Software 'functional' reset event has occurred since either the last clear or the last power-on reset assertion. 1 A Software 'functional' reset event has occurred or software triggered selftest has completed.
29 F_ST_DONE	Flag for Self-test 'functional' reset 0 No Self-test 'functional' reset event has occurred since either the last clear or the last power-on reset assertion. 1 A Self-test 'functional' reset event has occurred.
30 F_WAKEUP	Flag for Wake-up 'functional' reset(2) 0 No Wake-up 'functional' reset event has occurred since either the last clear or the last power-on reset assertion. 1 A Wake-up 'functional' reset event has occurred.

1. The software reset is generated by the Mode Entry module (see *Chapter 52: Mode Entry Module (MC_ME)*)
2. The software reset is generated by the NMI

47.3.2.6 Functional Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources.When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see *Section 47.3.2.7: Functional Event Alternate Request Register (RGM_FEAR)*). Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Each byte can be written only once after power-on reset. This register is reset only on power-on and any 'destructive' reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

47.3.2.7 Functional Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. This register is reset only on power-on and any 'destructive' reset.

47.3.2.8 Functional Bidirectional Reset Enable Register (RGM_FBRE)

This register enables the generation of an external reset on 'functional' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0x330 Access: User read, Supervisor read/write, Test read/write

47.3.2.9 Functional Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence is activated when a ‘functional’ reset sequence is triggered. The ‘functional’ reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2; this could be useful for fast reset sequence, for example to skip flash reset.Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x340 Access: User read, Supervisor read/write, Test read/write

47.3.2.10 Functional Reset Escalation Threshold Register (RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See *Section 47.4.5* for details on the 'functional' reset escalation function. This register is reset only on power-on and any 'destructive' reset events.

47.3.2.11 Destructive Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for 'destructive' reset escalation keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

Writing a non-zero value to the DRET field will enable the 'destructive' reset escalation function. Writing any value to this register will reset the 'destructive' reset counter. See *Section 47.4.6* for details on the 'destructive' reset escalation function. This register is reset only on power-on.

Table 945. RGM_DRET register field descriptions

Field	Description
4:7 DRET	‘Destructive’ Reset Escalation Threshold 0000 ‘destructive’ reset escalation function is disabled 0001 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0010 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0011 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0100 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0101 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0110 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 0111 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1000 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1001 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1010 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1011 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1100 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1101 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1110 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand 1111 Number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand

47.3.2.12 Peripheral Reset Register 0 (RGM_PRST0)

This register provides individual resets for various peripherals. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.Please refer to *Table 946* for details.

Address: 0x610 Access: User read, Supervisor read/write, Test read/write

Figure 987. Peripheral Reset Register 3 (RGM_PRST3)

Table 949. RGM_PRST3 register field descriptions

Field	Description
0 ADCSAR_dig_0_RST	ADCSAR_dig_0 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_0 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST3.ADCSAR_seq_0_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 ADCSAR_dig_1_RST	ADCSAR_dig_1 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_1 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST3.ADCSAR_seq_1_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
2 ADCSAR_dig_2_RST	ADCSAR_dig_2 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_2 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST3.ADCSAR_seq_2_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 ADCSAR_seq_0_RST	ADCSAR_seq_0 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_0 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
5 ADCSAR_seq_1_RST	ADCSAR_seq_1 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_1 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 ADCSAR_seq_2_RST	ADCSAR_seq_2 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_2 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 949. RGM_PRST3 register field descriptions (continued)

Field	Description
15 ADCSAR_dig_b_RST	ADCSAR_dig_b reset Writing a ‘1’ to this bit resets the ADCSAR_dig_b peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_b peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST3.ADCSAR_seq_b_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 ADCSAR_seq_b_RST	ADCSAR_seq_b reset Writing a ‘1’ to this bit resets the ADCSAR_seq_b peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_b peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
20 FLEXRAY_RST	FLEXRAY reset Writing a ‘1’ to this bit resets the FLEXRAY peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXRAY peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 SENT_0_RST	SENT_0 reset Writing a ‘1’ to this bit resets the SENT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SENT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_0_RST	DSPI_0 reset Writing a ‘1’ to this bit resets the DSPI_0 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_1_RST	DSPI_1 reset Writing a ‘1’ to this bit resets the DSPI_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

47.3.2.16 Peripheral Reset Register 4 (RGM_PRST4)

This register provides individual resets for various peripherals. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Please refer to *Table 950* for details.

Address: 0x620 Access: User read, Supervisor read/write, Test read/write

Figure 988. Peripheral Reset Register 4 (RGM_PRST4)

Table 950. RGM_PRST4 register field descriptions

Field	Description
16 PWM_SYNCHR_RST	PWM_SYNCHR reset Writing a ‘1’ to this bit resets the PWM_SYNCHR peripheral. Writing a ‘0’ to this bit releases the reset to the PWM_SYNCHR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
18 FLEXPWM_2_RST	FLEXPWM_2 reset Writing a ‘1’ to this bit resets the FLEXPWM_2 peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXPWM_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
19 FLEXPWM_3_RST	FLEXPWM_3 reset Writing a ‘1’ to this bit resets the FLEXPWM_3 peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXPWM_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
20 FLEXPWM_0_RST	FLEXPWM_0 reset Writing a ‘1’ to this bit resets the FLEXPWM_0 peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXPWM_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 950. RGM_PRST4 register field descriptions (continued)

Field	Description
21 FLEXPWM_1_RST	FLEXPWM_1 reset Writing a '1' to this bit resets the FLEXPWM_1 peripheral. Writing a '0' to this bit releases the reset to the FLEXPWM_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 CTU_1_RST	CTU_1 reset Writing a '1' to this bit resets the CTU_1 peripheral. Writing a '0' to this bit releases the reset to the CTU_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 ETIMER_2_RST	ETIMER_2 reset Writing a '1' to this bit resets the ETIMER_2 peripheral. Writing a '0' to this bit releases the reset to the ETIMER_2 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 ETIMER_3_RST	ETIMER_3 reset Writing a '1' to this bit resets the ETIMER_3 peripheral. Writing a '0' to this bit releases the reset to the ETIMER_3 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 ETIMER_0_RST	ETIMER_0 reset Writing a '1' to this bit resets the ETIMER_0 peripheral. Writing a '0' to this bit releases the reset to the ETIMER_0 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 ETIMER_1_RST	ETIMER_1 reset Writing a '1' to this bit resets the ETIMER_1 peripheral. Writing a '0' to this bit releases the reset to the ETIMER_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

47.3.2.17 Peripheral Reset Register 5 (RGM_PRST5)

This register provides individual resets for various peripherals. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Please refer to *Table 951* for details.

Address: 0x624 Access: User read, Supervisor read/write, Test read/write

Figure 991. Peripheral Reset Register 7 (RGM_PRST7)

Table 953. RGM_PRST7 register field descriptions

Field	Description
0 ADCSAR_dig_3_RST	ADCSAR_dig_3 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_3 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST7.ADCSAR_seq_3_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 ADCSAR_dig_4_RST	ADCSAR_dig_4 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_4 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST7.ADCSAR_seq_4_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
2 ADCSAR_dig_5_RST	ADCSAR_dig_5 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_5 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST7.ADCSAR_seq_5_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 ADCSAR_seq_3_RST	ADCSAR_seq_3 reset Writing a ‘1’ to this bit resets the CTU peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
5 ADCSAR_seq_4_RST	ADCSAR_seq_4 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_4 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 ADCSAR_seq_5_RST	ADCSAR_seq_5 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_5 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 953. RGM_PRST7 register field descriptions (continued)

Field	Description
11 CTU_0_RST	CTU reset Writing a ‘1’ to this bit resets the CTU peripheral. Writing a ‘0’ to this bit releases the reset to the CTU peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 ADCSAR_dig_b1_RST	ADCSAR_dig_b1 reset Writing a ‘1’ to this bit resets the ADCSAR_dig_b1 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_dig_b1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST7.ADCSAR_seq_b1_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 ADCSAR_seq_b1_RST	ADCSAR_seq_b1 reset Writing a ‘1’ to this bit resets the ADCSAR_seq_b1 peripheral. Writing a ‘0’ to this bit releases the reset to the ADCSAR_seq_b1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 SENT_1_RST	SENT_1 reset Writing a ‘1’ to this bit resets the SENT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SENT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_2_RST	DSPI_2 reset Writing a ‘1’ to this bit resets the DSPI_2 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_3_RST	DSPI_3 reset Writing a ‘1’ to this bit resets the DSPI_3 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Caution: Use the ***RGM_PRSTn*** registers with care. See *Section 47.4.7* for the proper sequence to prevent unexpected chip behavior.

47.3.2.20 Peripheral Reset Status Register 0 (RGM_PSTAT0)

This register provides the current reset status for various peripherals. It can be accessed in read only in all modes. See *Table 954* for details.

Address: 0x630 Access: User read, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

47.4 Functional description

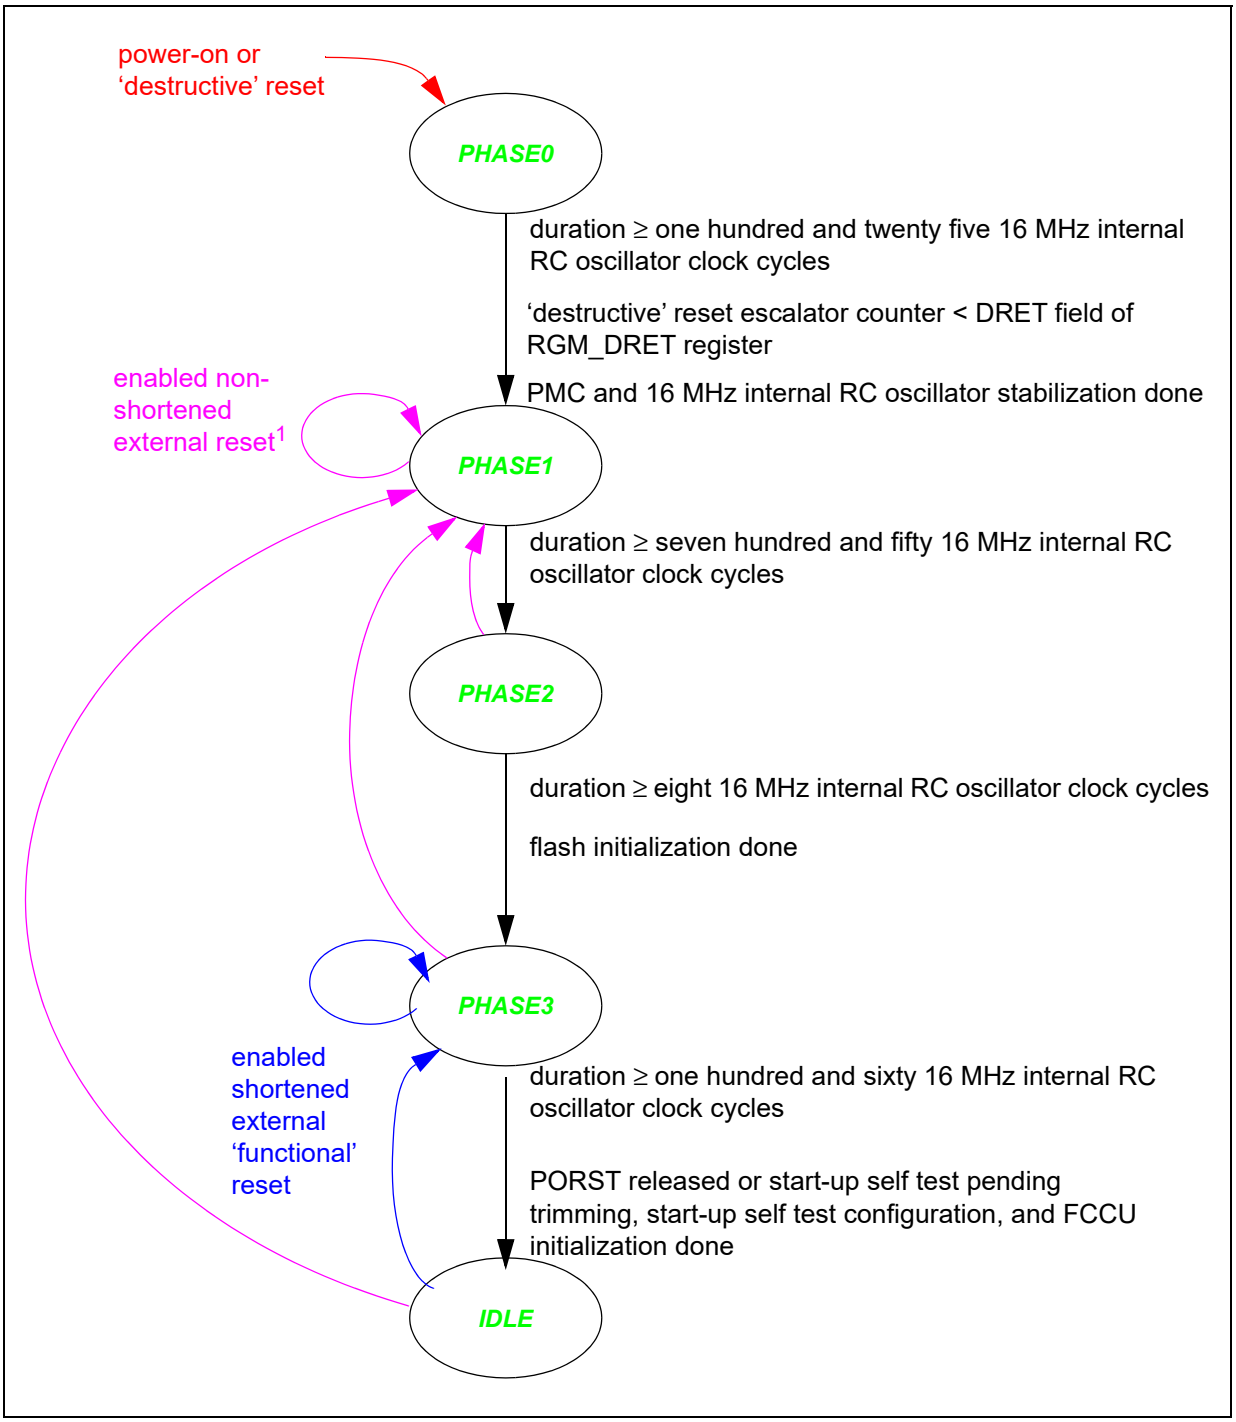
47.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in *Table 962*.

Table 962. MC_RGM reset implications

Source	What is reset	External reset assertion	Boot mode capture
Power-on reset	All	No	Yes
'Destructive' resets	All except some clock/reset management	No	Yes
External reset	All except some clock/reset management and debug	No	Yes
'Functional' resets	All except some clock/reset management, STCU, FCCU, and debug	No	Programmable (1)
Shortened 'functional' resets(2)	Flip-flops except some clock/reset management, STCU, FCCU, and debug	No	Programmable

1. the boot mode is captured if the external reset is asserted.
2. the short sequence is enabled via the RGM_FESS register.



Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and

until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in *Figure 1000*.

Figure 1000. MC_RGM State Machine

47.4.1.1 PHASE0 phase

This phase is entered immediately from any phase on a power-on or enabled ‘destructive’ reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled ‘destructive’ resets have been processed
- all processes that need to be done in PHASE0 are completed
  - PMC and 16 MHz internal RC oscillator stabilization (Power management Controller)
- a minimum of one hundred and twenty five 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled ‘destructive’ reset event
- the ‘destructive’ reset escalator counter has not reached the value in the DRET field of the RGM_DRET register

47.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or ‘functional’ reset event if it has not been configured to trigger a ‘short’ sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened ‘functional’ resets have been processed
- a minimum of seven hundred and fifty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened ‘functional’ reset event

47.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
  - flash initialization
- a minimum of eight 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

47.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened ‘functional’ reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization
- a minimum of one hundred and sixty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened ‘functional’ reset event
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

47.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

47.4.2 ‘Destructive’ resets

A ‘destructive’ reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exceptions to the latter are the software ‘destructive’ reset and the external power-on reset which do allow the memory content to be preserved if the chip is configured to not execute a self test on power-on, ‘destructive’, and external resets.

The status flag associated with a given ‘destructive’ reset event (RGM_DES.F_<destructive reset> bit) is set when the ‘destructive’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘destructive’ reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note: The RGM_DERD register can be written only once between two ‘destructive’ reset events.

The chip’s low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD or HVD, or both) is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled ‘destructive’ reset will trigger a reset sequence starting from the beginning of PHASE0.

47.4.2.1 External power-on reset—PORST

The external power-on reset pin PORST is a special case ‘destructive’ reset. Detection of a falling edge on PORST will start the reset sequence.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets, this is the exit of PHASE3 after self-test execution has completed.

47.4.3 ‘Functional’ resets

A ‘functional’ reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given ‘functional’ reset event (RGM_FES.F_<functional reset> bit) is set when the ‘functional’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘functional’ reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note: The RGM_FERD register can be written only once between two power-on reset events.

An enabled ‘functional’ reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further

configuring of the reset sequence triggered by a ‘functional’ reset. When RGM_FESS.SS_<functional reset> is set, the associated ‘functional’ reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a ‘functional’ reset should not reset the flash module.

47.4.4 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_DERD/FERD and RGM_DEAR/FEAR registers as shown in *Table 963*.

Table 963. MC_RGM Alternate Event Selection

RGM_DERD/FERD bit value	RGM_DEAR/FEAR bit value	Generated event
0	X	Reset
1	0	SAFE mode request
1	1	Interrupt request

The alternate event is cleared by deasserting the source of the request (that is at the reset source that caused the alternate request) and also clearing the appropriate RGM_DES/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, so if the system clock is disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

If a masked ‘destructive’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored and the MC_RGM does not send any safe mode/interrupt request to the MC_ME.

If a masked ‘functional’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

47.4.5 ‘Functional’ reset escalation

‘Functional’ reset escalation can be used to generate a ‘destructive’ reset if a number of ‘functional’ or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once ‘functional’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘functional’ or external reset which causes a reset sequence to be initiated (such as, entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or ‘destructive’ reset. If the counter reaches the value in the RGM_FRET register’s FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

47.4.6 'Destructive' reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset which causes a reset sequence to be initiated (such as, entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (such as, entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

47.4.7 Individual peripheral resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRSTn registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRSTn registers.
4. Wait at least two peripheral clock periods.
5. Clear the bit corresponding to the peripheral in the RGM_PRSTn registers.

The peripheral can be kept in reset indefinitely by not executing step 5. After the completion of step 5, the peripheral can be enabled again via the MC_ME.

48 Boot Assist Flash (BAF)

48.1 Introduction

The BAF code is programmed by ST. The two main tasks of BAF are to provide a serial bootloader feature and to search for the application entry point.
For details regarding how the BAF code is executed, refer to chapter *Chapter 8: Reset and boot*.

The BAF is executed via the IRCOSC as clock source.

The MCU is booted through a collaboration of several blocks, hardware and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the HW boot core of the device pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. If it is FAIL_ANALYSIS, the BAF enters a loop in which it services the watchdog. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module or the M_CAN module. The package pins used by LINFlexD are the same pins used by the M_CAN module. Hence, the external PHY can be either LIN or CAN (see *Section 48.3.6* for configuration details).

48.2 Memory map

For the BAF location in flash, refer to the Embedded memories chapter. The BAF block base address is 0x0040_4000. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in *Table 964*.

Note: The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic '0' the BAF Flash block can not be programmed.

Table 964. BAF memory organization

BAF Component	Address
BAF image header	0x0040_4000
BAF code entry point	0x0040_4100
BAF data area and stack	5000_0000h–0x5000_03FFh

48.2.1 BAF image header

BAF image contains a 256-byte header starting from address 0x0040_4000. The BAF header is explained in *Table 965*.

Table 965. BAF image header

Address offset	Size (bits)	Field description
0x0000	32	SSCM boot record tag
0x0004	32	BAF start address
0x0008	32	BAF version number
0x000C–0x00FF	Reserved	

48.2.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0x0040_4000. The 32-bit field is explained in *Table 966*.

Table 966. BAF image version

Field	Description
0:7	Major Number: This field contains the major version number for the BAF image
8:15	Minor Number: This field contains the minor version number for the BAF image
16:31	Reserved

48.3 Functional description

A functional description of the BAF modes is contained in the following sections.

48.3.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of these different boot modes.

- Application code execution

  If the internal flash contains application code with a valid boot header, the application is executed.

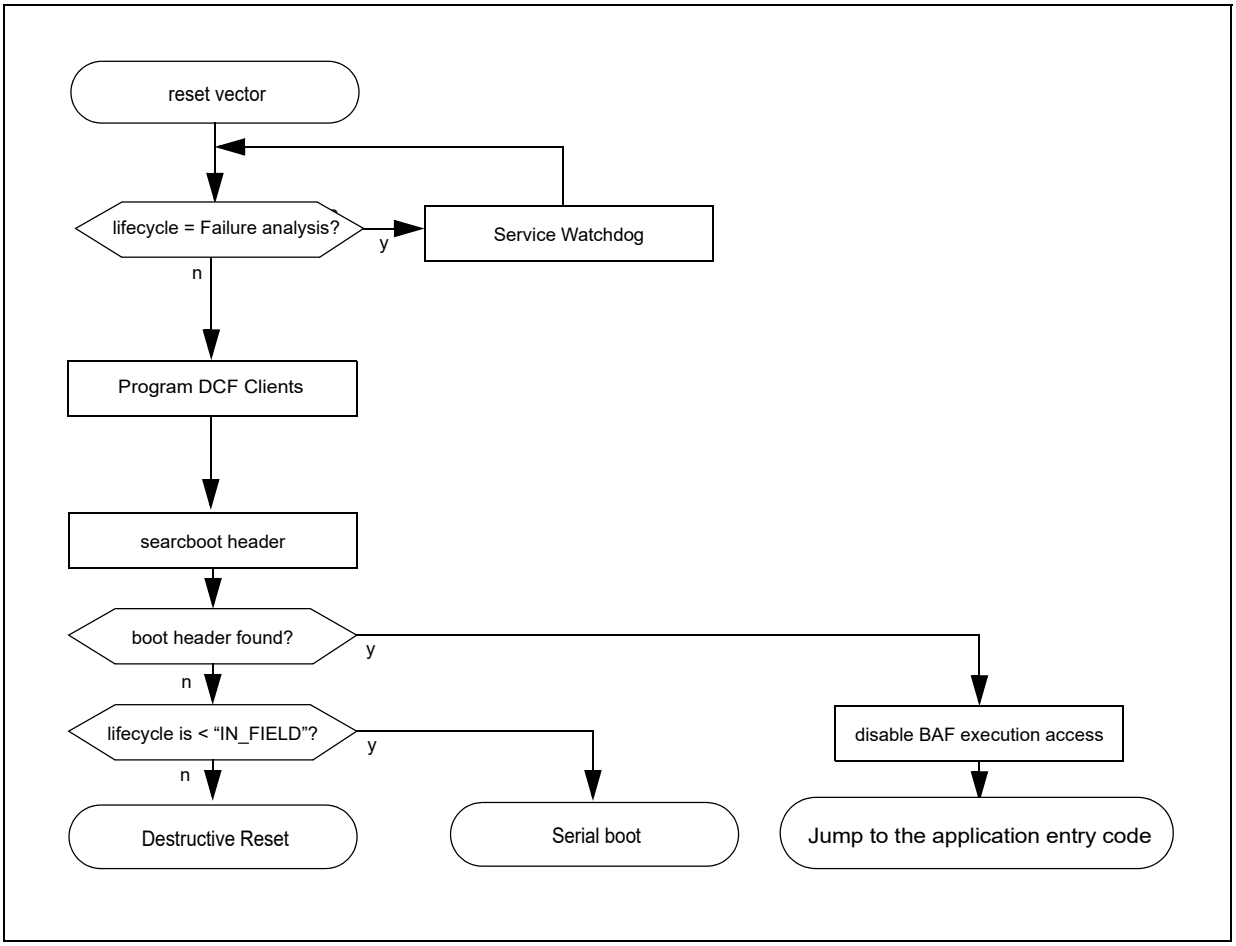
- Serial boot

  If no valid boot header is found and the current life cycle phase of the device is less than Infield, an attempt is made to download the application by a serial protocol using the LINFlexD module or M_CAN module. The downloaded code is then executed by the boot CPU.

- Static mode

  The device enters power safe mode and waits for an external reset.

48.3.2 Device initialization



The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact in the following way:

- BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of System RAM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module's MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
- BAF uses memory of the system RAM as in *Table 964: BAF memory organization* for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.
- The memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration. At this point the BAF has finished its operation.

48.3.3 Flow of control

Figure 1001 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

Figure 1001. Flow of control

48.3.4 Initialization of BAF DCF clients

48.3.4.1 ‘Soft’ DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bits chip select field (selects the module which implements the DCF clients)
- 15-bits address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start

Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is 0xFFFF_FFFF). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in *Table 967*.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in *Table 967* provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside within the BAF or UTEST blocks only. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in *Section 48.3.4.5*.

Table 967. BAF DCF client list

Address (hex)	Name	Label	Description
0x0000–0x01FF	Reserved		
0x0200	Address	ADDR	The address to which DATAX is written
0x0201	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0x0202	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0x0203	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0x0204–0x020F	Reserved		
0x0210	Callback Address	CALLBACK	The address of a callback function
0x0211	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0x0212–0x0213	Reserved		Reserved for future use.
0x0214	Reserved		Reserved for future use.
0x0215–0x7FFF	Reserved		Reserved for future use.

Note: BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

48.3.4.2 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0x0200 while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

DCF Client Address 0x0200

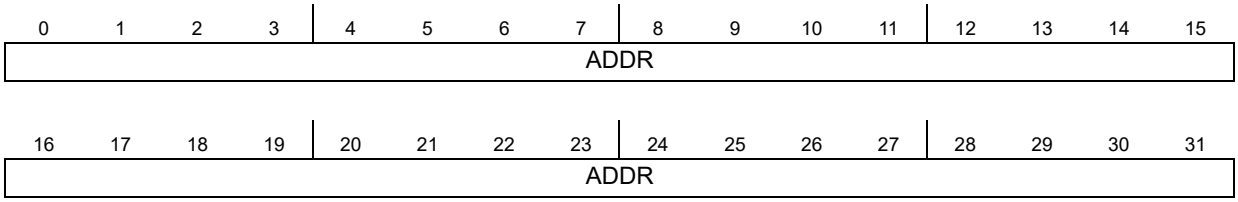


Figure 1002. BAF DCF ADDR client configuration

Table 968. BAF DCF ADDR client description

Field	Description
0:31 ADDR	32-Bit Address DCF client This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU.

48.3.4.3 BAF DCF client - DATAX

Caution: While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

48.3.4.3.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0201 while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

DCF Client Address 0x0201

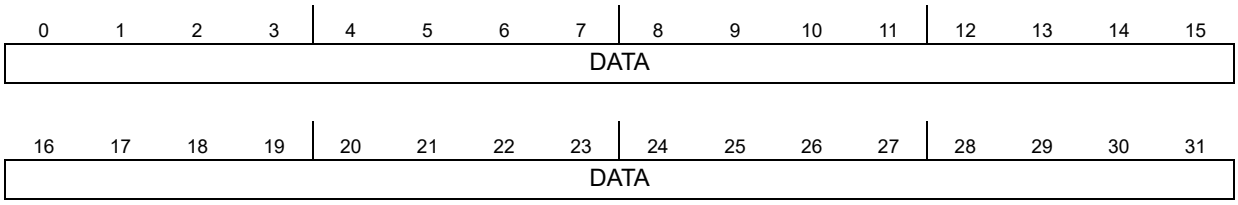

Figure 1003. DATA32 DCF client configuration

Table 969. DATA32 DCF client configuration

Field	Description
0:31 DATA	32-Bit DCF data

48.3.4.3.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0202 while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to '0' (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

DCF Client Address 0x0202

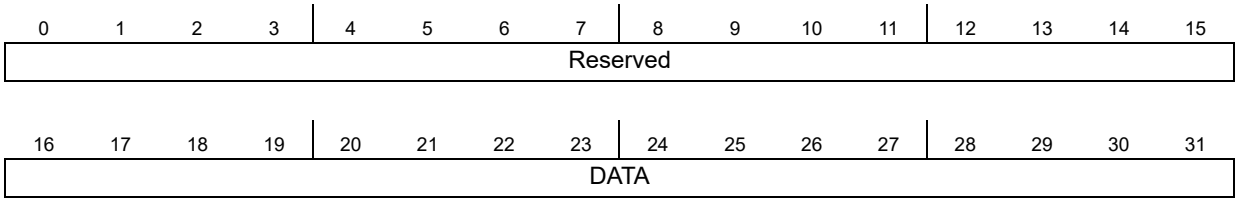

Figure 1004. DATA16 DCF Client Configuration

Table 970. DATA16 DCF client configuration

Field	Description
16:31 DATA	16-Bit DCF data

48.3.4.3.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0203 while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

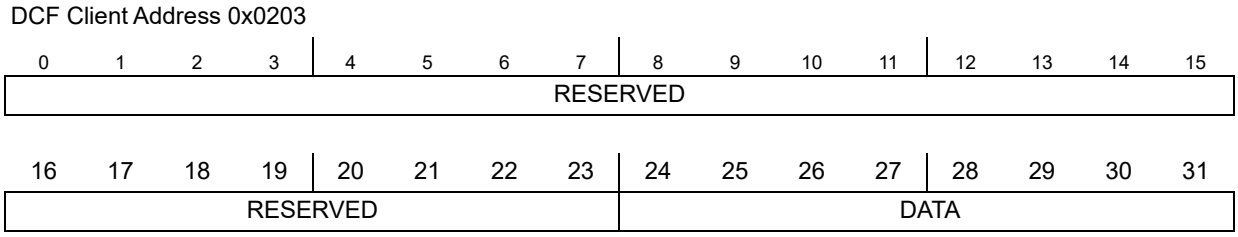

Figure 1005. DATA8 DCF Client Configuration

Table 971. DATA8 DCF client configuration

Field	Description
24:31 DATA	8-Bit DCF data

48.3.4.4 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0210 while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in Power Architecture web site and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Caution: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore, several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

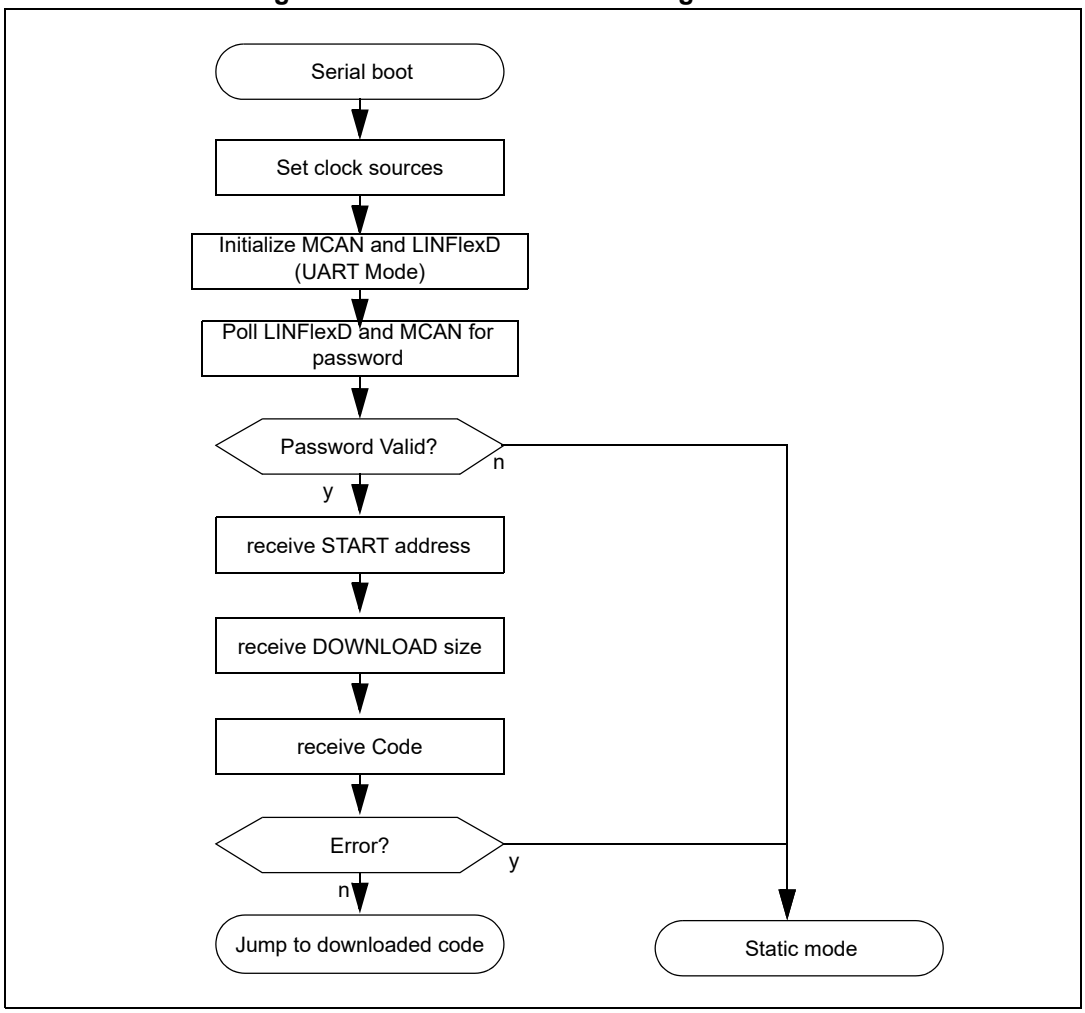
48.3.4.5 SER_BOOT_CBACK – BAF serial boot DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0211 while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32 bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in ower Architecture web site and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: No parameters are passed to the function invoked by the BAF.Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed (see *Table 972* for details regarding return value).

Table 972. Serial boot callback function return value definition



Return values	Description
0x00	Boot from internal flash using standard search for boot record (see 'Search boot header and boot options' in *Chapter 7: Device configuration*).
0x01	Serial boot using both M_CAN and LINFlexD (in UART mode) (see 'Search boot header and boot options' in *Chapter 7: Device configuration*). **Note:** Serial boot is conditioned by life cycle as described in *Figure 1001*

48.3.5 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above, then BAF detemines the Life Cycle statusof the device. If the the Life Cycle is lower than In Field, it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

f the customer selects serial boot using serial boot using serial boot DCF client, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than Failure Analysis, it attempts a serial boot.

Figure 1006. Flow of control during serial boot

The clock source in the MC_CGM is configured and the PADs are set up for LINFlexD and M_CAN signals, then the code is downloaded using LINFlexD or M_CAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via LINFlexD or M_CAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process both LINFlexD and M_CAN are configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and doesn't participate further in serial boot.

If a CAN message of 8 bytes with ID 0x11 is received on the M_CAN controller first, the BAF program

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message not containing 8 bytes or NOT with ID 0x11 is received by M_CAN controller or a M_CAN controller generates a CAN error, it is probable that the tool is sending a LINFlexD frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is 0xFE of the password. If not continue polling. The data may be a valid CAN message.
- If it is first byte of the password (0xFE) then disable the M_CAN controller and restore to its reset state.
- Configures the M_CAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

48.3.5.1 Serial boot mode protocol

From a high-level perspective, the download protocol over M_CAN and LIN interfaces follows steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.

   NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Note: Since this device supports only VLE code and no Book E code, the VLE bit is used only for backward compatibility.

3. Host transmits a sequence of data bytes that are to be executed.
4. The boot CPU executes code from start address provided in step 2.

Each step must be completed before the next step starts.

The exact protocol between LINFlexD and M_CAN are slightly different.

48.3.5.2 LINFlexD download protocol

The communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   – If the data is correct, the host can send the next byte of data.
   – If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. *x* bytes of code that is downloaded to SRAM and executed (*x* must match the value specified in step 3.).

48.3.5.3 M_CAN download protocol

The M_CAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by M_CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 0x11 as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 0x1.
2. A message with 0x12 as the ID and and 8-byte length to send the start address, size of the code and VLE mode bit.The MCU transmits back the same data but with an ID of 0x2.
3. A message with 0x13 as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 0x3.

48.3.5.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password 0xFEED_FACE_CAFE_BEEF.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode(low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

48.3.5.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in *Figure 1007* and *Figure 1008*.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

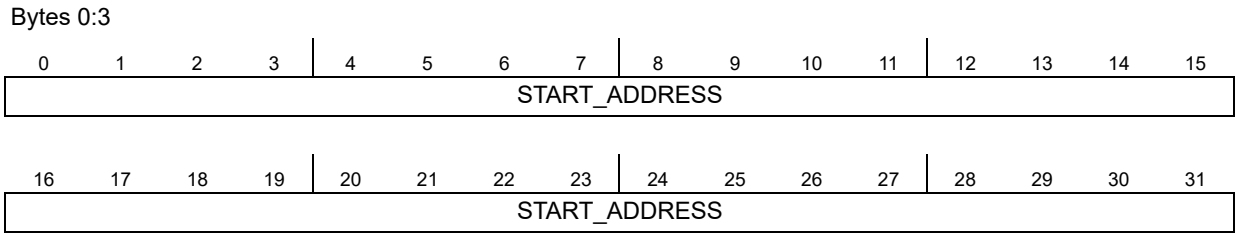


Figure 1007. Start address

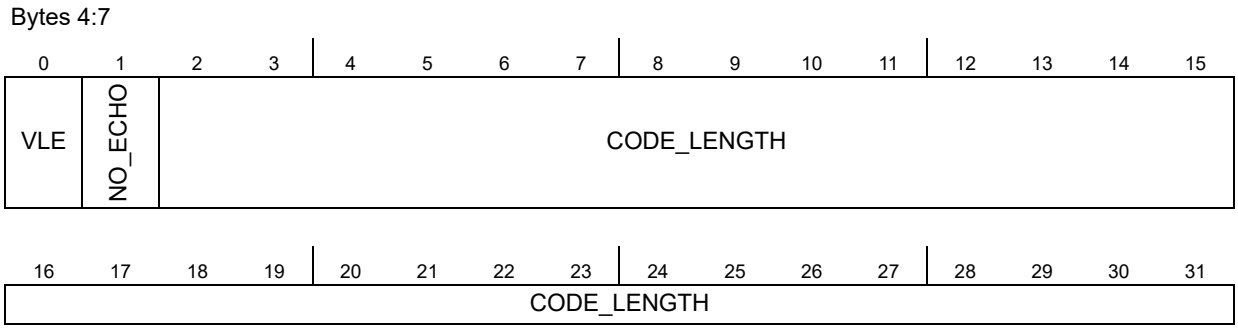

Figure 1008. VLE bit, NO_ECHO bit and code size

48.3.5.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero's and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0x0000_0000_0000_0000) to the next address location. This is written to avoid possible ECC error during core prefetch.

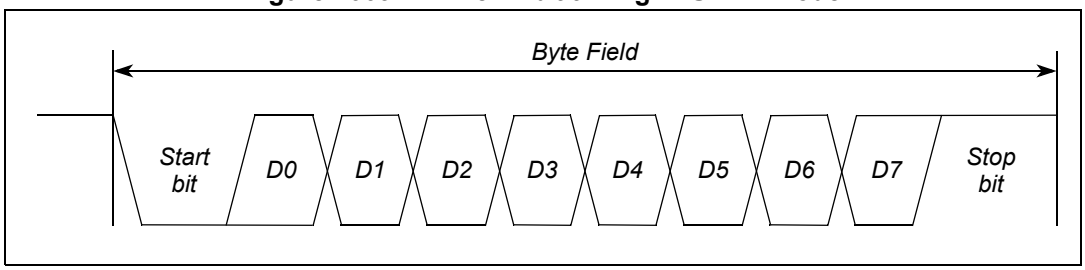
48.3.5.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

48.3.6 Serial boot configuration

48.3.6.1 LINFlexD configuration

Boot using UART protocol is implemented by LINFlexD module.



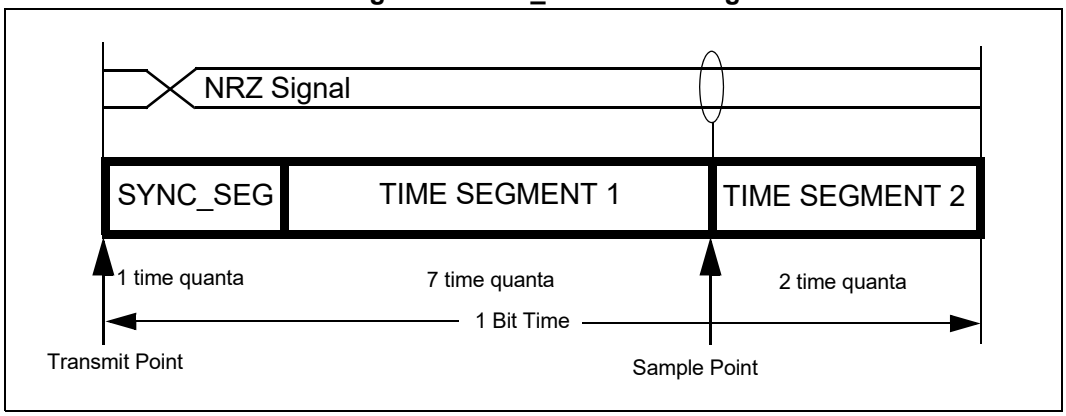
Note: See the pin configuration table in Chapter 7: Device configuration for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx is configured as an input and multiplexed to the LINFlexD module. The LINFlexD_Tx remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data . The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx pin transmission.

The LINFlexD controller is configured to operate with an 8-bit data frame without parity bit and 1 stop bit.

Figure 1009. LINFlexD bit timing in UART mode



48.3.6.2 M_CAN configuration

The M_CAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0A specification (see *Table 973* for baud rates).

The Bit timing is configured as shown in *Figure 1010*

Figure 1010. M_CAN Bit Timing

48.3.6.3 Baud rates

The LINFlexD baud rate is set by frequency of external crystal oscillator/833.333 . *Table 973* below shows some possible baud rates.

The M_CAN baud rate is set by the frequency of the external crystal/40.

Table 973. LinFlexD_0 and M_CAN_1 baud rates

Frequency	LINFlexD baud rate	M_CAN baud rate
8 MHz	9,600 baud	200 kbaud
12 MHz	14,400 baud	300 kbaud
16 MHz	19,200 baud	400 kbaud
20 MHz	24,000 baud	500 kbaud
40 MHz	48,000 baud	1000 kbaud

48.3.6.4 LINFlexD and M_CAN pin configuration

Please see *Chapter 7: Device configuration* for pin details.

48.3.6.5 Protocol summary

Table 974 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 974. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.

Table 974. LINFlexD serial boot mode download protocol (continued)

Protocol steps	Host message sent	BAF response message	Action
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is not echoed, otherwise data is echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	None	None	Branch to downloaded code

Table 975 shows the M_CAN serial boot protocol.

Table 975. M_CAN serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	CAN ID 0x011 + 64-bit password	CAN ID 0x001 + 64-bit password	Password checked against fixed password (0xFEED_FACE_CAFE_BEEF). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 0x012 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	CAN ID 0x002 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 0x013 + 8 to 64-bits of raw binary data	VLE bit + 31 bit number of bytes (MSB first)	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	None	None	Branch to downloaded code

48.4 Resources accessed by BAF code execution

The BAF code execution uses several IPs to achieve the main functions.

- Magic carpet (clocks)

Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD and M_CAN

The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.

- PFLASH

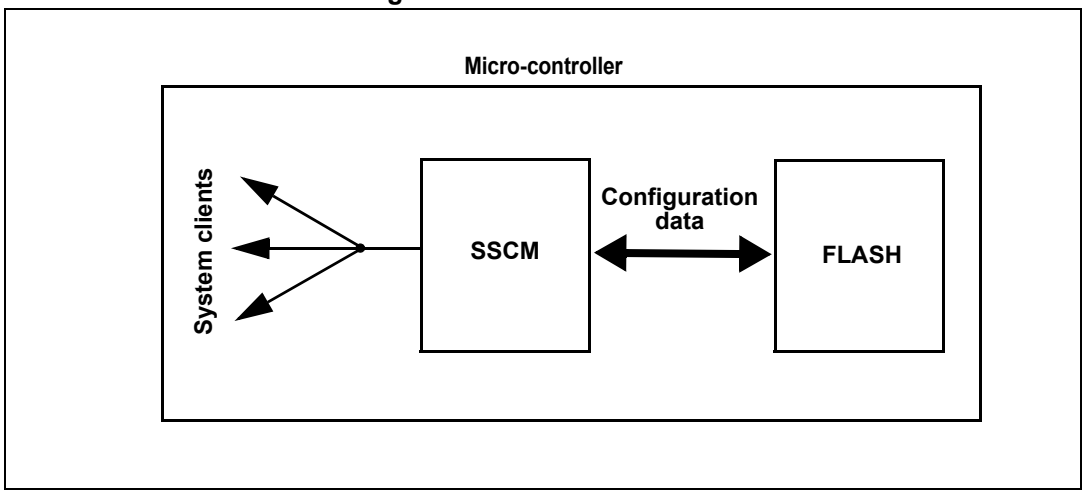
PFLASH module is used to disable BAF execution. Remapping of the external overlay memory is configured automatically under certain conditions.

- Interrupts

No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.

- SSCM

Used to read some register bits (mirrors of DCF)



49 System Status and Configuration Module (SSCM)

49.1 Introduction

49.1.1 Overview

The System Status and Configuration Module (SSCM) is aimed to read the system configuration from the Flash and distribute to various clients inside the micro-controller, pictured in *Figure 1011*.

Figure 1011. SSCM overview

49.1.2 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Decodes the Device Life Cycle

49.1.3 Modes of operation

The SSCM operates identically in all system modes.

49.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

Table 976 shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Note: All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit READ/WRITE to

address Base + 0x0002, but performing a 16-bit access to Base + 0x0003 is illegal.

Table 976. SSCM memory map

Address offset	Register	Access	Reset value	Section
0x0000	SSCM System Status (STATUS)	R/W	0xyyy0(1)	*Section 49.2.1.1*
0x0002	SSCM System Memory and ID Register (MEMCONFIG)	R	0xyyyy(1)	*Section 49.2.1.2*
0x0004–0x0005	Reserved			
0x0006	SSCM Error Configuration Register (ERROR)	R/W	0x0000	*Section 49.2.1.3*
0x0008–0x0009	Reserved(2)			
0x000A–0x001C	Reserved			
0x0020–0x0023	Reserved			
0x0024–0x0027	Reserved			
0x0028	Processor Start Address Register (PSA)	R	0xyyyy_yyyy(1)	*Section 49.2.1.4*
0x002C–0x002F	Reserved			
0x0030–0x0033	Reserved			
0x0034	Life Cycle Status Register (LCSTAT)	R	0x0000_0y0y(1)	*Section 49.2.1.5*
0x0038–0x004F	Reserved			

1. See *Section 49.2.1: Register descriptions* for reset value details.
2. No register abort on this location.

49.2.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

49.2.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CER	0	0	NXEN	1	0	0	BMODE			VLE	0	0	0	0
W		w1c														
Reset	0	0	0	-(2)	-(2)	1	0	0	-(2)			-(1)	0	0	0	0

1. Reset value depends on the associated option bits in flash memory.
2. Reset value depends on the device status after leaving reset.

Figure 1012. System Status Register (STATUS)

Table 977. STATUS field descriptions

Field	Description
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error while loading DCF clients (with PARITY Enabled). This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
4 NXEN	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
8:10 BMODE	Device Boot Mode 000 Reserved 001 Reserved 010 Reserved 011 User Code Boot (BAF not executed) 100 Reserved 101 BAF Code Boot (BAF executed) 110 Reserved 111 Reserved This field is only updated during reset.
11 VLE	Variable Length Instruction Mode When booting in User Code Boot mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0 User Code Boot Location contains standard PPC code 1 User Code Boot Location contains VLE code

49.2.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Offset: 0x0002 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	1	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0

1. Reset value reflects the JTAG ID of the device.

Figure 1013. System memory and ID register (MEMCONFIG)

Table 978. MEMCONFIG field descriptions

Field	Description
0:9 JPIN	JTAG Part ID Number
11:14 MREV	Minor Mask Revision

49.2.1.3 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Offset: 0x0006 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0(1)	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1014. Error Configuration Register (ERROR)

Table 979. ERROR field descriptions

Field	Description
14 PAE	Peripheral Bus Abort Enable This bit enables bus aborts on: – Any access to a peripheral slot that is not used on the device. This feature is intended to aid in debugging when developing application code. – Illegal accesses to off-platform peripherals. On platform peripherals cannot be controlled by SSCM peripheral abort. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
15 RAE	Register Bus Abort Enable This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. This feature is intended to aid in debugging when developing application code. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception **Note:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the PBRIDGE level). In this case, the PAE and RAE register bits have no effect on the abort.

49.2.1.4 Processor Start Address Register (PSA)

Offset 0x0028 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SADR(1)															
W																
Reset	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1

W																
Reset	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1

1. Reset value is the start address.

Figure 1015. Processor Start Address Register (PSA)

Table 980. PSA field descriptions

Field	Description
0:31 SADR	Start Address The boot processor will start executing application code from this address. In User Code Boot mode this indicates the location determined by the RCHW search. In BAF Code Boot mode this will show the start address of the BAF code. In the case of a serial download, this register will point to the BAM start location.

49.2.1.5 Life Cycle Status Register (LCSTAT)

Offset 0x0034 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	LC		
W																
Reset	0	0	0	0	0	0	0/1(1)	0/1(1)	0	0	0	0	0	0/1(2)	0/1(2)	0/1(2)

1. Reset value reflects the Test Life Cycle of the device.
2. Reset value is the Life Cycle of the device.

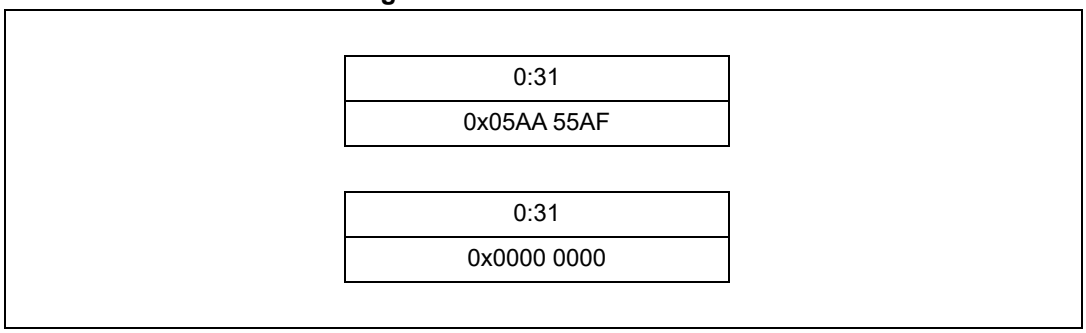
Figure 1016. Life Cycle Status Register (LCSTAT)

Table 981. LCSTAT field descriptions

Field	Description
29:31 LC	Life Cycle As determined by the SSCM by reading the LC slots. The encoding is: 000 FAIL_ANALYSIS 001 Reserved 010 PROD_OEM 011 CUST_DELIV 100 Reserved 101 Reserved 110 ST_PROD 111 IN_FIELD

49.3 Functional description

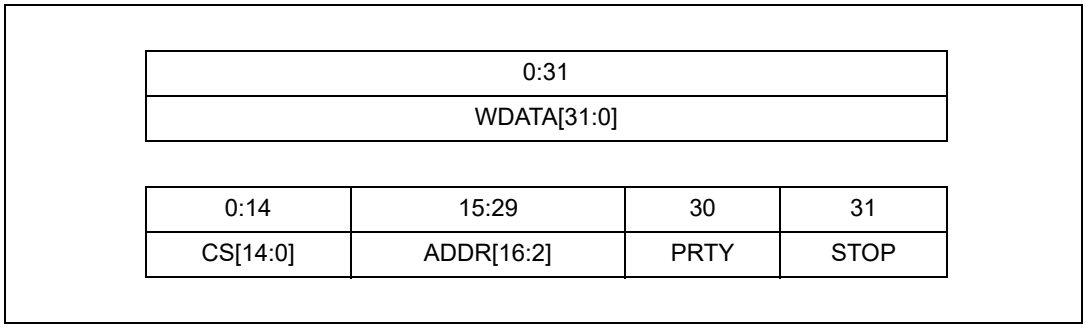
The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.



49.3.1 DCF mechanism

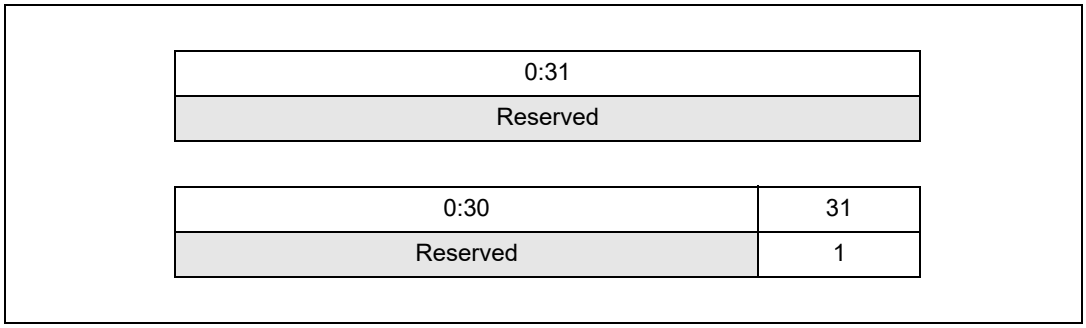
The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.



Each record is 64 bits in length. *Figure 1017* shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Figure 1017. DCF start record

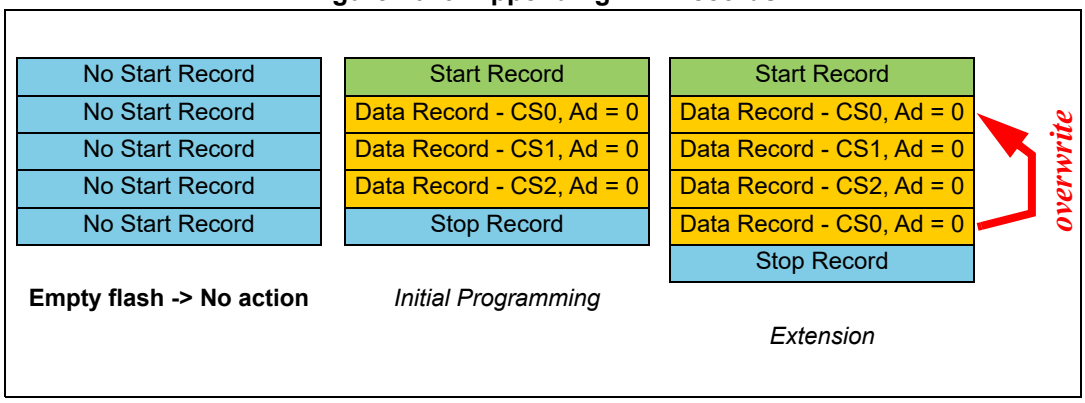


The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See *Figure 1018*. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Figure 1018. Format of a DCF data record

The stop record indicates that processing should stop. The general format of the stop record is shown in *Figure 1019*. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Figure 1019. DCF stop record



If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 982*.

Table 982. Series of DCF records in UTEST

ADDR offset	DATA			
0x00	0x05AA_55AF			
0x04	0x0000_0000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8n - 1 + 0x0	Reserved			
8n - 1 + 0x4	Reserved			1
8n + 0x0				
8n + 0x4				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 1020*.

Figure 1020. Appending DCF records

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0x0000_0001 then the PRTY field needs to be set to '1', so that the total number of 1s is even).

49.3.2 Boot mode functionality

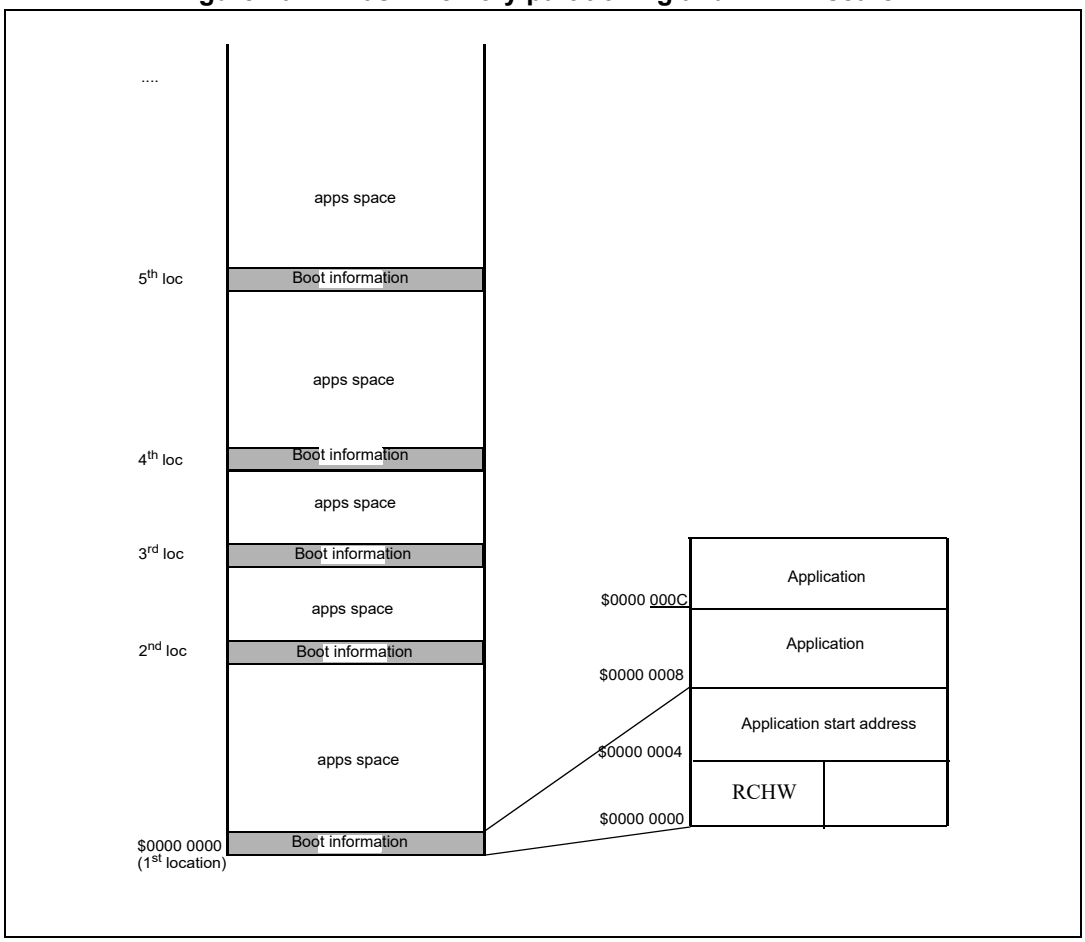
The device supports the following boot modes for the main boot core:

- User Code Boot mode (SSCM): the device will boot from the first bootable section of the flash memory main array (BOOT_ID = 0x5A).
- BAF Code Boot: the device will boot from UTEST NVM Flash Block, (interface with the HSM if available) and perform device setup (BOOT_ID = 0xA5).

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location for SSCM and BAF, that is 0x5A and 0xA5 respectively) then the device will enter serial boot mode.

49.3.3 BAF configuration

In BAF Code Boot mode the boot core will start to execute the BAF code at the location provided in the "Embedded Flash Memory" chapter (TestFlash block memory map). The BMODE field in the SSCM status register will be set to the value 0b101. Details of the BAF operation are described in the BAF chapter.



49.3.4 User code boot sector search

49.3.4.1 Potential boot sectors

As shown in *Figure 1021* in User Code Boot mode, several locations are searched for a valid boot ID. The lowest sector which starts with a valid boot ID will be used to boot the device.

The flash memory location that are searched for boot information are shown in the “Reset and Boot” chapter (section “HW boot record search (SSCM search)”).

Figure 1021. Flash memory partitioning and RCHW search

49.3.4.2 Reset Configuration Half-Word

For each boot sector in the flash memory, SSCM checks the content of the Reset Configuration Half-Word (RCHW) at offset 0x00. If the RCHW field BOOT_ID holds the value 0x5A then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. (If a device only supports VLE code for future compatibility the flag must always be set to ‘1’.) All other bits are reserved.

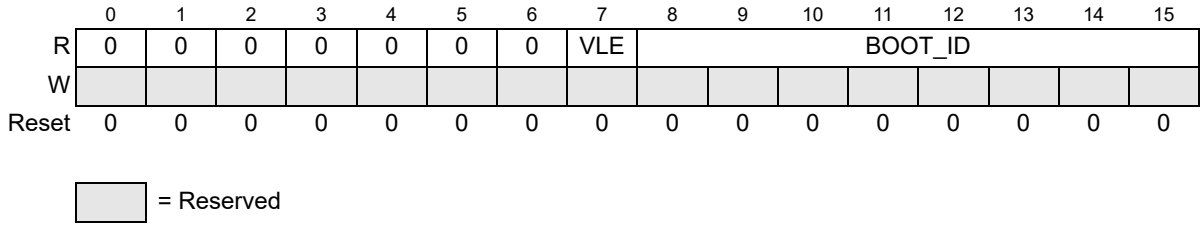


Figure 1022. Reset Configuration Half-Word

Once the device detects that it needs to boot from flash memory, and finds a valid BOOT_ID, it will boot from the application start address at offset 0x04 within the boot sector.

49.3.5 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from UTEST flash memory area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- ST Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 128 bits each, at fixed locations in UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- The valid field
- The invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 status:

Table 983. Life Cycle slots

Use case	Offset	LC slot	Valid field (64 bits)		Invalid field (64 bits)		LC slot status
1	0x00-0x10	1	Erased	Erased	Erased	Erased	Erased
2	0x00-0x10	1	Marked	Erased	Marked	Erased	Inactive
3	0x00-0x10	1	Marked	Erased	Erased	Erased	Active
4	0x00-0x10	1	Any other value				Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 0x55AA_50AF_55AA_50AF, “Erased” is detected by the bit pattern 0xFFFF_FFFF_FFFF_FFFF.

Table 984 shows how the slots are arranged in memory.

Table 984. Life Cycle Slots in Memory

Offset	LC Slot word
0x00	Valid[31:0]
0x04	Valid[63:32]
0x08	Valid[31:0]
0x0C	Valid[63:32]
0x10	Invalid[31:0]
0x14	Invalid[63:32]
0x18	Invalid[31:0]
0x1C	Invalid[63:32]

The Life Cycle is determined as shown in *Table 985*. The priority of the entries is from top to bottom, so the first row which applies determines the resulting Life Cycle.

Table 985. Resulting Life Cycle

LC Slot 0 ST_PROD(1)	LC Slot 1 CUST_DEL(1)	LC Slot 2 OEM_PROD(1)	LC Slot 3 IN_FIELD(1)	LC Slot 4 FA(1)	Resulting LifeCycle
Active	Erased	Erased	Erased	Erased	ST Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	*Inactive*	**Active**	Erased	Erased	OEM Production
Inactive	*Inactive*	*Inactive*	**Active**	Erased	In Field
Inactive	*Inactive*	*Inactive*	*Inactive*	**Active**	FA
Erased	Erased	Erased	Erased	Erased	System Reset

1. Erased = all slot bits at ‘1’

49.4 Initialization and application information

49.4.1 Reset

The reset state of each individual bit is shown within the Register Description section (see *Section 49.2.1: Register descriptions*).

49.5 Additional safety measures

49.5.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the MC_RGM. In case of a spurious reset the SSCM will not interfere with the flash memory bus or overwrite configuration registers. Status internal to the SSCM will be lost, however.

50 Power management controller digital interface (PMC_Dig)

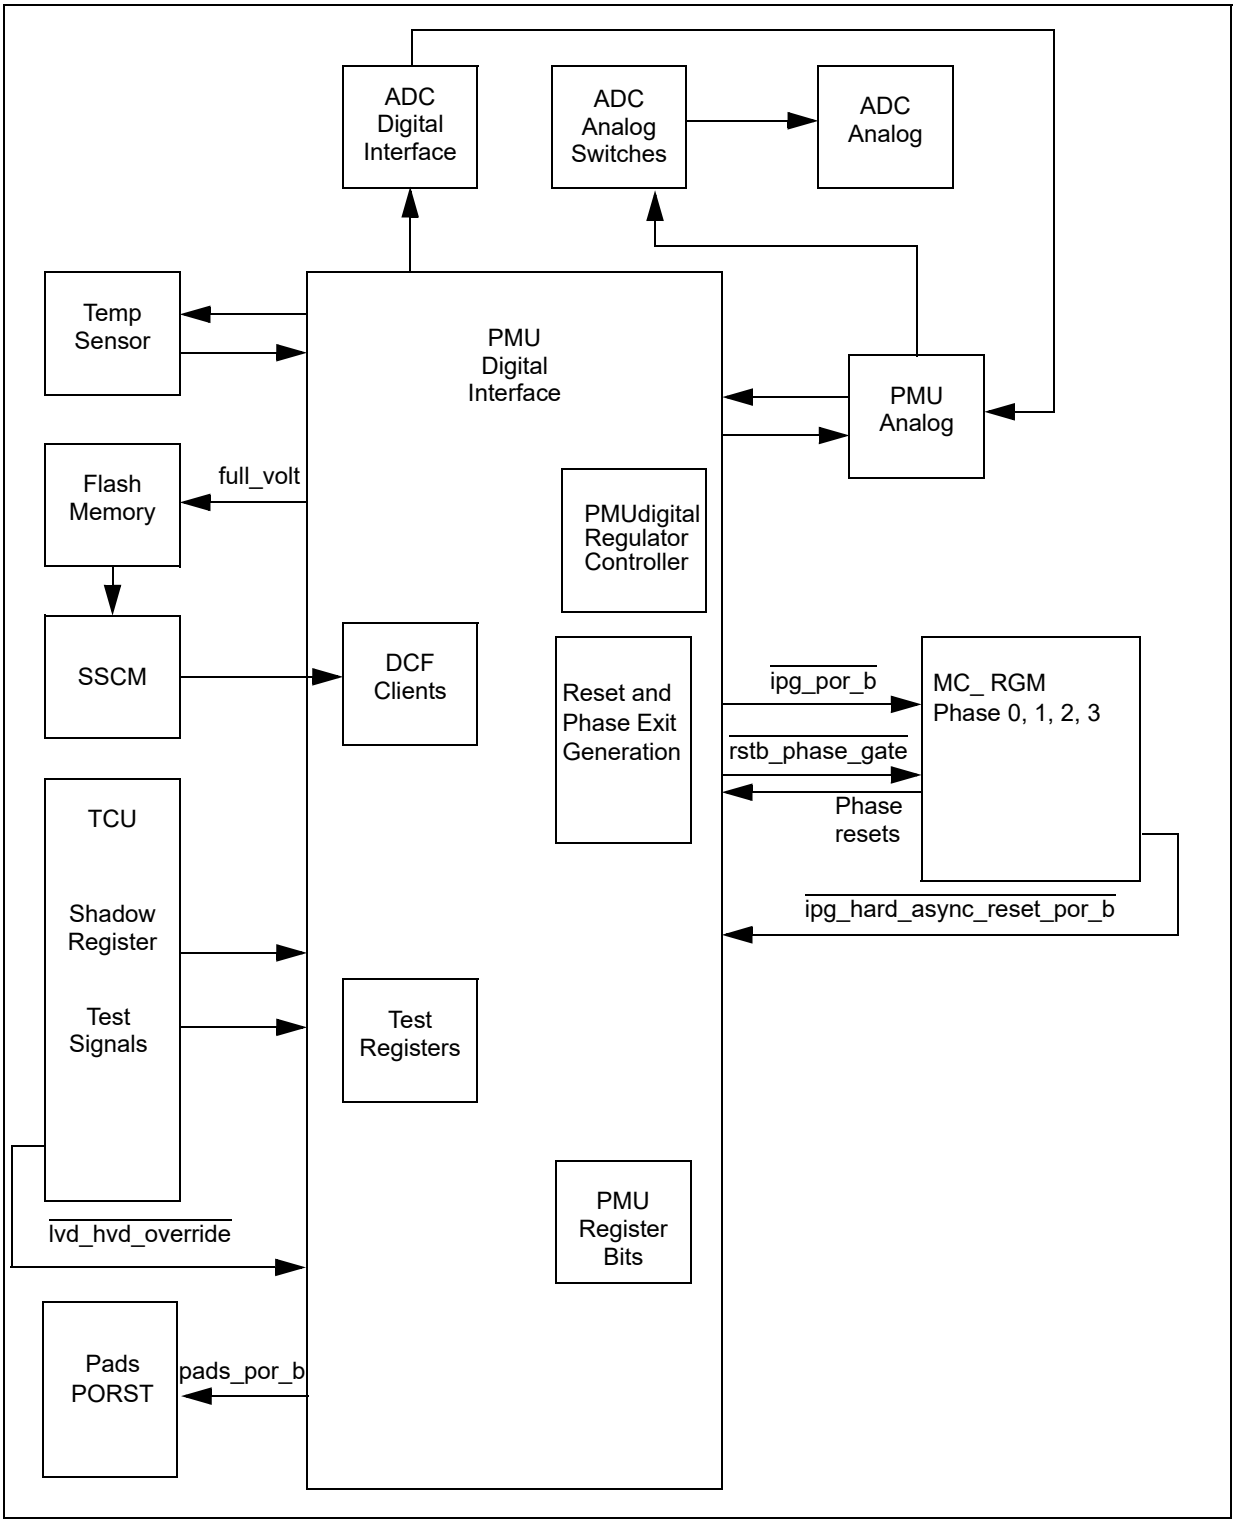
50.1 Introduction

The Control PMU manages the PMU at the reset and during the run, it checks the LVD or HVD accuracy.

The PMC analog block interfaces the digital part of the device by the PMC_dig block .

This chapter describes the digital block of the PMU.

The PMC_Dig contains all of the registers and digital logic to generate all of the enable signals, trim control bits, POR reset generation, and test mode logic for the analog block.



In addition, the PMU digital logic contains the enable signals, trim bits and other registers for the temperature sensor.

There are also several custom interfaces to various other blocks: The Reset Generation Module (MC_RGM) block receives the LVD values during POR to use for phase transition conditions.

There is also a custom interface to flash memory via the SSCM (and DCF client blocks) that is used to load the trim values.

The PMU digital block generates a transfer error event to the system if the selected address is greater than the highest address in the PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed. See in *Figure 1023* the PMUDig top level block diagram interfaced to the device modules.

Figure 1023. Digital PMU block diagram

50.2 Main features

- PMU management at a main reset
- Resets signal generation

50.2.1 Standard features

- IPS bus interface

50.3 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported.

- Word (32 bits) data write/read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers, except BIST time registers (BIST_TIME10, BIST_TIME32 and BIST_TIME65).
- Any other operation (free byte enables or other operations) must be avoided.

The PMC_DIG block generates a transfer error in the following cases.

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.

The registers of the PMC_DIG block are accessible (read/write) in each access mode: user, supervisor or test.

About the Reset used among the register.

- The POR reset is used on EPR registers.
- The destructive reset is used on REE, RES and FEE registers.
- The functional reset is used IE, CTL_TD.

50.4 Memory Map and Registers

Table 986 shows the PMU memory map. The PMU includes many registers for configuring and monitoring LVD monitors, some other control registers.

Table 986. Power Management Controller Memory Map

0x03E0	User BIST Time6 and Time5 register (BIST_TIME65)	*Section 50.5.38*
0x03E4	User BIST VD Under Test Monitor Register (BIST_DEBUG)	*Section 50.5.39*

Register ESR0_CFG can be accessed both by IPS and DCF with their corresponding IPS and DCF addresses respectively.

Table 987 shows how the 32-bit registers for LV0, LV1, HV0, and HV1 are organized.

Table 987. 32-bit registers LV0, LV1, HV0, HV1 arrangement table

Register class	BYTE 3	BYTE 2	BYTE 1	BYTE 0
LV0	VD3=lvd108_c	VD2=mvd098_fl_c	VD1=mvd085t_c	VD0=por041_c
LV1	VD7=uvd145_fl_c	VD6=hvd140_c	VD5=Reserved	VD4=Reserved
HV0	VD11=lvd290_adl1_adl0_fl_iol1_osc_c	VD10=mvd270_fl_c	VD9=mvd240t_c	VD8=por200_c
HV1	VD15 = uvd600_c	VD14=lvd400_adl1_adl0_iol1_aiol0	VD13=hvd400_c	VD12=Reserved

Where each byte VD# is so structured:

Bit7, ADL1, ADL0 , FLASH, IOL1, IOL0, Bit1, CORE.

Table 988 shows the correspondence between VD number and VD name, where HV means a 3.3V/5.0V supply and LV means a 1.2V supply.

Table 988. VD number versus VD name table

VD Number	VD Name	VD Meaning
VD0	POR041_C	LV detector asserts when PMU supply < 0.41V
VD1	MVD085t_C	LV detector asserts when PMU supply < 0.85V
VD2	MVD098_C	LV detector asserts when PMU supply < 0.98V
VD2	MVD098_FL	LV detector asserts when FLASH supply < 0.98V
VD3	LVD108_C	LV detector asserts when PMU supply < 1.08V

Table 988. VD number versus VD name table (continued)

VD Number	VD Name	VD Meaning
VD6	HVD140_C	LV detector asserts when PMU supply > 1.40V
VD7	UVD145_C	LV detector asserts when PMU supply > 1.45V
VD7	UVD145_FL	LV detector asserts when FLASH supply > 1.45V
VD8	POR200_C	HV detector asserts when PMU supply < 2.00V
VD9	MVD240t_C	HV detector asserts when PMU supply < 2.40V
VD10	MVD270_C	HV detector asserts when PMU supply < 2.70V
VD10	MVD270_FL	HV detector asserts when FLASH supply < 2.70V
VD11	LVD290_C	HV detector asserts when PMU supply < 2.90V
VD11	LVD290_XOSC	HV detector asserts when XOSC supply < 2.90V
VD11	LVD290_IOL1	HV detector asserts when IO1 supply < 2.90V
VD11	LVD290_FL	HV detector asserts when FLASH supply < 2.90V
VD11	LVD290_ADL0	HV detector asserts when ADC0 supply < 2.90V
VD11	LVD290_ADL1	HV detector asserts when ADC1 supply < 2.90V
VD13	HVD400_C	HV detector asserts when PMU supply > 4.00V
VD14	LVD400_IOL0	HV detector asserts when IO0 PMU supply < 4.00V
VD14	LVD400_IOL1	HV detector asserts when IO1 supply< 4.00V
VD14	LVD400_ADL0	HV detector asserts when ADC0 supply < 4.00V
VD14	LVD400_ADL1	HV detector asserts when ADC1 supply< 4.00V
VD15	UVD600_C	HV detector asserts when PMU supply > 6.00V

50.5 Register description

50.5.1 Event Pending Register (EPR_LV0)

This Event Pending Register indicates the present and past state of the voltage detect signalsin LOW VOLTAGE 0 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Offset: 0x0000 Access: User read/write

Table 989. EPR_LV0 field descriptions

Field	Description
7 LVD3_C	LVD3_C flag This bit is the low-voltage status flag associated with LVD108_C VD, the voltage level detect for the low voltage Core 1.08V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage1.08V point supply

50.5.2 Reset Event Enable Register (REE_LV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Field	Description
7 REE3_C	REE3_C reset enable This bit defines whether LVD108_C VD, the voltage level detect for the low voltage CORE 1.08V supply of the cold point, generates a system reset. The REE3_C bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset 1 Enabled. LVD assertion on the supply of the cold point causes system reset

50.5.3 Reset Event Select Register (RES_LV0)

This Reset Event Select Register, in LOW VOLTAGE 0 range, controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

Field	Description
7 RES3_C	RES3_C reset event select This bit defines whether LVD108_C VD, the voltage level detect for the low voltage CORE 1.08 V supply of the cold point, generates a destructive reset or a functional reset. The RES3_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset

50.5.4 Interrupt Enable (IE_LV0)

This configuration register contains a set of LV0 interrupt Enable bits that correspond to each of the LV0 Event Pending Registers (EPR_LV0). These bits indicate whether an interrupt occurs when the voltage event is seen. A ‘0’ indicates that no interrupt is to be sent, and a ‘1’ indicates that an interrupt is to occur when the voltage detect event occurs. These

bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_LV0 bits can be read or written at any time.

Offset: 0x000C Access: User read/write

50.5.5 FCCU Event Enable Register (FEE_LV0)

This FCCU Event Enable Register LV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

An VD assertion of LV0 on the supply of the CORE does not cause an FCCU event 1 Enabled. An VD assertion of LV0 on the supply of the CORE causes an FCCU event

50.5.6 Event Pending Register (EPR_LV1)

This Event Pending Register indicates the present and past state of the voltage detect signals, in LOW VOLTAGE1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a '1' must be written to the flag bit that needs to be cleared.

The REE_LV0.LVD11_AC bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset 1 Enabled. LVD assertion on the supply of the cold point causes system reset
4 REE11_IOL1	LVD11_IOL1 reset enable This bit defines whether LVD290_IOL1 VD, the voltage level detect for the high voltage assertion on the IO1 supply generates a system reset. The REE_LV0.LVD11_AC bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset 1 Enabled. LVD assertion on the supply of the cold point causes system reset
5 REE11_OSC	LVD11_OSC reset enable This bit defines whether LVD290_OSC VD, the voltage level detect for the high voltage assertion on the XOSC supply generates a system reset. The REE_LV0.LVD11_OSC bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset 1 Enabled. LVD assertion on the supply of the cold point causes system reset

50.5.13 Reset Event Select Register (RES_HV0)

This Reset Event Select Register, in HIGH VOLTAGE 0 range, controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

Table 1001. RES_HV0 field descriptions

Field	Description
1 RES11_ADL1	RES11_ADL1 reset event select This bit defines whether an LVD assertion on the ADC1 supply of the cold point generates a destructive reset or a functional reset. The RES_HV0.RES11_ADL1 bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset
2 RES11_ADL0	RES11_ADL0 reset event select This bit defines whether an LVD assertion on the ADC0 supply of the cold point generates a destructive reset or a functional reset. The RES_HV0.RES11_ADL0 bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset

Table 1001. RES_HV0 field descriptions (continued)

Field	Description
4 RES11_IOL1	RES11_IOL1 reset event select This bit defines whether an LVD assertion on the IO1 supply of the cold point generates a destructive reset or a functional reset. The RES_HV0.RES11_IOL1 bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset
5 RES11_OSC	RES11_OSC reset event select This bit defines whether an LVD assertion on the XOSC supply of the cold point generates a destructive reset or a functional reset. The RES_HV0.RES11_OSC bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset

50.5.14 Interrupt Enable (IE_HV0)

This configuration register contains a set of HV0 interrupt Enable bits that correspond to each of the HV0 Event Pending Registers (EPR_HV0). These bits indicate whether an interrupt occurs when the voltage event is seen. A ‘0’ indicates that no interrupt is to be sent, and a ‘1’ indicates that an interrupt is to occur when the voltage detect event occurs. These bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_HV0 bits can be read or written at any time.

Field	Description
1 LVD11IE_ADL1	LVD11IE_ADL1 Interrupt Enable This bit determines whether an interrupt is seen by the system when LVD290_ADL1VD, the voltage level detect for the high voltage assertion on the ADC1 supply event occurs. 0 No interrupt occurs 1 An interrupt occurs
2 LVD11IE_ADL0	LVD11IE_ADL0 Interrupt Enable This bit determines whether an interrupt is seen by the system when LVD290_ADL0 VD, the voltage level detect for the high voltage assertion on the ADC0 supply event occurs. 0 No interrupt occurs 1 An interrupt occurs
4 LVD11IE_IOL1	LVD11IE_IOL1 Interrupt Enable This bit determines whether an interrupt is seen by the system when LVD290_IOL1 VD, the voltage level detect for the high voltage assertion on the IO1 supply event occurs. 0 No interrupt occurs 1 An interrupt occurs
5 LVD11IE_OSC	LVD11IE_OSC Interrupt Enable This bit determines whether an interrupt is seen by the system when LVD290_OSC VD, the voltage level detect for the high voltage assertion on the XOSC supply event occurs. 0 No interrupt occurs 1 An interrupt occurs

50.5.15 FCCU Event Enable Register (FEE_HV0)

This FCCU Event Enable Register HV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Field	Description
1 FEE11_ADL1	FEE11_ADL1 FCCU event enable This bit defines whether a LVD290_ADL1 VD, the voltage level detect for the high voltage assertion on the ADC1 2.90V supply assertion generates an FCCU event. 0 Disabled. VD assertion of HV0 on the supply of the ADC1 does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the ADC1 causes an FCCU event
2 FEE11_ADL0	FEE11_ADL0 FCCU event enable This bit defines whether a LVD290_ADL0 VD, the voltage level detect for the high voltage assertion on the ADC0 2.90V supply assertion generates an FCCU event. 0 Disabled. VD assertion of HV0 on the supply of the ADC0 does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the ADC0 causes an FCCU event
3 FEE11_FL	FEE11_FL FCCU event enable This bit defines whether a LVD290_FL VD, the voltage level detect for the high voltage assertion on the FLASH 2.90V supply assertion generates an FCCU event. 0 Disabled. VD assertion of HV0 on the supply of the FLASH does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the FLASH causes an FCCU event
4 FEE11_IOL1	FEE11_IOL1 FCCU event enable This bit defines whether a LVD290_IOL1 VD, the voltage level detect for the high voltage assertion on the IO1 2.90V supply assertion generates an FCCU event. 0 Disabled. VD assertion of HV0 on the supply of the IO1 does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the IO1 causes an FCCU event

Table 1003. FEE_HV0 field descriptions (continued)

Field	Description
5 FEE11_OSC	FEE11_OSC FCCU event enable This bit defines whether a LVD290_OSC VD, the voltage level detect for the high voltage assertion on the XOSC 2.90V supply assertion generates an FCCU event. 0 Disabled. VD assertion of HV0 on the supply of the XOSC does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the XOSC causes an FCCU event
7 FEE11_C	FEE11_C FCCU event enable This bit defines whether a LVD290_C VD, the voltage level detect for the high voltage assertion on the CORE/PMU 2.90V supply assertion generates an FCCU event. 0 Disabled. an VD assertion of HV0 on the supply of the CORE does not cause an FCCU event 1 Enabled. VD assertion of HV0 on the supply of the CORE causes an FCCU event

50.5.16 Event Pending Register (EPR_HV1)

This Event Pending Register indicates the present and past state of the voltage detect signals, in HIGH VOLTAGE1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Figure 1039. Event Pending Register (EPR_HV1)

Table 1004. EPR_HV1 field descriptions

Field	Description
9 LVD14_ADL1	LVD14_ADL1 flag This bit is the High voltage status flag associated with LVD400_ADL1 VD, the VD for the high voltage ADC1 4.00V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_ADL1 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the high voltage 4.00V point supply
10 LVD14_ADL0	LVD14_ADL0 flag This bit is the High voltage status flag associated with LVD400_ADL0 VD, the VD for the high voltage ADC0 4.00V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_ADL0 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the high voltage 4.00V point supply
12 LVD14_IOL1	LVD14_IOL1 flag This bit is the High voltage status flag associated with LVD400_IOL1 VD, the VD for the high voltage IO1 4.00V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IOL1 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the high voltage 4.00V point supply
13 LVD14_IOL0	LVD14_IOL0 flag This bit is the High voltage status flag associated with LVD400_IOL0 VD, the VD for the high voltage IO0 PMU 4.00V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IOL0 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the high voltage 4.00V point supply
23 HVD13_C	HVD13_C flag This bit is the High Voltage status flag associated with HVD400_C VD, the VD for the high voltage CORE 4.00V supply. It is asserted when the supply falls below its corresponding Voltage Detector 13 threshold, and clears when the supply rises above its corresponding HVD13 threshold and a one is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the high voltage 4.00V point supply

50.5.17 Reset Event Enable Register (REE_HV1)

This Reset Event Enable Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Figure 1044. Supply Gauge Status Register (*GR_S*)

Table 1009. *GR_S* field descriptions

Field	Description
1 VD14_ADL1	VD14_ADL1 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd400_adl1 for the high voltage 4 V ADCL1 supplies. It is asserted when ADCL1 supplies rises above the corresponding LVD threshold, and clears when ADCL1 supplies falls below the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
2 VD14_ADL0	VD14_ADL0 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd400_adl0 for the high voltage 4 V ADCL0 supplies. It is asserted when ADCL0 supplies rises above the corresponding LVD threshold, and clears when ADCL0 supplies falls below the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
3 VD14_IOL1	VD14_IOL1low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd400_iol1 for the high voltage 4 V IO1 supplies. It is asserted when IO1 supplies rises above the corresponding LVD threshold, and clears when IO1 supplies falls below the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
4 VD14_IOL0	VD14_IOL0 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd400_iol0 for the high voltage 4 V IO0 supplies. It is asserted when IO0 supplies rises above the corresponding LVD threshold, and clears when IO0 supplies falls below the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
5 VD13_C	VD13_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect hvd400_c for the high voltage 4 V CORE supply. It is asserted when the CORE supplies falls below its corresponding HVD threshold, and clears when the supplies rises above its corresponding HVD threshold. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 4.00 V supply
6 VD11_ADL1	VD11_ADL1 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_adl1 for the high voltage 2.9 V ADC1 supplies . It is asserted when ADC1 supplies falls below the corresponding LVD threshold, and clears when ADC1 supplies rises above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies

Table 1009. *GR_S* field descriptions (continued)

Field	Description
7 VD11_ADL0	VD11_ADL0 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_adl0 for the high voltage 2.9 V ADC0 supplies . It is asserted when ADC0 supplies falls below the corresponding LVD threshold, and clears when ADC0 supplies rises above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies
8 VD11_FL	VD11_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_fl for the high voltage 2.9 V FLASH supplies. It is asserted when any of the FLASH supplies falls below the corresponding LVD threshold, and clears when all the FLASH supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies
9 VD11_IOL1	VD11_IOL1 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_iol1 for the high voltage 2.9 V IO1 supply . It is asserted when IO1 supplies falls below the corresponding LVD threshold, and clears when IO1 supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies
10 VD11_OSC	VD11_OSC low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_OSC for the high voltage 2.9 V OSC supply . It is asserted when OSC supplies falls below the corresponding LVD threshold, and clears when OSC supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies
11 VD11_C	VD11_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd290_c for the high voltage 2.9 V CORE supplies. It is asserted when any of the CORE supplies falls below the corresponding LVD threshold, and clears when all the CORE supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.9 V supplies

Table 1009. *GR_S* field descriptions (continued)

Field	Description
19 VD6_C	VD6_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect hvd140_c for the high voltage 1.40V CORE supplies. It is asserted when any of the CORE supplies rises above the corresponding HVD threshold, and clears when all the CORE supplies fall below the corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 1.40 V supply
25 VD3_C	VD3_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect lvd108_c for the high voltage 1.08 V CORE supplies. It is asserted when any of the CORE supplies falls below the corresponding LVD threshold, and clears when all the CORE supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.08 V supplies

50.5.22 Pending Gauge Status Register (GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

50.5.23 Interrupt Enable Pending Register (IE_G)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt occurs when the voltage event is seen. A ‘0’ indicates that no interrupt is to be sent, and a ‘1’ indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of ‘1’ to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

	X	1	0	NREG enabled
	X	1	1	Both disabled

50.5.26 Event Pending Register (EPR_TD)

This Event Pending Register indicates the present and past state of the temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Figure 1049. Event Pending Register (EPR_TD)

Table 1015. EPR_TD field descriptions

Field	Description
14 TEMP1_1	TEMP1_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C) for temperature sensor 1. It is asserted when the temperature exceeds its corresponding threshold, and cleared by the user by writing ‘1’ in this bit location when the temperature falls below its corresponding threshold. If the IETD_1 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP_1] is also asserted, a system reset is generated, which clears IETD_1 and negate the interrupt request. If REE_TD[TEMP_1] is asserted and a destructive reset is selected (via RES_TD[TEMP_1] being 0), then a destructive reset is generated. If RES_TD[TEMP_1] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
15 TEMP1_0	TEMP1_0 flag This bit is the temperature status flag associated with the temperature for the *cold* temperature sensor point (-40 °C) for temperature sensor 1. It is asserted when the temperature exceeds its corresponding threshold, and cleared by the user by writing ‘1’ in this bit location when the temperature falls below its corresponding threshold. If the IETD1_0 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_0] is also asserted, a system reset is generated, which clears IETD1_0 and negate the interrupt request. If REE_TD[TEMP1_0] is asserted and a destructive reset is selected (via RES_TD[TEMP1_0] being 0), then a destructive reset is generated. If RES_TD[TEMP1_0] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected

Table 1015. EPR_TD field descriptions (continued)

Field	Description
30 TEMP0_1	TEMP0_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C) for temperature sensor 0. It is asserted when the temperature exceeds its corresponding threshold, and cleared by the user by writing '1' in this bit location when the temperature falls below its corresponding threshold. If the IETD0_1 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP0_1] is also asserted, a system reset is generated, which clears IETD0_1 and negate the interrupt request. If REE_TD[TEMP0_1] is asserted and a destructive reset is selected (via RES_TD[TEMP0_1] being 0), then a destructive reset is generated. If R ES_TD[TEMP0_1] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
31 TEMP0_0	TEMP0_0 flag This bit is the temperature status flag associated with the temperature for the *cold* temperature sensor point (-40 °C) for temperature sensor 0. It is asserted when the temperature exceeds its corresponding threshold, and cleared by the user by writing '1' in this bit location when the temperature falls below its corresponding threshold. If the IETD0_0 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP0_0] is also asserted, a system reset is generated, which clears IETD0_0 and negate the interrupt request. If REE_TD[TEMP0_0] is asserted and a destructive reset is selected (via RES_TD[TEMP0_0] being 0), then a destructive reset is generated. If RES_TD[TEMP0_0] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected

50.5.27 Reset Event Enable Register (REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Figure 1050. Reset Event Enable Register (*REE_TD*)

Table 1016. REE_TD field descriptions

Field	Description
27 TEMP1_1	TEMP1_1 reset enable This bit defines whether a temperature detect assertion generates a system reset for temperature sensor 1. The RES_TD[TEMP1_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset
28 TEMP1_0	TEMP1_0 reset enable This bit defines whether a temperature detect assertion generates a system reset for temperature sensor 1. The RES_TD[TEMP1_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset
30 TEMP0_1	TEMP0_1 reset enable This bit defines whether a temperature detect assertion generates a system reset for temperature sensor 0. The RES_TD[TEMP0_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset
31 TEMP0_0	TEMP0_0 reset enable This bit defines whether a temperature detect assertion generates a system reset for temperature sensor 0. The RES_TD[TEMP0_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset

50.5.28 Reset Event Select Register (RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Field	Description
27 TEMP1_1	TEMP1_1 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset for temperature sensor 1. The REE_TD[TEMP1_1] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor 1 assertion causes a d structive system reset 1 Functional Reset Generated. Temperature Sensor 1 assertion causes a functional system reset
28 TEMP1_0	TEMP1_0 reset event select. This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset for temperature sensor 1. The REE_TD[TEMP1_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor 1 assertion causes a destructive system reset 1 Functional Reset Generated. Temperature Sensor 1 assertion causes a functional system reset
30 TEMP0_1	TEMP0_1 reset event select This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset for temperature sensor 0. The REE_TD[TEMP0_1] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor 0 assertion causes a destructive system reset 1 Functional Reset Generated. Temperature Sensor 0 assertion causes a functional system reset
31 TEMP0_0	TEMP0_0 reset event select This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset for temperature sensor 0. The REE_TD[TEMP0_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor 0 assertion causes a destructive system reset 1 Functional Reset Generated. Temperature Sensor 0 assertion causes a functional system reset

50.5.29 Temperature Sensor Configuration register (CTL_TD)

The Temperature Sensor Configuration Registers (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to be operable. It also includes two 4-bit signed trim adjustment register fields that are used to modify both TS trim values (one bus for over temperature and one bus for under temperature).

Field	Description
1 TS1IE1	TS1IE1 Temperature Sensor input 1 Interrupt Enable for temperature sensor 1. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
2 TS0IE1	TS0IE1 Temperature Sensor input 0 Interrupt Enable. for temperature sensor 1 This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
14 DOUT1_EN	DOUT_EN1. Digital Output Enable for temperature sensor 1. See the Temperature Sensor Chapter for details.
15 AOUT1_EN	AOUT_EN1. Analog Output Enable for temperature sensor 1. See the Temperature Sensor Chapter for details.

Table 1018. CTL_TD field descriptions (continued)

Field	Description
17 TS1IE0	TS1IE0 Temperature Sensor input 1 Interrupt Enable for temperature sensor 0. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
18 TS0IE0	TS0IE0 Temperature Sensor input 0 Interrupt Enable for temperature sensor 0. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
30 DOUT0_EN	DOUT_EN0. Digital Output Enable for temperature sensor 0. See the Temperature Sensor Chapter for details.
31 AOUT0_EN	AOUT0_EN. Analog Output Enable for temperature sensor 0. See the Temperature Sensor Chapter for details.

50.5.30 Temperature Sensor FCCU Event Enable Register (FEE_TD)

This Temperature Sensor FCCU Event Enable Register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

Figure 1058. User BIST Control Register (BIST_CTRL)

Table 1024. BIST_CTRL field descriptions

Field	Description
11 IRQST	IRQST is the InteRrupt reQuest pending STatus bit to generate a User BIST Interrupt. It is a R/W0 register. That means Set by HW and Cleared by SW. The destructive ipg_hard_async_reset_dest_b resets this bit. 0 No interrupt occurs 1 An interrupt occurs
15 IRQEN	IRQEN is the InteRrupt reQuest ENable bit to permit a User BIST Interrupt. It is a R/W register. The destructive ipg_hard_async_reset_dest_b resets this bit. 0 No interrupt occurs 1 An interrupt occurs
19 NCFST	NCFST is the Not Critical Fault STatus bit for User BIST. It is set by HW when NCFEN is set and User BIST fault occurs and Cleared by SW by writing '1' to a FCCU Register bit. The destructive ipg_hard_async_reset_dest_b resets this bit. 0 No User BIST NCF occured 1 A User BIST NCF occured

Table 1024. BIST_CTRL field descriptions (continued)

Field	Description
23 NCFEN	NCFEN is the Not Critical Fault ENable bit to permit a User BIST Not Critical Fault. It is a R/W register. The destructive ipg_hard_async_reset_dest_b resets these bits. 0 No User BIST NCF enabled 1 A User BIST NCF enabled
25:27 STATUS	STATUS Register are three read-only bits, that according to the value has a own meaning. 000 BIST_IDLE 001 BIST_RUN 010 BIST_PASSED 011 BIST_FAILED 100 BIST_ABORT 101 Reserved 110 Reserved 111 Reserved
31 START	START User BIST bit. If set by SW a 1 is present in the START bit for a ipg_clk clock cycle only, then the START bit register is clear by HW. The destructive ipg_hard_async_reset_dest_b resets this bit. 0 No start pulse 1 A start pulse occurs of a 1 ipg_clk clock cycle duration

50.5.36 User BIST Time1 and Time0 Register (BIST_TIME10)

The User BIST Time1 and Time0 Register (BIST_TIME10) contains two time numbers Time1 and the Time0 giving the ipg_clk cycles number required by the User BIST timer1 and timer0. The reset value is calculated based on 70MHz. This register cannot be written bytewise. See *Table 147: Calculating the BIST_TIME values* of *Chapter 10: Power management*.

Offset: 0x03D8 Access: User read/write

Figure 1062. User BIST VD Under Test Monitor Register (BIST_DEBUG)

Table 1028. BIST_DEBUG field description

Field	Description
26:31 VD_MON	The six read only bits of field VD_MON give the current VD Under Test of the User BIST unit, among 14 VDs available, according to the following values: 001011 MVD098_C 001100 MVD098_FL 000100 MVD270_C 000101 MVD270_FL 001010 LVD108_C 000001 LVD290_C 001111 LVD290_XOSC 001110 LVD290_IOL1 000011 LVD290_FL 000010 LVD290_ADL0 010101 LVD290_ADL1 010001 LVD400_IOL0 010000 LVD400_IOL1 010011 LVD400_ADL0 010010 LVD400_ADL1 001001 HVD140_C 011101 HVD400_C 000111 UVD145_FL 001000 UVD145_C 011100 UVD600_C 000000 No VD under Test

50.6 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of two enables: an analog and digital enable, a set of mode registers, and an overtemp threshold select control.

For more information regarding the Temperature Sensor function, please refer to the *Chapter 23: Temperature sensor (TSENS)*.

50.7 FCCU Interface

The PMU digital generates five different failure events to the FCCU.

- **HVD_ERROR** : This failure event is generated to the FCCU when any of the HVD trips and FCCU event is enabled in FEE_HVx registers.
- **LVD_ERROR** : This failure event is generated to the FCCU when any of the LVD trips and FCCU event is enabled in FEE_LVx registers.
- **TEMP_ERROR** : This failure event is generated to the FCCU when undertemp or overtemp event is occured and this event is enabled in FEE_TD register.
- **PMC VD BIST**: This failure event is generated to the FCCU when PMC BIST failure happens.
- **DPMC_DCF_SAFETY_ERR** : This failure event is generated to the FCCU if any of the safety features of the DCF client occurs, that is parity error, second write mismatch or triple voted register flip. This event can be a pulse if the failure is transient or toggle if the failure is permanent such as parity error.

50.8 Power On Reset (MC_RGM Phase Gates)

The PMU digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMU and Temperature Sensor Analog blocks.

There are two signals for each the PMU and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMU digital logic also indicates when is ok to for the RGM to allow transition to the next POR phase.

The digital PMU also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMU digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled LVDs and HVDs have become deasserted and the time from the LVD circuits to adjust to new trim values has elapsed, then the signal is sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

50.9 Flash interface (DCF client usage)

The PMU digital is updated during POR from the Flash block via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMU and Temperature Sensor).

These trim bits that are loaded from the flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

A DCF client is used to interface to the flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES bits. Please see *Section 50.5.27* for more information regarding the REE/RES bits load from flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (thus to allow the bits to be rewriteable), but the reset value of the REE register bits are all high (to enable the resets normally out of POR).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the destructive reset signal.

For more information regarding the DCF records, please refer to the *Chapter 9: Device Configuration Format (DCF) Records*.

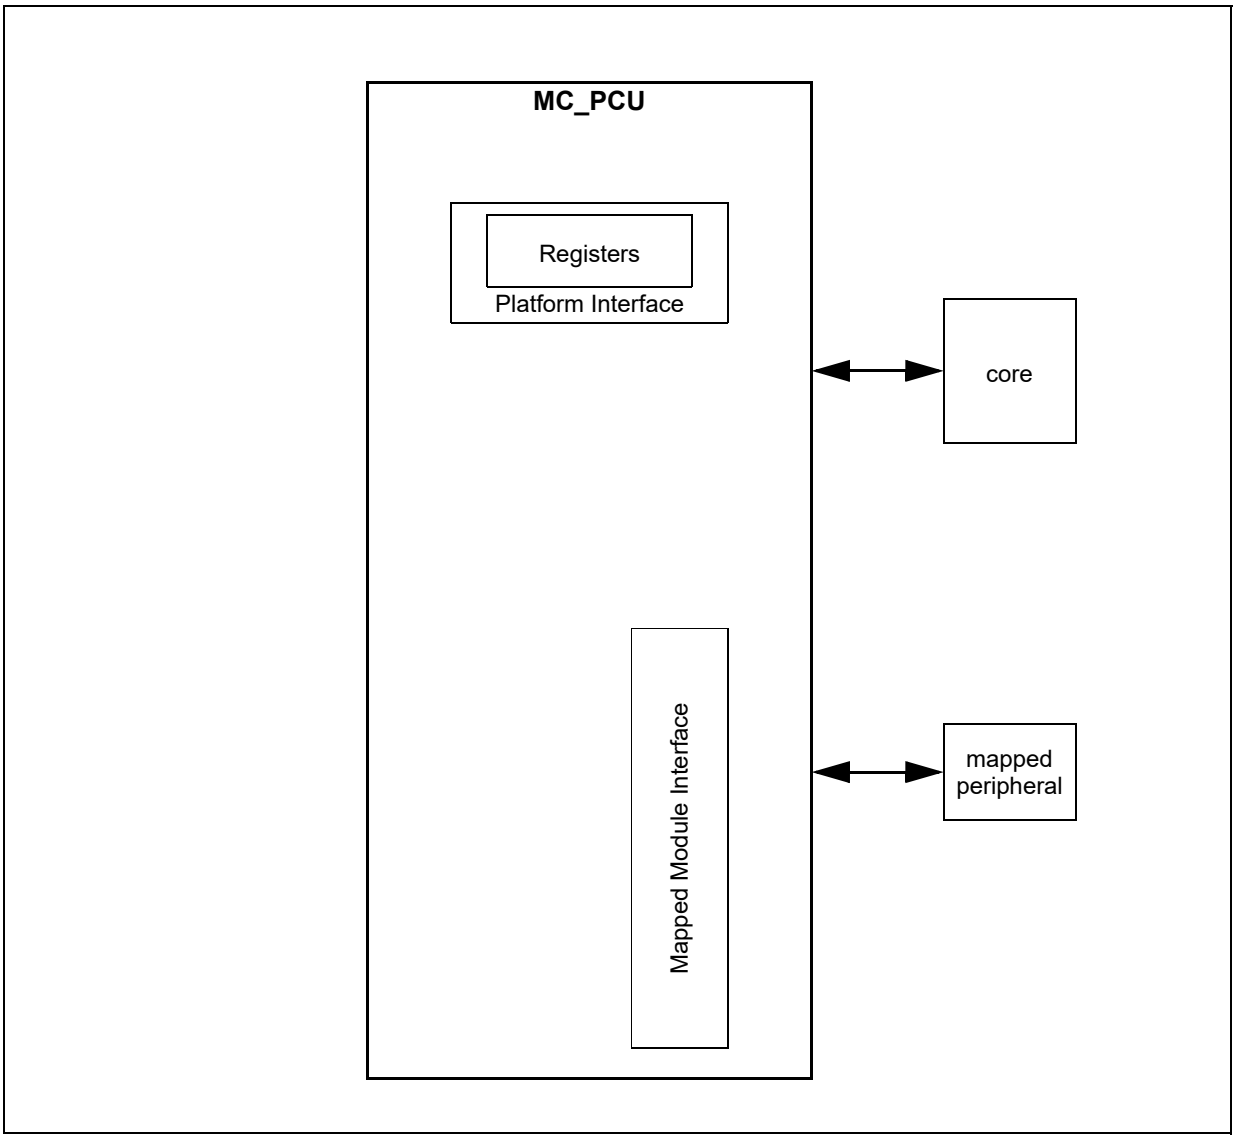
The trim data is read out of the flash's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the flash indicates this to the PMU digital via the SSCM module.

Once the PMU trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD signals must indicate that a valid voltage has been reached before the voltage indication will be sent to the flash.

For more information regarding the Flash differential reads and voltage levels required, please refer to the Flash chapter.

51 Power Control Unit (MC_PCU)



51.1 Introduction

51.1.1 Overview

The power control unit (MC_PCU) acts as a bridge for mapping the PMC peripheral to the MC_PCU address space.

Figure 1063 shows the MC_PCU block diagram.

Figure 1063. MC_PCU block diagram

51.1.2 Features

The MC_PCU includes the following feature:

- Maps the PMC registers to the MC_PCU address space

51.2 External signal description

The MC_PCU has no connections to any external pins.

51.3 Memory map and register definition

51.3.1 Memory map

Table 1029. MC_PCU register description

Offset Address	Name	Description	Size	Access			Location
				User	Supervisor	Test	
0x0040	PCU_PSTAT	Power Domain Status Register	word	read	read	read	*51.3.2.1 on page 1777*

Note: Any access to unused registers as well as write accesses to read-only registers:
– does not change register content
– causes a transfer error

Table 1030. MC_PCU memory map

Address	Name
0x0004 – 0x003C	Reserved
0x0040	PCU_PSTAT
0x0044 – 0x03FC	Reserved
0x0400 – 0x07FC	PMC registers
0x0800 – 0x3FFC	Reserved

51.3.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at address 0x0040, as a half-word at address 0x0042, or as a byte at address 0x0043.

51.3.2.1 Power Domain Status Register (PCU_PSTAT)

Address: 0x0040 Access: User read, Supervisor read, Test read

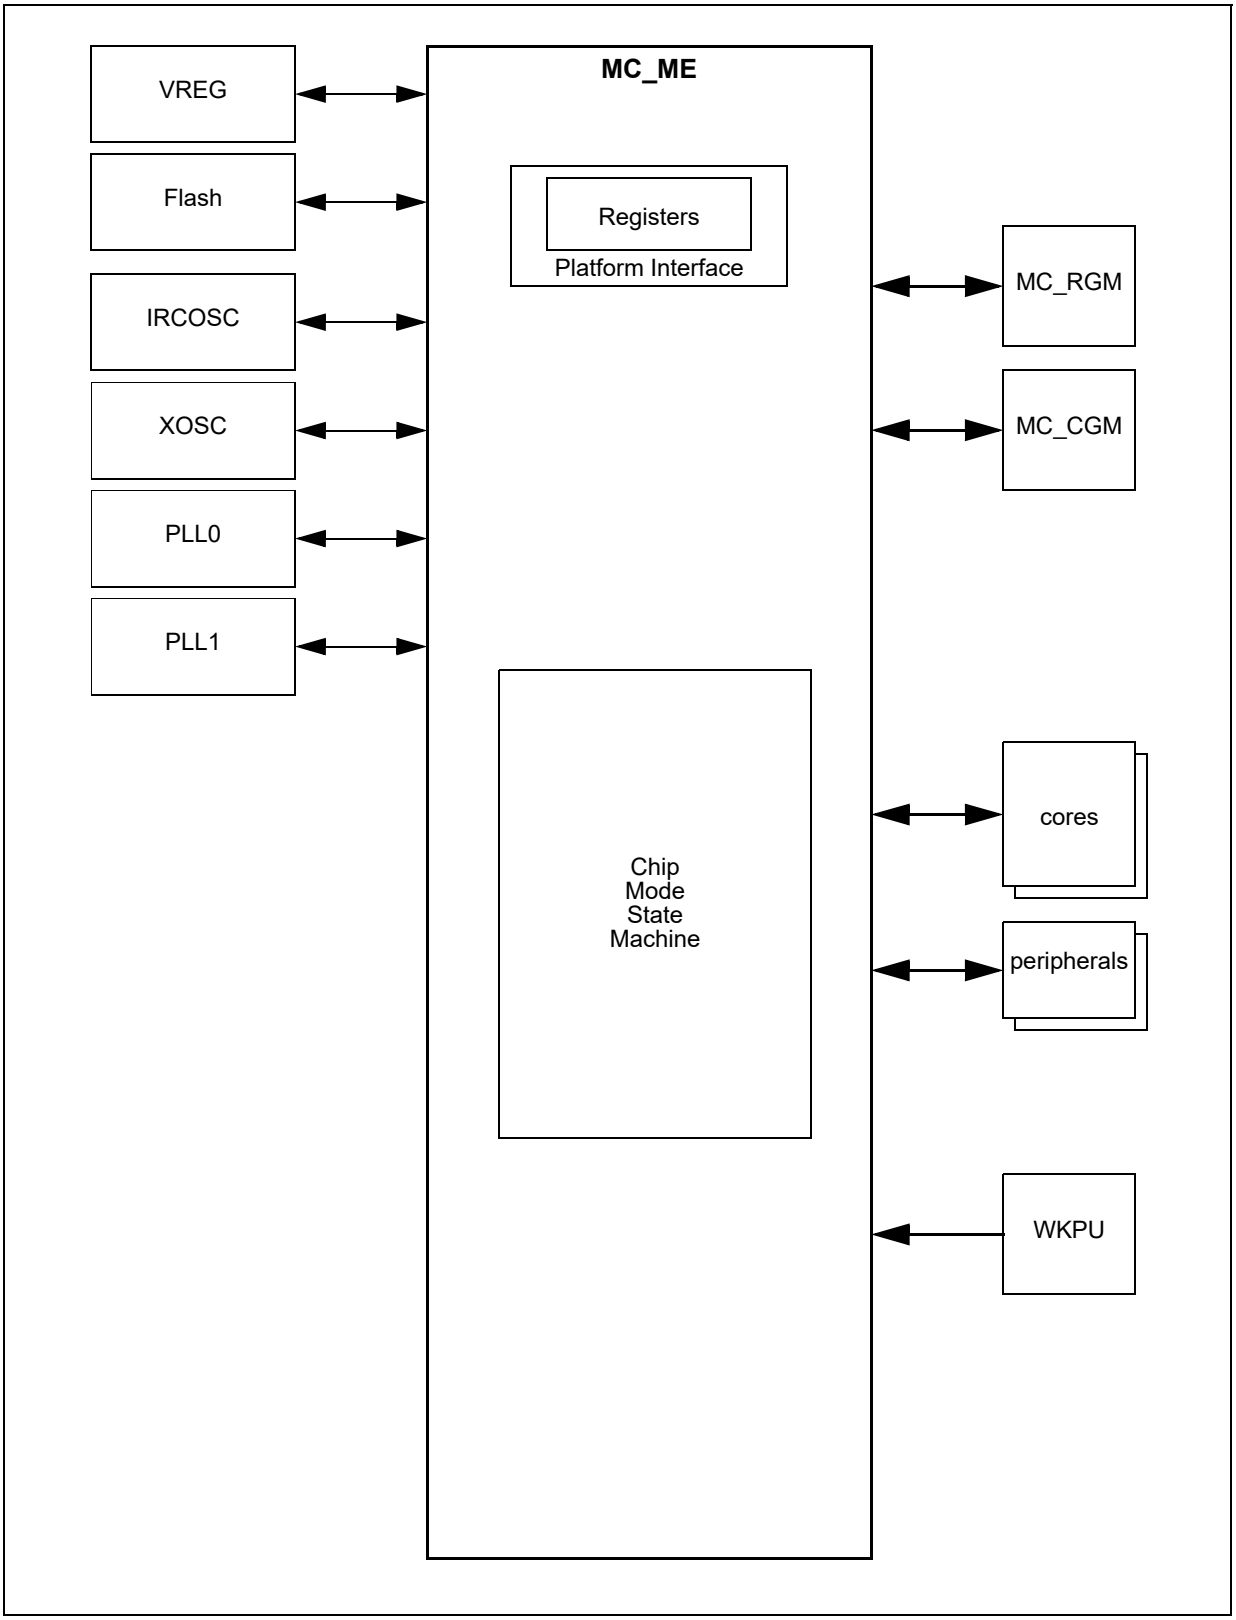
PD0	Power status for power domain #0 0 Power domain is inoperable 1 Power domain is operable

52 Mode Entry Module (MC_ME)



52.1 Introduction

52.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

Figure 1065 shows the MC_ME block diagram.

Figure 1065. MC_ME block diagram

52.1.2 Features

The MC_ME includes the following features:

- Control of the available modes by the ME_ME register
- Definition of various chip mode configurations by the ME_<*mode*>_MC registers
- Control of the actual chip mode by the ME_MCTL register
- Capture of the current mode and various resource status within the contents of the ME_GS register
- Optional generation of various mode transition interrupts
- Status bits for each cause of invalid mode transitions
- Peripheral clock gating control based on the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers
- Capture of current peripheral and additional core clock gated/enabled status
- Progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

52.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0–3, HALT0, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0–3 are the chip software running modes.

Table 1032 describes the MC_ME modes.

Table 1032. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0–3	system reset assertion, RUN0–3, TEST via software, SAFE via software or hardware failure.

Table 1032. MC_ME mode descriptions (continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a predefined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0–3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0–3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock and power configurations of the system with respect to each other.	software request from DRUN or other RUN0–3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0–3 modes, HALT0, STOP0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals such as: clock sources, flash, main regulator, for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event or wakeup event

52.2 External signal description

The MC_ME has no connections to any external pins.

52.3 Memory map and register definition

The MC_ME contains registers for:

- Mode selection and status reporting
- Mode configuration
- Mode transition interrupts status and mask control
- Scalable number of peripheral sub-mode selection and status reporting
- Scalable number of additional core enabling and disabling control and status reporting

52.3.1 Memory map

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *Not change register content*
- *Cause a transfer error*

52.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

52.3.2.1 Global Status Register (ME_GS)

Address: 0x000 Access: User read, Supervisor read, Test read

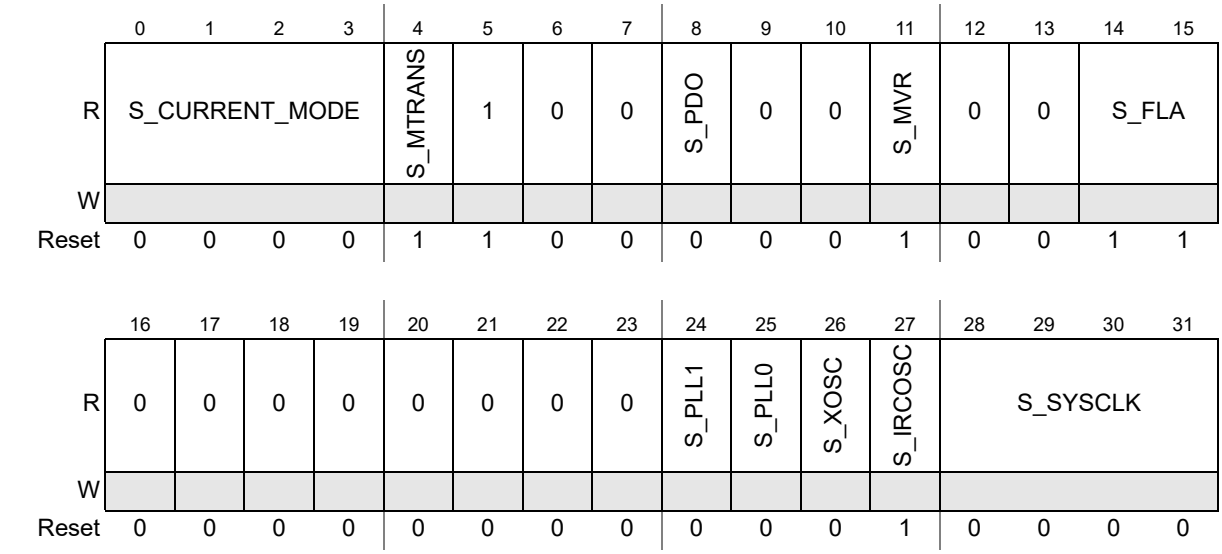

Figure 1066. Global Status Register (ME_GS)

This register contains global mode status.

Table 1034. ME_GS field descriptions

Field	Description
0:3 S_CURRENT_MODE	Current chip mode status 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 Reserved 1010 STOP0 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
4 S_MTRANS	Mode transition status 0 Mode transition process is not active 1 Mode transition is ongoing

Table 1034. ME_GS field descriptions (continued)

Field	Description
8 S_PDO	Output power-down status This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In STOP0 mode, the power sequence driver of the output pads is disable to reduce power consumption, but the state of the output remains functional.
11 S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
14:15 S_FLA	Flash availability status 00 Flash is not available 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode and available for use

R	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1
W	KEY															
Reset	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1

Figure 1067. Mode Control Register (ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<*mode*>_MC registers must respect this for successful mode requests.

Note: Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Table 1035. ME_MCTL field descriptions

Field	Description
0:3 TARGET_MODE	Target chip mode These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0–3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 RESET (triggers a 'destructive' reset event)
16:31 KEY	Control key These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. 0101 1010 1111 0000 (0x5AF0): KEY 1010 0101 0000 1111 (0xA50F): INVERTED KEY

Figure 1069. Interrupt Status Register (ME_IS)

This register provides the current interrupt status.

Table 1037. ME_IS field descriptions

Field	Description
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) This bit is set if a write access to one of the ME_CCTL registers is attempted while a mode transition is in progress. 0 No write to an ME_CCTL register was attempted during an ongoing mode transition 1 A write to an ME_CCTL register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (clock usage) This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending
28 I_ICONF	Invalid mode configuration interrupt This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt This bit is set whenever an invalid mode transition is requested. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending

Table 1037. ME_IS field descriptions (continued)

Field	Description
30 I_SAFE	SAFE mode interrupt This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

52.3.2.5 Interrupt Mask Register (ME_IM)

Address: 0x010 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1071. Invalid Mode Transition Status Register (ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Table 1039. ME_IMTS field descriptions

Field	Description
27 S_MTI	Mode Transition Illegal status This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is ‘1’). Please refer to *Section 52.4.5* for the exceptions to this behavior. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode

Table 1039. ME_IMTS field descriptions (continued)

Field	Description
30 S_NMA	Non-existing Mode Access status This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

52.3.2.7 Debug Mode Transition Status Register (ME_DMTS)

Address: 0x018 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1072. Debug Mode Transition Status Register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS[S_MTRANS] may be taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Table 1040. ME_DMTS field descriptions

Field	Description
0:3 PREVIOUS_MODE	Previous chip mode These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 Reserved 1010 STOP0 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has power-up/down sequencing. 0 Handshake is not busy 1 Handshake is busy
11 PMC_PROG	MC_PCU Mode Change in Progress indicator This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress

Table 1040. ME_DMTS field descriptions (continued)

Field	Description
15 SMR	SAFE mode request from MC_RGM is active indicator This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
19 IRCOSC_SC	IRCOSC State Change during mode transition indicator This bit is set when the 16 MHz Internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz Internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A ‘secondary clock source’ is a clock source other than IRCOSC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status 0 No system clock source switching is pending 1 A system clock source switching is pending
23 FLASH_SC	FLASH State Change during mode transition indicator This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224–255(1) This bit is set when any peripheral has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1040. ME_DMTS field descriptions (continued)

Field	Description
25 CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192–223(1) This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_160_191	Clock Disable Process Pending status for Peripherals 160–191(1) This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
27 CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128–159(1) This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96–127(1) This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64–95(1) This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1040. ME_DMTS field descriptions (continued)

Field	Description
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32–63(1) This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0–31(1) This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTL*n* register. Please refer to *Table 1033* for the ME_PCTL*n* locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

52.3.2.8 RESET Mode Configuration Register (ME_RESET_MC)

Address: 0x020 Access: User read/write, Supervisor read/write, Test read/write

W																
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	0

Figure 1092. Core Control Register (ME_CCTL0)

This register controls whether main core_0 is disabled or running during run modes.

This register cannot be written after a mode change request has been made until the mode transition has completed (that is, while the bit ME_GS[S_MTRANS] = ‘1’). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

Table 1053. ME_CCTL0 field descriptions

Field	Description
5 STOP0	Core control during STOP0 Main core_0 is always disabled during STOP0.
7 HALT0	Core control during HALT0 Main core_0 is always disabled during HALT0.
8 RUN3	Core control during RUN3 0 Main core_0 is disabled with clock gated 1 Main core_0 is running
9 RUN2	Core control during RUN2 0 Main core_0 is disabled with clock gated 1 Main core_0 is running
10 RUN1	Core control during RUN1 0 Main core_0 is disabled with clock gated 1 Main core_0 is running
11 RUN0	Core control during RUN0 0 Main core_0 is frozen with clock gated 1 Main core_0 is running

Table 1053. ME_CCTL0 field descriptions (continued)

Field	Description
12 DRUN	Core control during DRUN 0 Main core_0 is frozen with clock gated 1 Main core_0 is running
13 SAFE	Core control during SAFE 0 Main core_0 is frozen with clock gated 1 Main core_0 is running
14 TEST	Core control during TEST 0 Main core_0 is frozen with clock gated 1 Main core_0 is running
15 RESET	Core control during RESET Main core_0 is always disabled during RESET.

52.3.2.28 Core Address Register (ME_CADDR0)

Address: 0x1E0 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ADDR															
Reset	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ADDR														0	RMC
Reset	X	X	X	X	X	X	X	X	X	X	X	X	X	X	0	0

Figure 1093. Core Address Register (ME_CADDR0)

This register gives the boot address for main core_0 and a bit for controlling whether main core_0 is to be reset on the next mode change that has main core_0 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (that is, while the bit ME_GS[S_MTRANS] register = ‘1’). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

Note: The reset value of the field ME_CADDR0[ADDR] is determined by the chip configuration and boot mode.

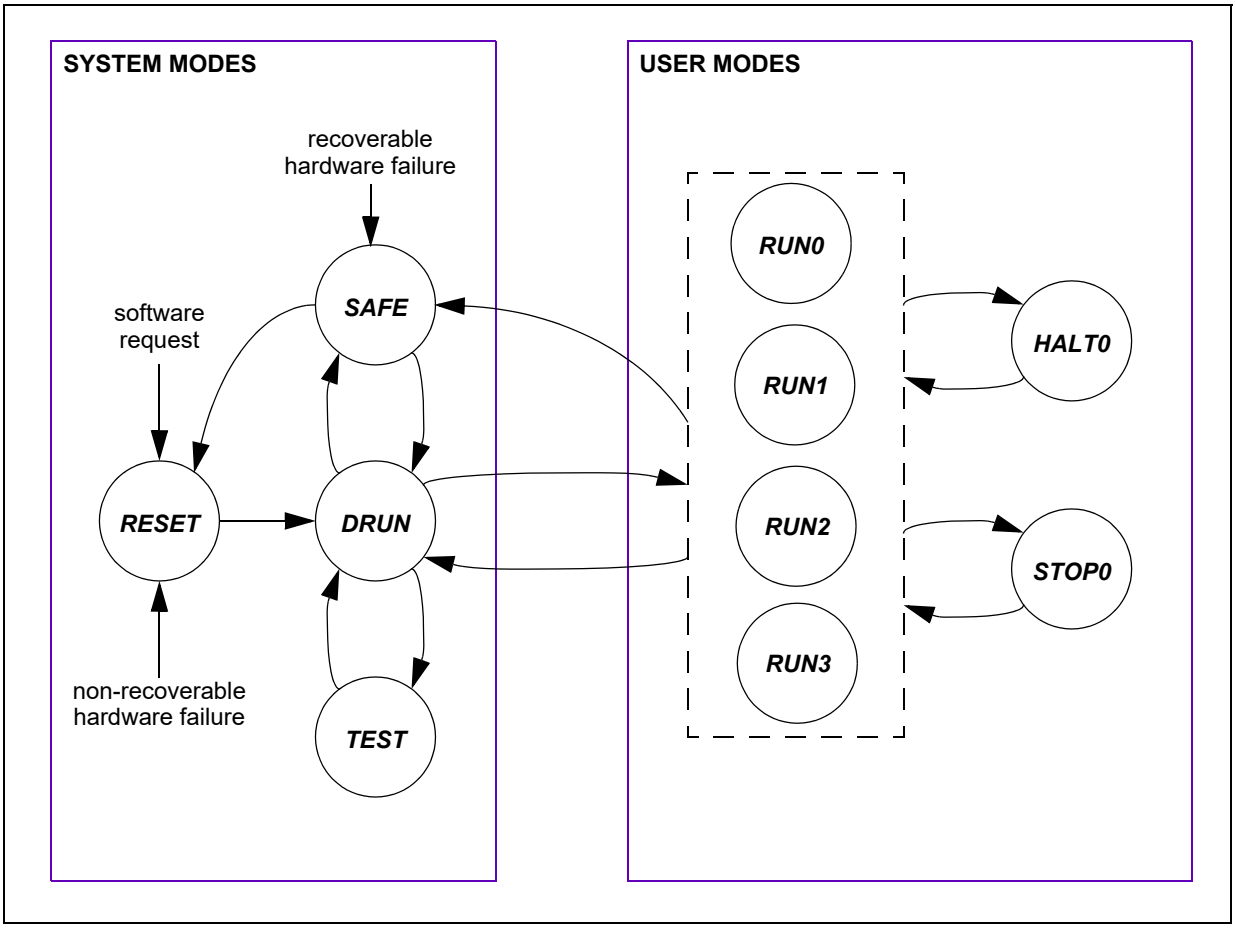
Table 1054. ME_CADDR0 field descriptions

Field	Description
0:29 ADDR	Core Address This field is used by main core_0 as the boot address (32-bit word aligned) when main core_0 next exits reset.
31 RMC	Reset on Mode Change Main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode. 0 Main core_0 will not be reset on the next mode change 1 Main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode

52.4 Functional description

52.4.1 Mode Transition Request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But in the case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing



- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<*mode*>_MC register. The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to *Section 52.4.5*.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as RUN0–3 to RUN0–3, DRUN to DRUN, SAFE to SAFE, and TEST to TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: It is recommended that software polls bit ME_GS[S_MTRANS] after requesting a transition to HALT0 or STOP0 modes.

Figure 1094. MC_ME mode diagram

52.4.2 Modes details

52.4.2.1 RESET mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0–3, or TEST mode when the field ME_MCTL[TARGET_MODE] is written with either ‘0000’ for a ‘functional’ reset or ‘1111’ for a ‘destructive’ reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a predefined configuration, and the 16 MHz Internal RC oscillator is selected as the system clock.

52.4.2.2 DRUN mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0–3, SAFE, or TEST mode when the field ME_MCTL[TARGET_MODE] is written with ‘0011’

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz Internal RC oscillator as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

52.4.2.3 SAFE mode

The chip enters this mode on the following events:

- from any mode except RESET when the field ME_MCTL[TARGET_MODE] is written with ‘0010’
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see the MC_RGM chapter for details)

Note: If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz Internal RC oscillator is selected as the system clock.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note: If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip’s final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the bit ME_SAFE_MC[PDO] should be set. The input levels remain unchanged.

52.4.2.4 TEST mode

The chip enters this mode on the following events:

- from the DRUN mode when the field ME_MCTL[TARGET_MODE] is written with '0001'

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to '1111', and in this case, the only way to exit this mode is via a chip reset.

This mode is used by software to execute software test routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

52.4.2.5 RUN0–3 modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0–3 mode when the field ME_MCTL[TARGET_MODE] is written with '0100–0111'
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0–3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0–3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

52.4.2.6 HALT0 mode

The chip enters this mode on the following events:

- from one of the RUN0–3 modes when the field ME_MCTL[TARGET_MODE] is written with '1000'.

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request

is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (that is, within a few system clock cycles of an interrupt event)

Note: It is good practice for software to ensure that bit ME_GS[S_MTRANS] has been cleared on HALT0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

52.4.2.7 STOP0 mode

The chip enters this mode on the following events:

- from one of the RUN0–3 modes when the field ME_MCTL[TARGET_MODE] is written with ‘1010’.

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- The Primary PLL
- The Secondary PLL

The flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- The core clock frozen
- Almost all peripherals stopped

and to be used by software

- To wait until it is required to do something with no need to react quickly (for example, allow for system clock source to be restarted)

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz Internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: It is good practice for software to ensure that bit ME_GS[S_MTRANS] has been cleared on STOP0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

52.4.3 Mode Transition Process

The following subsections describe the mode transition process steps. The steps are followed in a predefined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

52.4.3.1 Target Mode Request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of predefined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the field ME_MCTL[TARGET_MODE] is not updated. An optional interrupt can be generated for invalid mode requests. Refer to *Section 52.4.5* for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the field ME_MCTL[TARGET_MODE] is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit ME_GS[S_MTRANS].

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

52.4.3.2 Target Mode Configuration Loading

On completion of the *Section 52.4.3.1* step, the target mode configuration from the ME_<*target mode*>_MC register is loaded to start the resources (such as: voltage sources, clock sources, flash, pads) control process.

An overview of resource control possibilities for each mode is shown in *Table 1055*. A '√' indicates that a given resource is configurable for a given mode.

Table 1055. MC_ME resource control overview

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0
IRCOSC	On	√ On	On	On	On	On	On
XOSC	Off	√ Off	Off	√ Off	√ Off	√ Off	√ Off
PLL0	Off	√ Off	Off	√ Off	√ Off	√ Off	Off

Table 1055. MC_ME resource control overview (continued)

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0
PLL1	Off	√ Off	Off	√ Off	√ Off	√ Off	√ Off
FLASH	Normal	√ normal	Normal	√ Normal	√ Normal	√ Low-power	√ Power-down
MVREG	On	On	On	On	On	On	On
PDO	Off	√ Off	√ On	Off	Off	Off	√ Off

52.4.3.3 Peripheral Clocks Disable

On completion of the *Section 52.4.3.1* step and the system clock frequency ramp-down of the *Section 52.4.3.13* step, the MC_ME requests each peripheral to enter its stop mode when:

- The peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0–7 and ME_LP_PC0–7, and the peripheral control registers ME_PCTL*n*

Note: The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a *SAFE* mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The *SAFE* mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to *Section 52.4.6* for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

52.4.3.4 Processor Low-Power Mode Entry

If, on completion of the *Section 52.4.3.3* step, the mode transition is to the HALT0, STOP0 mode, the MC_ME requests processor to enter its stopped state. processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the *Section 52.4.3.3* step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC_ME requests processor which is configured in the ME_CCTL registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

52.4.3.5 Processor Clocks Disable

If, on completion of the *Section 52.4.3.4* step, and processor which are configured in the ME_CCTL register to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processor which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

52.4.3.6 System Clock Disable

If, on completion of the *Section 52.4.3.5* step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

52.4.3.7 Clock Sources Switch-On

On completion of the *Section 52.4.3.4* step, the MC_ME switches on all clock sources based on the <*clock source*>ON bits of the ME_<*current mode*>_MC and ME_<*target mode*>_MC registers. The following clock sources are switched on at this step:

- The 16 MHz Internal RC oscillator
- The External crystal oscillator
- The Primary PLL
- The Secondary PLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<*clock source*> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

52.4.3.8 Flash Module Switch-On

On completion of the step, if the flash needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<*current mode*>_MC and ME_<*target mode*>_MC registers, the MC_ME requests the flash to exit from its low-power/power-down mode. When the flash is available for access, the field ME_GS[S_FLA] is updated to ‘11’ by hardware.

Warning: It is illegal to switch the FLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

52.4.3.9 Pad Outputs-On

On completion of the step, if the PDO bit of the ME_<*target mode*>_MC register is cleared, then

- All pad outputs are enabled to return to their previous state
- The power sequence driver is switched on

52.4.3.10 Peripheral Clocks Enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0–7, ME_LP_PC0–7, and the peripheral control registers ME_PCTL*n*, the MC_ME enables the clocks for selected modules as required. This step is executed only after the process is completed, and if the value of the PWRLVL field of the ME_<*target mode*>_MC register is process is completed.

52.4.3.11 System and Processor Clocks Enable

On completion of the *Section 52.4.3.8* step, the MC_ME enables the non-processor system clock and the clocks of processor which are configured in the ME_CCTL register to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of processor which are configured in the ME_CCTL register to be running in the target mode and which have their RMC bits in the ME_CADDR register set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the bit ME_GS[S_MTRANS] at which time they are deasserted.

If the value of the PWRLVL field of the ME_<*target mode*>_MC register is different from that of the ME_<*current mode*>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the *Section 52.4.3.13* process is completed.

52.4.3.12 Processor Low-Power Mode Exit

On completion of the *Section 52.4.3.11* step, the MC_ME requests processor which are configured in the ME_CCTL registers to be disabled in the current mode and to be running in the target mode.

52.4.3.13 System Clock Switching

Based on the SYSCLK bit field of the ME_<*current mode*>_MC and ME_<*target mode*>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching:

- The target clock configuration for the 16 MHz Internal RC oscillator takes effect only after the bit ME_GS[S_IRCOSC] is set by hardware (that is, the 16 MHz Internal RC oscillator has stabilized).
- The target clock configuration for the external crystal oscillator takes effect only after the bit ME_GS[S_XOSC] is set by hardware (that is, the External crystal oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the bit ME_GS[S_PLL0] is set by hardware (that is, the Primary PLL has stabilized).
- The target clock configuration for the Secondary PLL takes effect only after the bit ME_GS[S_PLL1] is set by hardware (that is, the Secondary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with '1111'. This is possible only in the TEST mode.

If the value of the PWRLVL field of the ME_<*target mode*>_MC register not equal to that of the ME_<*current mode*>_MC register's, a progressive clock switching is performed.

The current system clock configuration can be observed by reading the field ME_GS[S_SYSCLK], which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the *Section 52.4.3.7* process has completed if the target system clock source is one of the following:
  - The 16 MHz Internal RC oscillator
  - The External crystal oscillator
  - The Primary PLL
- the *Section 52.4.3.3* process has completed in order to ensure that a system clock frequency change does not lead to unpredictable peripheral behavior before peripherals have been cleanly turned off

An overview of system clock source selection possibilities for each mode is shown in the following table. A shaded cell indicates the given clock source is not selectable for a given mode. A '√' indicates that a given clock source is selectable for a given mode.

Table 1056. MC_ME system clock selection overview

System clock source	Mode						
	RESET	TEST	SAFE	DRUN	RUN 0–3	HALT0	STOP0
16 MHz Internal RC oscillator	√ (Default)	√ (Default)	√ (Default)	√ (Default)	√ (Default)	√ (Default)	√ (Default)
external crystal oscillator		√		√	√	√	√

Table 1056. MC_ME system clock selection overview (continued)

System clock source	Mode						
	RESET	TEST	SAFE	DRUN	RUN 0–3	HALT0	STOP0
primary PLL (PHI)		√		√	√	√	√
Secondary PLL		√		√	√		
system clock is disabled		√(1)					

1. Disabling the system clock during ***TEST*** mode will require a reset in order to exit ***TEST*** mode.

52.4.3.14 Pad Switch-Off

If the PDO bit of the ME_<target mode>_MC register is ‘1’ then

- The outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the *Section 52.4.3.3* process has completed.

52.4.3.15 Clock Sources Switch-Off

Based on the chip mode and the <*clock source*>ON bits of the ME_<*mode*>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<*clock source*> of the ME_GS register to ‘0’. The following clock sources are switched off at this step:

- The 16 MHz Internal RC oscillator
- The External crystal oscillator
- The Primary PLL
- The Secondary PLL

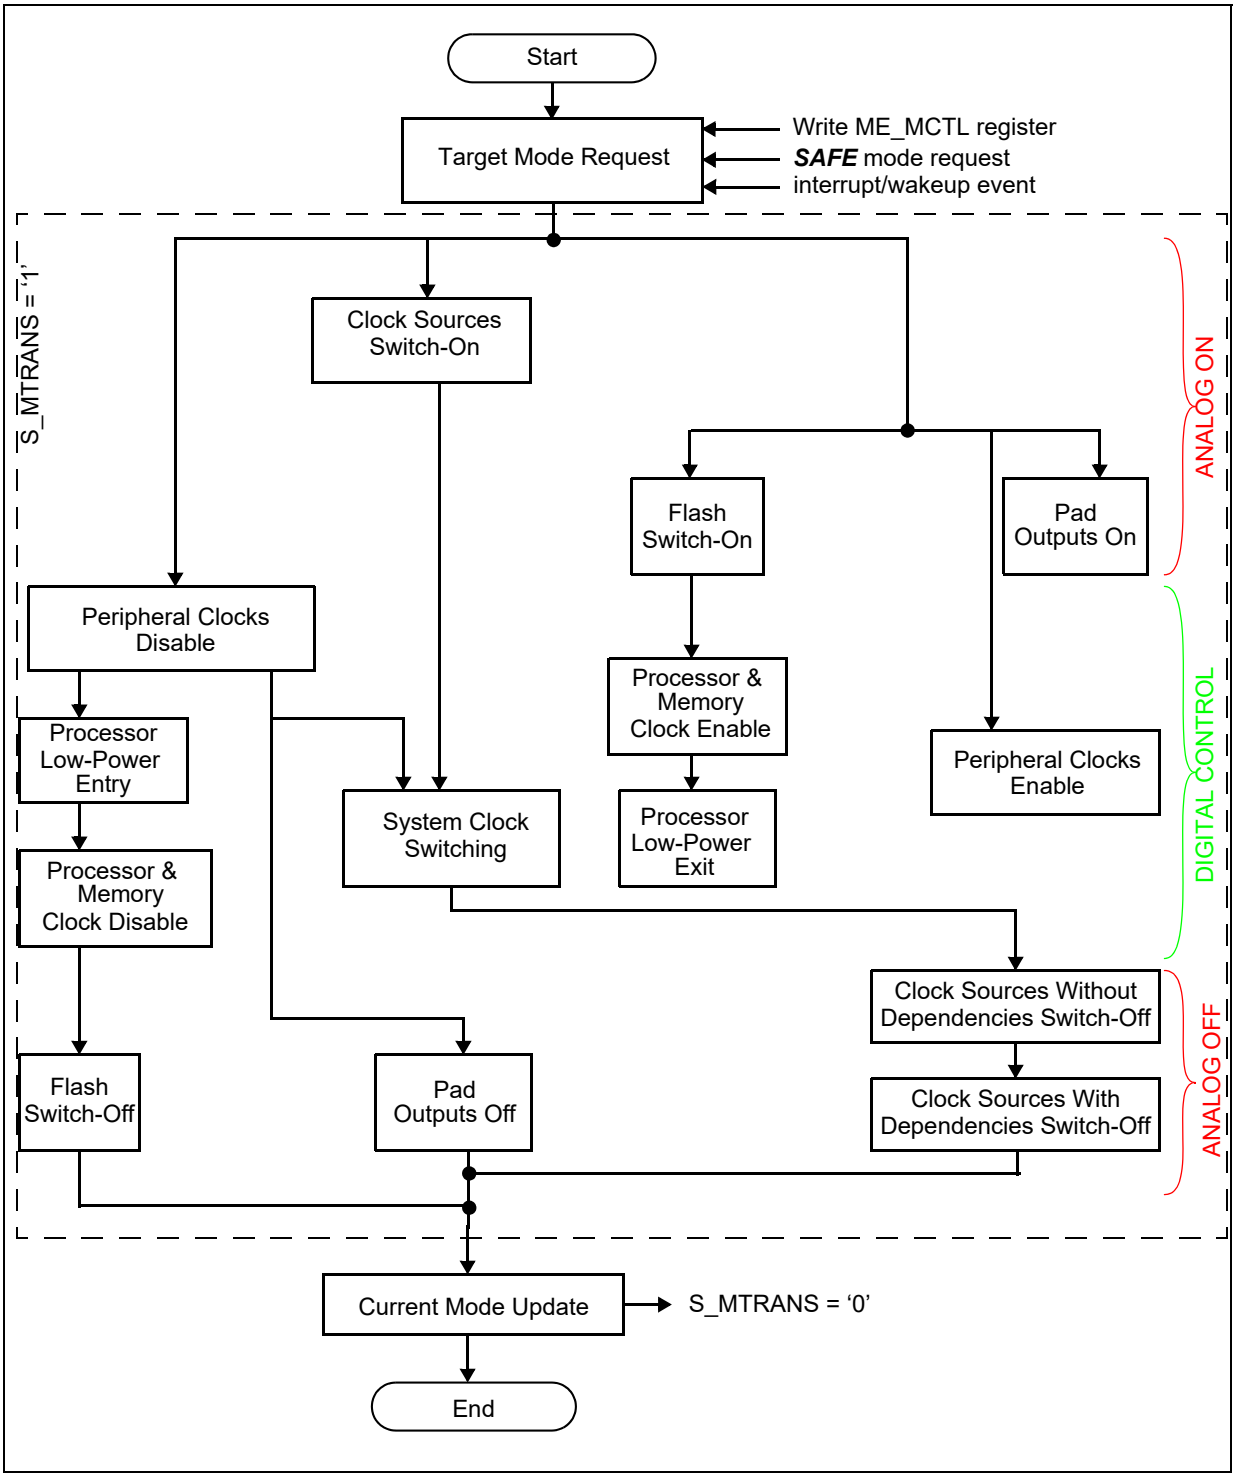
For the clock sources related to the system clock, this step is executed only after the *Section 52.4.3.13* process has completed.

52.4.3.16 Flash Switch-Off

Based on the FLAON bit field of the ME_<*current mode*>_MC and ME_<*target mode*>_MC registers, if the flash is to be put in its low-power or power-down mode, the MC_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the field ME_GS[S_FLA]. This step is executed only when the *Section 52.4.3.5* and *Section 52.4.3.6* processes have completed.

52.4.3.17 Current Mode Update

The current mode status field ME_GS[S_CURRENT_MODE] is updated with the target mode field ME_MCTL[TARGET_MODE] when:



- All the updated status bits in the ME_GS register match the configuration specified in the ME_<*target mode*>_MC register
- Power sequences are done
- Clock disable/enable process is finished
- Processor low-power mode (stop) entry and exit processes are finished

Note: SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS[S_RC] bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the bit ME_GS[S_MTRANS]. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

Figure 1095. MC_ME transition diagram

52.4.4 Protection of mode configuration registers

While programming the mode configuration registers ME_<*mode*>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz Internal RC oscillator is selected as the system clock, IRCOSC must be on.
- If the external crystal oscillator clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the Secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration '00' for the FLAON bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration '1111' for the SYSCLK bit field is allowed only for the TEST mode, and only in this case may all system clock sources be turned off.

Warning: If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

52.4.5 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

52.4.5.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<*mode*>_MC registers violating the protection rules mentioned in the *Section 52.4.4*, the interrupt pending bit ME_IS[I_ICONF] is set and an interrupt request is generated if the mask bit ME_IM[M_ICONF] is '1'.

In addition, during a mode transition, if a clock source has been configured in the ME_<*target mode*>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0–7/ME_LP_PC0–7 and ME_PCTL*n* registers, the interrupt pending bit ME_IS[I_ICONF_CU] is set and an interrupt request is generated if the mask bit ME_IM[M_ICONF_CU] is '1'.

If an attempt to write to one of the ME_CCTL0 or ME_CADDR0 registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the bit ME_GS[S_MTRANS] deasserting, the interrupt pending bit ME_IS[I_ICONF_CC] is set and an interrupt request is generated if the mask bit ME_IM[M_ICONF_CC] is '1'.

52.4.5.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the bit ME_IMTS[S_SEA] is set.
- If the field ME_MCTL[TARGET_MODE] is written with a value different from the specified mode values (that is, a non-existing mode), an invalid mode transition event is generated. When such a non-existing mode is requested, the bit ME_IMTS[S_NMA] is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the bit ME_IMTS[S_DMA] is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit ME_IMTS[S_MRI] is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition is in progress (the bit ME_GS[S_MTRANS] is ‘1’), the mode transition illegal status bit ME_IMTS[S_MTI] is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note: As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0–3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined ‘reasonable’ amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.
- Self-transition requests (for example, RUN0 to RUN0) are not considered as invalid even when the mode transition process is active (that is, S_MTRANS is ‘1’). During the low-power mode exit process, if the system is not able to enter the respective RUN0–3 mode properly (that is, all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit ME_IS[I_IMODE] is set, and an interrupt request is generated if the mask bit ME_IM[M_IMODE] is ‘1’.

52.4.5.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit ME_IS[I_SAFE] is set, and an interrupt is generated if the mask bit ME_IM[M_SAFE] is ‘1’.

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (that is, programming of ME_MCTL register).

52.4.5.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (that is, the bit ME_GS[S_MTRANS] transits from ‘1’ to ‘0’), the interrupt pending bit ME_IS[I_MTC] is set, and an interrupt request is generated if the mask bit ME_IM[M_MTC] is ‘1’. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

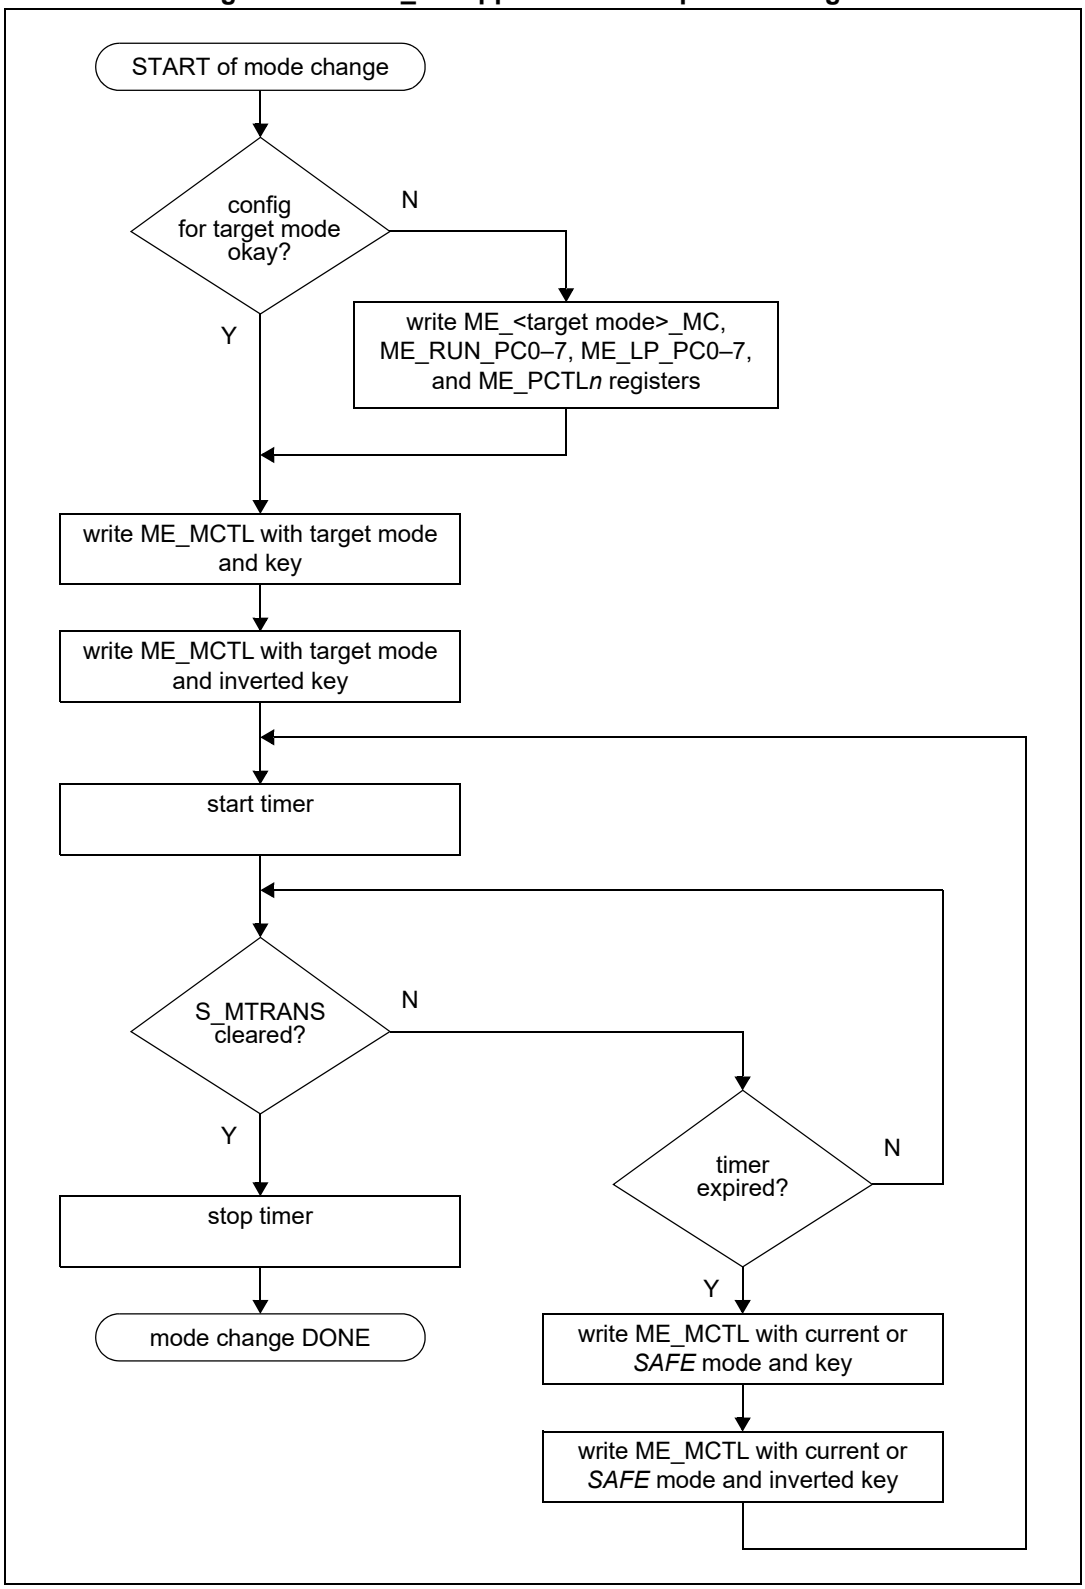
52.4.6 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0–7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0–3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTL*n* registers.

The low-power peripheral configuration registers ME_LP_PC0–7 are chosen only during the low-power modes HALT0 and STOP0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTL*n* registers.

Any modifications to the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers do not affect the clock gating behavior until a new mode transition request is generated.



Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTL*n* register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits.

52.4.7 Application example

Figure 1096 shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

53 e200z420n3 Core Debug Support

This chapter describes the debug features of the e200z420n3 core.

53.1 Overview

Internal debug support in the e200z420n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of <asisitalic>PowerISA 2.06. e200z420n3 supports a subset of these defined facilities. In addition to the facilities defined in <asisitalic>PowerISA 2.06, e200z420n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

53.1.1 Software Debug Facilities

e200z420n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

53.1.1.1 <asisitalic>PowerISA 2.06 Compatibility

The e200z420n3 core implements a subset of the <asisitalic>PowerISA 2.06 internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

53.1.2 Additional Debug Facilities

In addition to the debug functionality defined in <asisitalic>PowerISA 2.06, e200z420n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See *Section 53.1.4*.) A data trace port is also provided.

53.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z420n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (that is the normal setting), see the “Data Trace Control Register (DTC)” section in the Core (e200z420n3) Nexus 3 Module chapter). The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

53.1.3 Hardware Debug Facilities

The e200z420n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z420n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

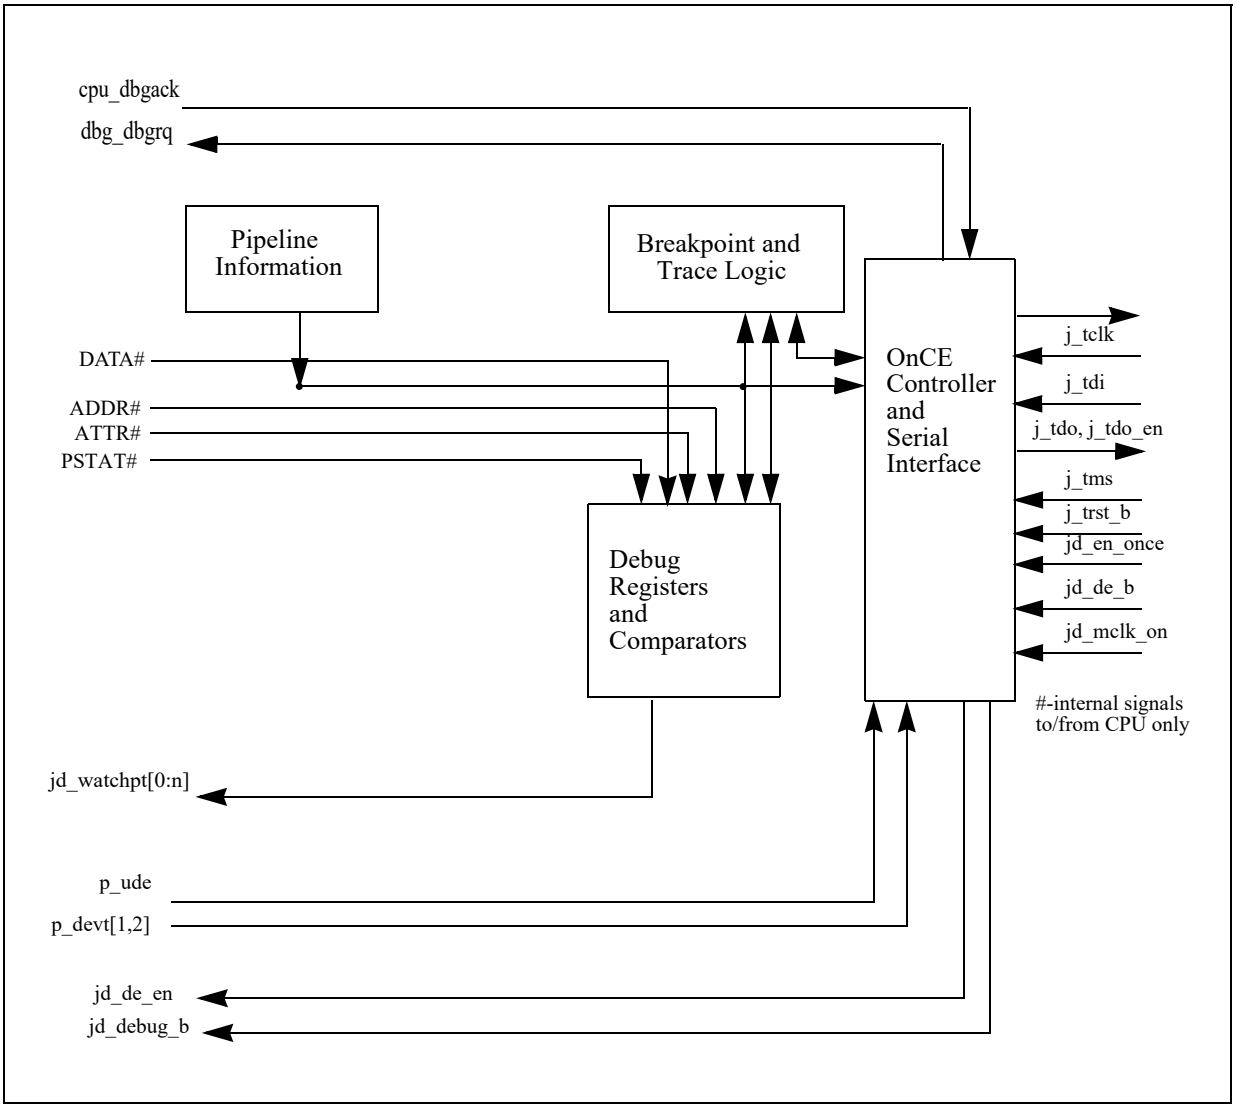
Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$ = 1, the control registers and resources described in *Section 53.3* are reserved for use by the external debugger. The same events described in *Section 53.2* are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by

the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

53.1.4 Sharing Debug Resources by Software/Hardware



Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$ = 1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$ = 1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$ = 1 and $EDBRAC0_{IDM}$ = 1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

53.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1097 shows the e200z420n3 debug resources.

Figure 1097. e200z420n3 Debug Resources

53.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$ = 1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE} = 0 and $DBCR0_{IDM}$ = 1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE} = 0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by <asisitalic>PowerISA 2.06:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z420n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in *Section 53.2.11*.
- The Performance Monitor Interrupt event PMI which is described in *Section 53.2.13*.

The e200z420n3 debug configuration supports most of these event types. Unsupported <asisitalic>PowerISA 2.06 defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

53.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

53.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the <asisitalic>PowerISA 2.06 definition, Data Address Compare events on e200z420n3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$ = 1, this circumstance can also occur when $EDBCR0_{EDM}$ = 1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, that is no data comparisons are performed since these instructions do not have associated data values.

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer which caused the DAC event.*

53.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions which are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 1057 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in *Table 1057*, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 1057. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b010. DSRR0 points to instruction after 3rd instruction. No ESR update.

Table 1057. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. In this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

Table 1057. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** In this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1058 through *Table 1061* show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 1058. DAC events and Resultant Updates, Dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** In this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1059. DAC events and Resultant Updates, Dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction (7). No ESR update. **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instruction (4). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. In this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b101. No ESR update. DSRR0 points to instruction (7). No debug event updates for instruction (7). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1060. DAC events and Resultant Updates, Dual-issue case 3

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1061. DAC events and Resultant Updates, Dual-issue case 4

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** In this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

53.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction which generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless

of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

53.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$ = 1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

53.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$ = 1) and execution is attempted of a branch instruction which will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE} = 1. Branch Taken debug events are not recognized if MSR_{DE} = 0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

53.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$ = 1), execution of any instruction is completed, and MSR_{DE} = 1. If execution of an instruction is suppressed due to the instruction causing some other exception which is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE} = 0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug

interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction which generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$ = 1, this circumstance can also occur when $EDBCR0_{EDM}$ = 1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction which sets MSR_{DE} to '1' while $DBCR0_{ICMP}$ = 1, nor by the execution of an instruction which sets $DBCR0_{ICMP}$ to '1' while MSR_{DE} = 1.

53.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$ = 1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

53.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$ = 1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

53.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$ = 1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE} = 0 at the time of the execution of the **se_rfi** (that is before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE} = 1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception which is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

53.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$ = 1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE} = 0 at the time of the execution of the **se_rfci** (that is before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE} = 1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception which is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

53.2.11 External Debug Event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$ = 1 or $DBCR0_{DEVT2}$ = 1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

53.2.12 Unconditional Debug Event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event which does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

53.2.13 Performance Monitor Interrupt Debug Event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$ = 1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

53.3 Debug Registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug Mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug

firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

53.3.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 1098*) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in *Figure 1099*) corresponds to byte offset 7, F, …. When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z420n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses which cross a 64-bit boundary cannot be fully matched. For address and size combinations which involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

53.3.2 Debug Control and Status Registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug Mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug Mode is enabled.

e200z420n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

53.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z420n3 adds some implementation specific bits to this register, as seen in *Figure 1100*.

1. $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

Figure 1100. Debug Control Register 0 Register (DBCR0)

Table 1062 provides bit definitions for Debug Control Register 0.

Table 1062. DBCR0 Field descriptions

Field	Description
0 EDM	External Debug Mode This bit is read-only by software. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset. Programming: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1 IDM	Internal Debug Mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE} = 1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.

Table 1062. DBCR0 Field descriptions (continued)

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.**

Figure 1101. Debug Control Register 1 (DBCR1)

Table 1063 provides bit definitions for Debug Control Register 1.

Table 1063. DBCR1 field descriptions

Field	Description
0:1 IAC1US	Instruction Address Compare 1 User/Supervisor Mode 00 IAC1 debug events not affected by MSR_{PR} 01 Reserved 10 IAC1 debug events can only occur if MSR_{PR} = 0 (Supervisor mode) 11 IAC1 debug events can only occur if MSR_{PR} = 1. (User mode)
2:3 IAC1ER	Instruction Address Compare 1 Effective/Real Mode 00 IAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC1 debug events are based on effective address and can only occur if MSR_{IS} = 0 11 IAC1 debug events are based on effective address and can only occur if MSR_{IS} = 1
4:5 IAC2US	Instruction Address Compare 2 User/Supervisor Mode 00 IAC2 debug events not affected by MSR_{PR} 01 Reserved 10 IAC2 debug events can only occur if MSR_{PR} = 0 (Supervisor mode) 11 IAC2 debug events can only occur if MSR_{PR} = 1. (User mode)
6:7 IAC2ER	Instruction Address Compare 2 Effective/Real Mode 00 IAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC2 debug events are based on effective address and can only occur if MSR_{IS} = 0 11 IAC2 debug events are based on effective address and can only occur if MSR_{IS} = 1
8:9 IAC12M	Instruction Address Compare 1/2 Mode 00 Exact address compare. IAC1 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC1. IAC2 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC2. 01 Address bit match. IAC1 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC2 are equal to the contents of IAC1, also ANDed with the contents of IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used. 10 Inclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC1 and less than the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used. 11 Exclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC1 or is greater than or equal to the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used.
16:17 IAC3US	Instruction Address Compare 3 User/Supervisor Mode 00 IAC3 debug events not affected by MSR_{PR} 01 Reserved 10 IAC3 debug events can only occur if MSR_{PR} = 0 (Supervisor mode) 11 IAC3 debug events can only occur if MSR_{PR} = 1 (User mode)
18:19 IAC3ER	Instruction Address Compare 3 Effective/Real Mode 00 IAC3 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC3 debug events are based on effective address and can only occur if MSR_{IS} = 0 11 IAC3 debug events are based on effective address and can only occur if MSR_{IS} = 1

Table 1063. DBCR1 field descriptions (continued)

Field	Description
20:21 IAC4US	Instruction Address Compare 4 User/Supervisor Mode 00 IAC4 debug events not affected by MSR_{PR} 01 Reserved 10 IAC4 debug events can only occur if MSR_{PR} = 0 (Supervisor mode). 11 IAC4 debug events can only occur if MSR_{PR} = 1. (User mode)
22:23 IAC4ER	Instruction Address Compare 4 Effective/Real Mode 00 IAC4 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC4 debug events are based on effective address and can only occur if MSR_{IS} = 0 11 IAC4 debug events are based on effective address and can only occur if MSR_{IS} = 1
24:25 IAC34M	Instruction Address Compare 3/4 Mode 00 Exact address compare. IAC3 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC3. IAC4 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC4. 01 Address bit match. IAC3 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC4 are equal to the contents of IAC3, also ANDed with the contents of IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 10 Inclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.

53.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in *Figure 1102*.

Offset: Refer to SPR - 310 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Figure 1102. Debug Control Register 2 (DBCR2)

Table 1064 provides bit definitions for Debug Control Register 2.

Table 1064. DBCR2 field descriptions

Field	Description
0:1 DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR} = 0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR} = 1 (User mode)
2:3 DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS} = 0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS} = 1
4:5 DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR} = 0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR} = 1. (User mode)
6:7 DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS} = 0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS} = 1
8:9 DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10 DAC1LNK	Data Address Compare 1 Linked 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.

Table 1064. DBCR2 field descriptions (continued)

Field	Description
11 DAC2LNK	Data Address Compare 2 Linked 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM.
12:13 DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$ = 0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$ = 1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved Inactive byte lanes of the memory access are automatically masked.

Table 1064. DBCR2 field descriptions (continued)

Field	Description
14:15 DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$ = 0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$ = 1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved Inactive byte lanes of the memory access are automatically masked.

Table 1064. DBCR2 field descriptions (continued)

Field	Description
16:23 DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses which cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31 24:31 DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses which cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

53.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 1103*.

Offset: Refer to SPR - 563 Access: Read/Write

1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Figure 1103. 32-bit register (REG NAME)

Table 1065 provides bit definitions for Debug Control Register 4.

Table 1065. DBCR4 Field descriptions

Field	Description
1 DVC1C	Data Value Compare 1 Control 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition.
3 DVC2C	Data Value Compare 2 Control 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition.
13 DAC1XMH	Data Address Compare 1 Extended Mask Control High 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits DAC1XMH extends the range of the DAC1XM field.
15 DAC2XMH	Data Address Compare 2 Extended Mask Control High 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits DAC2XMH extends the range of the DAC2XM field.

Table 1065. DBCR4 Field descriptions (continued)

Field	Description
16:19 DAC1XM	Data Address Compare 1 Extended Mask Control Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported ... 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2.
20:23 DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported ... 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1065. DBCR4 Field descriptions (continued)

Field	Description
24:27 DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$ = 00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$ = 00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$ = 00 0011 Reserved … 0111 Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 Reserved … 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$ = 0; when $DBCR0_{DAC1}$!= 00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31 DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$ = 00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$ = 00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$ = 00 0011 Reserved … 1111 Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$ = 00. When $DBCR0_{DAC2}$!= 00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

53.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 1104*

Offset: Refer to SPR - 564 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1069. DBCR8 Field descriptions (continued)

Field	Description
8:9 DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used
10 DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11 DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.

53.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$ = 1). When debug interrupts are enabled (MSR_{DE} = 1 $DBCR0_{IDM}$ = 1 and $EDBCR0_{EDM}$ = 0, or MSR_{DE} = 1, $DBCR0_{IDM}$ = 1, $EDBCR0_{EDM}$ = 1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$ = 1 and $EDBRAC0_{IDM}$ = 1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 1108*.

Figure 1108. Debug Status Register (DBSR)

Table 1070 provides bit definitions for the Debug Status Register.

Table 1070. DBSR field descriptions

Field	Description
0 IDE	Imprecise Debug Event Set to 1 if MSR_{DE} = 0 and $DBCR0_{IDM}$ = 1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1 UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2 MRR	Most Recent Reset 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
3 ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
4 BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6 IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7 TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8 IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
12 DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred

Table 1070. DBSR field descriptions (continued)

Field	Description
13 DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
15 DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16 RET	Return Debug Event Set to 1 if a Return debug event occurred
21 21 DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22 DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23 PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$ = 1
24 MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25 CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26 CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27 VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:31 DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.

53.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 1109*.

Figure 1109. Debug Data Effective Address Register (DDEAR)

53.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$ = 1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$ = 0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$ = 1 update DBSR, causing debug interrupts to occur if MSR_{DE} = 1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE} = 1 $DBCR0_{IDM}$ = 1 and $EDBCR0_{EDM}$ = 0, or MSR_{DE} = 1, $DBCR0_{IDM}$ = 1 and $EDBCR0_{EDM}$ = 1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$ = 1). When $EDBCR0_{EDM}$ = 1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$ = 1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0 CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control

and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in *Figure 1110*.

Table 1071. EDBRAC0 register field descriptions (continued)

Field	Description
18 IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields 1 Event owned by software debug. IAC6 control fields are software readable/writable
19 IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields 1 Event owned by software debug. IAC7 control fields are software readable/writable
20 IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields 1 Event owned by software debug. IAC8 control are software readable/writable
21 DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable
22 DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable
23 PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable **Note:** This bit is reset to ‘1’.
24 MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to ‘1’ or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG = 1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted) 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable **Note:** This bit is reset to ‘1’.
25 CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable
26 CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable

Table 1071. EDBRAC0 register field descriptions (continued)

Field	Description
27 DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$ = 1 and MSR_{DE} = 1) or a nop ($DBCR0_{IDM}$ = 0 or MSR_{DE} = 0) **Note:** DNI events are not blocked during a debug session
28 DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register

Table 1072 shows which resources are controlled by EDBRAC0 settings.

1	(1) -	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	1	$DEVENT_{DQTAG}$, DDAM

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$ = 1. Only software-owned bits or fields as shown in *Table 1072* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

53.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z420n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 1111*.

Offset: Refer to SPR - 975 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0								DEVNT							
W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.** Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

Figure 1111. Debug Event Select Register (DEVENT)

Table 1073 provides bit definitions for the Debug Event Register.

Table 1073. DEVENT field descriptions

Field	Description
0:7 DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	Reserved, should be cleared.

53.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the “Data Acquisition Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 1112*.

Offset: Refer to SPR - 576 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DDAM[0:15]															
W

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Figure 1112. Debug Data Acquisition Message Register (DDAM)

Table 1074 provides bit definitions for the Debug Data Acquisition Message Register.

Table 1074. DDAM field descriptions

Field	Description
0:31 DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

53.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources

configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 1065*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, that is after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode

accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 1065* and *Table 1068* in *Section 53.3.2*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

53.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 53.2* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

*It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$ = 1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously*

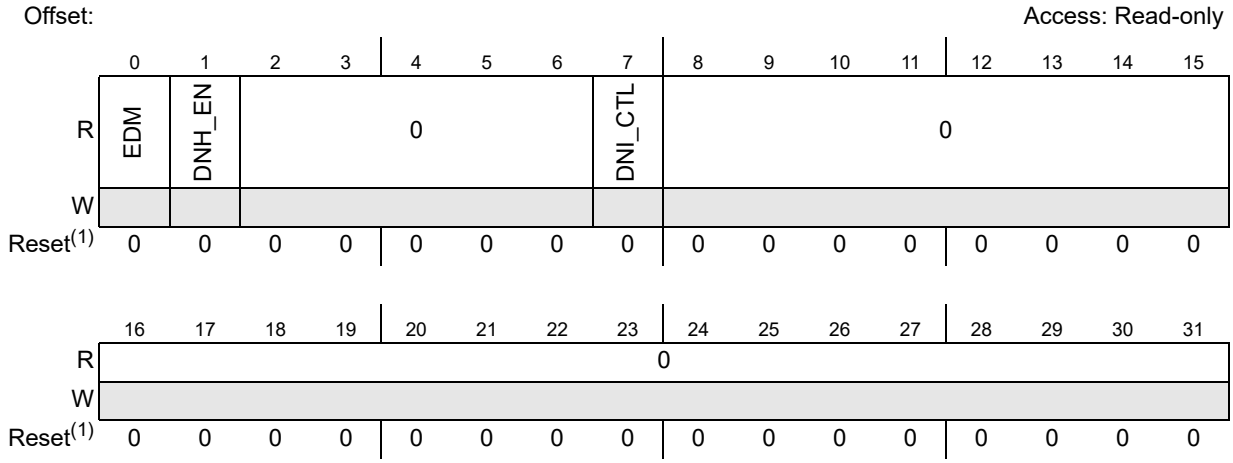
*set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

53.5.1 External Debug Registers



The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

53.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 1113*.

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Figure 1113. External Debug Control Register 0 (EDBCR0)

Table 1075 provides bit definitions for External Debug Control Register 0.

Table 1075. EDBCR0 field descriptions

Field	Description
0 EDM	External Debug Mode. This bit is also reflected in DBCR0 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1 DNH_EN	**dnh** Instruction Enable 0 execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
7 DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE} = 0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM = 1

53.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and

cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 1114*.

Offset: Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RET	0				DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST			0
W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$ = 0.

Figure 1114. External Debug Status Register 0 (EDBSR0)

Table 1076 provides bit definitions for External Debug Status Register 0.

Table 1076. EDBSR0 field descriptions

Field	Description
0 IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$ = 1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1 UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2 DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
4 ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5 BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6 IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7 TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8 IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.

Table 1076. EDBSR0 field descriptions (continued)

Field	Description
12 DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13 DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
15 DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16 RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
21 DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22 DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23 PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$ = 0 regardless of the setting of $PMGC0_{UDI}$
24 MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25 CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26 CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27 VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:31 DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.

53.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 1115*.

Offset: Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0			DACR	DACW	0	DNI
W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

22 DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23 PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24 MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25 CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26 CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$

53.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 1116*.

Offset: Access: Read/Write

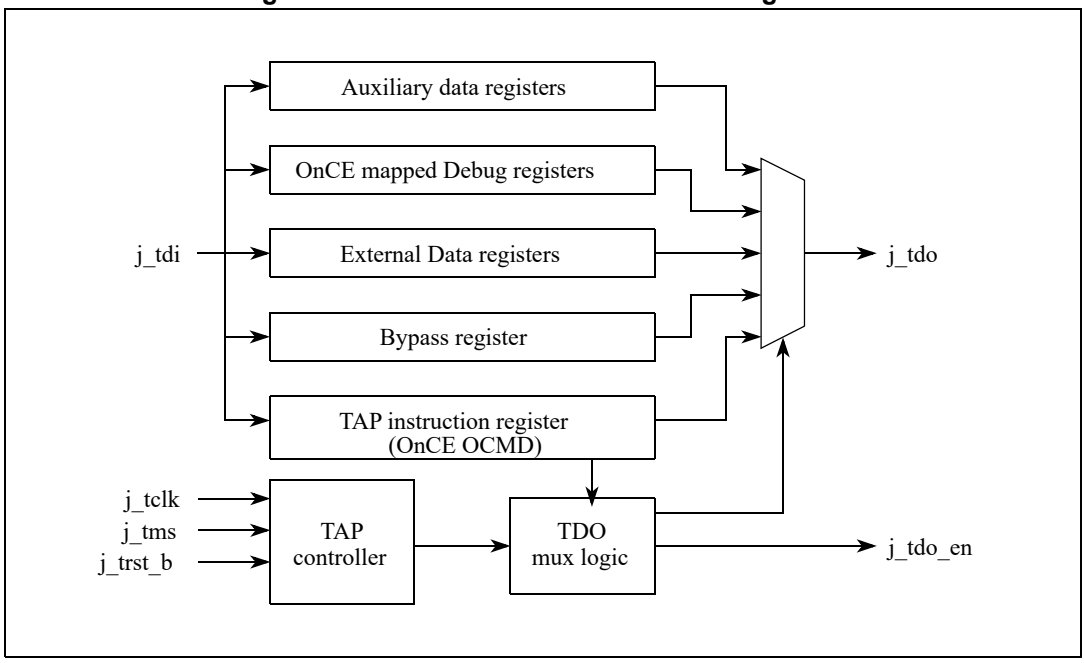
Figure 1116. External Debug Data Effective Address Register (EDDEAR)

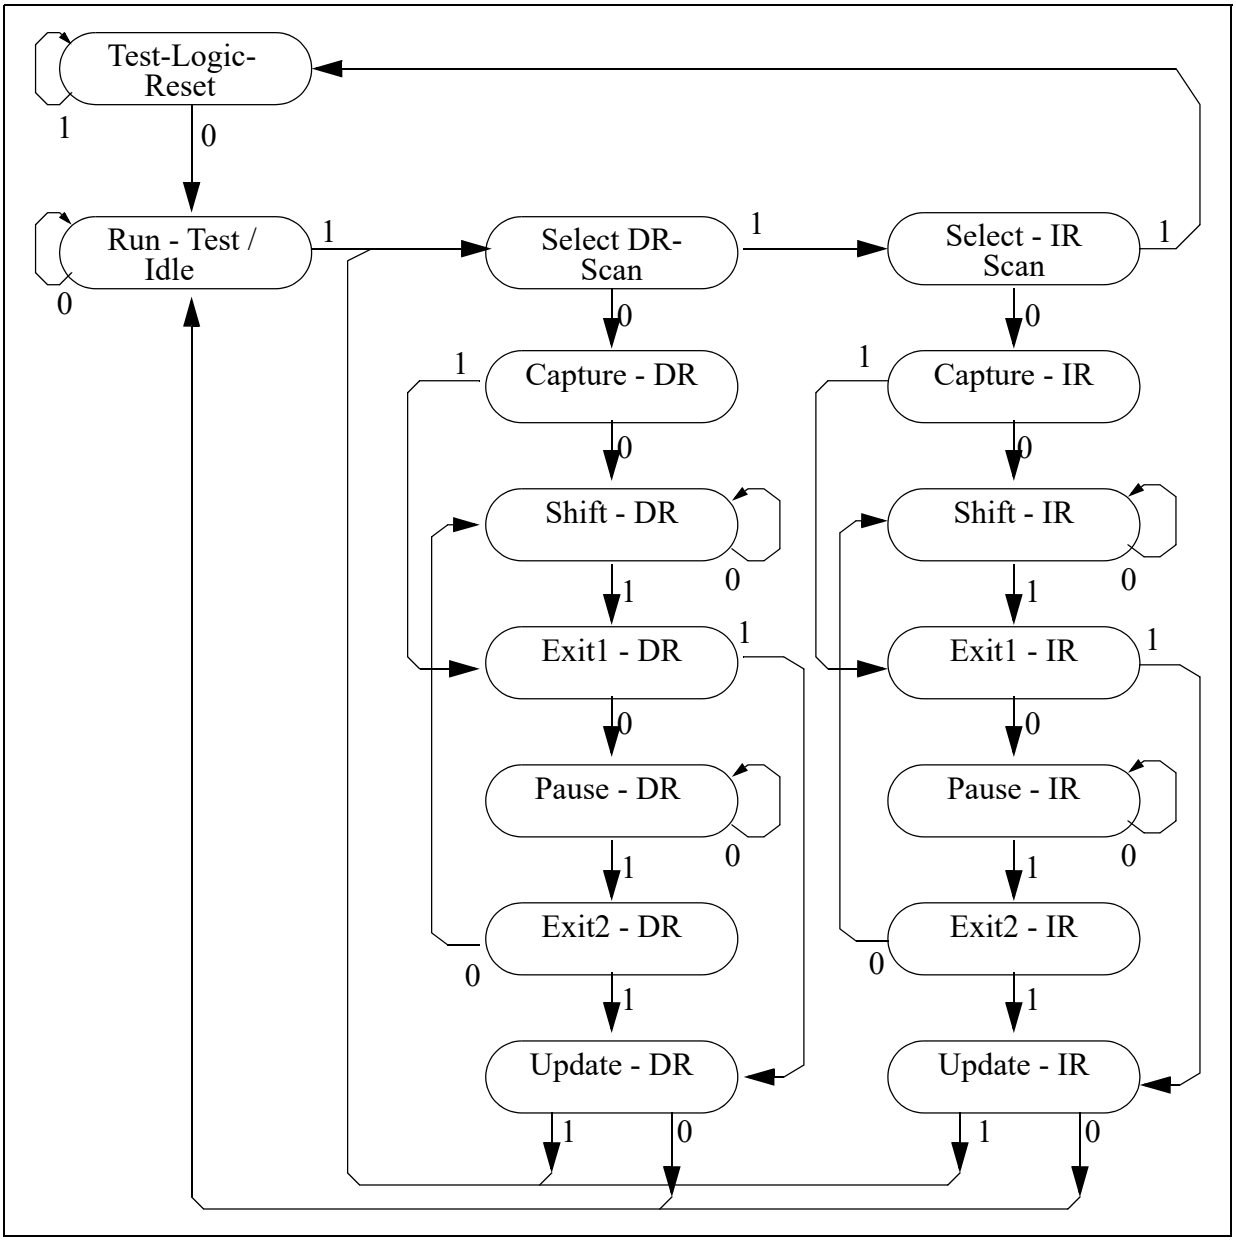
53.5.2 OnCE Introduction



The e200z420n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z420n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.



The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1117. OnCE TAP Controller and Registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1118. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 53.5.6.1*) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in

the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See *Section 53.5.6.2*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

53.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to exit the low power mode enabled by the setting of MSR_{WE}, as well as temporarily exiting the Waiting, Stopped or Halted power management states.

Table 1078 details the primary JTAG/OnCE interface signals.

Table 1078. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en(1)	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z420n3) Core Complex Overview.

53.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

53.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

53.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

53.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

53.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

53.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus Controller and external blocks which may need information pertaining to debug operation.

53.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

53.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z420n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

53.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See *Section 53.5.6.2* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

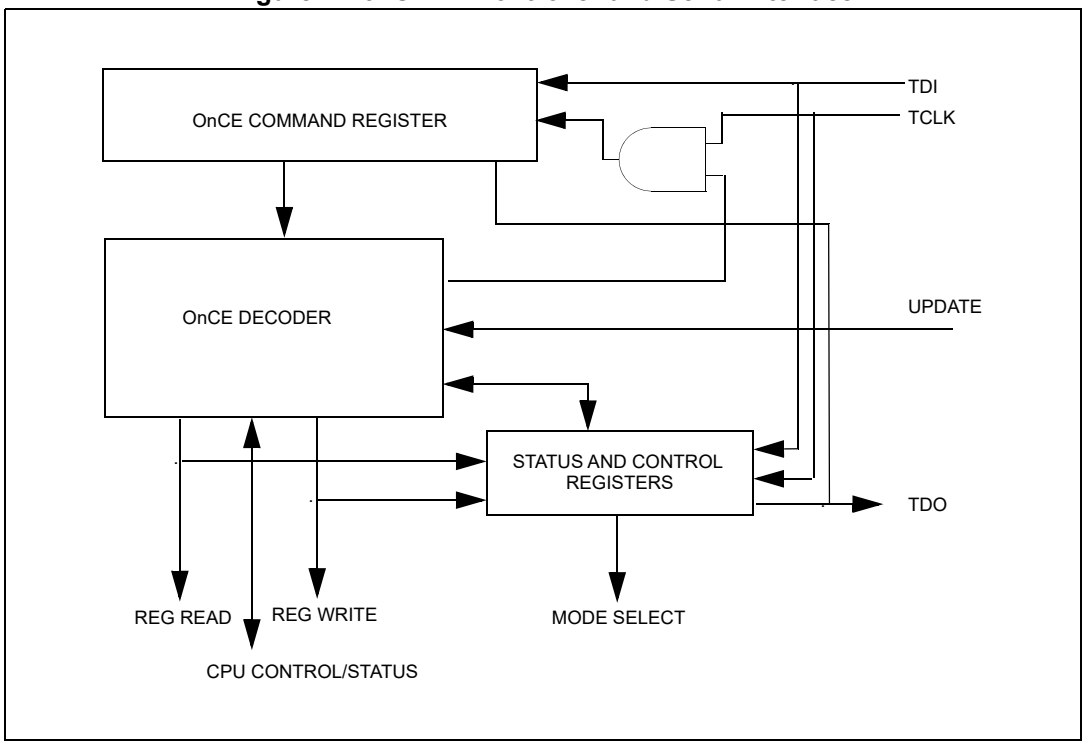
53.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z420n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

53.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 1084* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

53.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)



This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

53.5.6 OnCE Controller and Serial Interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 1119* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

Figure 1119. OnCE Controller and Serial Interface

53.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

Figure 1120. OnCE Status Register

Table 1079 provides bit definitions for the Once Status Register.

Table 1079. OnCE Status Register field descriptions

Field	Description
0 MCLK	**m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1 ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage and Alignment, Program) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3 RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4 HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5 STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6 DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7 WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8 0	Reserved, set to 0 for 1149.1 compliance
9 1	Reserved, set to 1 for 1149.1 compliance

53.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 1121*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields

for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Figure 1121. OnCE Command Register (OCMD)

Table 1080 provides bit definitions for the Once Command Register.

Table 1080. OnCE Command Register field descriptions

Field	Description
0 R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W = 1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1 GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 53.5.9.6*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1080. OnCE Command Register field descriptions (continued)

Field	Description
2 EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$ = 1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 53.5.9.6*.
3:9 RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 1081* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 1081 indicates the OnCE register addresses.

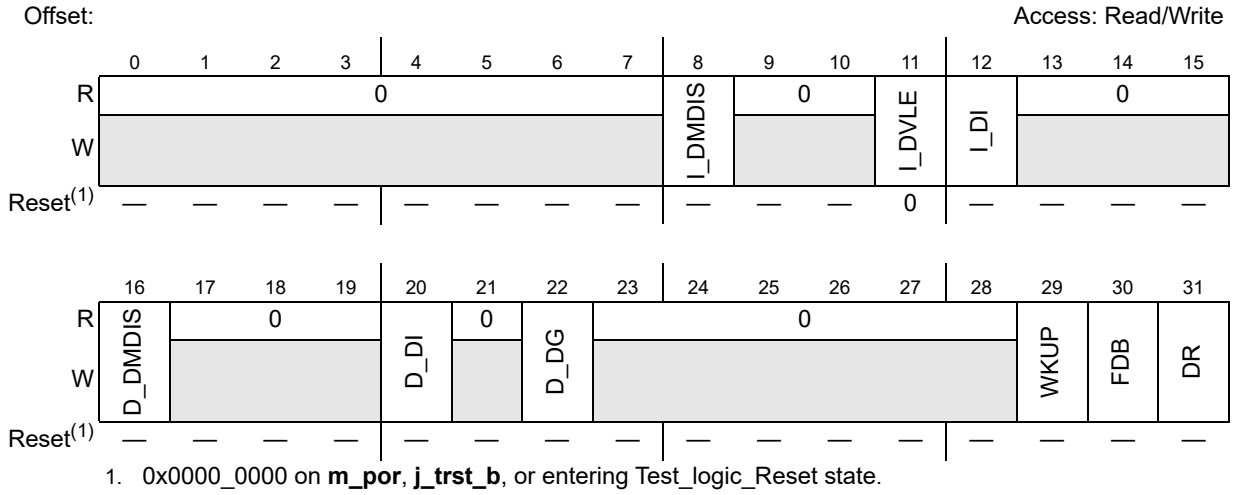
1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.



Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (such as interrupts, machine checks, bus error conditions) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

53.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z420n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see *Section 53.7*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 1122*.

1. 0x0000_0000 on **m_por**, **j_trst_b**, or entering Test_logic_Reset state.

Figure 1122. OnCE Control Register (OCR)

Table 1082 provides bit definitions for the OnCE Control Register.

Table 1082. OnCE Control Register Field descriptions

Field	Description
8 I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG = 1 are not affected by this control bit.
11 I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit (I_DVLE) This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12 I_DI	Instruction Side Debug ‘I’ Attribute Bit (I_DI) This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
16 D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG = 1 are not affected by this control bit.

Table 1082. OnCE Control Register Field descriptions (continued)

Field	Description
20 D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
22 D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
29 WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30 FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31 DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 No Debug Mode request 1 Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

53.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z420n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z420n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z420n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (such as DBSR) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the

contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 1083 provides a list of access requirements for OnCE registers.

Table 1083. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access

Table 1083. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
External GPRs	Y	N	N	N	N	—
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

53.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See *Section 53.5.5.1*.

53.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z420n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z420n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

53.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

53.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

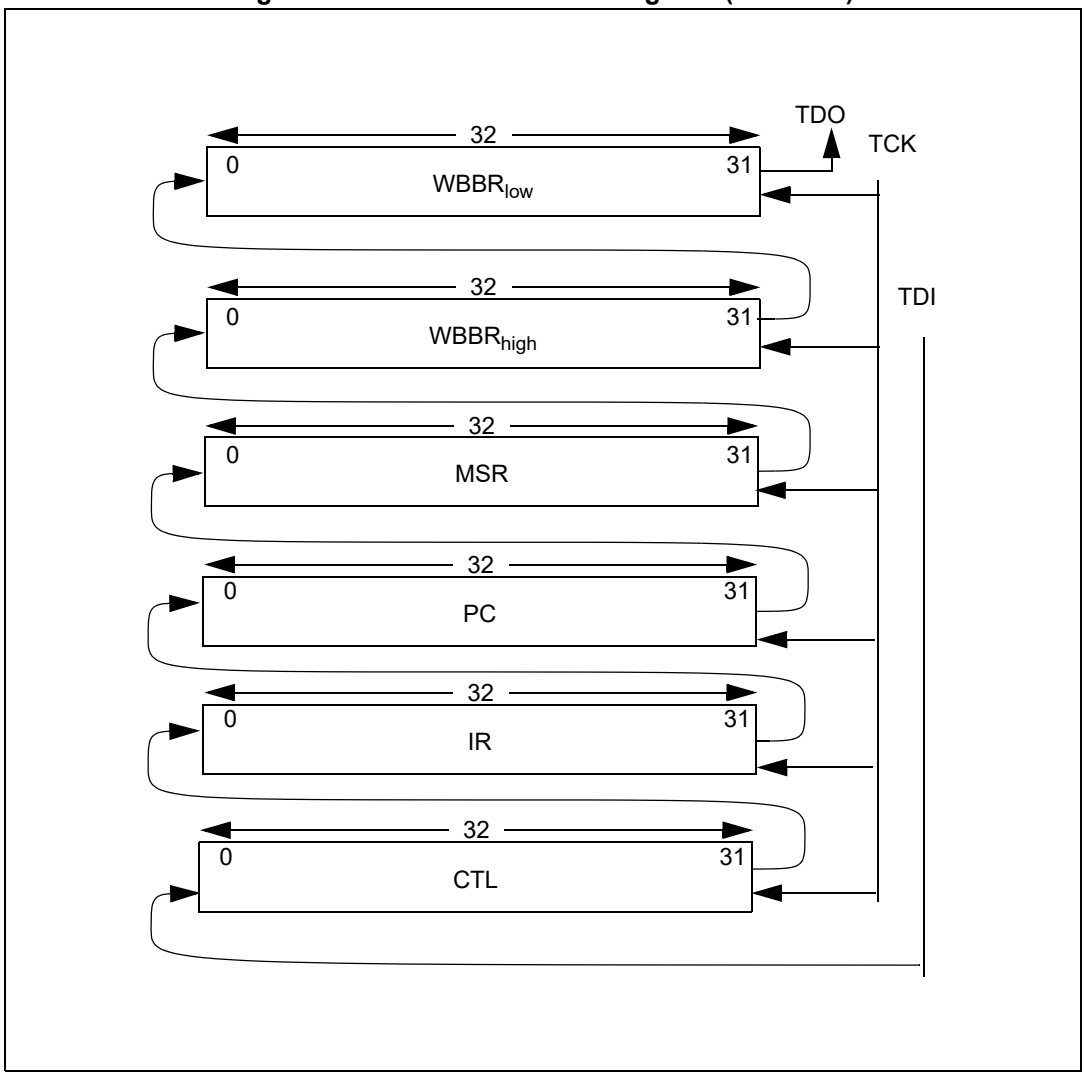
53.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

53.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z420n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$ = 1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.



53.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z420n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

53.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 1123* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1123. CPU Scan Chain Register (CPUSCR)

53.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

53.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

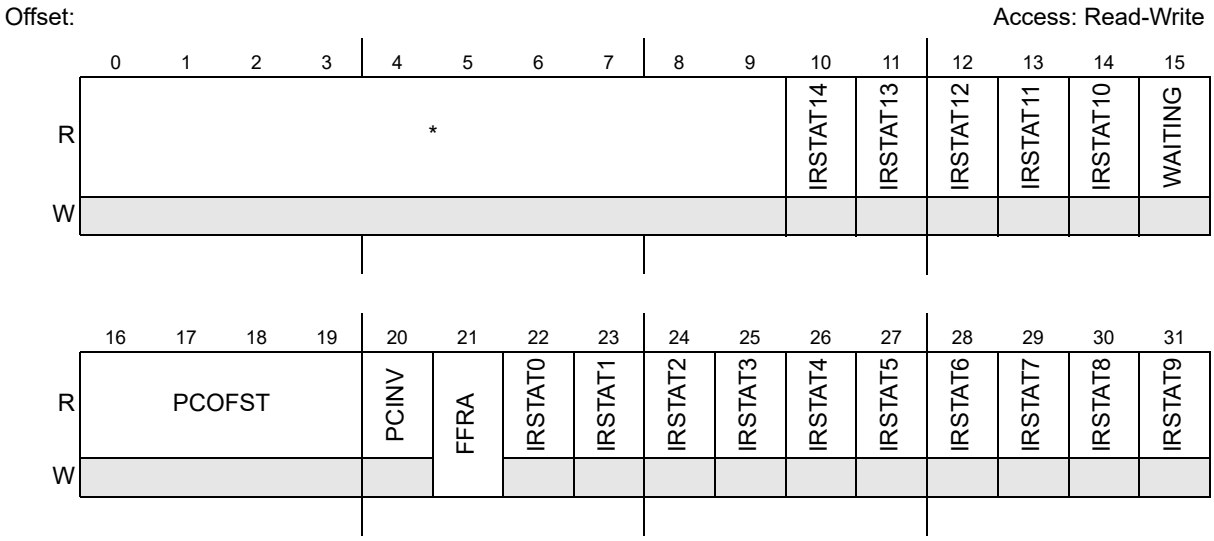


Figure 1124. Control State Register (CTL)

53.5.9.2.1 WAITING: WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0 CPU was not in the waiting state when debug mode was entered

1 CPU was in the waiting state when debug mode was entered

53.5.9.2.2 PCOFST: PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead

of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 No correction required.

0001 Subtract 0x04 from PC.

0010 Subtract 0x08 from PC.

0011 Subtract 0x0C from PC.

0100 Subtract 0x10 from PC.

0101 Subtract 0x14 from PC.

all other encodings are reserved

53.5.9.2.3 *: Internal State Bits

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, that is when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See *Section 53.5.5.3*, which is not part of the normal program execution flow, these bits should be set to a 0.

53.5.9.2.4 PCINV: PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0 No error condition exists.

1 Error condition exists. PC and IR are corrupted.

53.5.9.2.5 FFRA: Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{low}$ to be used as the RA operand value (RS for logical, **mtspr**, **mtdcr**, **cntlzw**, and shift operations, RX for VLE **se_** instructions, RT for **e_{logical_op}2i** type instructions, RB for **evaddiw**, **evsubifw**, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{low}$ with the desired value, set the FFRA bit, and execute an **ori** Rx,Rx,0 instruction to the desired register.

*Note: Not all instructions support using the FFRA control. FFRA is mainly intended for use with the **ori** instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.*

0 No action.

1 Content of $WBBR_{low}$ used as operand value

53.5.9.2.6 IRStat0: IR Status Bit 0

This control bit indicates a TEA status for the IR.

0 No TEA occurred on the fetch of this instruction.

1 TEA occurred on the fetch of this instruction.

53.5.9.2.7 IRStat1: IR Status Bit 1

This control bit is reserved.

53.5.9.2.8 IRStat2: IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0 No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.

53.5.9.2.9 IRStat3: IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0 No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.

53.5.9.2.10 IRStat4: IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0 No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.

53.5.9.2.11 IRStat5: IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

0 No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.

53.5.9.2.12 IRStat6: IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0 No Parity Error occurred on the fetch of this instruction.

1 Parity Error occurred on the fetch of this instruction from the ICache or the IMEM.

53.5.9.2.13 IRStat7: IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0 No Precise External Termination Error occurred on the fetch of this instruction.

1 A Precise External Termination Error occurred on the fetch of this instruction.

53.5.9.2.14 IRStat8: IR Status Bit 8

This control bit indicates the PowerISA VLE status for the IR.

0 IR contains a BookE instruction. (unused encoding)

1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

– This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (= 1).

53.5.9.2.15 IRStat9: IR Status Bit 9

This control bit is reserved.

53.5.9.2.16 IRStat10: IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0 No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.

53.5.9.2.17 IRStat11: IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0 No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.

53.5.9.2.18 IRStat12: IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0 No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.

53.5.9.2.19 IRStat13: IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0 No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.

53.5.9.2.20 IRStat14: IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0 No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to ‘0’, and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction

present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

53.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

53.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 53.5.9.2* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

53.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

53.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

53.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

53.6 Watchpoint Support

e200z420n3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$ = 1) or in external debug mode ($EDBCR0_{EDM}$ = 1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes. (See the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1084 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1084. Watchpoint Output Signal Assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]

Table 1084. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a ‘0’ to a ‘1’ while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status

Table 1084. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

53.7 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (*Section 53.5.6.3* for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 53.5.6.3* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

53.8 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

53.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set
- Clear the DBSR status bits
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 53.5.9.2*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred

To return the CPU to normal operation (without disabling external debug mode):

- The OCR_{DR}, control bit should be cleared, leaving the OCR_{WKUP} bit set
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 53.5.9.2*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

To exit External Debug Mode:

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit
- The debugger should write the DBSR to a cleared state
- The debugger should re-write the DBCR0 with all bits including EDM cleared
- The debugger should clear the OCR_{DR} bit
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 53.5.9.2*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

54 Debug and Calibration Interface (DCI)

54.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

54.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

54.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using software debug mode.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

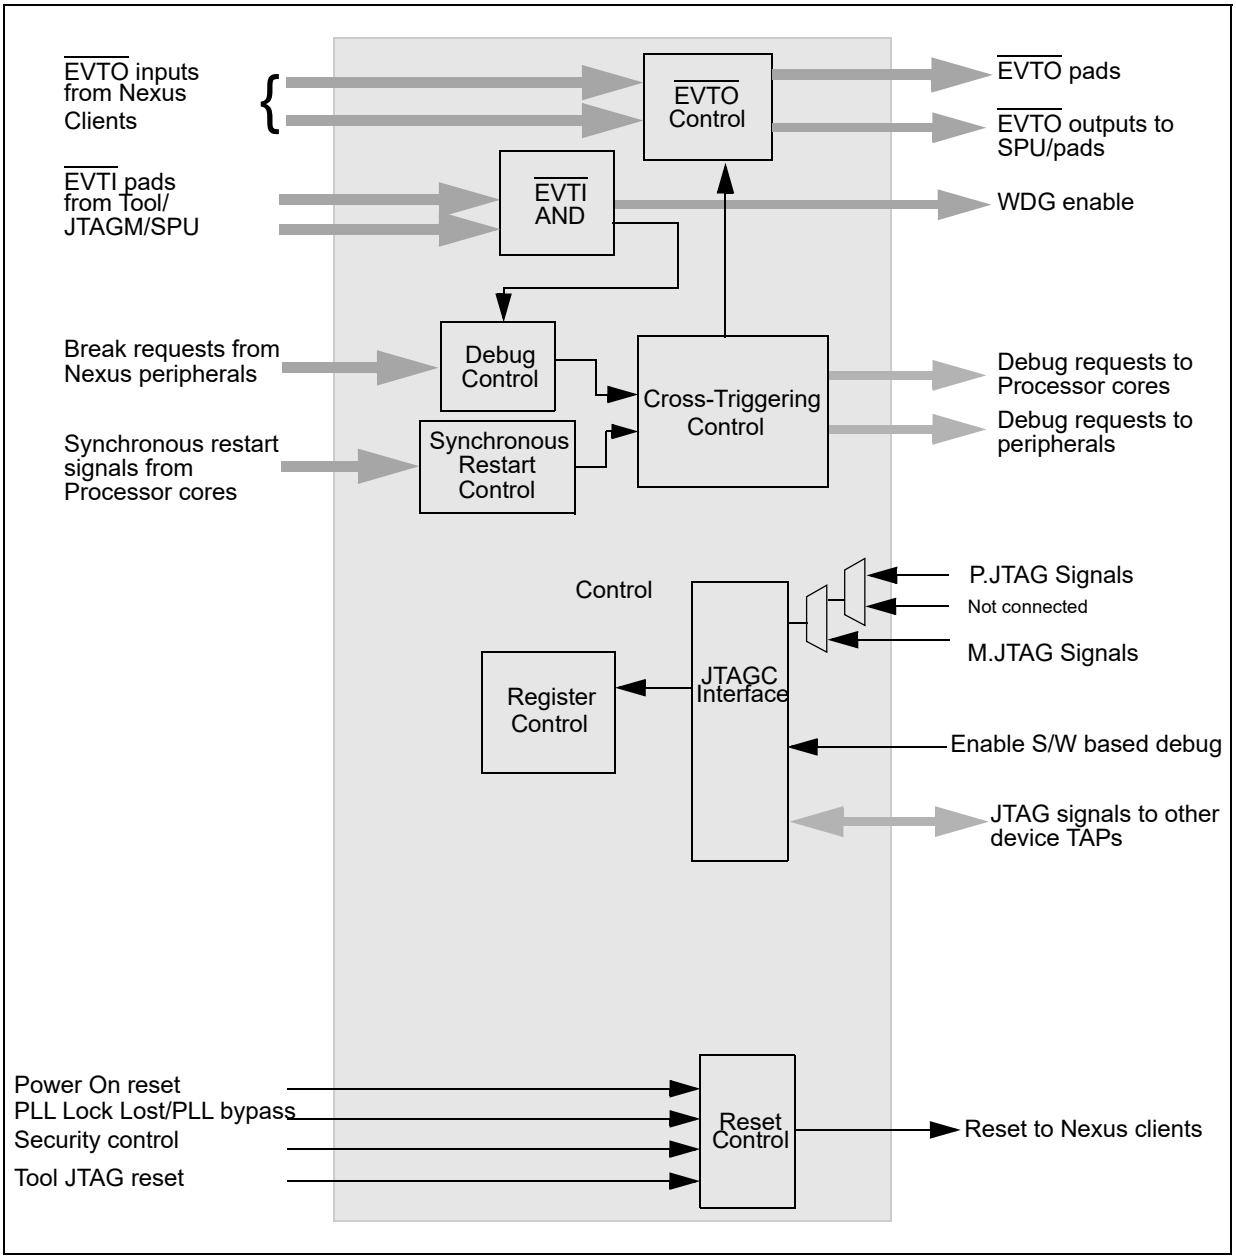
By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as SPU. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signal to the debug tool in case of the occurrence of any internal debug event.

Figure 1125 shows the DCI block diagram.

Figure 1125. DCI block diagram



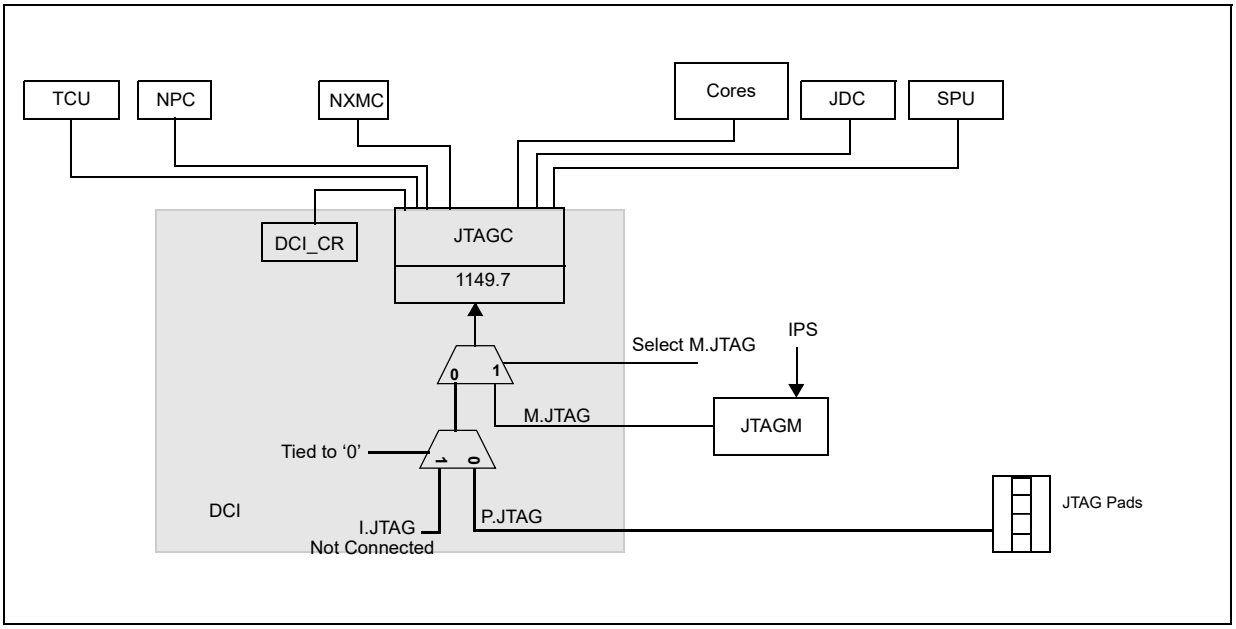


Figure 1126 shows the DCI configuration for the standard production package.

Figure 1126. DCI in a standard configuration

54.1.3 Operating modes

Selection between various JTAG sources is done using a JTAGM register bit, JTAGM_MCR[DTM]. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when JTAGM_MCR[DTM] is set.

Table 1085 shows a summary of the configuration options.

Table 1085. DCI JTAG source selection

JTAGM_MCR[DTM]	DCI Source	JCOMP
0	P.JTAG (Standard JTAG)	Asserted
1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1086 contains the operating mode descriptions.

Table 1086. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.

54.1.3.1 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool , it is possible to generate JTAG sequences through software programming using JTAGM IP.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

54.1.3.2 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug

functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1087. Nexus reset truth table

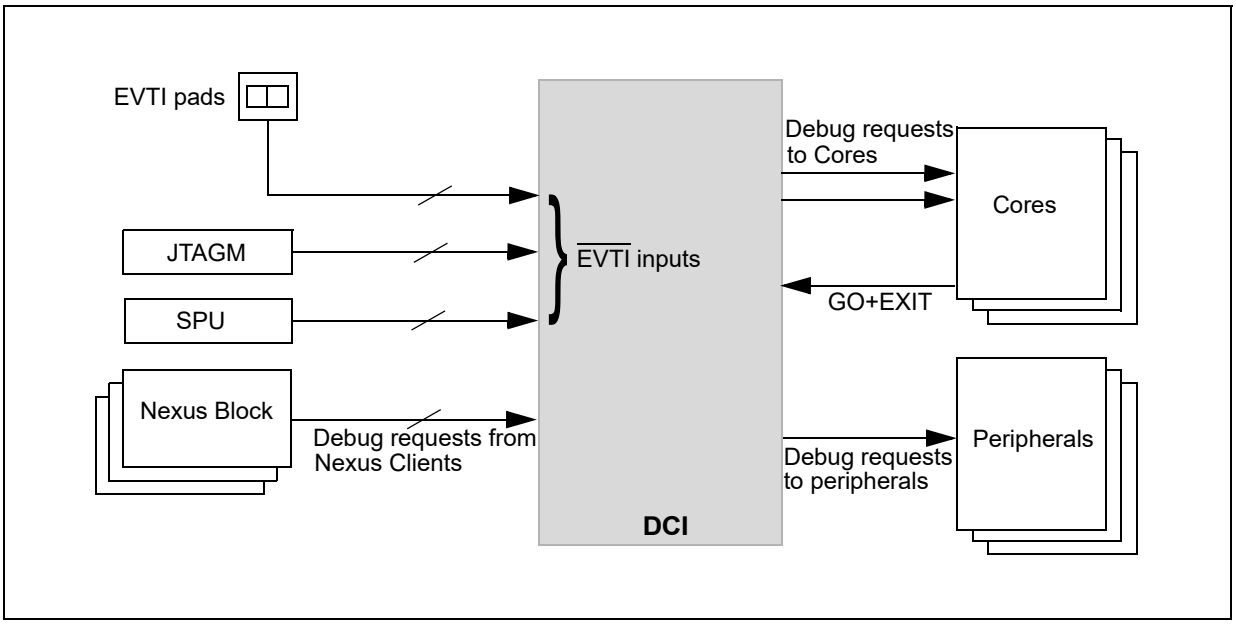
POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

54.1.3.3 System watchdog control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the EVTI[0] pin is used. If the EVTI[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the EVTI[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the EVTI[0] pin.

54.1.3.4 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as DMA, Watchdog and other peripherals.



There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[0] signal from EVTI pad
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

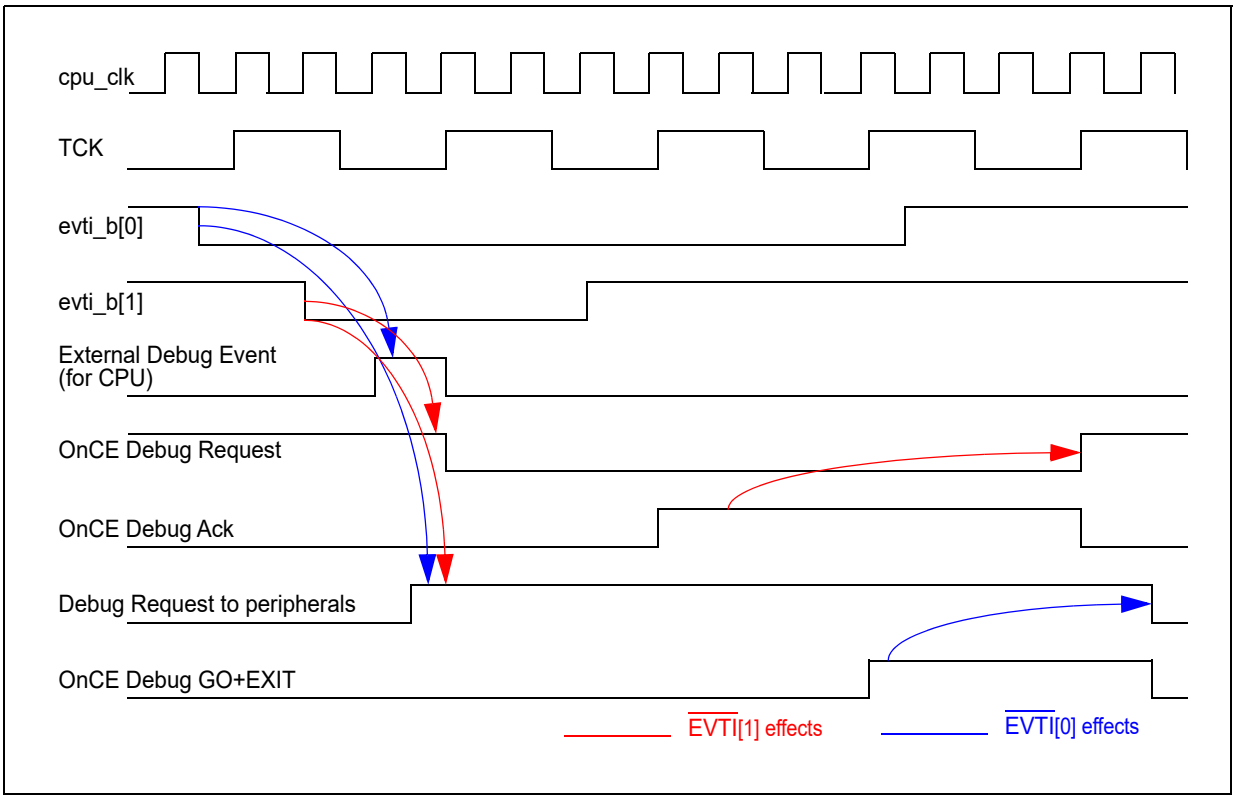
The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1127. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$ inputs are synchronized and logically ANDed in the DCI to generate the following:

- Debug requests for each processor core
- External debug requests for each processor core
- Debug request for all non-CPU peripherals



The $\overline{\text{EVTI}}$[0] from the EVTI pads, SPU and JTAGM are used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The $\overline{\text{EVTI}}$[1] from the SPU and JTAGM, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The $\overline{\text{EVTI}}$[0] signal coming from the pad is enabled for debug control using DCI_CR[4] bit.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 1128 shows the timing sequence.

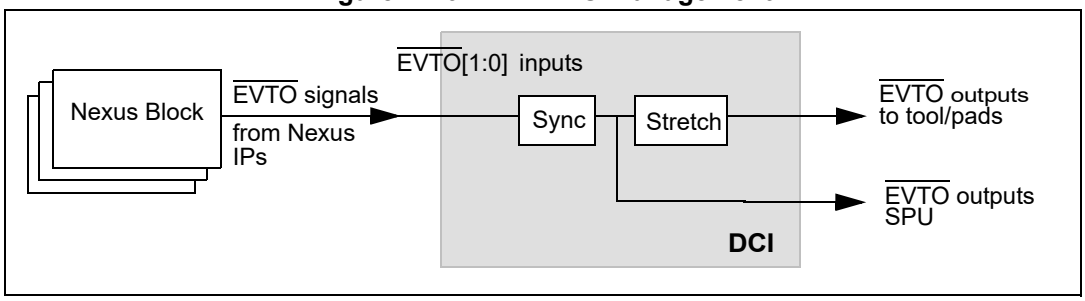
Figure 1128. DCI debug signal generation

54.1.3.5 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

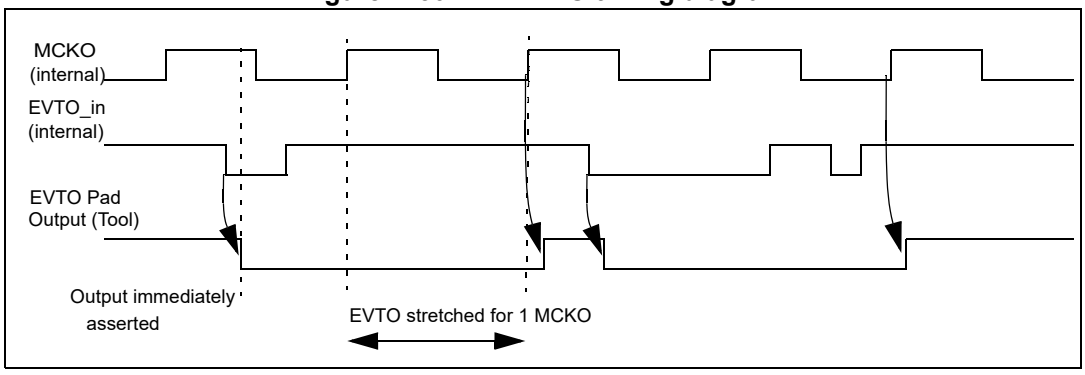
54.1.3.6 Synchronous restart control



The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (that is set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

54.1.3.7 EVTO management



The EVTO management block diagram is presented in *Figure 1129*.

Figure 1129. DCI EVTO management

The DCI module controls distribution of the EVTO output from all Nexus Clients including the cores that produce EVTO[0] signals. The DCI uses a high frequency clock to sample EVTO signal coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[0] signals from any Nexus client, the DCI immediately asserts EVTO[0] outputs and stretches it for a minimum of one output clock period for the output to the tool(*Figure 1130*). The DCI also generates EVTO output in other device clock domains so that other Nexus clients can receive EVTO input without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

Figure 1130. DCI EVTO timing diagram

54.1.3.8 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset

control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

54.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

54.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

54.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 1131* shows the format of the DCI_CR.

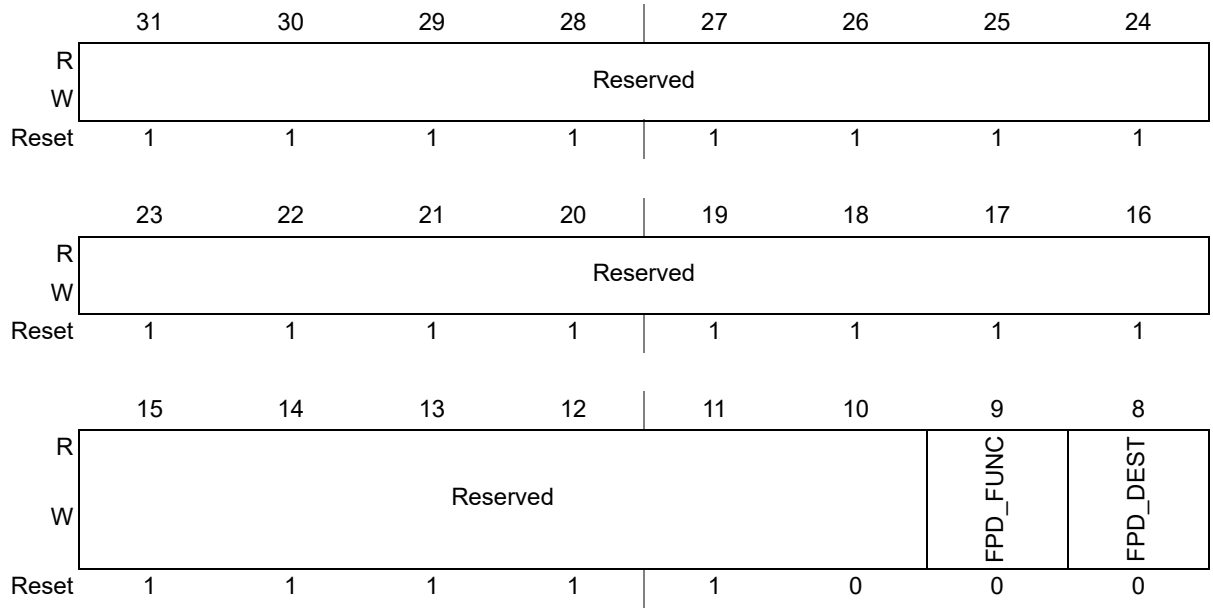


Figure 1131. DCI control register (DCI_CR)

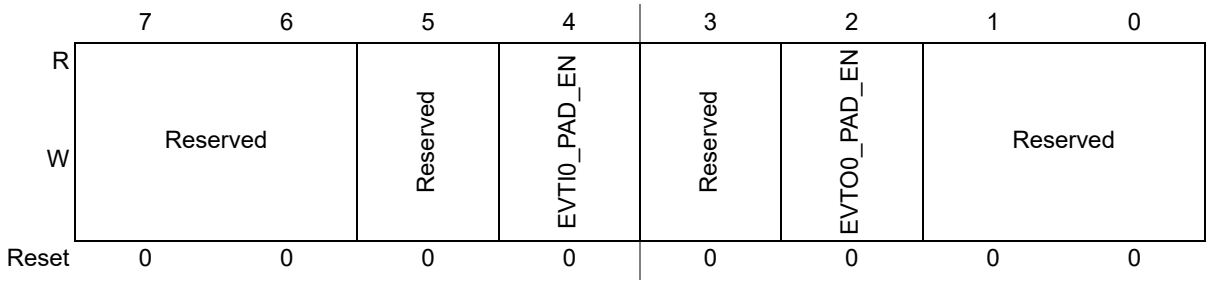

Figure 1131. DCI control register (DCI_CR) (continued)

The DCI_CR is described in *Table 1088*.

Table 1088. DCI_CR field descriptions

Field	Description
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
4 EVTI0_PAD_EN	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled

54.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 64-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter, ENABLE_DATA2. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter (or the Debug and Trace chapter) which describes how the modules are configured.

55 Debug and Trace

55.1 Introduction

55.1.1 Features

SPC574Sx includes comprehensive features to assist in the software development process:

- Supports Nexus class 3 debug and trace
- Supports memory reconstruction[r]
- Supports data tracing without loss of data
- Supports CPU controlled dump via the trace port and NXMC clients
- All bus masters are traceable
- Device CPU instruction/data trace captured using the CPU's own Nexus 3 module
- Device Flexray trace captured using a dedicated NXMC Nexus trace client
- Device DMA trace captured using a dedicated NXMC Nexus trace client
- Debug mode enable control for connected tool or software
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for CPU when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

Internal debug support in the e200z420n3 and e200z419n3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes.

The e200z420n3 and e200z419n3 Nexus 3 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

r. For the instrumentation use case, external reconstruction of the internal RAM content is required.

55.1.2 Architecture

The top level debug and trace architecture is shown in *Figure 1132*. It comprises the following modules:

- Debug Control Interface (DCI)
- JTAG Master (JTAGM)
- 2 Nexus Crossbar Multimaster Trace Clients (NXMC)
- Nexus Port Controller (NPC)
- Sequence Processing Unit (SPU)
- JTAG Data Communication Module (JDC)

The CPUs themselves provide the Nexus 3 module and the OnCE module. *Figure 1132* shows the interconnections between the debug and trace modules. The JTAG port pins are shared between different modules. The DCI block acts as a port sharing controller among the Nexus class 1 (JTAG) features, the JDC (JTAG to SW interface), and the JTAGM block (JTAG control via SW). The Multi-Nexus architecture ends up to the NPC (Nexus Port Controller) module, which arbitrates the various Nexus tracing requests coming from different Nexus clients. The Nexus scheme includes the possibility to trace the CPU data and instructions and the DMA accesses. Two additional Nexus clients (NXMC0 and NXMC1) have been added to trace respectively the DMA and FlexRay accesses.

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. *Table 1089* summarizes the sources and destinations of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the PD. For example, for the PD, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU, and inputs to the Cores and NXMC.

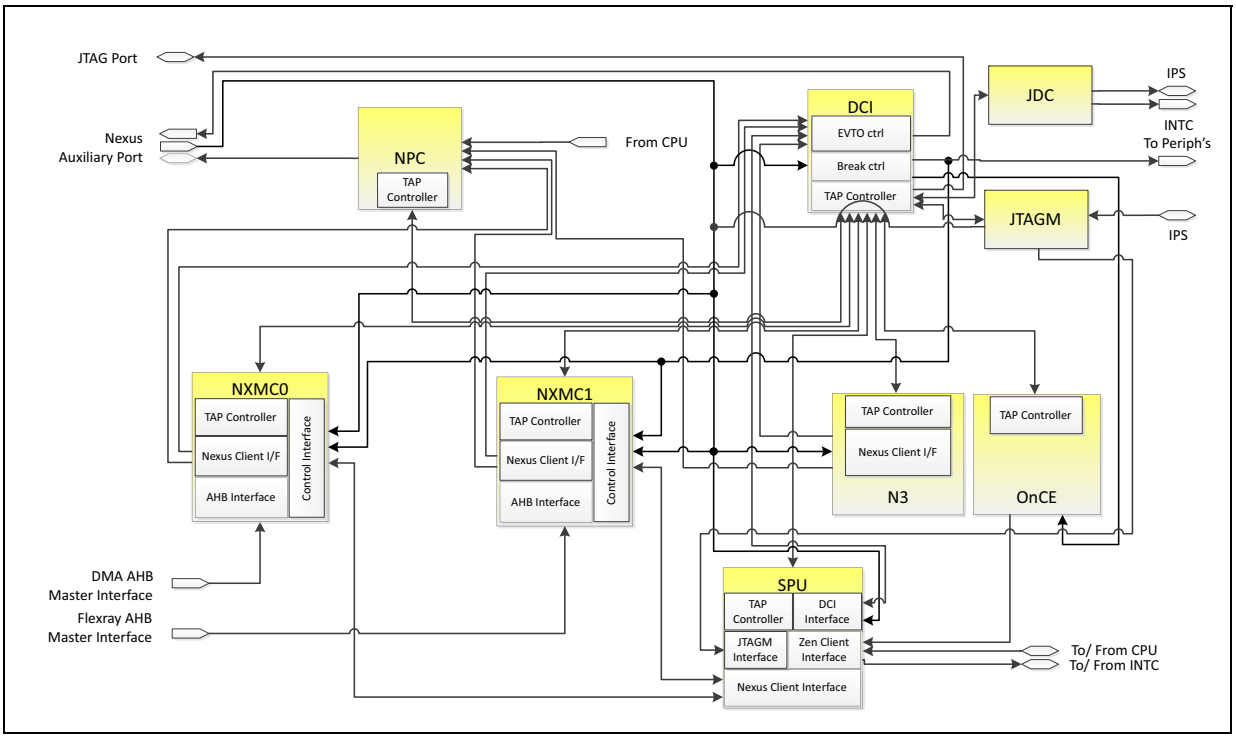

Table 1089. PD DCI signals

Signal	Cores	NXMC	JTAGM	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	O	O	—
$\overline{\text{EVTI}}$[1]	—	—	O	O	—
$\overline{\text{EVTO}}$[0]	O	O	I	I	—
$\overline{\text{EVTO}}$[1]	—	—	I	I	O
Core debug event	I	—	—	—	—
DCI cross triggering	O	—	—	—	—

The DCI sends the system debug signal, ipg_debug, to the following modules. For details regarding module functionality during system debug, refer to the individual module chapter.

- CAN
- eTimer
- DSPI
- eDMA
- FCCU
- PWM
- NXMC
- PIT
- SARADC
- SRX
- SSCM
- STM
- SWT

Figure 1132. Debug architecture

55.2 Register description

55.2.1 Nexus Crossbar Multimaster Trace Clients (NXMC)

The source of each Nexus trace message is identified in the source field (SRC) of the Nexus trace message. This 4-bit field is used by tools, along with the Nexus Message type (TCODE), to determine the decoding of the trace message.

The Nexus trace sources are shown in *Table 1090*.

Table 1090. Nexus trace source identifiers

Nexus Trace Source	Source Trace ID	
e200_CORE_0	0b0000	0x0
AUX_BUS_MON_0	0b1100	0xC
AUX_BUS_MON_1	0b1101	0xD

55.2.2 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

55.2.2.1 SPU Level1 Input Mux Configuration registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0 to 7) are described in the following tables.
Table 1091 contains the L1SEL0 register field descriptions.

Table 1091. L1SEL0 register field descriptions

55.3 Lock step behavior

This feature will be provided for the external tool control only, while it will not be available for the JTAGM and SW-debug control. The lockstep debugging shall be intended as the possibility to inspect the registers of the lock-step core during a debug session[s].

In order to guarantee this, the TDI signal shall be sent to both cores, so that the two cores get the same debug configuration and evolve, even during the debug mode, along the same states.

Figure 1133 shows the proposed architecture for the lock-step debugging. Three AUX_PARALLEL modes exist:

- AUX_PARALLEL_0: this TAP chain is used to broadcast the same JTAG commands to both cores and to read the output from the Main core. TDI is connected to both the Main and Lockstep cores; TDO is connected to the Main core.
- AUX_PARALLEL_DELAY_0: this TAP chain is used to broadcast the same JTAG commands to both cores, but with a delay of 2 x **m_clk**, and to read the output from the Main core. TDI is connected to both the Main and Lockstep cores; TDO is connected to

s. No system data access via the XBAR is possible through the lock-step core only

the Main core; the JTAG input signals are synchronized to the **m_clk** (see *Figure 1134* and *Figure 1135*) a delay of 2 x **m_clk** is then applied to the JTAG input signals connected to the Lock-Step core.

- AUX_PARALLEL_1: this TAP chain is used to broadcast the same JTAG commands to both cores and to read the output from the Lockstep core. TDI is connected to both the Main and Lockstep cores; TDO is connected to the Main core.

Figure 1133. Lock-step debugging architecture

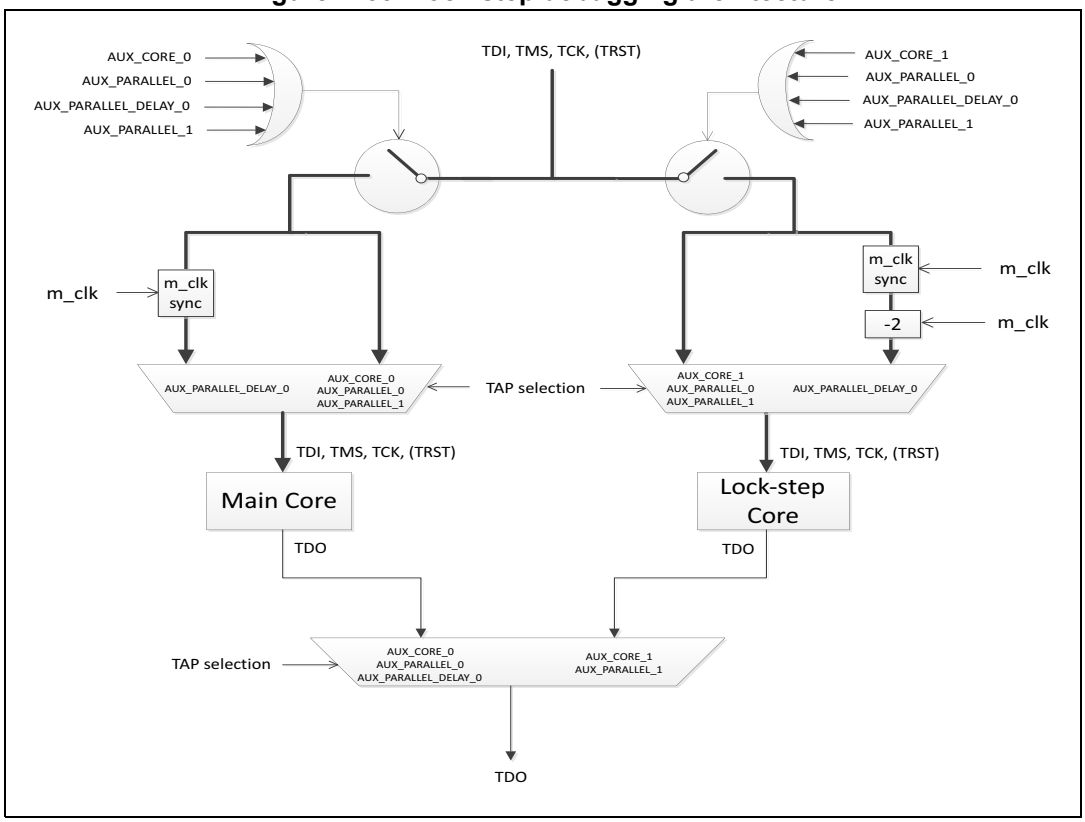

Figure 1134 and *Figure 1135* show how the synchronization is done. The TCK clock is synchronized to the system clock (**m_clk**) and a TCK_EN signal is also generated. The TCK_EN and the system clock are then used to sample the TMS and TDI signals.

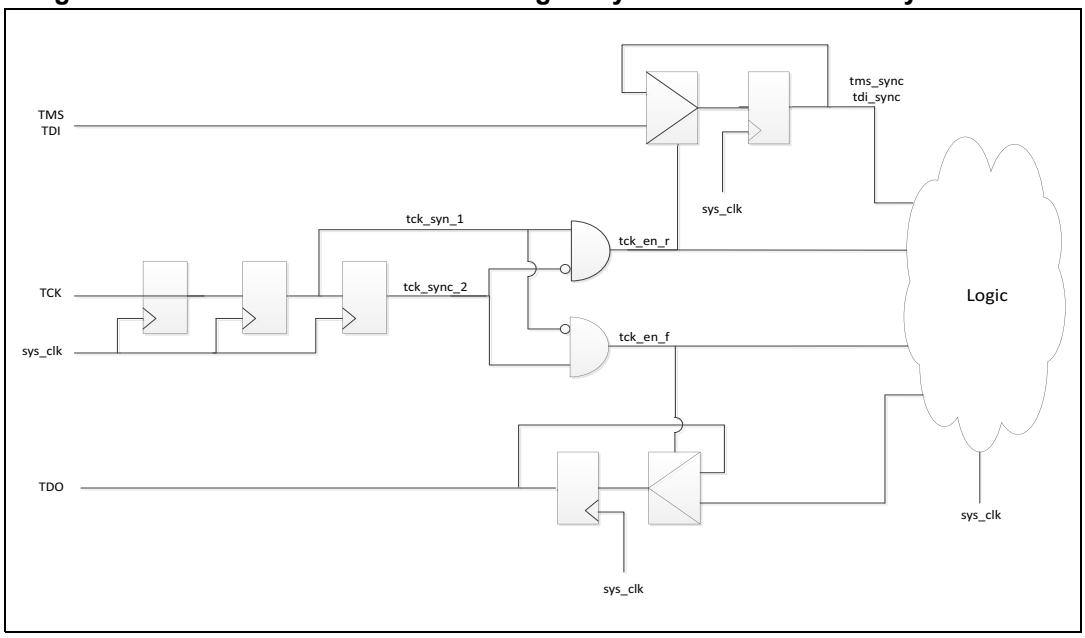
Figure 1134. Architecture of the JTAG signal synchronization to the system clock



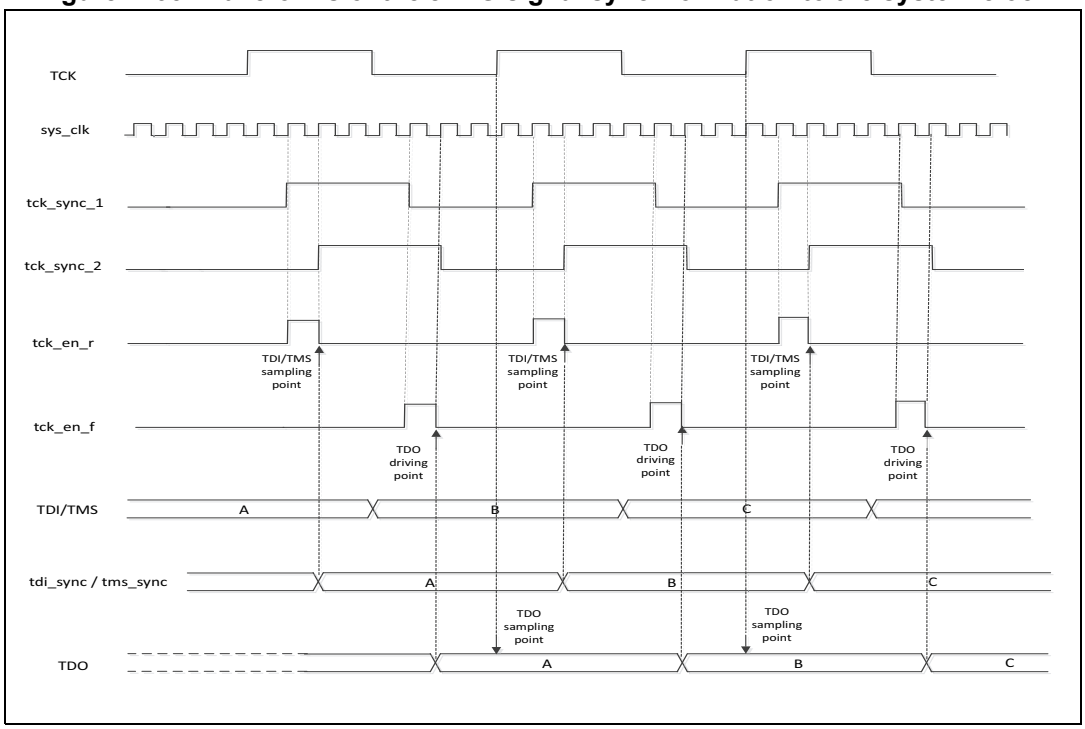


Figure 1135. Waveforms of the JTAG signal synchronization to the system clock

55.3.1 Debugging phases

The debug session can be divided into 4 phases:

1. Entry into the core Debug Mode
2. External tool acknowledge of the core Debug Mode
3. JTAG operations while the core is in Debug Mode
4. Exit from the core Debug Mode (step-by-step and free-run)

55.3.1.1 Entry into the core Debug Mode

The events causing the core to enter the debug mode can be internal or external. The internal debug events will be implicitly delayed by the fact that the cores are progressing with 2 x **m_clk** delay phase. Because the two cores are executing the same instructions, but delayed with 2 x **m_clk**, we can assume that the lock-step core will enter the debug state after the same delay. In case of external event, the **p_devt1** signal shall also be delayed between the Main core and the Lock-step core, in order to guarantee that after 2 x **m_clk**, the lock-step core is in debug state too.

55.3.1.2 External tool acknowledge of the core Debug Mode

Once a core enters into Debug Mode, the external tool will have to acknowledge this status and take control. The external tool will acknowledge the status by reading the OnCE status register. In order to make sure that both cores are stalled, the external tool shall read the OnCE status register of both cores.

55.3.1.3 JTAG operations while the core is in Debug Mode

Once the debug mode state has been acknowledged by the external tool for both the Main and Lock-step cores, then both cores are stalled in the same state.

Now the external tool can take control and send JTAG commands in order to set-up breakpoints and watchpoints.

By selecting the AUX_PARALLEL_0 or AUX_PARALLEL_1 TAPs, the external tool can send the same JTAG input signals (TCK, TMS, TDI) synchronously to both cores and select which TDO shall be used to read the data out.

This operation is suitable to set up the debug configurations (such as breakpoints and watchpoints) and also to read the core registers.

55.3.1.4 Exit from the core Debug Mode (step-by-step and free-run)

To let the core execute the code again (step-by-step or free-run), the external tool shall send a GO instruction. Due to the fact that the input bus signals of the lock-step core are hard-wired with a delay of 2 x **m_clk**, it is mandatory that the two cores restart with 2 x **m_clk** delay, otherwise the Lock-Step core will not be able to run correctly[t]. In order to achieve this, the external tool shall connect the AUX_PARALLEL_DELAY_0 TAP before the GO instruction is sent. From a timing point of view, this means that the core restart operation is possible only if the Main and Lock-step cores evolve synchronously, keeping a delay of 2 x **m_clk** clock cycles, otherwise the state of the two cores will never be synchronized.

t. The situation is similar to what happens after a system reset. In that case, the system reset shall be delayed for the lock-step core, otherwise the lock-step core will start fetching wrong data instructions

Therefore, the JTAG signals shall be synchronized to the **m_clk** when the AUX_PARALLEL_DELAY_0 TAP is selected.

55.3.2 Internal register reading

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting DBCR0EDM to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR).

Execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the Zen core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction (by using the GO command) that brings that information to the WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions. As an example, to read the lower 32 bits of processor register r1, an **e_ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$.

For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (dbg_dbgrq) may be asserted to the CPU by the OnCE controller, causing the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands.

Before executing any instruction, the external tool shall save the CPU context (CPUSCR chain). This operation is done by using the dedicated TAP chains, which send the JTAG command to one core only (AUX_CORE_0 or AUX_CORE_1).

By selecting the AUX_CORE_0 or AUX_CORE_1 TAPs, the external tool can send the JTAG input signals (TCK, TMS, TDI) to one core only, and connect it to the TDO output. This operation is suitable to read out each core register.

55.3.3 Step-by-step execution

Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR register, and setting the GO bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. The instruction opcode is inserted into the IR register. The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired. The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (indicated via the OnCE Status Register).

55.3.4 Exiting a debug session

The debug session remains in force until the final OnCE “go+exit” command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each “go+exit” or “go+noexit” OnCE command.

55.3.5 External tool operation

The external tool should implement the following flows (for the lock-step debugging case):

1. The external tool activates the AUX_CORE_0 and polls the debug status register of the Main core in order to check whether it is stalled.
2. The external tool activates the AUX_CORE_1 and polls the debug status register of the Lockstep core in order to confirm that the lockstep core is also stalled.
3. Now the 2 cores are stalled in the same state and the external tool, using the AUX_PARALLEL_0 and AUX_PARALLEL_1 can read their registers and set new breakpoints.
4. When the GO instruction is requested, the external tool selects the AUX_PARALLEL_DELAY_0 and afterwards sends the GO instruction

55.4 Lock step tracing

The current implementation does not foresee any data or instruction tracing capability for the lock-step core. The following reasons explain which are the issues with the lock-step core Nexus tracing:

- the core has no data trace capability
- the lockstep core is not able to drive any signal on the XBAR

During the lock-step debug session, the TDI commands go in parallel to both cores. If the instruction tracing is enabled and if the lock-step core Nexus client is connected to the NPC, then the same duplicated instructions will appear at the tool level.

55.5 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of four signals (TDI/TDO/TCK/TMS) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

55.5.1 Interfaces

Two interfaces are used to support debug and trace functionality. These are the JTAG port and the Nexus Auxiliary Port (NAP). The JTAG is port is used for debug and test purposes while the NAP is used to transfer trace data streams.

55.5.1.1 JTAG port

The SPC574Sx features a JTAG port with a 4-pin interface. The supported signals are TDI, TDO, TCK and TMS. TRST is not used.

Table 1099. JTAG signals

Signal	Description	Direction	Width
TDI	Test Data Input	Input	1
TDO	Test Data Output	Output	1
TCK	Test Clock	Input	1
TMS	Test Mode Select	Input	1

55.5.1.2 Nexus auxiliary port

Table 1100. Nexus signals

Channel	Functionality	Direction	Width

MDO(0…N[(1)])	Trace	Output	N[(1)]

1. 4 MDO pin configuration for QFP100. 12 MDO pin configuration for QFP144.

55.5.2 Nexus trace enabling during reset

During the reset phase it is possible to enable the Nexus tracing, so that the application can be monitored immediately after the reset phase. The steps needed to accomplish this feature are described hereafter:

1. Nexus program trace enabling

These steps are performed to enable the Nexus program tracing.

a) Reset the system

b) Select NPC TAP: Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction.

c) Program NPC.PCR register for FPM/RPM, MCKO enable, …: When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index. All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a

register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

d) Select CPU TAP: CPU OnCE module is enabled by default. The OCMD JTAG register is used to shift in the OnCE instructions.

e) Enable the Nexus module: The Nexus module is enabled by loading a single instruction (NEXUS3-ACCESS) into the JTAG Instruction Register (IR) (OnCE OCMD register). Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register. Note that the OnCE is always enabled (jd_en_once is fixed to '1').

f) Program DC1 and DC2 for required trace enabling (registers are present in core)

g) Select NXMC0 and NXMC1 TAP

h) Program Nexus Development Control registers DC1 and DC2 for required trace enabling (the registers are in the CPU)

i) Program DTC for data trace enabling (in NXMC module)

j) Program DTSA/DTSE with start and end address of data to be traced (in NXMC module)

2. Nexus AF (alternate function) enabling

These steps are performed to select alternate function mapping for Nexus pads.

a) Select DCI TAP

b) Program DCI_PINCR to select which pads are to be used as Nexus pads

The DCI $\overline{\text{EVTx}}$ pin multiplexing control register (DCI_PINCR) is described below. The $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ functions share the same set of possible pins. If this register is written to enable both $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ on the same pin, the $\overline{\text{EVTI}}$ function is selected, although this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}$[0] input to come from more than one pin is considered a programming error and no pin is enabled.

55.6 Functionality

55.6.1 JTAG Master (JTAGM)

The SPC574Sx Nexus infrastructure is configurable by software from within the device.

The JTAGM module drives the JTAG signals from within the device and provides a parallel interface that can exchange data via customer software or another serial communication module.

The JTAGM is connected to the IPS interface. The data transferred to this module drives the TDI and TMS outputs, and accepts TDO as input to and from the DCI.

The JTAGM module also allows control of the EVTO and EVTI signals. Asserting EVTI in the JTAGM triggers the debug mode in the DCI.

55.6.2 Nexus Crossbar Multimaster Trace Client (NXMC)

The NXMC module provides real time trace capabilities for peripherals and works in conjunction with the Nexus Auxiliary Port. This module is present twice in the device to cover all master accesses to memories and allow external memory reconstruction by external measurement and online data acquisition tools.

- FlexRay NXMC: it is used to trace FlexRay accesses.
- DMA Master Port NXMC: A second NXMC module is used to trace the DMA accesses.

The NXMC clients are connected to and interact with the following modules:

- DCI: TAP controller interface for configuration via JTAG and EVTO management
- SPU: trace control
- NPC: arbitration for access to NAP and MDO pads
- AHB bus: trace source, connected to the data snoop block

The NXMC peripheral interface block is unused, since the module is used for data snooping on the AHB bus only.

55.6.3 JTAG Data Communication module (JDC)

The JDC provides the functionality to move register data between the JTAG and the IPS domain. It consists of JTAG accessible and IPS accessible registers and the associated logic to coordinate the transfers. The module connects to the peripheral bridge and the DCI.

55.6.4 Nexus Port Controller (NPC)

The Nexus Port Controller controls the usage and sharing of the Nexus Auxiliary Port between Nexus clients. The Nexus Auxiliary Port is accessed by:

- The N3 block of the CPU
- The DMA master port NXMC client
- The FlexRay master port NXMC client

The NPC is placed in disabled mode upon exit of reset. Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. Once the NPC is enabled, if message transmission via the auxiliary port is

desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

55.6.5 Sequence Processing Unit (SPU)

The SPU is able to generate complex debug events, based upon input events from sources throughout the SOC. It generates trace control events for data, program, ownership, and watchdog trace (DTM, PTM, OTM and WTM), as well as EVTO, HALT and debug events for the clients.

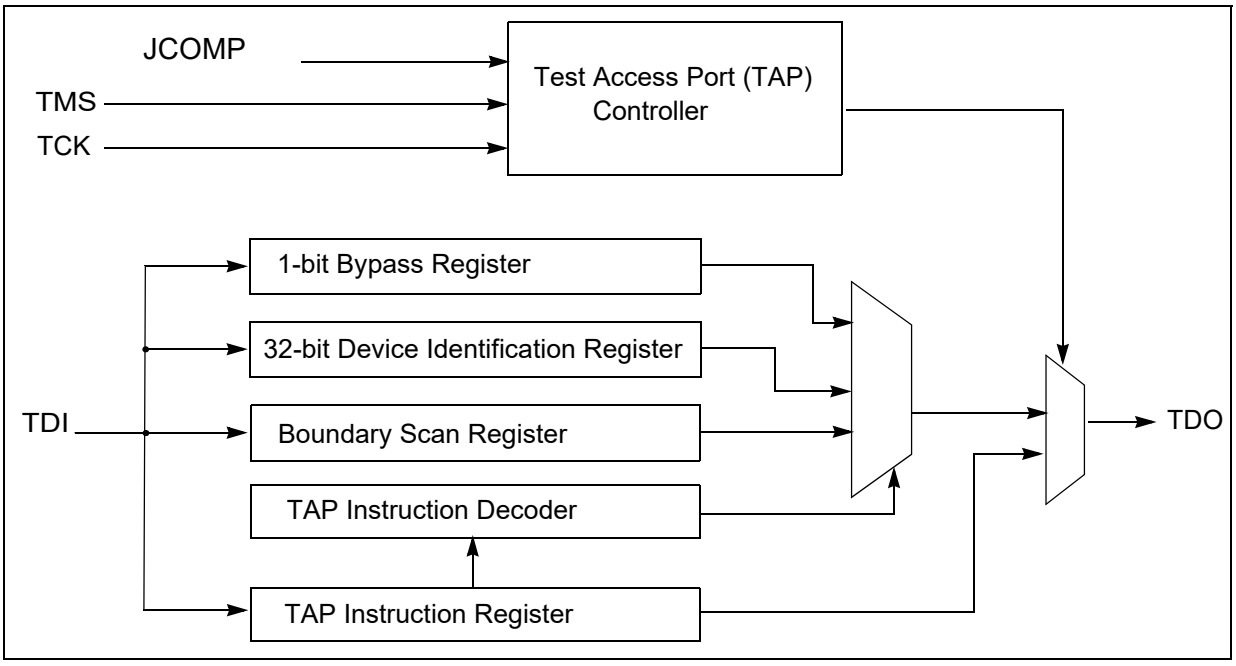
On SPC574Sx the required client interfaces are:

- One e200z420 client
- Two NXMC clients

Furthermore, the SPU interfaces with the following modules:

- DCI for debug control and EVTO handling
- JTAGM for generating CPU interrupt via the INTC

56 JTAG Controller (JTAGC)



56.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

56.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1137. JTAG (IEEE 1149.1) block diagram

56.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1108* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- TEST_CTRL register
- JTAG_PASSWORD register
- DATA1 register
- DATA2 register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

56.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

56.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

56.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS,

HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 56.4.4*.

56.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

56.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1102. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

56.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

56.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

56.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 56.4.3*.

56.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

56.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

56.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

56.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

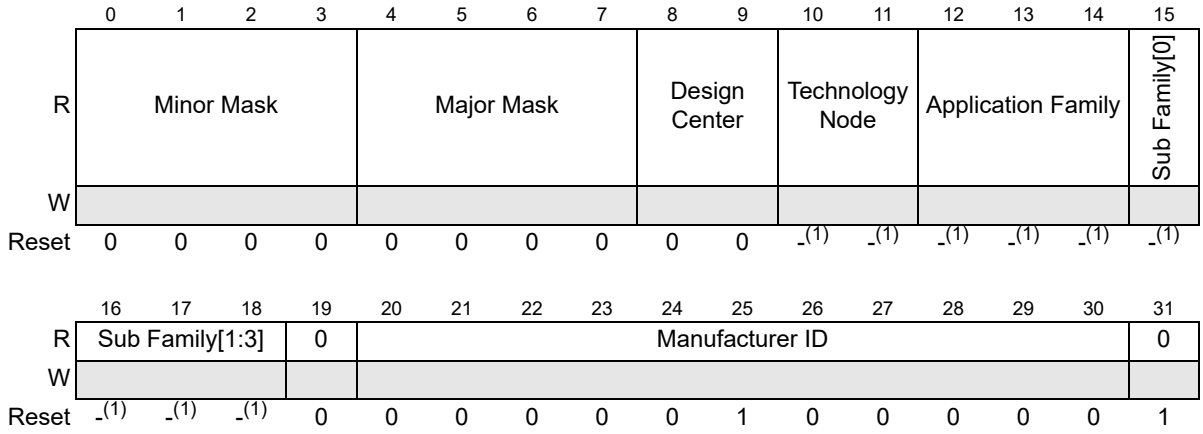


Figure 1138. 6-bit instruction register

56.3.2 Bypass register

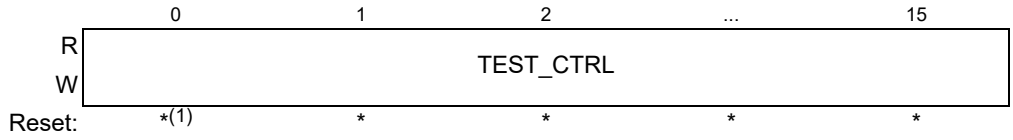
The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

56.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 1103*

Figure 1139. Device identification register



The following table describes the device identification register functions.

Table 1103. Device identification register field descriptions

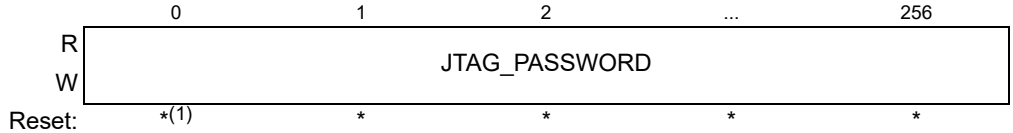
Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 00 55nm
12:14 Application Family	Application Family These bits indicate the device application family 101 SPC57S - Chassis & Safety 55nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 0100 SPC574S60
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

56.3.4 TEST_CTRL Register

The TEST_CTRL register is a 15-bit shift register path from TDI to TDO selected when the ENABLE_TEST_CTRL instruction is active. The TEST_CTRL register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state.

1. The reset value of TEST_CTRL is 0x1B

Figure 1140. TEST_CTRL Register



The following table describes the TEST_CTRL register functions.

Table 1104. TEST_CTRL register field descriptions

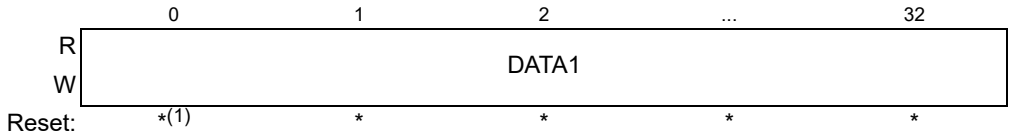
Field	Description
TEST_CTRL	Test Control. Used to control chiptop test functions.

56.3.5 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1141. JTAG_PASSWORD register



The following table describes the JTAG_PASSWORD register functions.

Table 1105. JTAG_PASSWORD register field descriptions

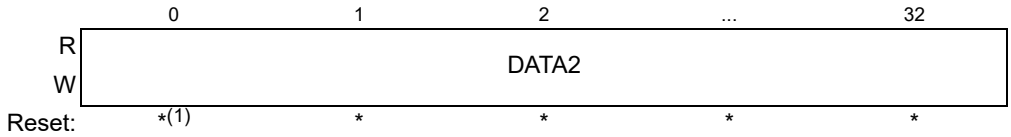
Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

56.3.6 DATA1 register

The DATA1 register is a 32-bit shift register path from TDI to TDO selected when the ENABLE_DATA1 instruction is active. The default reset value of the DATA1 register is 32'b0. The DATA1 register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_DATA1 instruction is executed, the register value remains valid until a JTAG reset occurs.

1. The reset value of DATA1 is 32’b0.

Figure 1142. DATA1 register



The following table describes the DATA1 register functions.

Table 1106. DATA1 register field descriptions

Field	Description
DATA1	JTAG data register 1.

56.3.7 DATA2 register

The DATA2 register is a 32-bit shift register path from TDI to TDO selected when the ENABLE_DATA2 instruction is active. The default reset value of the DATA2 register is 32’b0. The DATA2 register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_DATA2 instruction is executed, the register value remains valid until a JTAG reset occurs.

1. The reset value of DATA2 is 32’b0.

Figure 1143. DATA2 register

The following table describes the DATA2 register functions.

Table 1107. DATA2 register field descriptions

Field	Description
DATA2	JTAG data register 2.

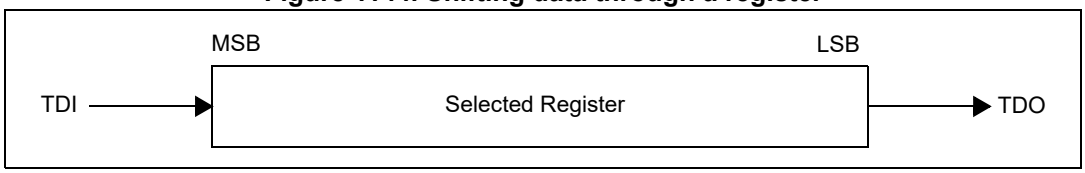
56.3.8 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 56.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

56.4 Functional description

This section explains the JTAGC functional description.

56.4.1 JTAGC reset configuration



While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

56.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 56.4.4.12*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

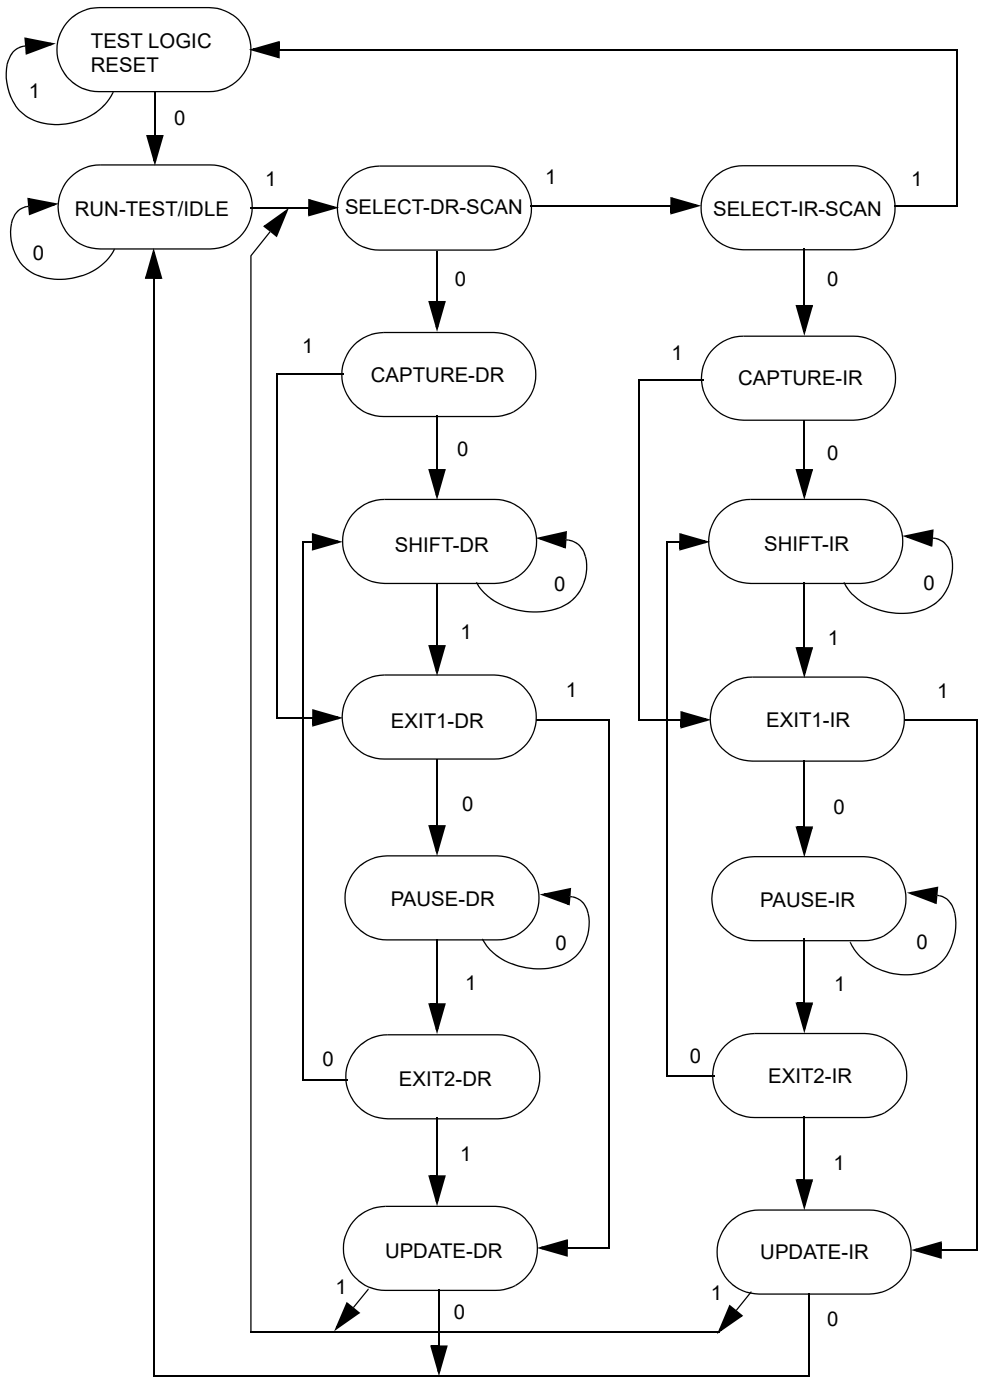


Figure 1144. Shifting data through a register

56.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 1145. IEEE 1149.1-2001 TAP controller finite state machine

Note:

1. The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

56.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

56.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

56.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1108. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
TEST_LEAKAGE(1),(2)	000101	Selects bypass register while tristating all output pins and asserts the jtag_leakage signal
ENABLE_TEST_CTRL(1)	000110	Selects TEST_CTRL register
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DATA1	001110	Enables access to DATA1 register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ENABLE_DATA2	001111	Enables access to DATA2 register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.

Table 1108. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100000	Reserved
ACCESS_AUX_NPC_PD	100001	Enables access to the NPC TAP controller on production device
Reserved	100001	Reserved
Reserved	100010	Reserved

BYPASS	111111	Selects bypass register for data operations
Reserved(4)	All other opcodes	Decoded to select bypass register

1. Instruction for manufacturing purposes only
2. Assertion of power-on reset or setting JCOMP for non-JTAGC operation required to exit this instruction
3. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
4. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

56.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

56.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

56.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

56.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the

preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

56.4.4.5 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR to the Run-Test-Idle state. Once asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

56.4.4.6 ENABLE_TEST_CTRL instruction

The ENABLE_TEST_CTRL instruction selects the TEST_CTRL register for connection as the shift path between TDI and TDO.

56.4.4.7 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

56.4.4.8 ENABLE_DATA1 instruction

The ENABLE_DATA1 instruction selects the DATA1 register for connection as the shift path between TDI and TDO.

56.4.4.9 ENABLE_DATA2 instruction

The ENABLE_DATA2 instruction selects the DATA2 register for connection as the shift path between TDI and TDO.

56.4.4.10 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (for example high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

56.4.4.11 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

56.4.4.12 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

56.4.4.13 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

56.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

56.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, must be loaded the appropriate instruction for the test or action to be performed.

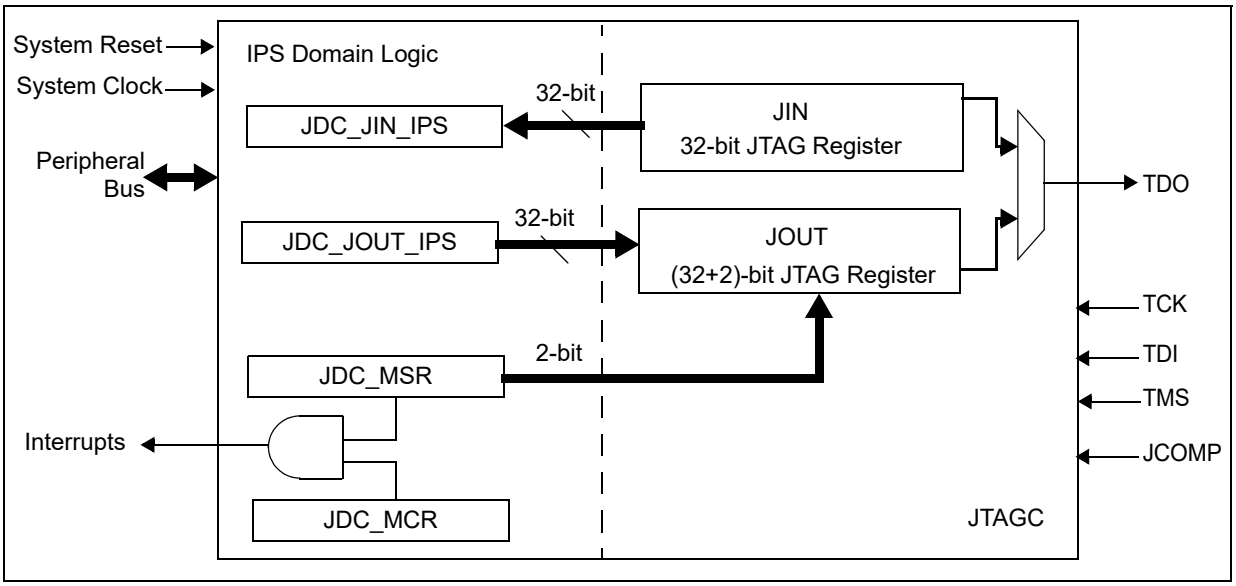
57 JTAG Data Communication (JDC)

57.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

57.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.



The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 1146*.

Figure 1146. JDC block diagram

57.3 Register definition

Table 1109 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1109. JDC memory map

Address offset	Register	Access	Reset value	Location

Figure 1149. JDC_JOUT_IPS register

The JDC_JOUT_IPS register is described in *Table 1112*.

Table 1112. JDC_JOUT_IPS register field descriptions

Field	Description
0:31 DATA	Contains JOUT_IPS data.

57.3.1.4 JTAG input IPS data register (JDC_JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JDC_JIN_IPS register, where it can be read via IPS. *Figure 1150* shows the format of the JDC_JIN_IPS register. This register is reset by system destructive reset.

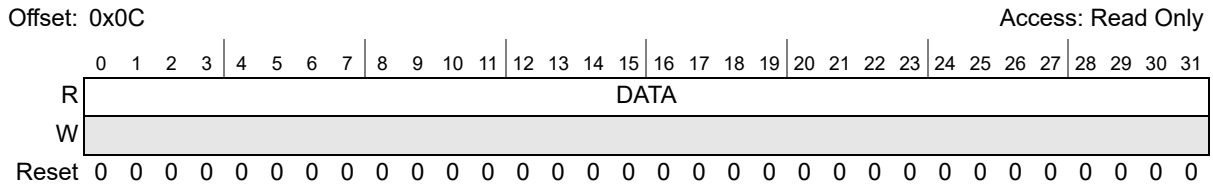

Figure 1150. JDC_JIN_IPS register

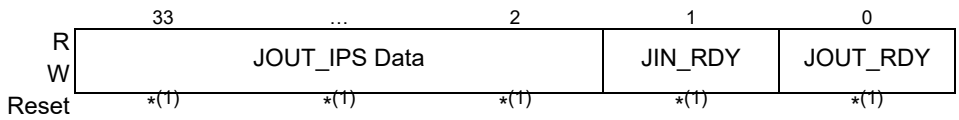
The JDC_JIN_IPS register is described in *Table 1113*.

Table 1113. JDC_JIN_IPS register field descriptions

Field	Description
0:31 DATA	Contains JIN_IPS data.



57.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

57.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JDC_JIN_RDY and JDC_JOUT_RDY status bits. *Figure 1151* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

Figure 1151. JOUT JTAG register

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in *Table 1114*.

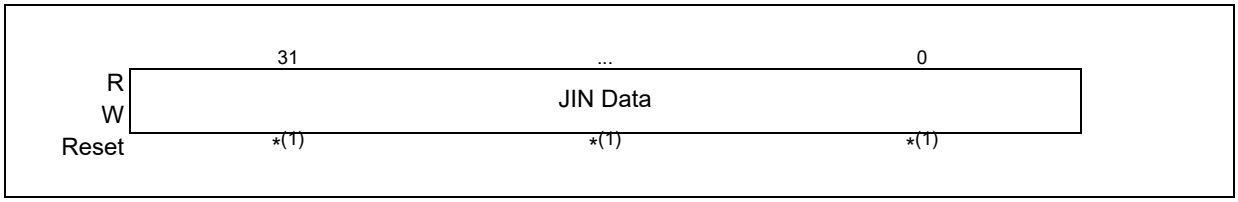


Table 1114. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

57.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 1152* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

Figure 1152. JIN JTAG Register

1. The reset value of the JIN register is 32'b0.

The JIN register is described in *Table 1115*.

Table 1115. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JDC_JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

57.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data

is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

57.4.1 IPS register access

IPS access is available to the registers described in *Section 57.3.1*.

57.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

57.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 1116*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1116. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

58 JTAG Master (JTAGM)

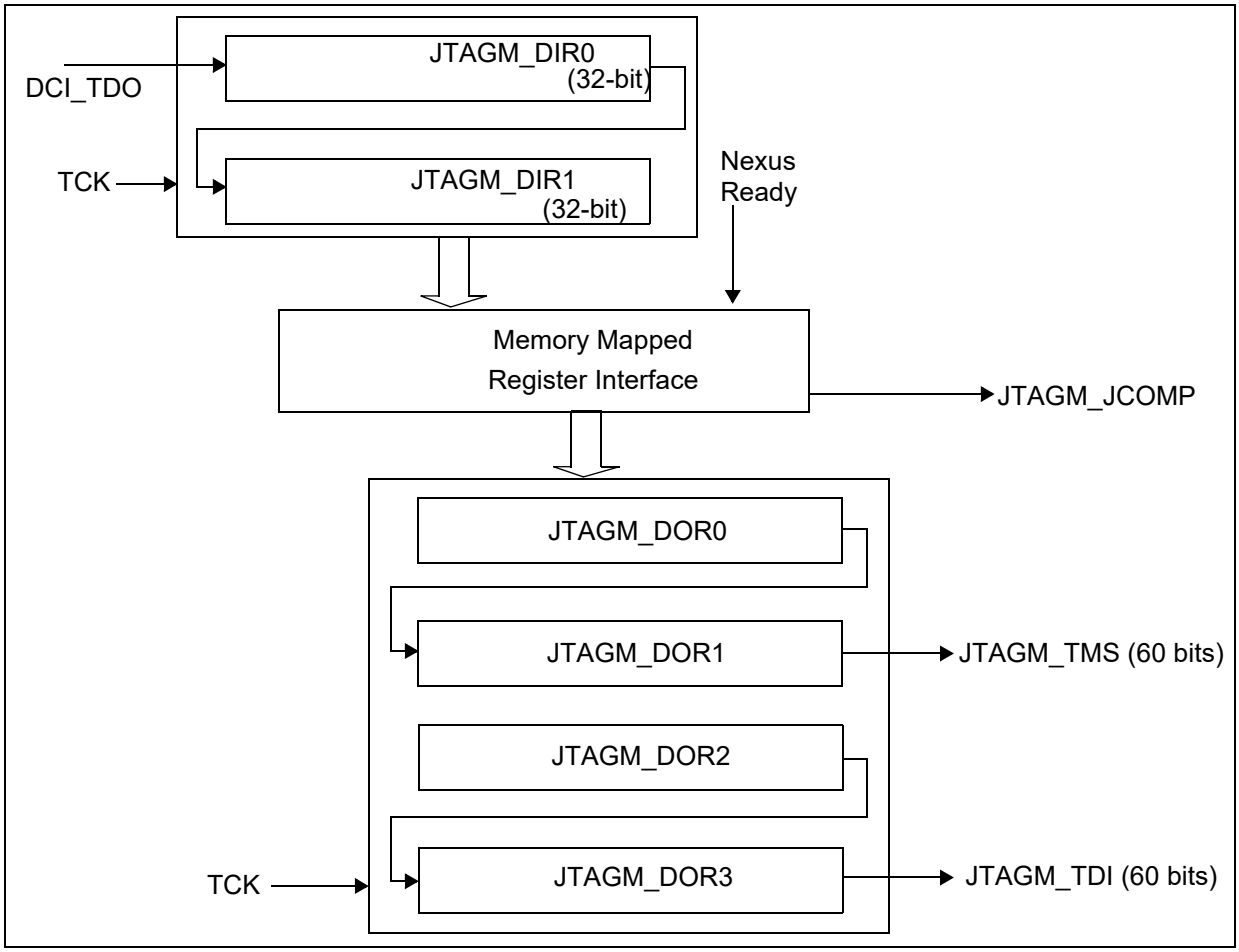
58.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

58.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- Two data input registers

All these registers, described in detail in *Section 58.4*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 1153 shows the block diagram of the JTAGM.

Figure 1153. JTAGM block diagram

58.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG

58.2 Functional description

58.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

58.2.2 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available.

58.2.2.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

58.2.2.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

58.2.3 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

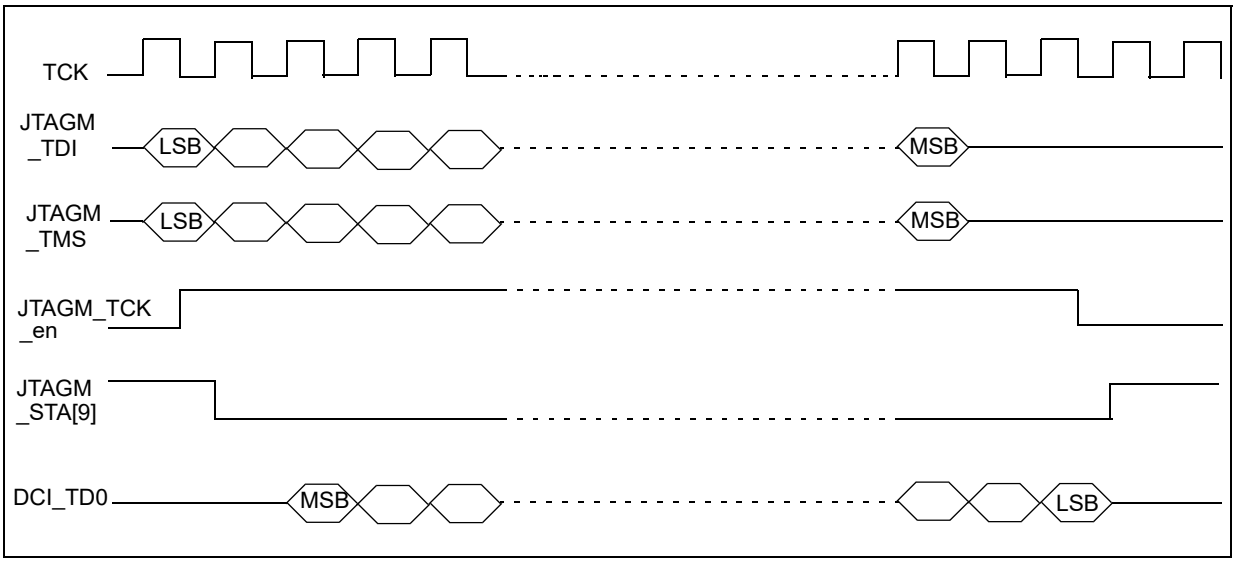
The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is a CPU interrupt.

The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI.

Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.



58.2.4 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 58.2.2.1*). The status register also includes status bits provided by the DCI module.

58.2.5 JTAGM to DCI serial interface

Figure 1154 shows the data transfer timings between JTAGM and DCI.

Figure 1154. JTAGM to DCI serial interface diagram

58.2.6 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

58.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

58.4 Memory map and register definition

Table 1117 contains the memory map of the JTAGM registers.

Table 1117. Memory map

Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Figure 1156. JTAGM_SR register

The JTAGM_SR register is described in *Table 1119*.

Table 1119. JTAGM_SR register field descriptions

Field	Description
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 Reserved bit 10 DCI JTAG port enable bit 11 Reserved bit 12 DCI JTAG safe mode bit 13 Reserved bit 14 Reserved bit 15 DCI tool present , set when a debug tool is connected
16 evto0_edge	In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO0}}$ 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO0}}$
17 evto1_edge	In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO1}}$ 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO1}}$
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.

Table 1119. JTAGM_SR register field descriptions (continued)

Field	Description
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to '1' when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready **Note:** 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24 evto0_clr	Used for clearing the evto0_edge bit.
25 evto1_clr	Used for clearing the evto1_edge bit.

58.4.1.3 Data out register 0 (JTAGM_DOR0)

Figure 1157 shows the format of the JTAGM_DOR0.

59 Nexus Port Controller (NPC)

59.1 Introduction

Figure 1163 is a block diagram of the Nexus Port Controller (NPC) block.

Figure 1163. Nexus Port Controller Block Diagram

59.1.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

59.1.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Auxiliary Output Port.
- Nexus Device Identification Register and Messaging.
- Generates MCKO enable and frequency division control signals.
- Controls sharing of $\overline{\text{EVTO}}$.
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle.
- Control of the device-wide debug mode.
- $\overline{\text{RDY}}$ pin support to increase the transfer rate of the IEEE 1149.1 port for large data read requests.

59.1.3 Modes of Operation

The NPC block uses the JCOMP input, and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

59.1.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access (ipp_ind_jcomp is set to a value other than npc_jcomp_plug) or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state.
- The auxiliary output port pins are negated.
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset or JCOMP not set for NPC operation only).
- Registers default back to their reset values.

59.1.3.2 Disabled-Port Mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

59.1.3.3 Full-Port Mode

Full-port mode (FPM) is entered by asserting the MCKO_EN and FPM bits in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

59.1.3.4 Reduced-Port Mode

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and negating the FPM bit in the PCR.All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. All MSEO signals need to be connected.

59.2 External signal description

59.2.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in *Table 1126*.

Table 1126. NPC Signal Properties

Name	Port	Function	Reset State	Pull(1)
EVTO_B	Auxiliary	Event Out pin	0b1	—
JCOMP	JTAG	JTAG Compliancy and TAP Sharing Control	—	Down
MDO	Auxiliary	Message Data Out pins	0	—
MSEO	Auxiliary	Message Start/End Out pins	0b11	—
TCK	JTAG	Test Clock Input	—	Down
TDI	JTAG	Test Data Input	—	Up
TDO	JTAG	Test Data Output	High Z(2)	—
TMS	JTAG	Test Mode Select Input	—	Up

1. The pull is not implemented in this block. Pullup/pulldown devices are implemented in the pads.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

59.2.2 Detailed Signal Descriptions

This section describes each of the signals listed in *Table 1126* in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

59.2.2.1 EVTO_B — Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

59.2.2.2 JCOMP — JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller remains in reset until it is enabled using the JCOMP signal.

59.2.2.3 MDO — Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

59.2.2.4 MSEO_B — Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

59.2.2.5 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

59.2.2.6 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

59.2.2.7 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

59.2.2.8 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

59.3 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

Table 1127 shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 1127. NPC registers

Index	Register
0	Device ID Register (DID)
127	Port Configuration Register (PCR)

59.3.1 Register descriptions

This section consists of NPC register descriptions.

59.3.1.1 Bypass Register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

59.3.1.2 Instruction Register

The NPC block uses a 4-bit instruction register as shown in *Figure 1164*. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

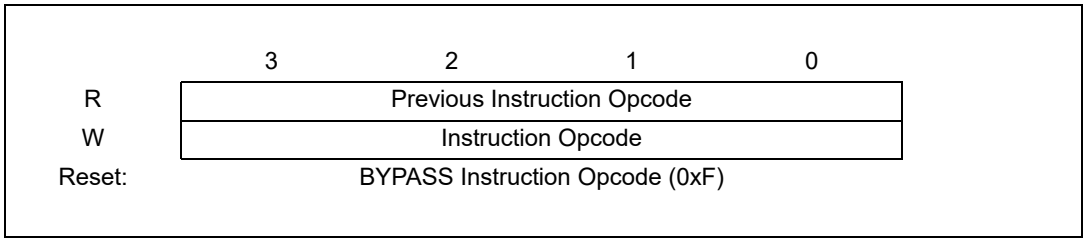

Figure 1164. 4-Bit Instruction Register

59.3.1.3 Nexus Device ID register (DID)

The device identification register, shown in *Figure 1165*, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the auxiliary output port.

Register index: 0

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Minor Mask				Major Mask				Design Center		Technology Node		Application Family			Sub Family

W																
Reset	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Figure 1165. Nexus Device ID register(DID)

Table 1128. DID field descriptions

Bit	Description
0:3	Minor Mask These bits contain the minor mask of the part
4:7	Major Mask These bits contain the major mask of the part
8:9	Design Center These bits indicate the device design center
10:11	Technology Node These bits indicate the device technology node 00 55nm 01 40nm
12:14	Application Family These bits indicate the device application family 101 SPC57S - C&S 55nm 110 SPC58S - C&S 40nm
15:18	Sub Family These bits indicate the device sub family 0001 Velvety 0010 Sphaero 0011 Tarento 0100 Caledo
20:30	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

59.3.1.4 Port Configuration Register (PCR)

Register index: 127

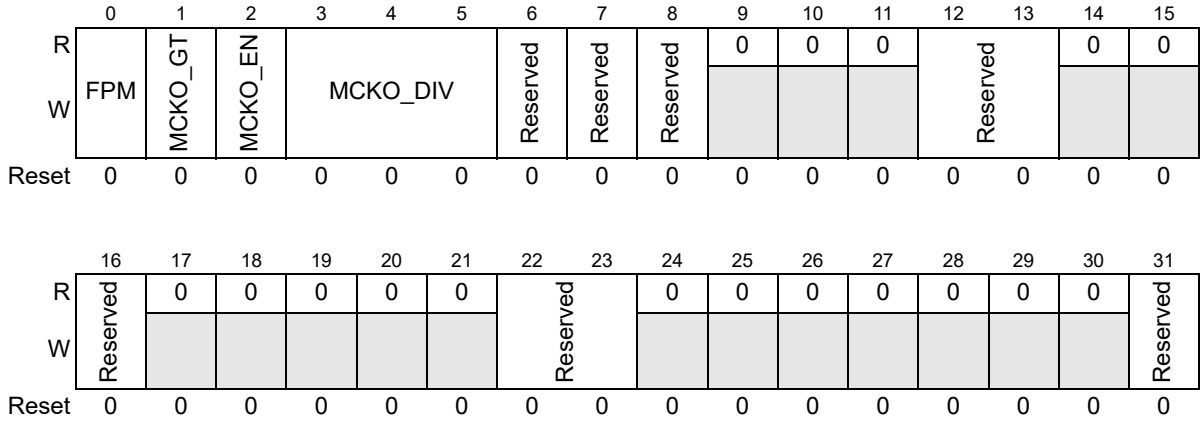

Figure 1166. Port Configuration Register (PCR)

The PCR, shown in *Figure 1166*, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

The PCR register may be rewritten by the debug tool subsequent to the enabling of the NPC for low power debug support. In this case, the debug tool may set and clear the LP_DBG and LPn_SYN bits, but must preserve the original state of the remaining bits in the register.

Note: The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Table 1129. PCR field descriptions

Bit	Name	Description
0	FPM	Full Port Mode The value of the FPM bit determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 1 All MDO pins are used to transmit messages 0 A subset of MDO pins are used to transmit messages
1	MCKO_GT	MCKO Clock Gating Control This bit is used to enable or disable MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 1 MCKO gating is enabled 0 MCKO gating is disabled

Table 1129. PCR field descriptions (continued)

Bit	Name	Description
2	MCKO_EN	MCKO Enable This bit enables the MCKO clock to run. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 1 MCKO clock is enabled 0 MCKO clock is driven to zero
3:5	MCKO_DIV	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. *Table 1130* shows the meaning of MCKO_DIV Values. In this table, SYS_CLK represents the system clock frequency.

Table 1130. MCKO_DIV Values

MCKO_DIV[2:0]	MCKO Frequency
0	SYS_CLK(1)
1	SYS_CLK/2
2	Reserved
3	SYS_CLK/4
4	Reserved
5	Reserved
6	Reserved
7	SYS_CLK/8

1. The SYS_CLK setting for MCKO frequency should only be used if this setting does not violate the maximum operating frequency of the auxiliary port pins.

59.4 Functional description

59.4.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

Table 1131 describes the NPC reset configuration options.

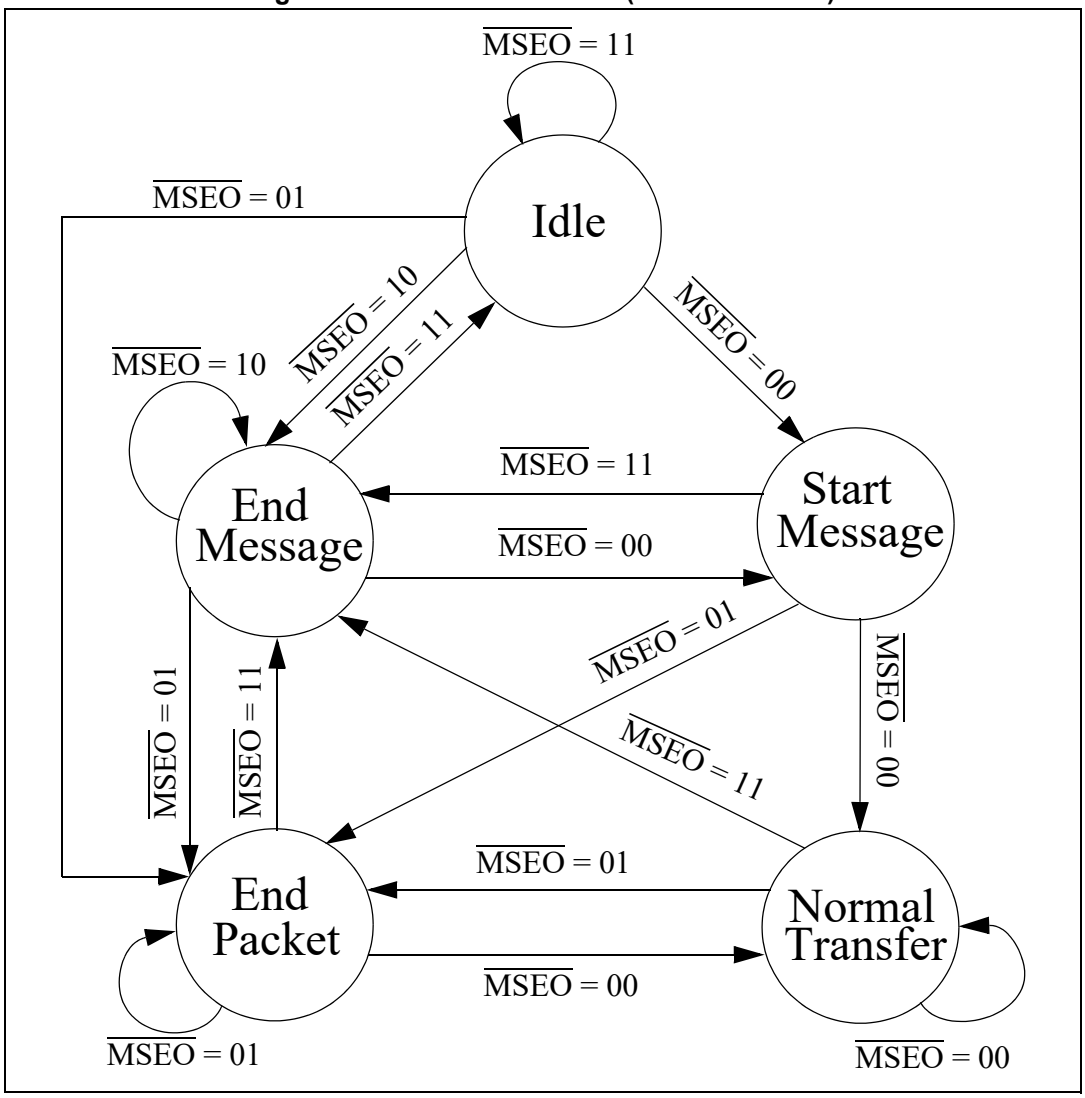
Table 1131. NPC reset configuration options

Power On Reset Status Asserted?	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register	Configuration
yes	X	X	Reset
no	0	X	Disabled

Table 1131. NPC reset configuration options (continued)

Power On Reset Status Asserted?	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register	Configuration
no	1	1	Full-Port Mode
no	1	0	Reduced-Port Mode

59.4.2 Auxiliary Output Port



The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

59.4.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the MSEO functions. The MSEO pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and MSEO are sampled on the rising edge of MCKO.

Figure 1167 illustrates the state diagram for MSEO transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 1167. $\overline{\text{MSEO}}$ Transfers (for 2-bit $\overline{\text{MSEO}}$)

59.4.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

Table 1132 describes the device ID output message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

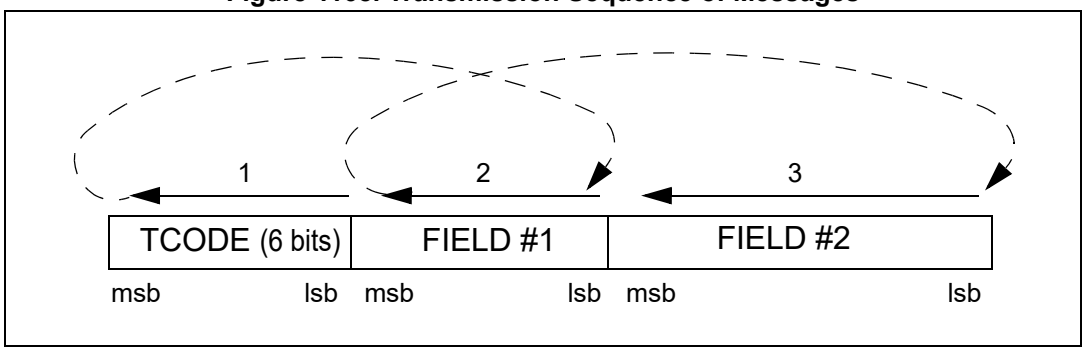
Table 1132. NPC output messages

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Device ID Message	6	6	fixed	TCODE	Value = 1
	32	32	fixed	ID	DID register contents

Table 1133 shows the various message formats that the pin interface formatter has to encounter. Note that for variable-length fields, the transmitted size of the field is determined from the range of the least significant bit to the most significant non-zero-valued bit (that is most significant zero-valued bits are not transmitted).

Table 1133. Message field sizes

Message	TCODE	Field #1	Field #2	Field #3	Field #4	Field #5	Min. Size(1) (bits)	Max. Size(2) (bits)
Device ID Message	1	Fixed = 32	NA	NA	NA	NA	38	38



1. Minimum information size. The actual number of bits transmitted depends on the number of MDO pins
2. Maximum information size. The actual number of bits transmitted depends on the number of MDO pins

The double edges in *Table 1133* indicate the starts and ends of messages. Fields without shaded areas between them are grouped into super-fields and can be transmitted together without end-of-packet indications between them.

59.4.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration).
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. *Figure 1168* shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

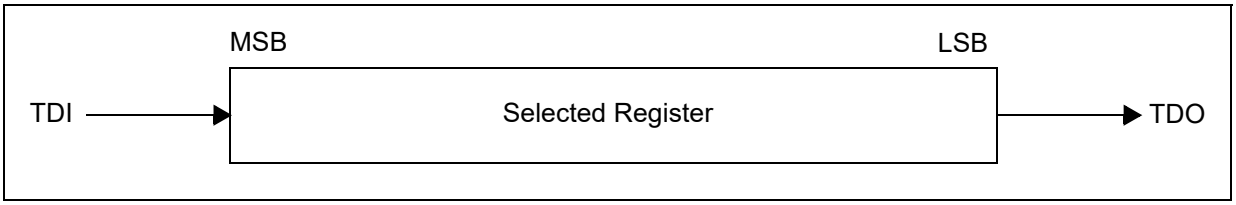
Figure 1168. Transmission Sequence of Messages

59.4.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 TAP for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in *Figure 1170*. The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in *Figure 1171*.



The instructions implemented by the NPC TAP controller are listed in *Table 1134*. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4-bits.

Table 1134. Implemented Instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS-ENABLE	public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in *Figure 1169*. This applies for the instruction register and all Nexus tool-mapped registers.

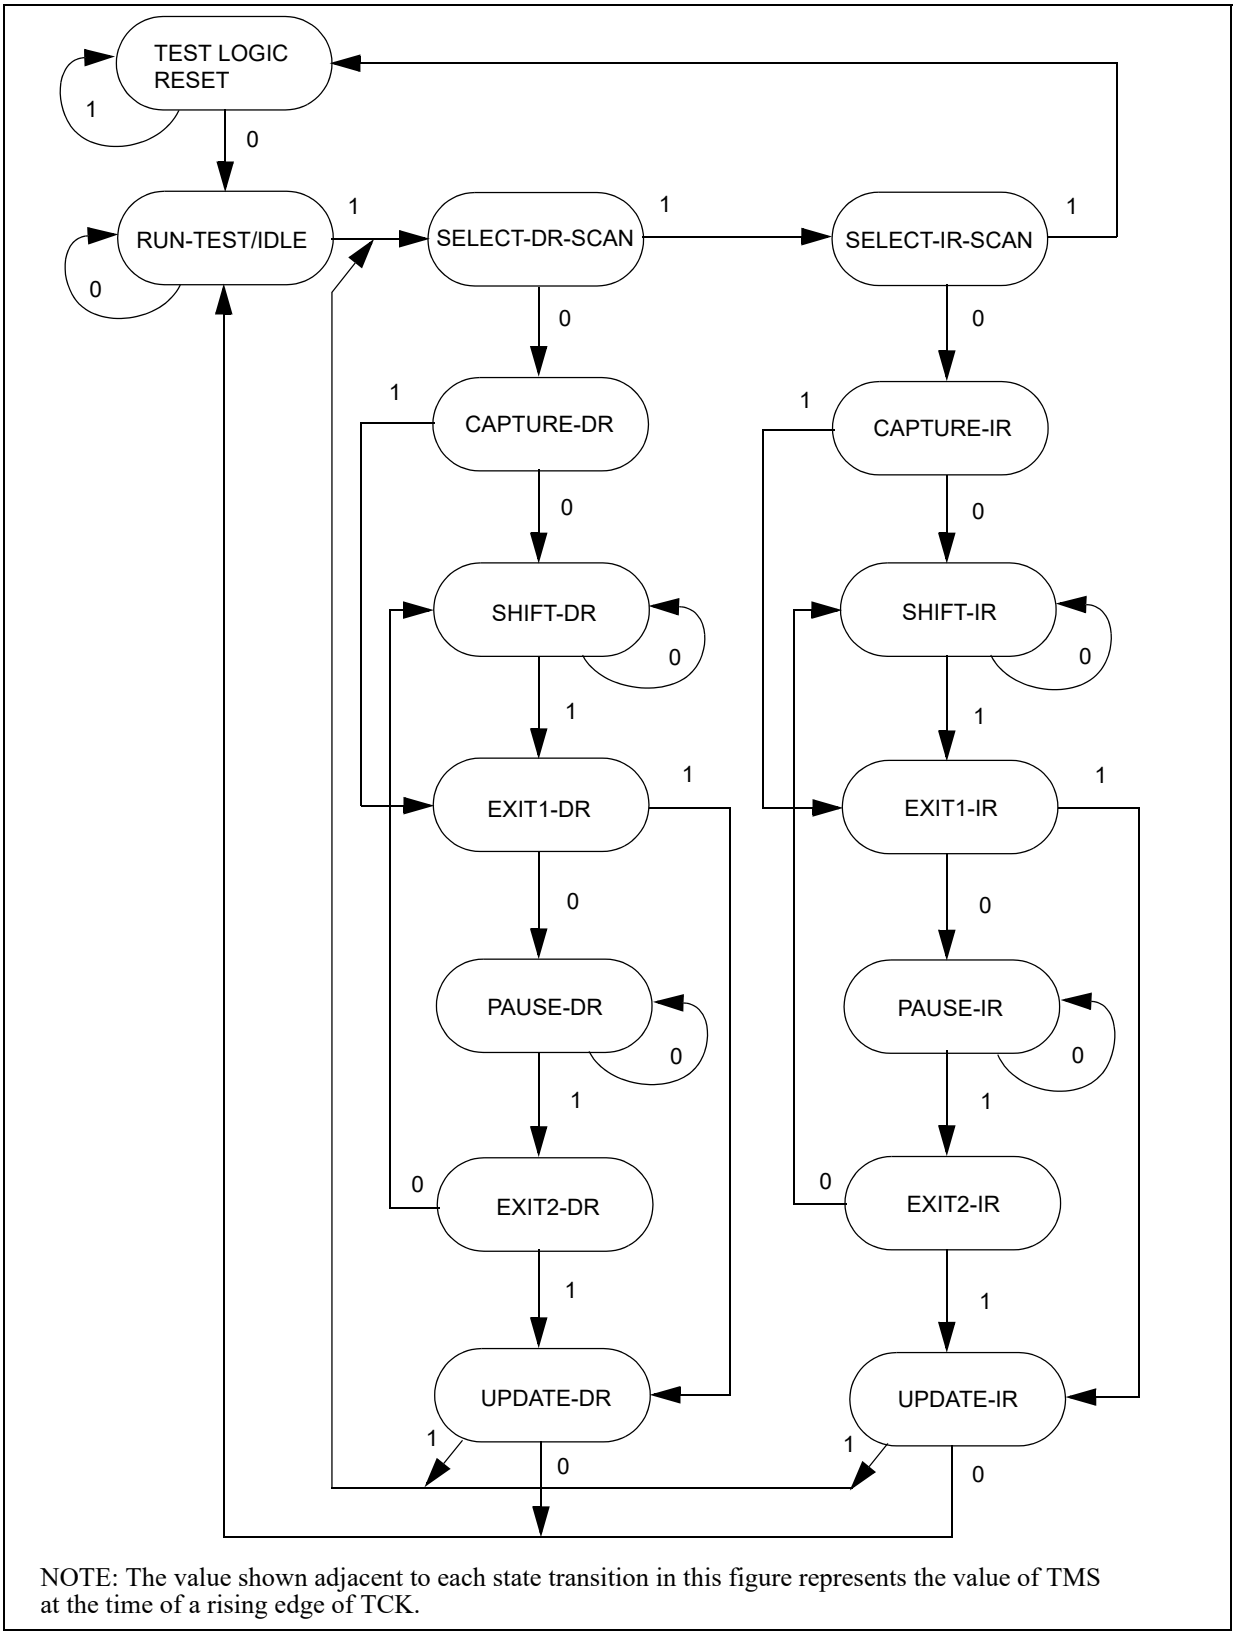


Figure 1169. Shifting Data Into Register

59.4.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

Figure 1170. IEEE 1149.1-2001 TAP Controller State Machine

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

59.4.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the auxiliary output port or shifted out serially by accessing the Nexus Device ID register through the TAP. Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled. Transmission of the device identification message serially via TDO is achieved by performing a read of the register contents as described in *Section 59.4.3.4*.

59.4.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 1171*, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. *Table 1135* illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 1171. NEXUS Controller State Machine

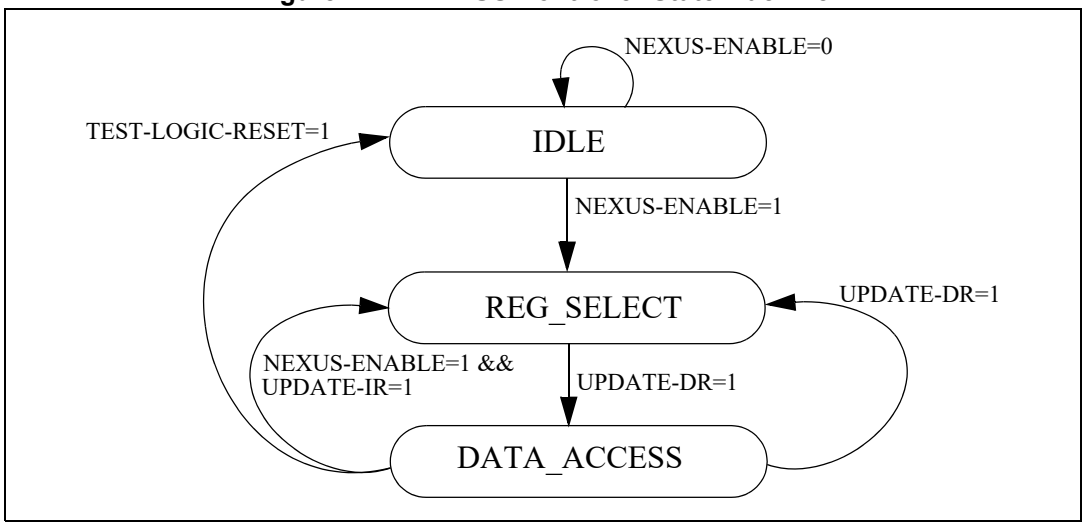

Table 1135. Loading NEXUS-ENABLE instruction

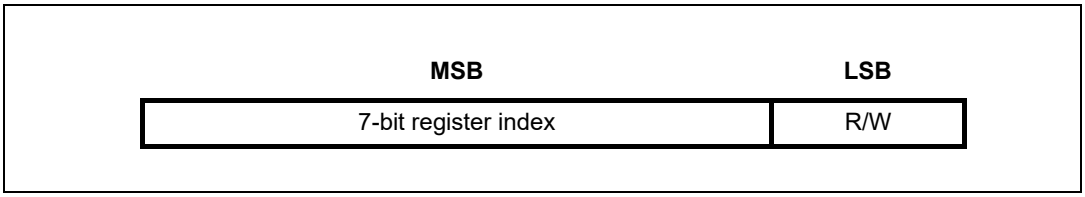
Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers



59.4.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 1172*. The read/write control bit is set to 1 for writes and 0 for reads.

Figure 1172. IEEE 1149.1 Controller Command Input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

Table 1136 illustrates a sequence which writes a 32-bit value to a register

Table 1136. Write to a 32-Bit Nexus Client Register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				

Table 1136. Write to a 32-Bit Nexus Client Register (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

59.4.4 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

59.4.5 MCKO Control

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

59.4.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

59.4.7 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset.

59.5 Initialization/Application Information

59.5.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

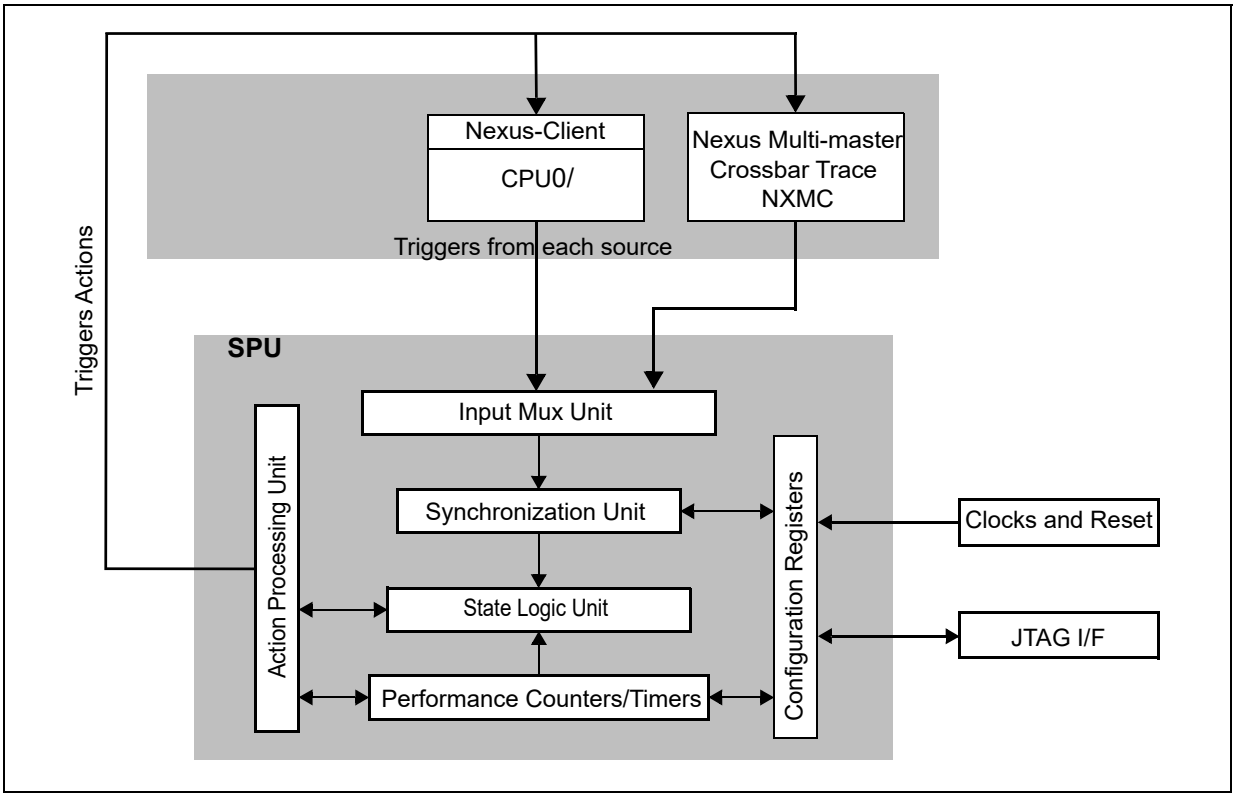
To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

60 Sequence Processing Unit (SPU)

60.1 Introduction



The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

60.1.1 SPU block diagram

Figure 1173 shows a top-level block diagram of the SPU.

Figure 1173. SPU block diagram

60.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 1208*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 1209*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 1210* and *Figure 1211*. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU writes to VariableB. If CPU writes a value to VariableB which is 0x100, then enable trace for the halt CPU.

The SPU consists of the following sub-blocks:

- Input Mux Unit: receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 1208*.
- State Logic Units (SLU): responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan's law, allows for generalized signal combinations. This is shown in *Figure 1209*.
- Action Processing Unit: takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers: the SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

60.1.3 Features

The features of the SPU are as follows:

- clients:
  - 1 CPU
  - 2 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics
  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
  - Access to timer/counter values via JTAG
- Prescaler for timer mode only

  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces
  - CPU
  - System bus
  - DCI
- Configuration registers: 32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions: SPU block triggers various actions based on the derived events, these actions are defined in *Section 60.2*

60.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Halt1: single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2: single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Single interrupt for INTC to interrupt a CPU: de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin: output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source: Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals): four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state.

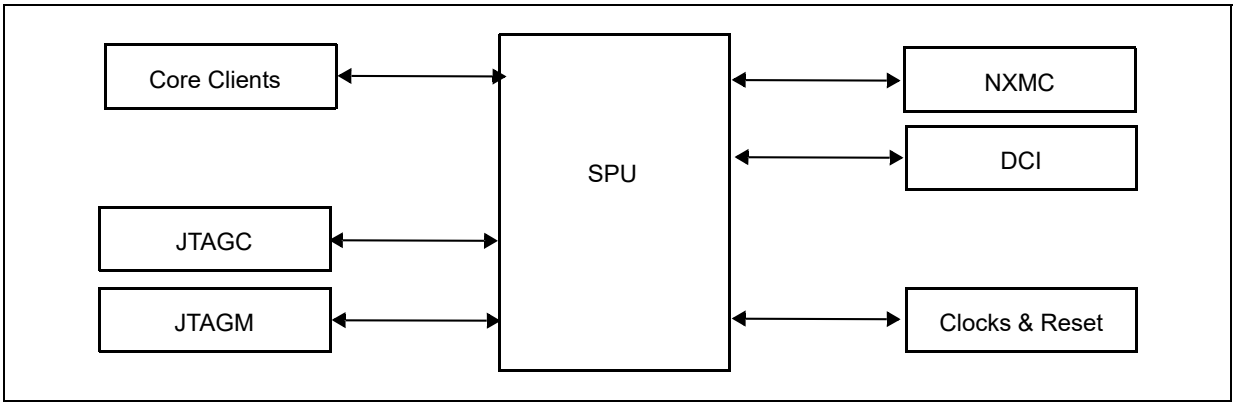
To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any

input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

60.3 Operation mode

60.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:



- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

60.4 SPU module interface

The SPU is connected to many clients such as the cores, system bus and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 1174*.

Figure 1174. SPU module interface

60.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 1137 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x01–0x49) registers is 4'h3.
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x01–0x72) is 4'h2.

60.5.1 Registers description

60.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 1208*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

60.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 1175 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see Calibration and Debug (or Debug and Trace) chapter that describes how the modules are configured.

60.5.1.1.11 CPU0 processor exception vector prefix (C0PEVP)

The SPU captures the exception vector from CPU0 when the exception enable signal is asserted. The exception vector decoding is defined in *Table 1163*. The SPU compares this captured vector with the value in the C0PEVP register. *Figure 1185* shows the format of the C0PEVP register.

The C0PEVP register is described in *Table 1140*.

Table 1140. C0PEVP register field descriptions

Field	Description
16:31 CPU0	CPU0 processor exception vector Program this field with one of the vector values from *Table 1163* to select the corresponding processor exception. This field must use the byte swapped values in the CnPEVP register CPUn field value column in *Table 1163*.

60.5.1.1.12 CPU0 interrupt priority selection (C0PIS)

Figure 1186 shows the format of the C0PIS register. The SPU compares the input CPR vector from CPU0 with the value programmed to the C0PIS register and generates a match signal if necessary. The typical use case would be for posedge detection on match (to detect when the priority level is set to the compare value) or high detection while match remains.

60.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 60.5.1.1*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 1208* for State0. Similar logic is provided for States 1 to 7.

Figure 1187. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

60.5.1.3 Sequence unit registers

60.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 1192* shows the format of the IOICn register where the state number, n = 0 to 7.

Offset: 0x37 n*0x1 (n=0 to 7) Access: Read/Write

60.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 1193* shows the format of the SCTRL register.

31 S1ST0	Sequence1 Enable/Disable Once enabled, this bit is disabled at the end of the Sequence 1. 0 Sequence 1 is disabled 1 Sequence 1 is enabled

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.

60.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 1194 shows the format of the SnGC register where the state number, n = 0 to 7.

Offset: 0x40 +n*0x1 (n= 0 to 7) Access: Read/Write

Table 1149. SS register field descriptions

Field	Description
8 IM0	Interrupt Match 0 This bit indicates the status of the match value on interrupt priority register of CPU0. 0 No match 1 Match occurred
11 EM0	Exception Match 0 This bit indicates the status of the processor exception vector match value of CPU0. 0 No match 1 Match occurred
12:14 SAS4	Sequence 4 Active State Two consecutive read cycles are required to know the active state.These bits capture the active state of sequence 4 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state
15:17 SAS3	Sequence 3 Active State Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 3 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 state5 is the active state 110 State6 is the active state 111 State7 is the active state
18:20 SAS2	Sequence 2 Active State Two consecutive read cycles are required to know the active state.These bits capture the active state of sequence 2 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state

Table 1149. SS register field descriptions (continued)

Field	Description
21:23 SAS1	Sequence 1 Active State Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 1 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state
24 SH7	State Hit 7 This bit is set when State7 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
25 SH6	State Hit 6 This bit is set when State6 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
26 SH5	State Hit 5 This bit is set when State5 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
27 SH4	State Hit 4 This bit is set when State4 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
28 SH3	State Hit 3 This bit is set when State3 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
29 SH2	State Hit 2 This bit is set when State2 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
30 SH1	State Hit 1 This bit is set when State1 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
31 SH0	State Hit 0 This bit is set when State0 is hit/encountered in any of the active sequences 0 State not hit 1 State hit

60.5.1.5 SPU enable register (SE)

The SPU enable/disable register is used to enable and disable the SPU. If disabled, all inputs are masked. *Figure 1196* shows the format of the SE register.

Offset: 0x49 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. This bit is writable.

Figure 1196. SPU enable register (SE)

The SE register fields are described in *Table 1150*.

Table 1150. SE register field descriptions

Field	Description
31 SED	SPU Enable/Disable This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled

60.5.1.6 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 60.2*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 1151* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 1151. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment	
00	Client group	00000	CPU0	0000	No action	—	0=Stop 1=Start
		00001	Reserved	—	DTM_gen0_trace—	Valid for Core, AHB and trace group actions

11	Reserved						

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

60.5.1.6.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a true condition of every state. All the possible actions and their encoding are listed in *Table 1151*. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

Figure 1197 shows the format of the SnTA0 register where the state number, n = 0 to 7.

Offset: 0x01 + n*0x2 (n=0 to 7) Access: Read/Write

Table 1152. SnTA0 register field descriptions

Field	Description
4:15 ACTION2	Action 2 to be performed for State n true condition The decoding of these bits is defined in *Table 1151*.
20:31 ACTION1	Action 1 to be performed for State n true condition The decoding of these bits is defined in *Table 1151*.

60.5.1.6.2 State n true action 1 (SnTA1)

The SPU can be programmed to enable up to four different actions against a true condition of every state. All the possible actions and their encoding are listed in *Table 1151*. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1. *Figure 1198* shows the format of the SnTA1 register where the state number, n = 0 to 7.

Offset: 0x02 + n*0x2 (n= 0 to 7) Access: Read/Write

20:31 ACTION3	Action 3 to be performed for State n true condition The decoding of these bits is defined in *Table 1151*.

60.5.1.6.3 State n false action 0 (SnFA0)

The SPU can be programmed to enable up to four different actions against a false condition of every state. All the possible actions and their encoding are listed in *Table 1151*. A total of 12 bits are needed to code every action. The first two actions for a false condition are defined in SnFA0 and the next two actions are defined in SnFA1. *Figure 1199* shows the format of the SnFA0 register where the state number, n = 0 to 7.

Offset: 0x11 + n*0x2 (n=0 to 7) Access: Read/Write

60.5.1.6.5 Trace group configuration registers (DTMTGC, PTMTGC, OTMTGC, WTMTGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace: clients are configured with the DTM trace group configuration (DTMTGC) register
- PTM trace: clients are configured with the PTM trace group configuration (PTMTGC) register
- OTM trace: clients are configured with the OTM trace group configuration (OTMTGC) register
- WTM trace: clients are configured with the WTM trace group configuration (WTMTGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 1201 shows the format of the trace group configuration registers.

Offset: 0x21 (DTMTGC), 0x22 (PTMTGC), 0x23 (OTMTGC), 0x24 (WTMTGC)

31 CPU0	0 Disable trace for CPU0 1 Enable trace for CPU0

60.5.1.6.6 Interrupt status (INTS)

The status of the external interrupt request to the processor core through the JTAGM is registered in the Interrupt status (INTS) register. This status bit is cleared when the acknowledge is received from the JTAGM. *Figure 1202* shows the format of the INTS register.

Offset: 0x25 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1157. INTS register field descriptions

Field	Description
31 INT	1 Interrupt status bit is cleared from JTAGM

60.5.1.7 Counters control n registers (CCTRLn)

There are 16 configurable counters/timers in the SPU. Configuration control of these counters is defined in the counter control registers. *Figure 1203* shows the format of the CCTRLn registers where the counter number, n = 0 to 15.

Offset: 0x26 + n*0x1 (n = 0 to 15) Access: Read/Write

Figure 1203. Counters control n registers (CCTRLn)

The CCTRLn register fields are described in *Table 1158*.

Table 1158. CCTRLn register field descriptions

Field	Description
23	Reserved. This bit is for internal use only and must be set to 0.
24 SW_RESET	Reset Counter can be reset by software. 0 Software reset is disabled 1 Software reset
25:27 PRESCALING	Prescaling Divides the timer clock by a defined value. 000 No scaling, divide by 1 001 Divide by 4 010 Divide by 16 011 Divide by 32 100 Reserved 101 Reserved 110 Reserved 111 Reserved
29 COUNT_INCR	Count Increment 0 Increment the counter based on the actions generated from the sequences 1 Increment the counter based on the PMC input. The mapping of the PMC inputs with the counters is shown in *Figure 1215*.
30 MODE	Mode Select Select counter or timer operation. 0 Counter 1 Timer
31 ENABLE	Enable 0 Counter disabled 1 Counter enabled

60.5.1.8 Counters compare n registers (CCMPn)

A 32-bit comparator value can be programmed for each of the counters. This value is compared with the corresponding counter/timer to generate an event for the SPU. *Figure 1204* shows the format of the CCMPn registers where the counter number, n = 0 to 15.

Offset: 0x36 + n*0x1 (n = 0 to 15) Access: Read/Write

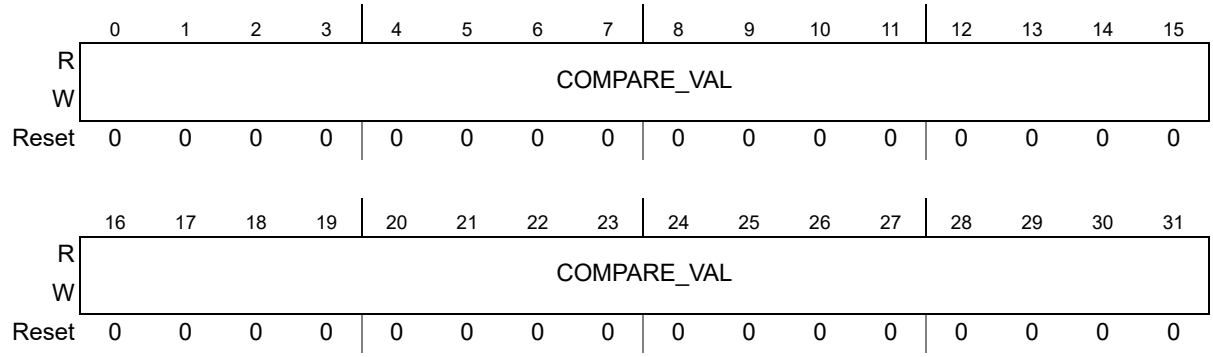

Figure 1204. Counters compare n registers (CCMPn)

The CCMPn register fields are described in *Table 1159*.

Table 1159. CCMPn register field descriptions

Field	Description
0:31 COMPARE_VAL	Compare value This value is compared with the corresponding counter/timer value to generate an event for the SPU.

60.5.1.9 Status registers

60.5.1.9.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. *Figure 1205* shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in *Table 1160*.

Note: Counter compare values and other settings are not recommended to change dynamically, so w1c on CCOMS should be performed in either condition:

- *Counter is in disabled state (ENABLE bit of CCTRLn set to 0)*
- *SW-Reset bit (SW_RESET) is set*

Offset: 0x46 Access: Read/Write

60.5.1.9.3 Counter capture status (CCAPS)

Whenever a counter value is captured, the corresponding capture status register bit for that counter is set. If the counter capture value causes a FIFO overflow, the captured value is lost and the status bit is not set. The bits in this register can be cleared by writing a 1 to them. *Figure 1207* shows the format of the CCAPS register.

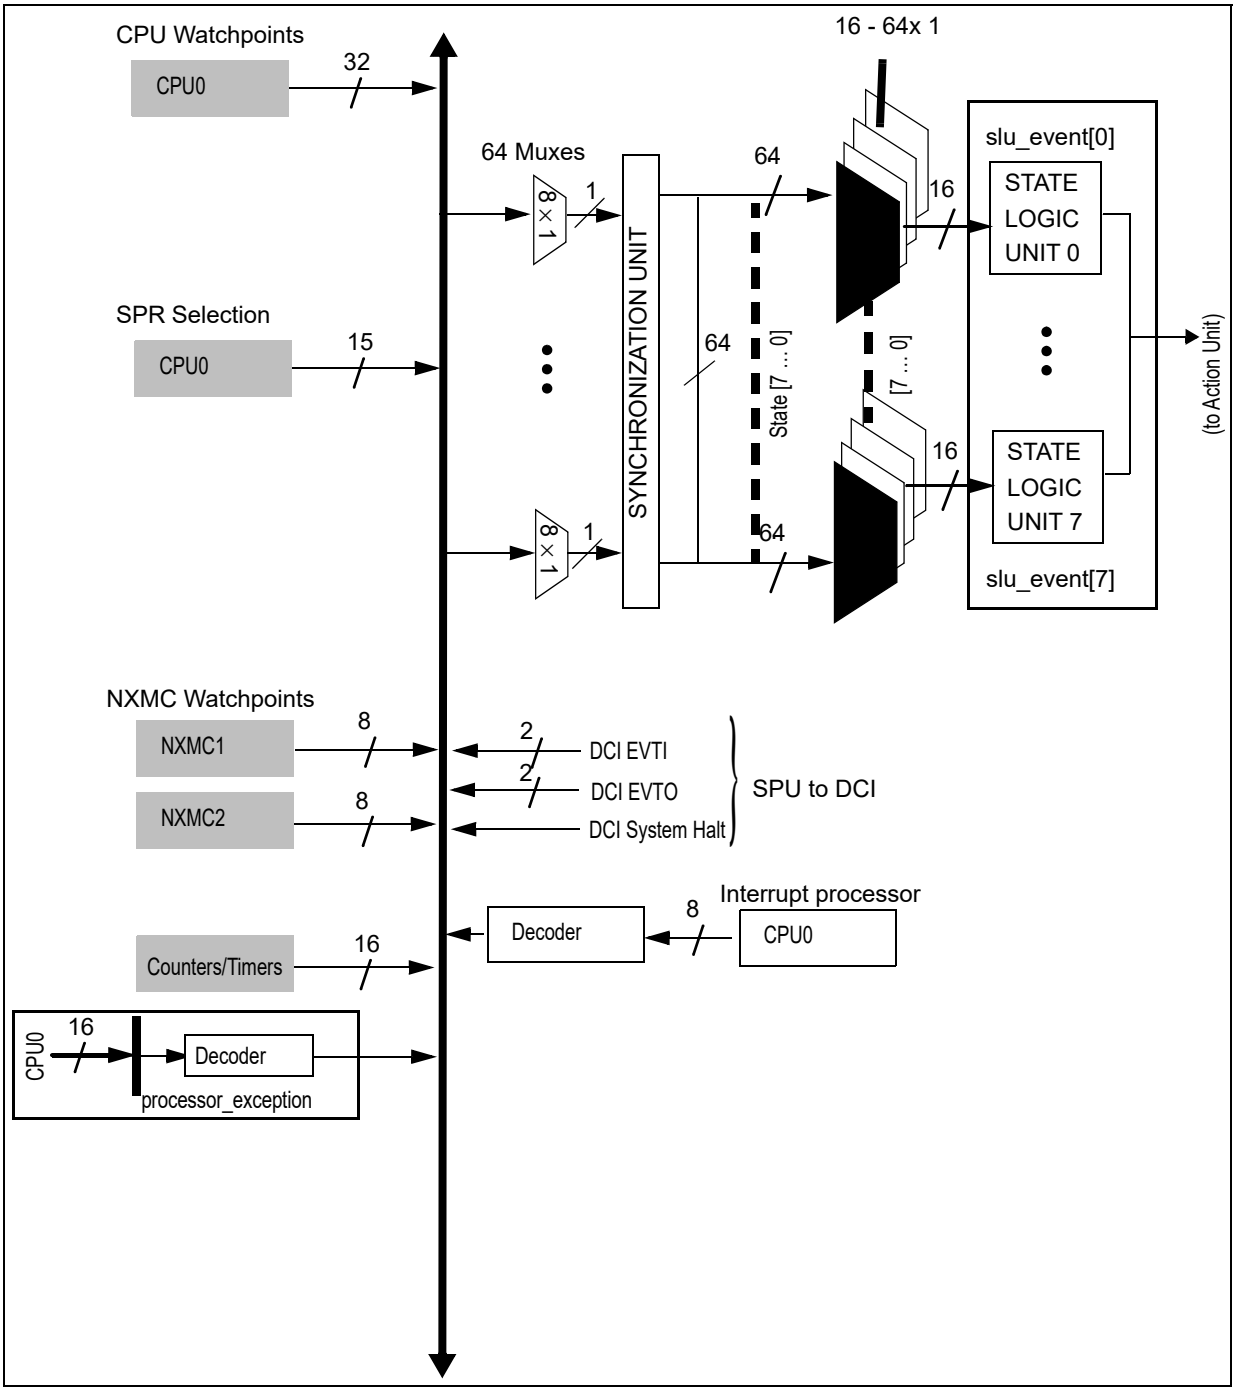
60.6 Functional description

60.6.1 Input Mux unit



The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client

input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in *Figure 1208*.

- Level 1 Muxing: At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 1208*.
- Level 2 Muxing: At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.
  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16×8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 1208*.

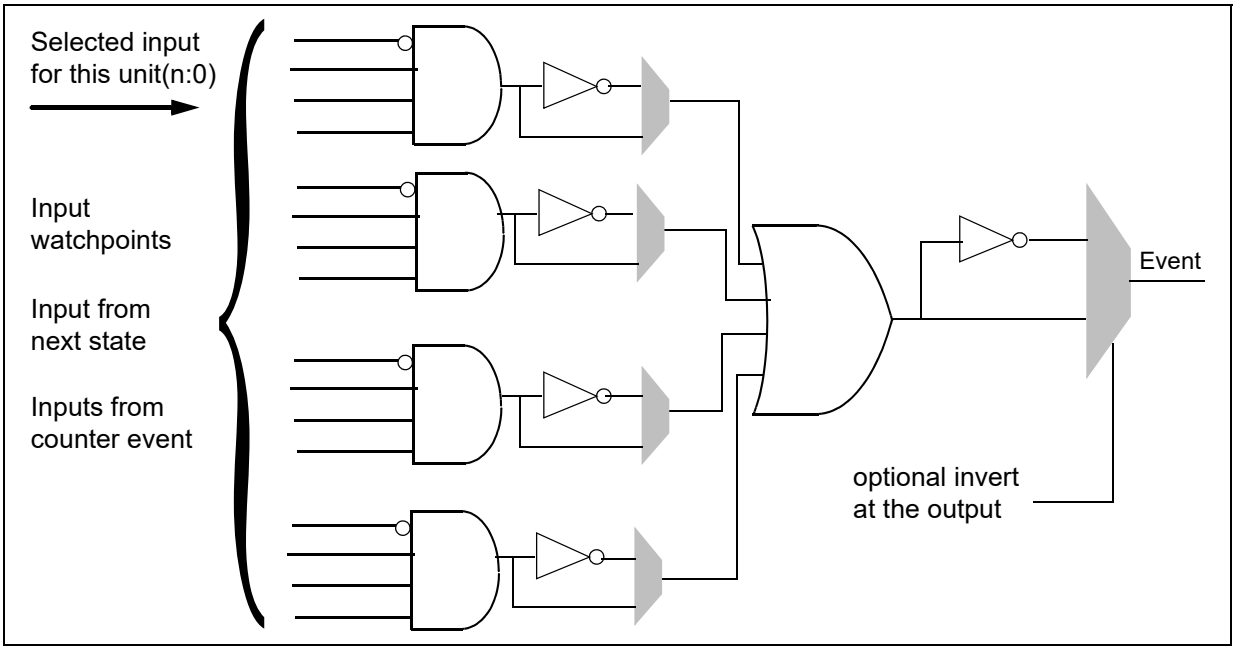
Figure 1208. Input Mux unit block diagram

60.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input

condition as shown in *Table 1163*. The CPU exception vector values from the CPU must be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0) registers as shown in *Table 1163*.

Table 1163. Processor exception processing conditions



CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input: autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input: autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input: vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input: vectored

60.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 1209*.

Figure 1209. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

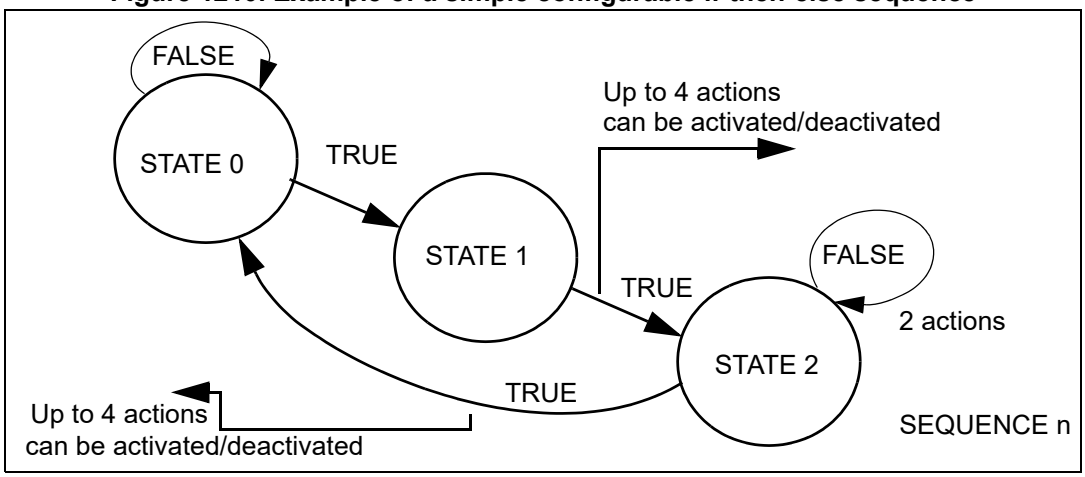
An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

60.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn be designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.



For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 1210*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic.

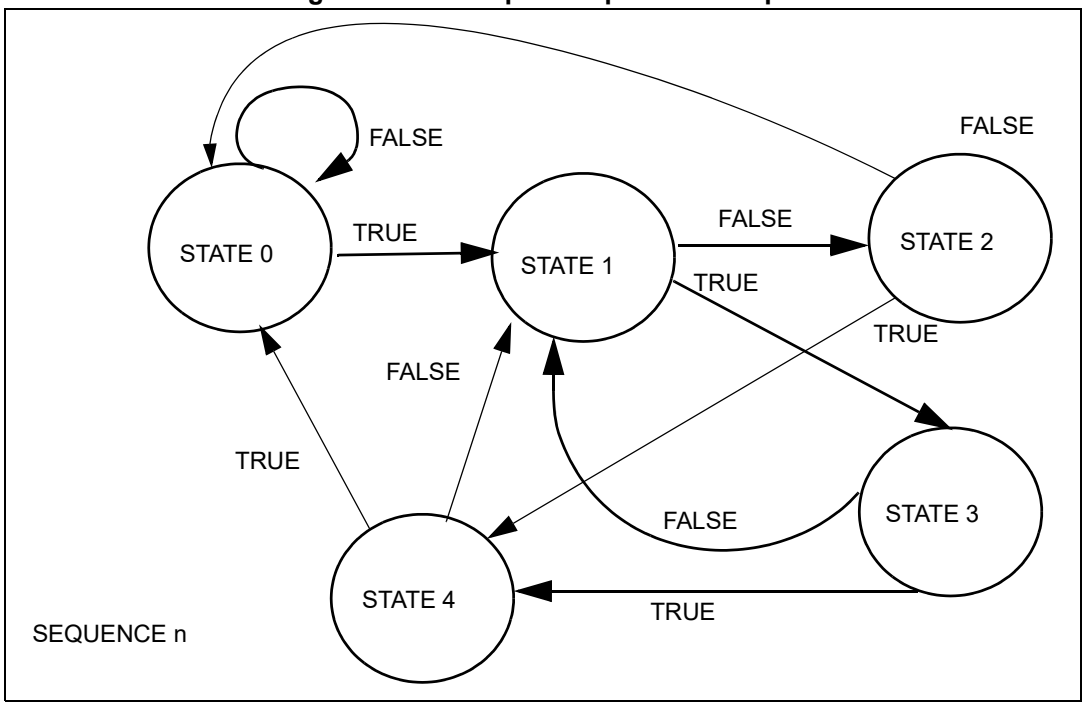


Figure 1210. Example of a simple configurable if-then-else sequence

60.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 1211*.

Figure 1211. Complex sequence example

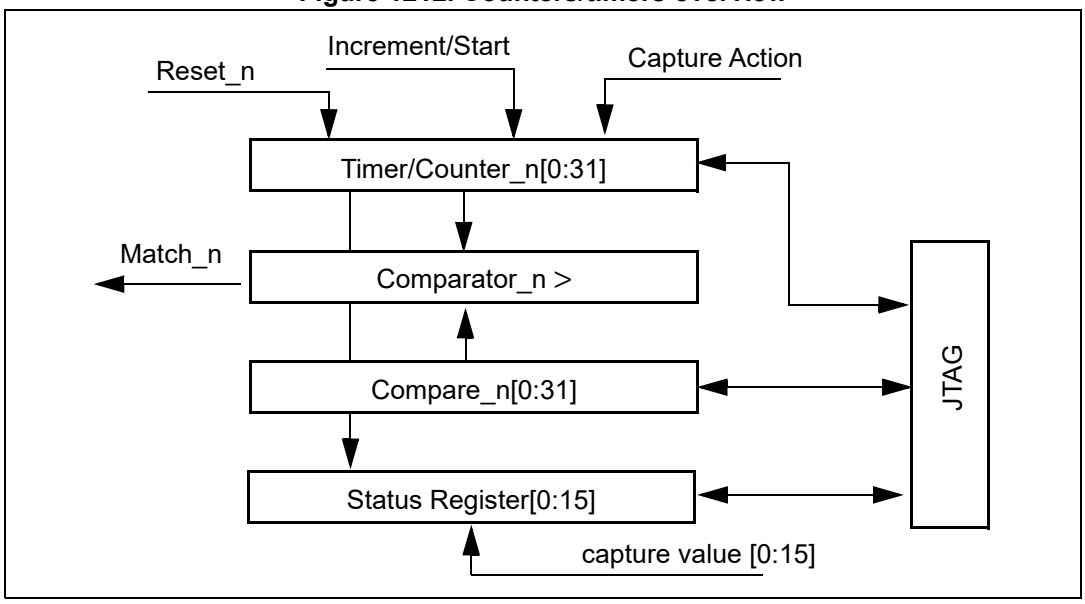
60.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurrence of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

60.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:



- States: each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register
- Sequence status: each sequence has a field indicating the active state of the state machine. This is a read only field

60.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 1212*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

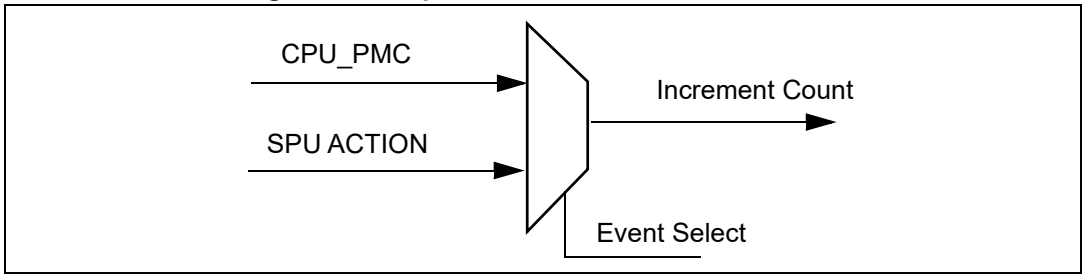
Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 1212. Counters/timers overview

60.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are type write 1 to clear (W1C).

There are two classes of signals, actions and events:



- Actions: each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.
- Event: on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

60.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 1213*. These inputs include signals from the primary SPU muxes or SPU events of counters.

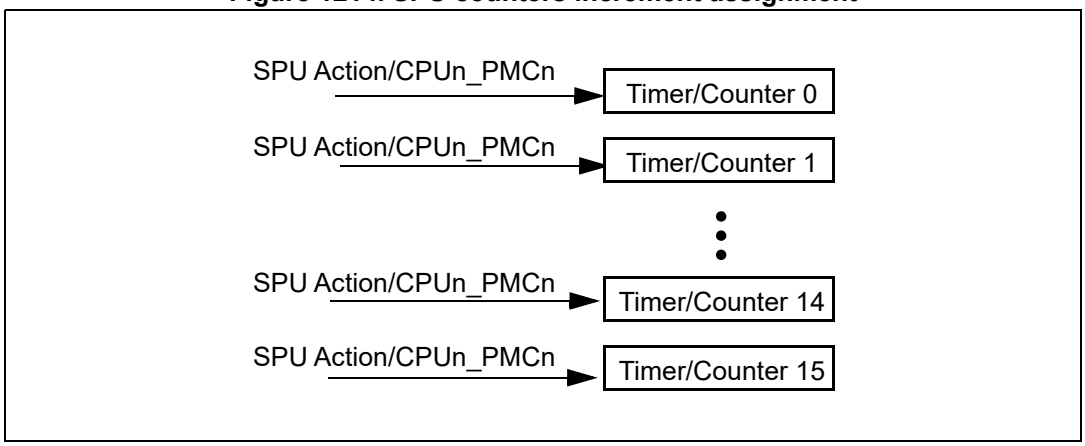


Figure 1213. nput selection for count increment

60.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 1214*.

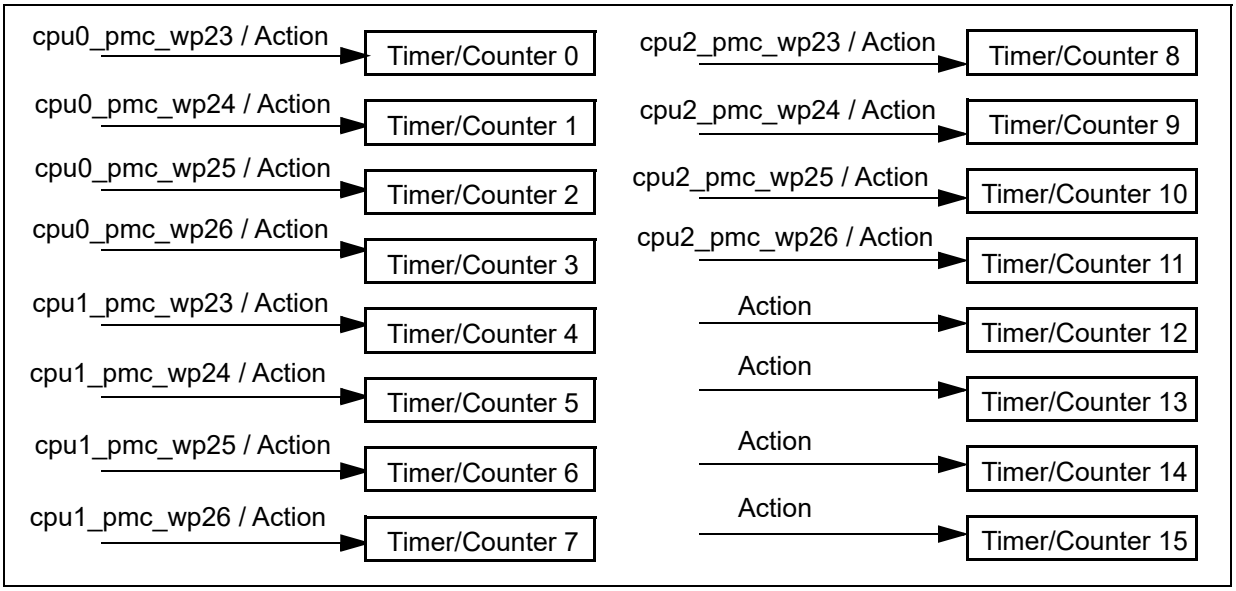

Figure 1214. SPU counters increment assignment

60.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 1215*.

Figure 1215. CPU PMC mapping inside the SPU unit

60.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 60.2*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers**.** Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

60.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers, defined in *Table 1156*, are available where the user can group the different traces from same or different clients.

61 e200z420n3 Nexus 3 Module

The e200z420n3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

61.1 Introduction

61.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

61.1.2 Terms and Definitions

Table 1164 contains a set of terms and definitions associated with the Nexus 3 module.

Table 1164. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1164. Terms and Definitions (continued)

Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event which does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

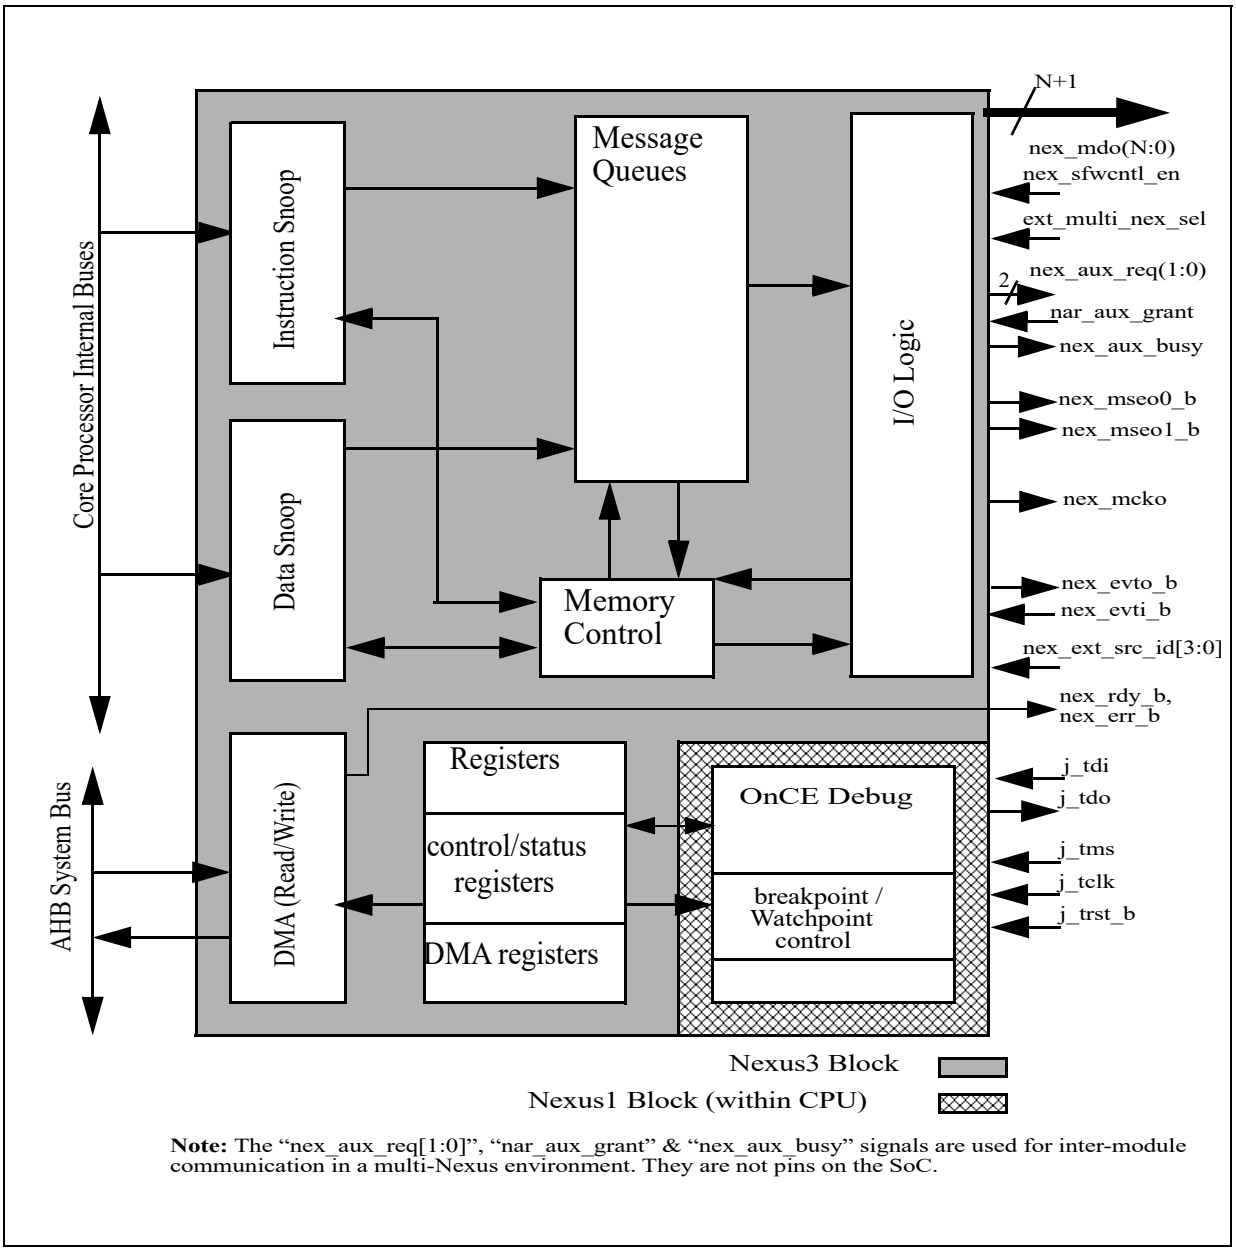
61.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated.

An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (nex_mdo[n:0])
  - One (1) or two (2) Message Start/End Out pins (nex_mseo_b[1:0])
  - One (1) Read/Write Ready pin (nex_rdy_b) pin
  - One (1) Read/Write Error pin (nex_err_b) pin
  - One (1) Watchpoint Event output pin (nex_evto_b)
  - One (1) Event In pin (nex_evti_b)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (nex_sfwcntl_en)



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

61.1.4 Functional Block Diagram

Figure 1216. Nexus 3 Functional Block Diagram

Note: The "nex_aux_req[1:0]", "nar_aux_grant" & "nex_aux_busy" signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

61.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms pin**. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0], nex_mseo[1:0], nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the **Test_Logic_Reset** state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

61.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

61.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001 2010 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 1165*.

Table 1165. Supported TCODEs

Message Name	Minimum Field Size (bits)	Maximum Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace: Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace: Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
Data Trace: Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (refer to *Table 1170*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table 1165. Supported TCODEs (continued)

Message Name	Minimum Field Size (bits)	Maximum Field Size (bits)	Field Name	Field Type	Field Description
Data Trace: Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (refer to *Table 1170*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace: Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace: Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)

Table 1165. Supported TCODEs (continued)

Message Name	Minimum Field Size (bits)	Maximum Field Size (bits)	Field Name	Field Type	Field Description
Program Trace: Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Data Trace: Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier

	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (refer to *Table 1168*): indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (see Section *Section 61.12.4*.)

Table 1165. Supported TCODEs (continued)

Message Name	Minimum Field Size (bits)	Maximum Field Size (bits)	Field Name	Field Type	Field Description
Program Trace: Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 61.12.1*)
Program Trace: Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (see *Section 61.12.1*.)
Program Trace: Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (refer to *Table 1169*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 reserved, 01 one field (CDATA1) (reserved), 10 two fields (CDATA1 + CDATA2), 11 three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 [branch / predicate instruction history] (see *Section 61.12.5*.)
	0	32	CDATA2	variable	correlation data field 2- PID info (see *Section 61.12.5*.)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 61.12.1. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 1166 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1166. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 1167 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1167. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110-1111	Reserved

Table 1168 shows the encodings used for resource codes for certain messages.

Table 1168. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 1169 shows the event code encodings used for certain messages.

Table 1169. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 1170 shows the data trace size encodings used for certain messages.

Table 1170. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

61.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 61.5* and *Section 61.6* for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 1171 details the register map for the Nexus 3 module.

Table 1171. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.

2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

61.4.1 Client Select Control Register (CSC)

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Offset: Refer to *Table 1171* Access: Read-only

Table 1172. CSC Register field descriptions

Field	Description
4:7 CS	Client Select Control xxxx Nexus client (SoC level)

61.4.2 Port Configuration Register - reference only (PCR)

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Note: This register is "reference only" and should not be used for any configuration (Instead SoC module NPC.PCR register is used for the configuration). Its OPC, MCK_EN and MCK_DIV bits are present but have no impact.

Offset: Refer to *Table 1171* Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

2 MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
3:5 MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

61.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 1219* and its fields are described in *Table 1174*.

Note: Its *OPC and MCK_DIV bits are present but have no impact.*

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 61.4.7* for more information on watchpoint triggering. Refer to *Section 61.16* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

61.4.4 Nexus Development Control Registers 2-3 (DC2-3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 1220* and its fields are described in *Table 1175*.

Offset: Refer to *Table 1171* Access: Read/Write

1. Refer to *Table 1169* for implemented EVCODEs.

61.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

61.4.7 Watchpoint Trigger Registers (WT, PTSTC, PTETC, DTSTC, DTETC)

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field

encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

61.4.10 Data Trace Control Register (DTC)

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Offset: Refer to *Table 1171* Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1231. Data Trace Control register (DTC)

The following table details the Data Trace Control register fields.

Table 1186. DTC Register field descriptions

Field	Description
0:1 RWT1	Read/Write Trace 1 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace
2:3 RWT2	Read/Write Trace 2 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace
4:5 RWT3	Read/Write Trace 3 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace
6:7 RWT4	Read/Write Trace 4 00 No trace enabled x1 Enable Data Read Trace 1x Enable Data Write Trace
16 STDC1	Stack Trace Disable Control 1 0 Tracing of stack accesses are not disabled for range 1 1 Tracing of stack accesses are disabled for range 1; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
17 STDC2	Stack Trace Disable Control 2 0 Tracing of stack accesses are not disabled for range 2 1 Tracing of stack accesses are disabled for range 2; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs

Table 1186. DTC Register field descriptions (continued)

Field	Description
18 STDC3	Stack Trace Disable Control 3 0 Tracing of stack accesses are not disabled for range 3 1 Tracing of stack accesses are disabled for range 3; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
19 STDC4	Stack Trace Disable Control 4 0 Tracing of stack accesses are not disabled for range 4 1 Tracing of stack accesses are disabled for range 4; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
24 RC1	Range Control 1 0 Condition trace on address within range 1 Condition trace on address outside of range
25 RC2	Range Control 2 0 Condition trace on address within range 1 Condition trace on address outside of range
26 RC3	Range Control 3 0 Condition trace on address within range 1 Condition trace on address outside of range
27 RC4	Range Control 4 0 Condition trace on address within range 1 Condition trace on address outside of range
28 DI	Data Access / Instruction Access Trace 0 Condition trace on data accesses 1 Condition trace on instruction accesses Note: the support for monitoring instruction accesses is not guaranteed to be present in all versions of the Nexus 3 module. Note: the setting of the DI bit also affects the information provided on the data trace port outputs (See the “Data Trace Port Signals” section in the Core (e200z420n3) Core Debug Support chapter.)

61.4.11 Data Trace Start Address Register n (DTSAn)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 1232* shows the format of the DTSAn registers where the counter number, n = 1 to 4.

Offset: Refer to Table 1171 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R W	Data Trace End Address[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1233. Data Trace End Address register n (DTEAn)

Table 1187 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1187. Data Trace: Address Range Options

Programmed Values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA -> <- DTEA
DTSA < DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace
DTSA = DTEA	N/A	Invalid Range - no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses which meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus theses range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions which are not executed (that is when the instruction prefetch is discarded).

61.4.13 Read/Write Access Control/Status (RWCS)

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. The RWCS Register also provides Read/Write Access Status information per *Table 1189*.

Offset: Refer to *Table 1171* Access: Read/Write

61.4.14 Read/Write Access Data (RWD)

The Read/Write Access Data Register (RWD) provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Offset: Refer to *Table 1171* Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Read/Write Data[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Read/Write Data[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1235. Read/Write Access Data register (RWD)

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 1190* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1190. RWD data placement for Transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword						
first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

1. “X” indicates byte lanes with valid data
“—” indicates byte lanes which will contain unused data.

Table 1191 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1191. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]
Byte @001	0 0 1	—	—	—	AHB[15:8]
Byte @010	0 1 0	—	—	—	AHB[23:16]
Byte @011	0 1 1	—	—	—	AHB[31:24]
Byte @100	1 0 0	—	—	—	AHB[39:32]
Byte @101	1 0 1	—	—	—	AHB[47:40]

Table 1191. RWD byte lane mapping (continued)

Transfer Size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Byte @110	1 1 0	—	—	—	AHB[55:48]

Doubleword @000 first RWD pass second RWD pass	0 0 0	AHB[31:24] AHB[63:56]	AHB[23:16] AHB[55:48]	AHB[15:8] AHB[47:40]	AHB[7:0] AHB[39:32]

1. "-" indicates byte lanes which will contain unused data.

61.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Offset: Refer to *Table 1171* Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Read/Write Address[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Read/Write Address[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1236. Read/Write Access Address register (RWA)

61.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 1171*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 61.23*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 1171*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1237. DR register format

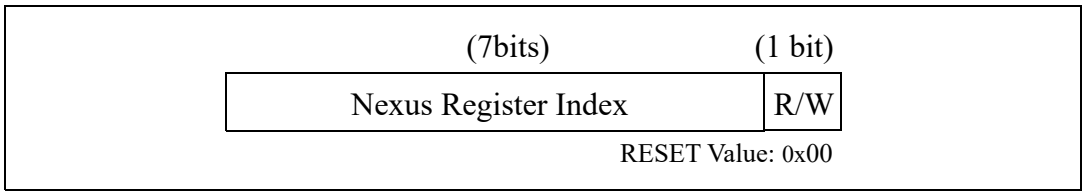

Table 1192. Nexus register index

Nexus Register Index	Selected from values in *Table 1171*
Read/Write (R/W):	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

61.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) which are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 1171* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

61.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following subsections describe a subset of the message field types.

61.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

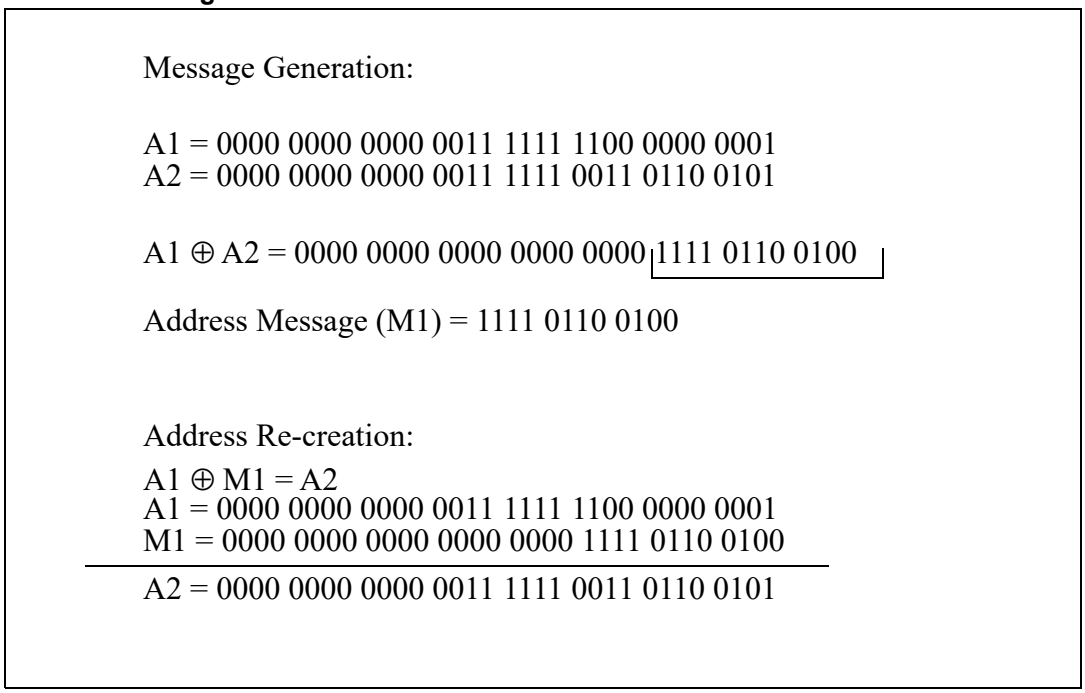
61.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

61.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses which are relative to the address that was transmitted in the previous Program or Data Trace message respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant ‘1’. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 1238. Relative Address Generation and Re-creation

61.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the reconstructed address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

61.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

61.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued which contains information about the types of messages that were discarded due to the overrun condition.

61.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough drop one threshold level below the level which triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 61.4.9* for complete programming options.

61.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 61.8.1*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

61.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 1193 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages which did not successfully queue into the message buffer in that cycle will generate subsequent responses as detailed in *Table 1193*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority:

Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). Up to three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions which complete at the same time or events that occur during the same cycle will be combined.

Table 1193. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP(Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ(Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM: PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT(Ownership)	OTM: PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

61.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

61.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

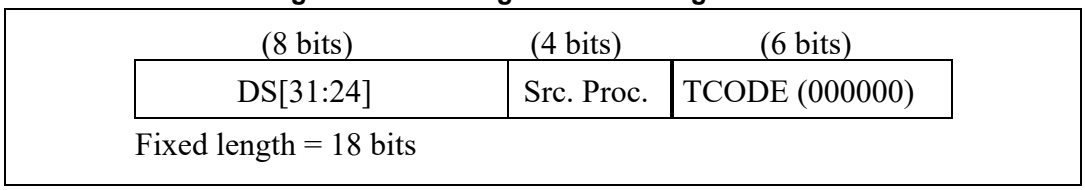
61.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

61.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



61.8.9 Data Trace Message Priority Loss Response

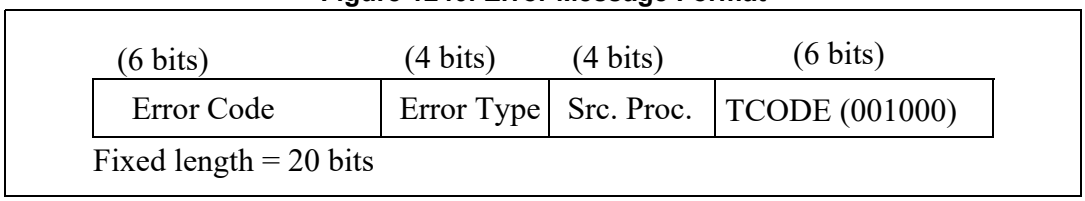
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

61.9 Debug Status Messages

Debug Status Messages report low power mode and debug status. Debug Status Messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status Message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 1239. Debug Status Message Format

61.10 Error Messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see *Table 1166* and *Table 1167*):

Figure 1240. Error Message Format

61.11 Ownership Trace

This section details the ownership trace features of the Nexus 3 module.

61.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

61.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z420n3) processors contain a <asisitalic>PowerISA 2.06 defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

Offset: Refer to SPR - 517 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Nexus 3 Process ID[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Nexus 3 Process ID[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1241. Nexus 3 Process ID Register (NPIDR)

Note: *Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.*

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions which will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index subfield that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value subfield. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 1242. Ownership Trace Message Format

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

61.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z420n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the

IEEE-ISTO 5001 standard definition. Branch Trace Messaging for Core (e200z420n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

61.12.1 Branch Trace Messaging Types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches which trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches which trigger generation of this message type, the branch is included in the count, but not in the history field.

61.12.1.1 Indirect Branch Message Instructions

Table 1194 shows the types of instructions and events which cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1194. Indirect Branch Message Sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count=1

61.12.1.2 Direct Branch Message Instructions

Table 1195 shows the types of instructions which will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1195. Direct Branch Message Sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

61.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

61.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM=1) or traditional Direct/Indirect Branch Messages (PTM=0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

61.12.2 BTM Message Formats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

61.12.2.1 Indirect Branch Messages (History)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to ‘1’, indirect branch information is messaged out in the following format:

Figure 1243. Indirect Branch Message (History) Format

(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

61.12.2.2 Indirect Branch Messages (Traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Figure 1244. Indirect Branch Message Format

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

61.12.2.3 Direct Branch Messages (Traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 1245. Direct Branch Message Format

(1-8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11bits

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

61.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

61.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch Messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch Messages. Branch instructions which trigger message generation are included in the ICNT.

For Branch History Messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions which trigger message generation are included in the ICNT. Instructions which generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

61.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1) which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1196. Branch/Predicate History Events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	bcctr, bcctrl, bclr, bclrl
Not taken direct branches	0	b, ba, bc, bca, bla, bcla, bl, bcl
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.

61.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

61.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow or, if program trace is in history mode, since the last instruction which recorded history information.

Figure 1246. Resource Full Message Format

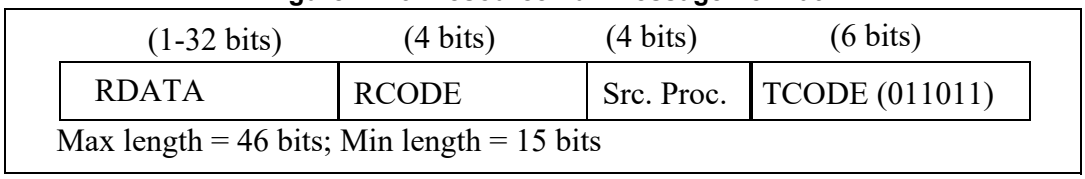


Table 1197 shows the RCODE encodings and RDATA information used for Resource Full messages.

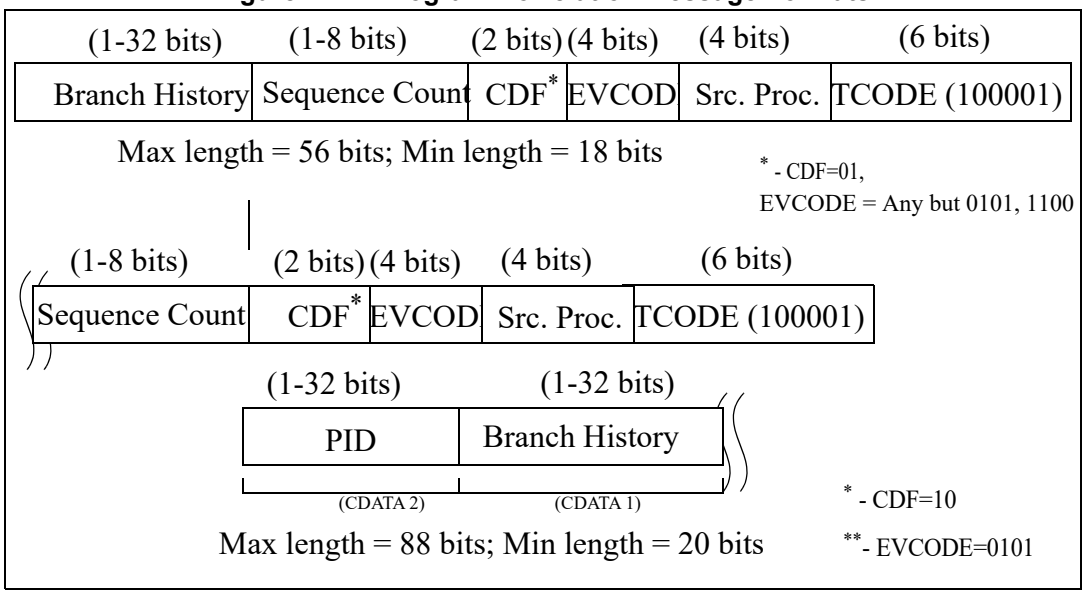
Table 1197. RCODE Encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

61.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call - **bl**/**bcl**/**bla**/**bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 1169* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 1247. Program Correlation Message Formats

61.12.5.1 Program Correlation Message Generation for PID Updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

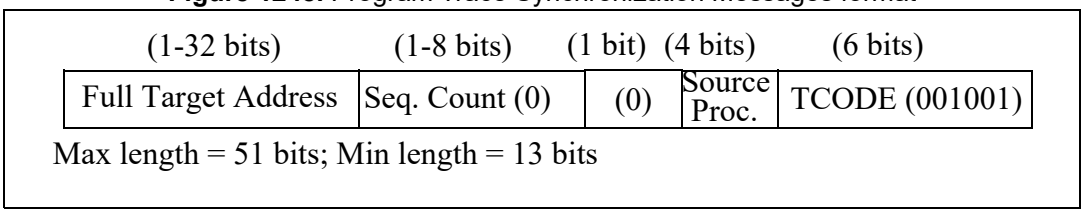
61.12.6 Program Trace Overflow Error Messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

61.12.7 Program Trace Synchronization Messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization Message is messaged via



the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1198*):

- Initial Program Trace Message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to MSR_{PMM}->'1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization Messages is as follow:

Figure 1248. Program Trace Synchronization Messages format

Exception conditions that result in Program Trace Synchronization are summarized in *Table 1198*.

Table 1198. Program Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address

of the instruction which caused program trace to be enabled, or may be the address of the first instruction of an exception handler which is executed in response to unsuccessful completion of that instruction.

61.12.8 Program Trace Direct/Indirect Branch with Sync Messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync Message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1198*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace Messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

Figure 1249. Direct/Indirect Branch with Sync Message Format

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 1250. Indirect Branch History w/ Sync. Message Format

(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 1199*.

Table 1199. Program Trace Exception Summary for w/Sync BTM Messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG}- > OTM -> BTM -> DTM)-> Instruction1 (WPM -> DQM -> OTM -> BTM -> DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 which attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch which did not generate a message due to the collision.

61.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

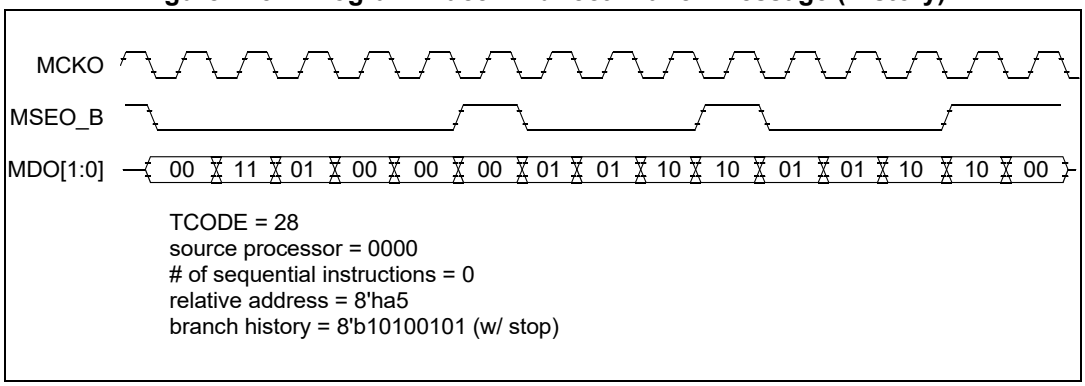

Figure 1253. Program Trace - Direct Branch (Traditional) & Error Messages

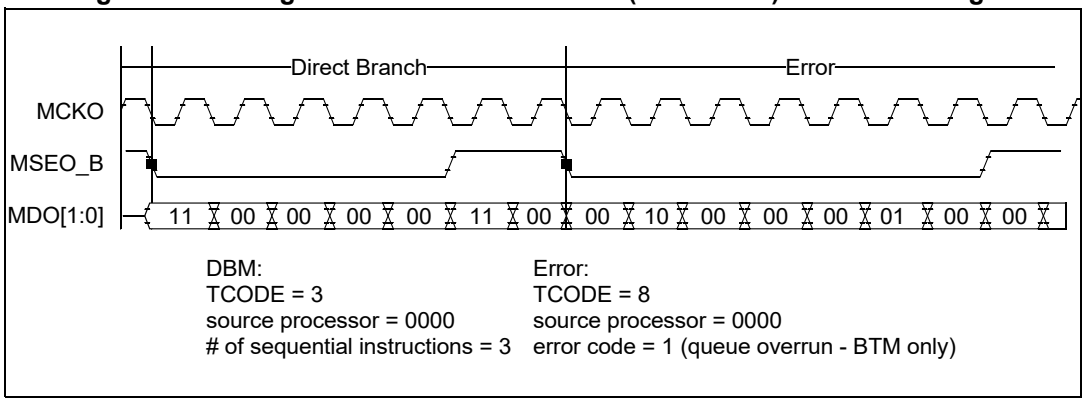

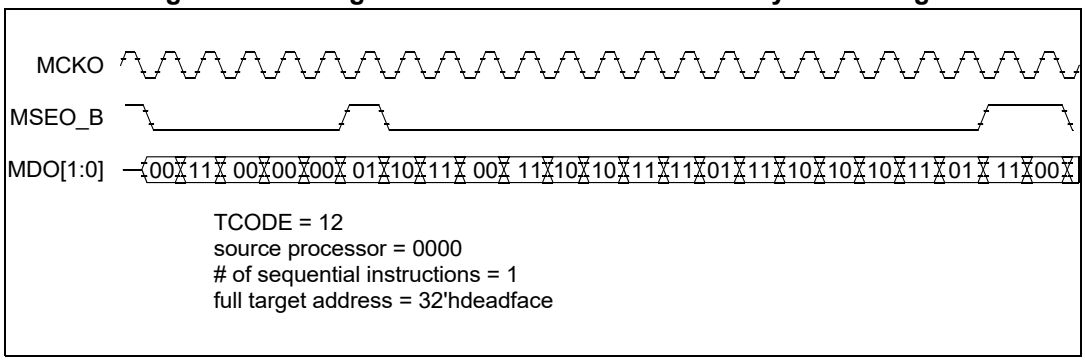

Figure 1254. Program Trace - Indirect Branch w/ Sync. Message

61.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

61.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z420n3) processors which incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

61.13.2 DTM Message Formats

The Nexus 3 block supports five types of DTM Messages - Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

61.13.2.1 Data Write Messages

The Data Write Message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write Message information is messaged out in the following format:

Figure 1255. Data Write Message Format

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

61.13.2.2 Data Read Messages

The Data Read Message contains the data read value and the address of the read access, relative to the previous Data Trace Message. Data Read Message information is messaged out in the following format:

Figure 1256. Data Read Message Format

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

*Note: * Core (e200z420n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.*

*For Core (e200z420n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.

61.13.2.3 Data Trace Synchronization Messages

A Data Trace Write/Read with Sync. Message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 1200*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace Messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM Message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM Message was lost due to a collision entering the FIFO between the DTM Message and any two of the following: Watchpoint Message, Ownership Trace Message, or Program Trace Message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 1257. Data Write/Read with Sync. Message Format

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Exception conditions that result in Data Trace Synchronization are summarized in *Table 1200*.

Table 1200. Data Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.

Table 1200. Data Trace Exception Summary (continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (WPM -> DQM -> OTM -> BTM -> DTM), where instruction0 is the oldest instruction. A DTM Message which attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

61.13.3 DTM Operation

61.13.3.1 Data Trace Windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

61.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

61.13.3.3 Data Trace Filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

61.13.3.4 Bus Cycle Special Cases

Table 1201. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error(1)	Cycle captured & transmitted

Table 1201. Bus Cycle Special Cases (continued)

Special Case	Action
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

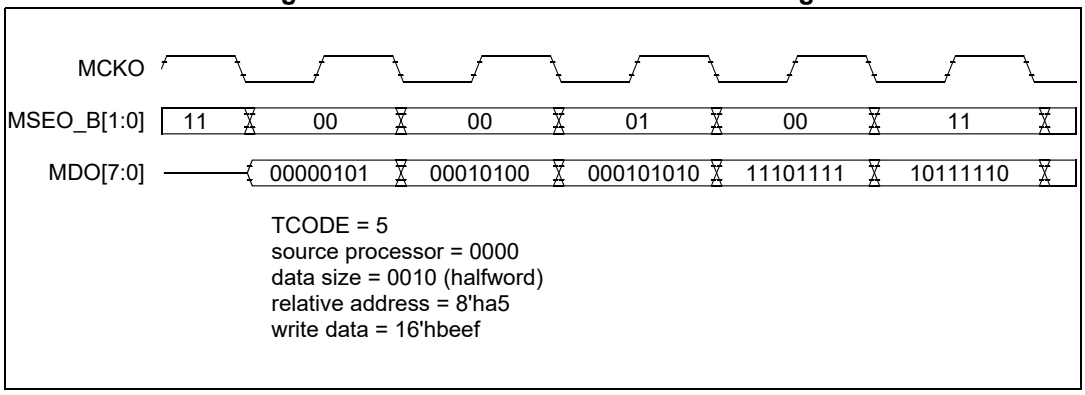
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z420n3) Core Debug Support chapter.)

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

61.13.4 Data Trace Timing Diagrams(8 MDO / 2 MSEO configuration)

Figure 1258. Data Trace - Data Write Message



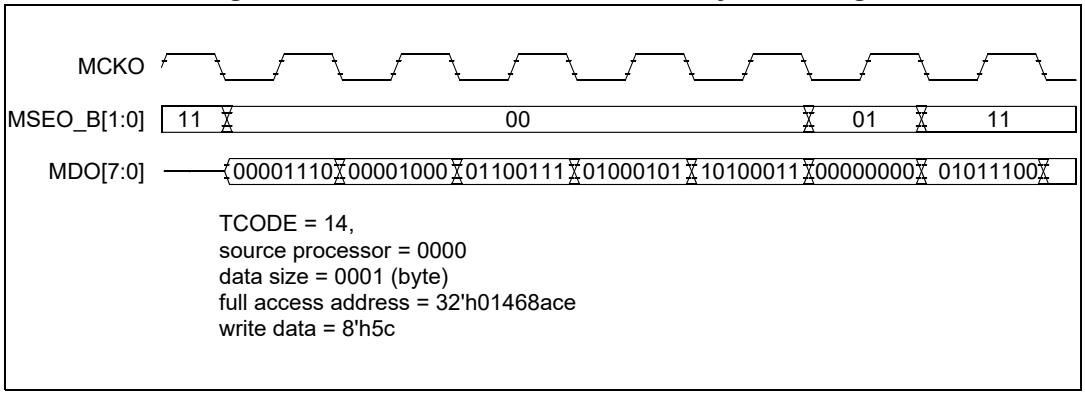


Figure 1259. Data Trace - Data Read w/ Sync Message

61.14 Data Acquisition Messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

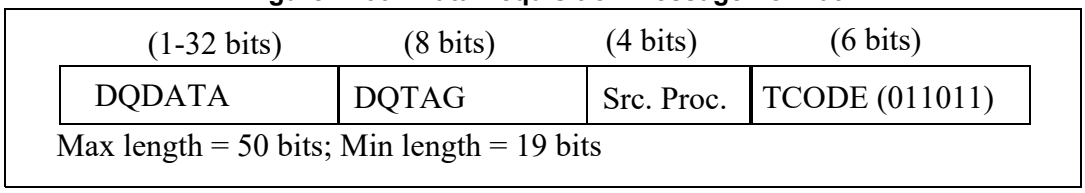
Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

61.14.1 Data Acquisition ID Tag Field

The DQTAG Tag field (DQTAG) is a 8-bit value specifying control or attribute information for the data included in the Data Acquisition Message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

61.14.2 Data Acquisition Data Field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.



61.14.3 Data Acquisition Trace event

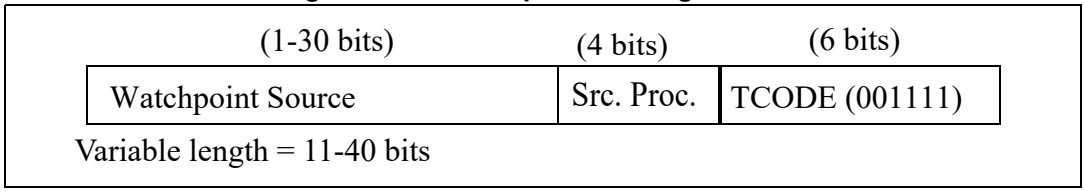
For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition Messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z420n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 1260. .Data Acquisition Message Format

61.15 Watchpoint Trace Messaging



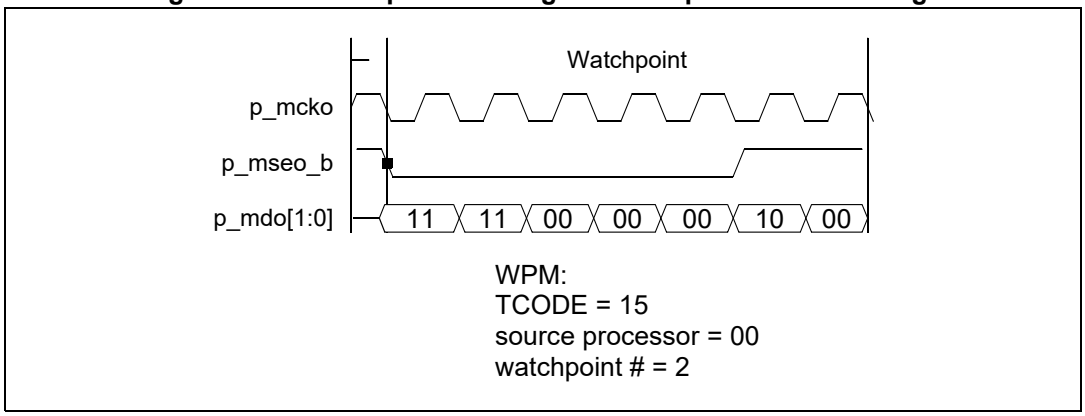
Enabling Watchpoint Messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z420n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 1205* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 1261. Watchpoint Message Format



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 1202. Watchpoint Source Encoding

Watchpoint Source (1:30 bits)	Watchpoint Description
00000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging

61.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1262. Watchpoint Message & Watchpoint Error Message

61.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 1203* details the external hardware trigger signals.

Table 1203. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0->1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0->1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0->1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0->1 on this input signals a stop trace condition.

Table 1203. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0->1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0->1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0->1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0->1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0->1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

61.17 Nexus 3 Read/Write Access to Memory-Mapped Resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps which are required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

61.17.1 Single Write Access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 61.5*. Configure as follows:
   – Write Address -> 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 61.5*. Configure the bits as follows:
   – Access Control (AC) -> 1b'1 (to indicate start access)
   – Map Select (MAP) -> 3b'000 (primary memory map)
   – Access Priority (PR) -> 2b'11 (highest priority)
   – Read/Write (RW) -> 1b'1 (write access)
   – Word Size (SZ) -> 3b'0xx (32-bit, 16-bit, 8-bit)

- Access Count (CNT) -> 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 61.5*. Configure as follows:
   – Write Data -> 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 1205* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

*Note: Only the **nex_rdy_b** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

61.17.2 Block Write Access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 61.17.1* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.
3. If AC has not been cleared due to an error, repeat Step 3 in *Section 61.17.1* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

61.17.3 Single Read Access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 61.5*. Configure as follows:
   – Read Address -> 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 61.5*. Configure the bits as follows:
   – Access Control (AC) -> 1b'1 (to indicate start access)
   – Map Select (MAP) -> 3b'000 (primary memory map)
   – Access Priority (PR) -> 2b'11 (highest priority)
   – Read/Write (RW) -> 1b'0 (read access)
   – Word Size (SZ) -> 3b'0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) -> 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 1205* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 61.5*.

*Note: Only the **nex_rdy_b** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

61.17.4 Block Read Access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 61.17.3* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 1205* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT

field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 1205* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.

4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 61.5*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 61.17.3* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32-bits at a time LSB first (that is doubleword read = two word reads from the RWD).

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

61.17.5 Error Handling

The Nexus 3 module handles various error conditions as follows:

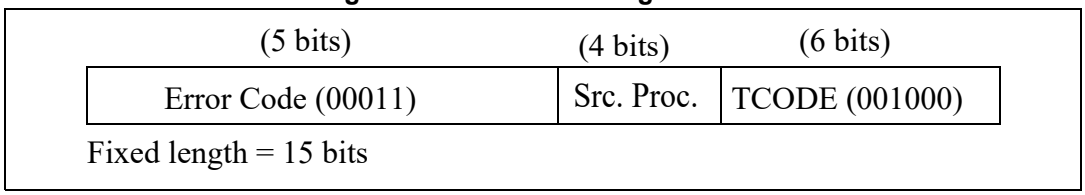
61.17.5.1 AHB Read/Write Error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without re-trying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write Error

61.17.5.2 Access Termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

61.17.6 Read/Write Access Error Message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 1263. Error Message Format

61.18 Nexus 3 Pin Interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

61.18.1 Pins Implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 1205*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 61.5* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z420n3) Core Debug Support chapter.

Table 1204. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 1205*.

Table 1205. Nexus 3 Auxiliary Pins

Auxiliary Pins	Input/ Output	Description of Auxiliary Pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins which indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains de-asserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains de-asserted
nex_evto_b	O	Event Out (**nex_evto_b**)is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) one (or more) watchpoints has occurred (from Nexus1) & EOC = 2’b00 2) debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2’b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input which, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2’b00). 2) Debug request to Nexus1 module (provided EIC = 2’b01 and this feature is implemented).

Table 1205. Nexus 3 Auxiliary Pins (continued)

Auxiliary Pins	Input/ Output	Description of Auxiliary Pins
nex_ext_src_id[0 :3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC which shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Auora Router (NAR). Refer to *Section 61.20* for detail on Nexus port arbitration.

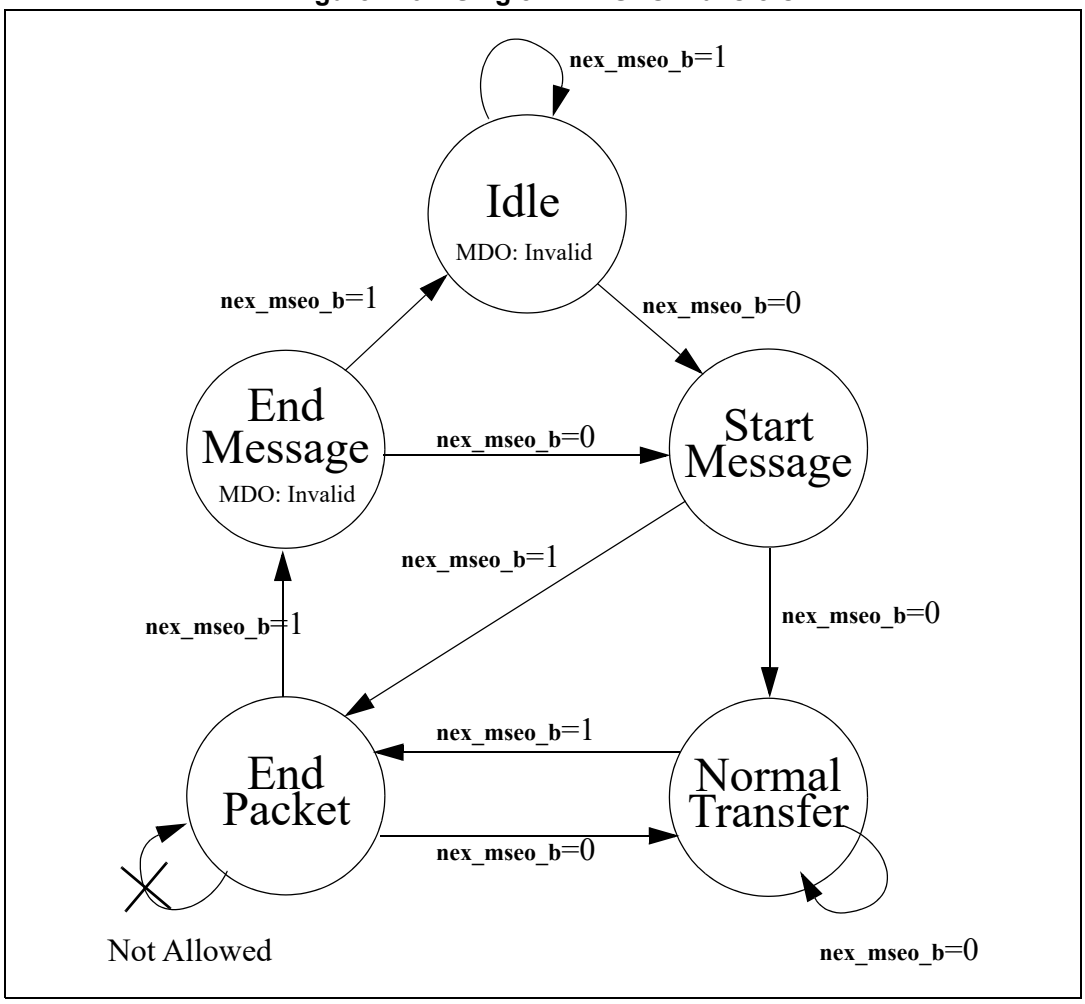
Table 1206. Nexus Port Arbitration Signals

Nexus Port Arbitration Pins	Input/ Output	Description of Arbitration Pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 1208*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

61.18.2 Pin Protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 1207*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



Single pin MSEO is not supported on the SPC574Sx.

Table 1207. MSEO Pin(s) Protocol

nex_mseo_b Function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 1264 illustrates the state diagram for single pin MSEO transfers.

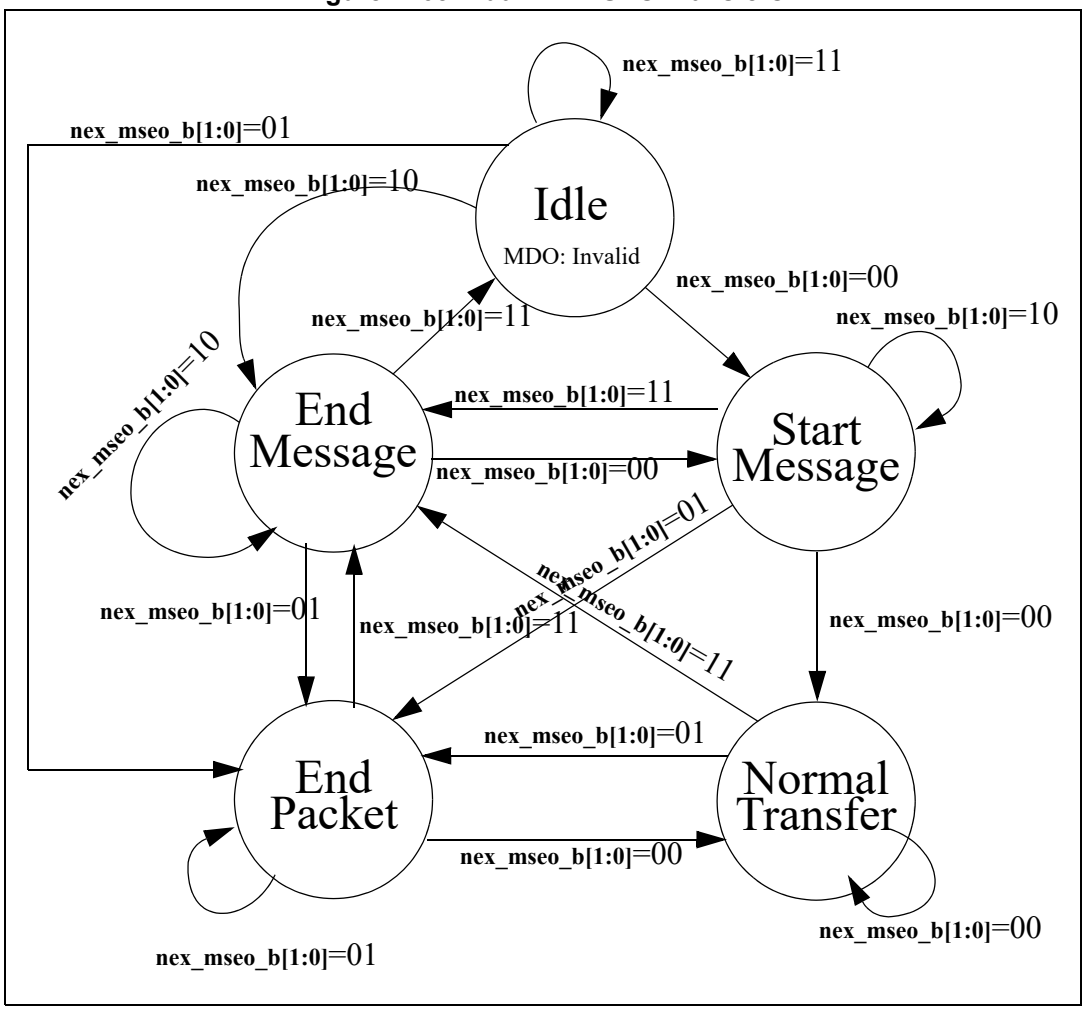


Figure 1264. Single Pin MSEO Transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 1265 illustrates the state diagram for dual pin MSEO transfers.

Figure 1265. Dual Pin MSEO Transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

61.19 Rules for Output Messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is

impossible to know which bit is from the last packet and which bit is from the next packet.)

- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary. For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

61.20 Auxiliary Port Arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 1208* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 61.18.2*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 1208. MDO Request Encodings

Request Level	MDO Request Encoding (nex_aux_req[1:0])	Condition of Queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

61.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 1209 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 1210* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1209. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1210. Indirect Branch Message Example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1211 and *Table 1212* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1211. Direct Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1212. Direct Branch Message Example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1213 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 1214* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable - 8, 16 or 32-bit)

Table 1213. Data Write Message Example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 1214. Data Write Message Example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

61.22 Electrical Characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC574Sx datasheet.

61.23 IEEE 1149.1 (JTAG) RD/WR Sequences

This section contains example JTAG/OnCE sequences used to access resources.

61.23.1 JTAG Sequence for Accessing Internal Nexus Registers

Table 1215. Accessing Internal Nexus 3 Registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

61.23.2 JTAG Sequence for Read Access of Memory-Mapped Resources

Table 1216. Accessing Memory-Mapped Resources (Reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address: data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value: data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

61.23.3 JTAG Sequence for Write Access of Memory-Mapped Resources

Table 1217. Accessing Memory-Mapped Resources (Writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

62 Nexus Crossbar Multi-Master Client (NXMC)

62.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA AHB, and CPU Data Bus AHB start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.This also provides the capability of sending user defined messages for the peripherals attached to it.

62.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

62.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 1219*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see *Section 62.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 1218* describes the JTAG pins.

Table 1218. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 1219. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see *Section 62.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

62.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 1220*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 1220. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1221*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1221*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See *Table 1222*)
	14	14	ECODE	fixed	Error code (See *Table 1223*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1221*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1220. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1221*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See *Table 1235*)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1221. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 1222. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 1223. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved
Source (SRC) n = peripheral index		
CKSRCn	XXXXXXX1	Reserved
CKSRCn	XXXXXX1X	Reserved
CKSRCn	XXXXX1XX	Reserved
CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	Reserved
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

62.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See *Section 62.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 1224*.

Table 1224. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	0x2	R/W	0x04	0x05
Development Control 2 (DC2)	0x3	R/W	0x06	0x07
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B
Data Trace Start Address1 (DTSA1)	0xE	R/W	0x1C	0x1D
Data Trace Start Address2 (DTSA2)	0xF	R/W	0x1E	0x1F

Table 1224. NXMC registers (continued)

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Data Trace End Address1 (DTEA1)	0x12	R/W	0x24	0x25
Data Trace End Address2 (DTEA2)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register1 (BWC1)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register2 (BWC2)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register1 (BWA1)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register2 (BWA2)	0x1F	R/W	0x3E	0x3F

62.4.1 Register definitions

Detailed register definitions for the current NXMC implementation are described in the following sections.

62.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. *Figure 1266* shows the format of the DC1.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0(1)	0(1)	0(1)	EOC		0	0	WEN	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0(1)
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and it's value has no impact on the system

Figure 1267. Development control register 2 (DC2)

The DC2 is described in *Table 1226*.

Table 1226. DC2 register field description

Field	Description
0:7 EWC	$\overline{\text{EVTO}}$ Watchpoint Configuration(1). 00000000 No Watchpoints trigger $\overline{\text{EVTO}}$ 1XXXXXXX External Watchpoint #1 triggers $\overline{\text{EVTO}}$ X1XXXXXX External Watchpoint #2 triggers $\overline{\text{EVTO}}$ XX1XXXXX Reserved(2) XXX1XXXX Reserved(2) XXXX1XXX Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$ XXXXX1XX Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$ XXXXXX1X Reserved(2) XXXXXXX1 Reserved(2)

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. Writing bits 2,3,6,7 has no impact and read value will be 0 for these bits.

62.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 1268* shows the format of the WT register.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	DTS			DTE			0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1268. Watchpoint trigger register (WT)

The WT register is described in *Table 1227*.

Table 1227. WT register field description

Field	Description(1)
6;8 DTS	Data Trace Start Control. 000 Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved
9;11 DTE	Data Trace End Control. 000Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

62.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels

controlled by the DTC for the NXMC module. *Figure 1269* shows the format of the DTC register.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1269. Data trace control (DTC) register

The DTC register is described in *Table 1228*.

Table 1228. DTC field description

Field	Description
0:1 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
2:3 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
7 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
12:15 MID	ID of the system bus Master to be traced(1)
24 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
25 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

62.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 1270* shows the format of the DTSA1 and DTSA2 registers.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1270. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

62.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. *Figure 1271* shows the format of the DTEA1 and DTEA2 registers.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1271. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 1229 illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1229. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range – no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

62.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. *Figure 1272* shows the format of the BWC1 register.

Address: refer to *Table 1224* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1	
W

14:15 BWR2	Breakpoint/Watchpoint #2 Register Compare. 00 No Register Compare (same as BWC2[31:30] = 2b00) 01 Reserved 10 Compare with BWA2 value 11 Reserved
16 BWT2	Breakpoint/Watchpoint #2 Type 0 Reserved 1 Watchpoint #2 on data accesses

62.4.1.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. *Figure 1274* shows the format of the BWA1 and BWA2 registers.

Address: refer to *Table 1224* Access: User read/write

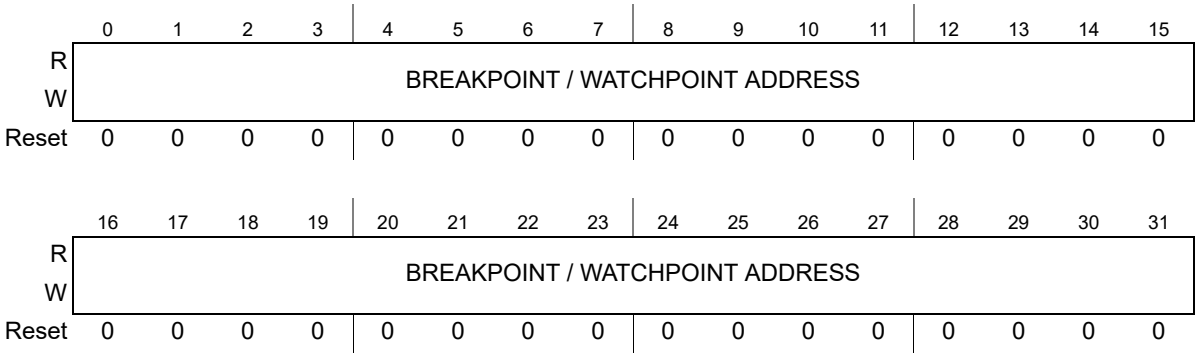

Figure 1274. Breakpoint /watchpoint address registers 1 and 2 (BWA1 and BWA2)

62.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 1224*. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

62.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion, after the JTAG ID register has been read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

62.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 62.5.4: NXMC register access via JTAG*.

62.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

62.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG

ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set.

62.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 1224*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see *Table 1224*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 1275* and *Table 1232*.

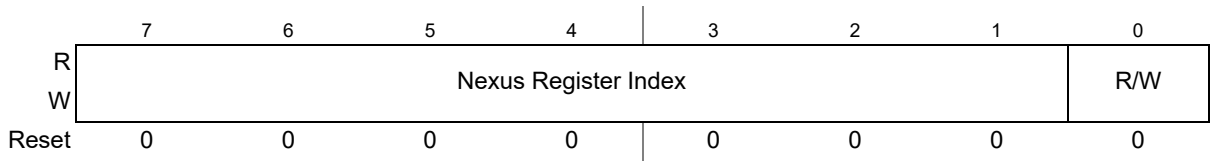

Figure 1275. JTAG DR for Nexus register access

Table 1232. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 1224*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

62.6 Functional description

62.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

62.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target

addresses). The NXMC module traces all data access that meet the selected range and attributes.

62.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

62.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. Data write message and data read message information is messaged out in the format shown in *Figure 1276*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

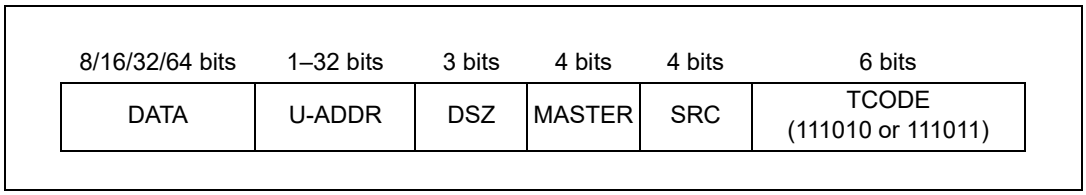

Figure 1276. DTM message format for DATA width = 64 bits

62.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

62.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 1277*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

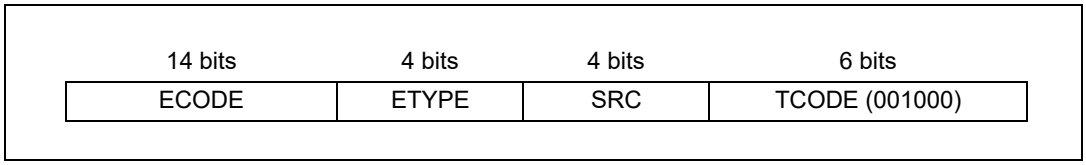

Figure 1277. DTM error message format (fixed length = 48 bits)

62.6.1.2.3.1 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see *Table 1233*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message
- Upon returning from a low power state, the first data trace message is a synchronization message
- Upon returning from debug mode, the first data trace message is a synchronization message
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 1278*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

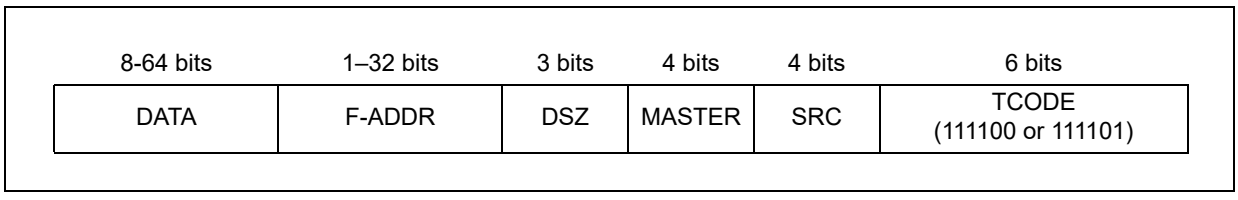

Figure 1278. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 1233*.

Table 1233. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

62.6.1.3 DTM operation

62.6.1.3.1 Enabling data trace messaging

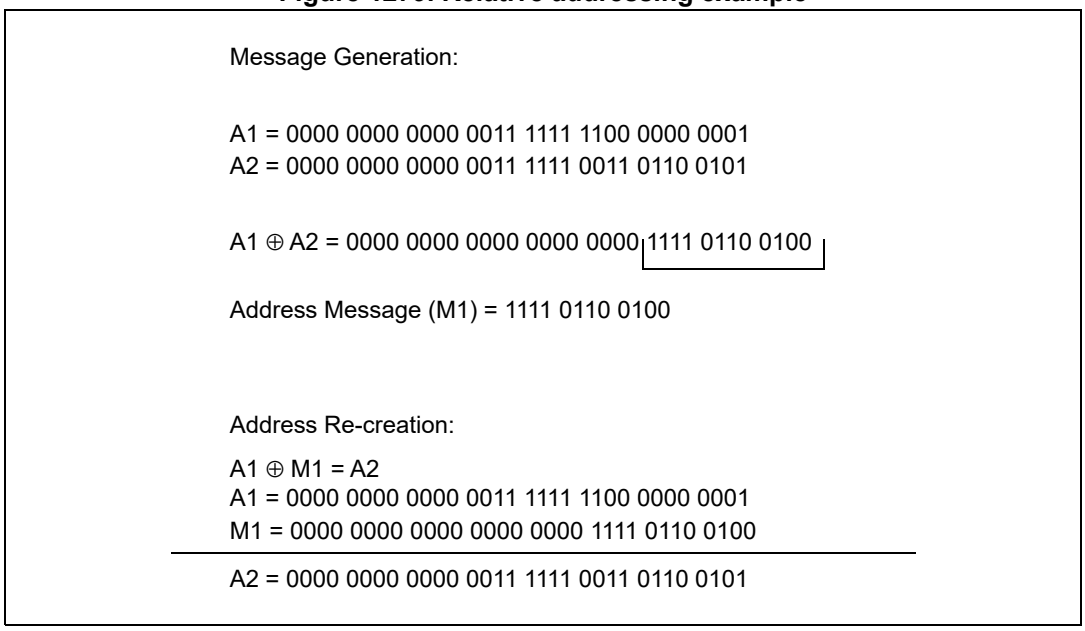
Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (that is DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

62.6.1.3.2 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.



Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).

62.6.1.3.3 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 1279*.

Figure 1279. Relative addressing example

62.6.1.3.4 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

62.6.1.3.5 System bus cycle special cases

The system bus cycle special cases are shown in *Table 1234*.

Table 1234. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

62.6.1.3.6 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in *Section 62.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

62.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

62.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (that are BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints: Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 62.6.1.3.6: System bus multi-master tracing*)
- External watchpoints: The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level.The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (that is on 0-to-1 transition), a watchpoint message is transmitted

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to

the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 1280* and *Table 1235*.

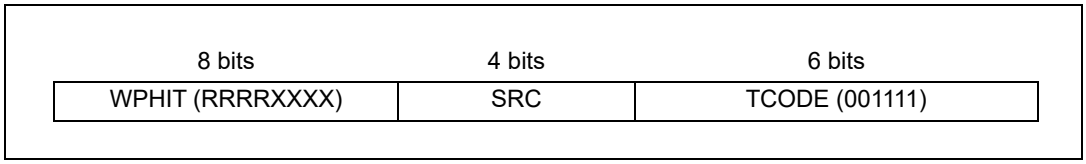


Figure 1280. Watchpoint message format (fixed length = 18 bits)

Table 1235. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1(1)	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

62.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 1281*.

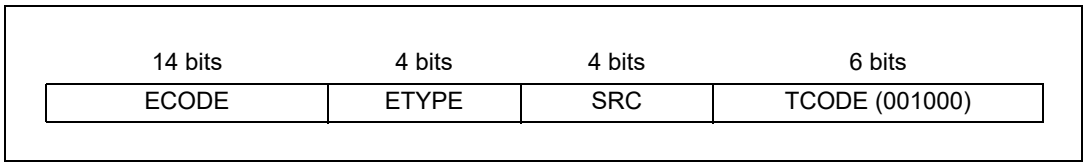

Figure 1281. Error message format (fixed length = 28 bits)

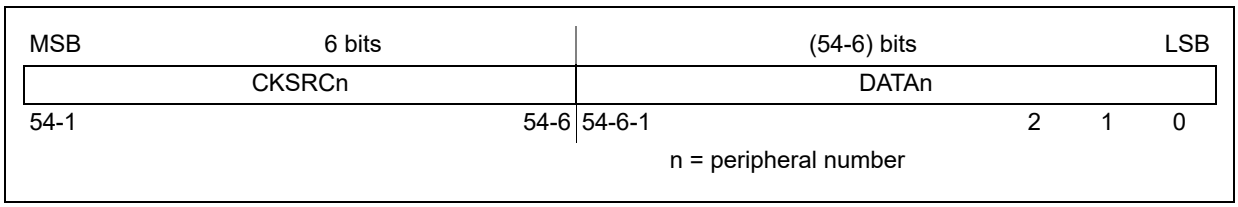

Figure 1282. Peripheral DATA bus fields

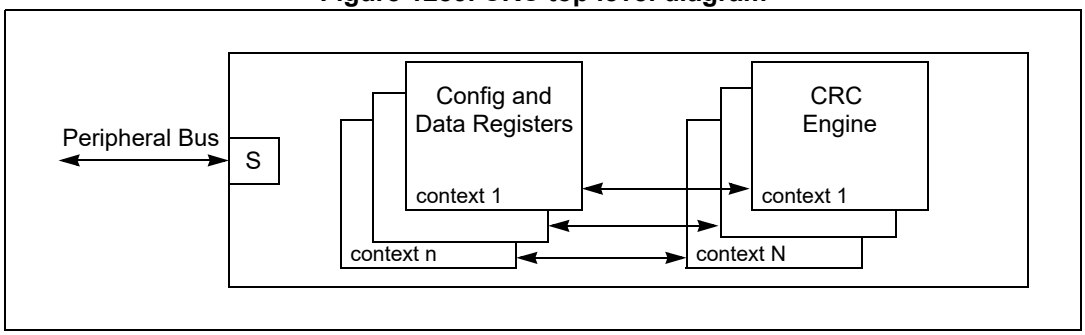
63 Cyclic Redundancy Check (CRC) Unit

63.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

63.2 Main features

- One contexts for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Four hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
  - Support for byte, halfword, or word width of the input data stream



63.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

63.3 Block diagram

The top level diagram of the CRC module is given in *Figure 1283*.

Figure 1283. CRC top level diagram

1. Where context number, n = 1.

63.4 Signal description

The CRC module does not generate any external signals.

63.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

63.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

63.5.1 Register description

Table 1236 shows the memory map for the CRC registers.

Table 1236. CRC unit memory map

Table 1240. CRC_OUTP*n* field descriptions

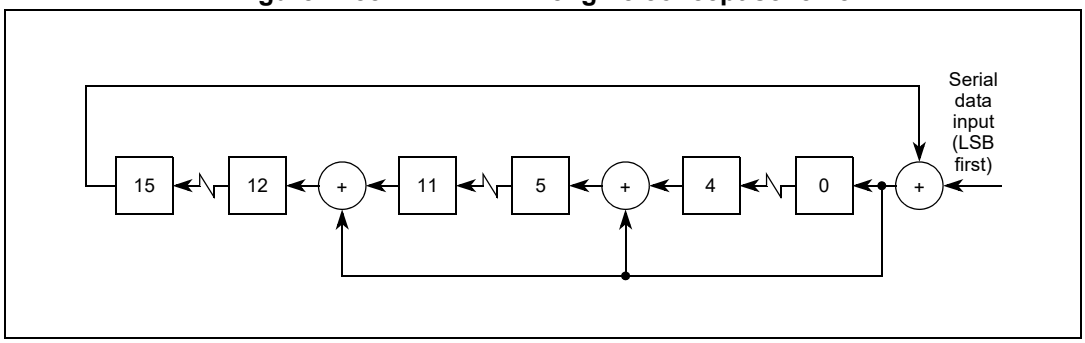
Field	Description
0:31 OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

63.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 73*, *Equation 74* and *Equation 75* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.



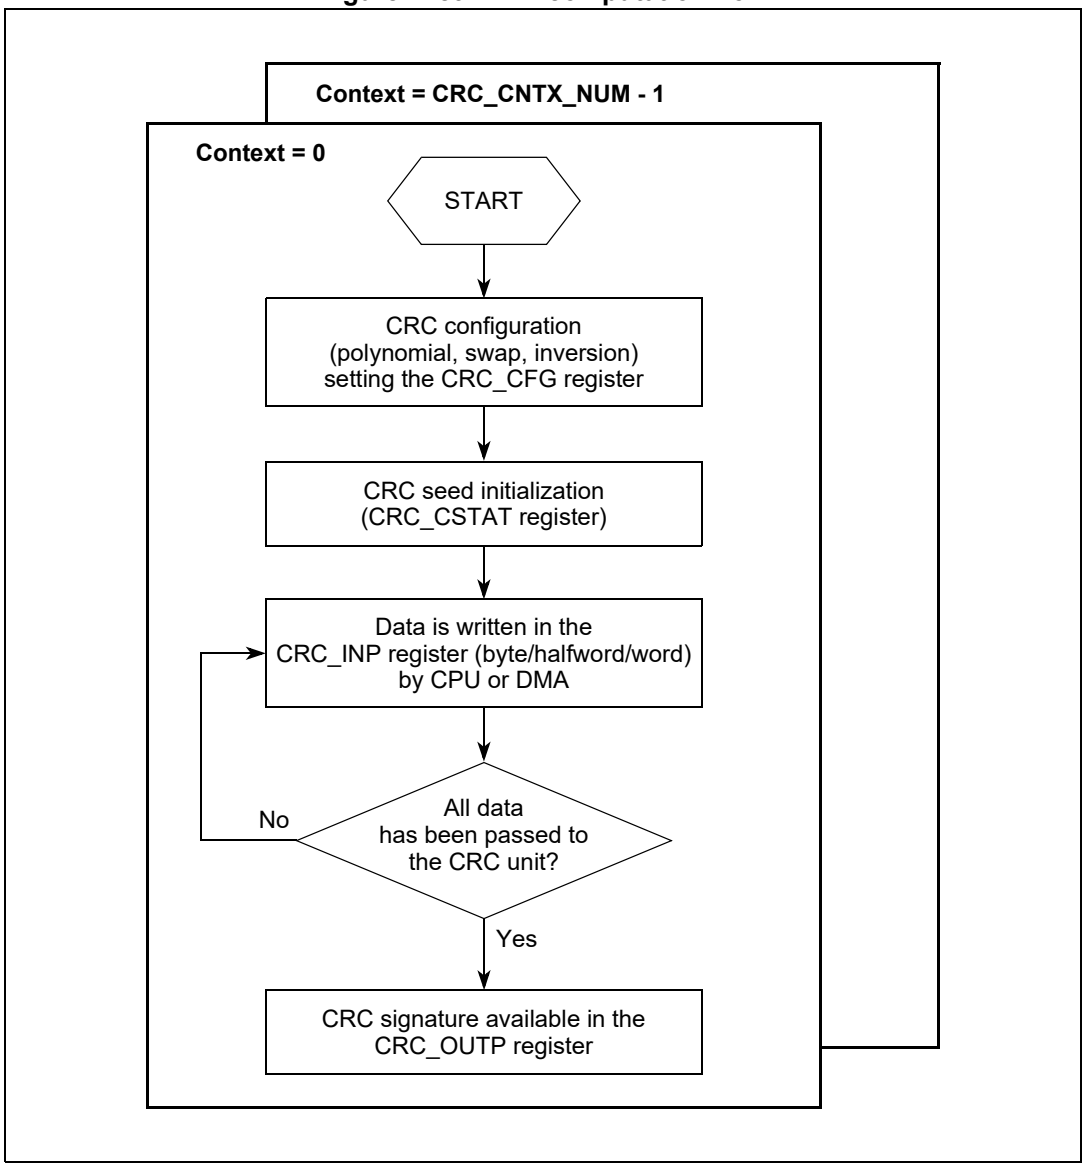
Equation 73 CRC8 VDA CAN:
$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 74 CRC-CCITT (x.25 protocol):
$$x^{16} + x^{12} + x^5 + 1$$

Equation 75 CRC-32 (Ethernet protocol):
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 76 CRC-8-H2F (Autosar 4.0 protocol):
$$x^8 + x^5 + x^3 + x^2 + x + 1$$

Figure 1288. CRC-CCITT engine concept scheme



The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 1288* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (such as SPI), a bit swap (MSB → LSB, LSB → MSB) or bit inversion of the final CRC signature, or both can be applied (CRC_OUTP register) before transmitting the CRC.

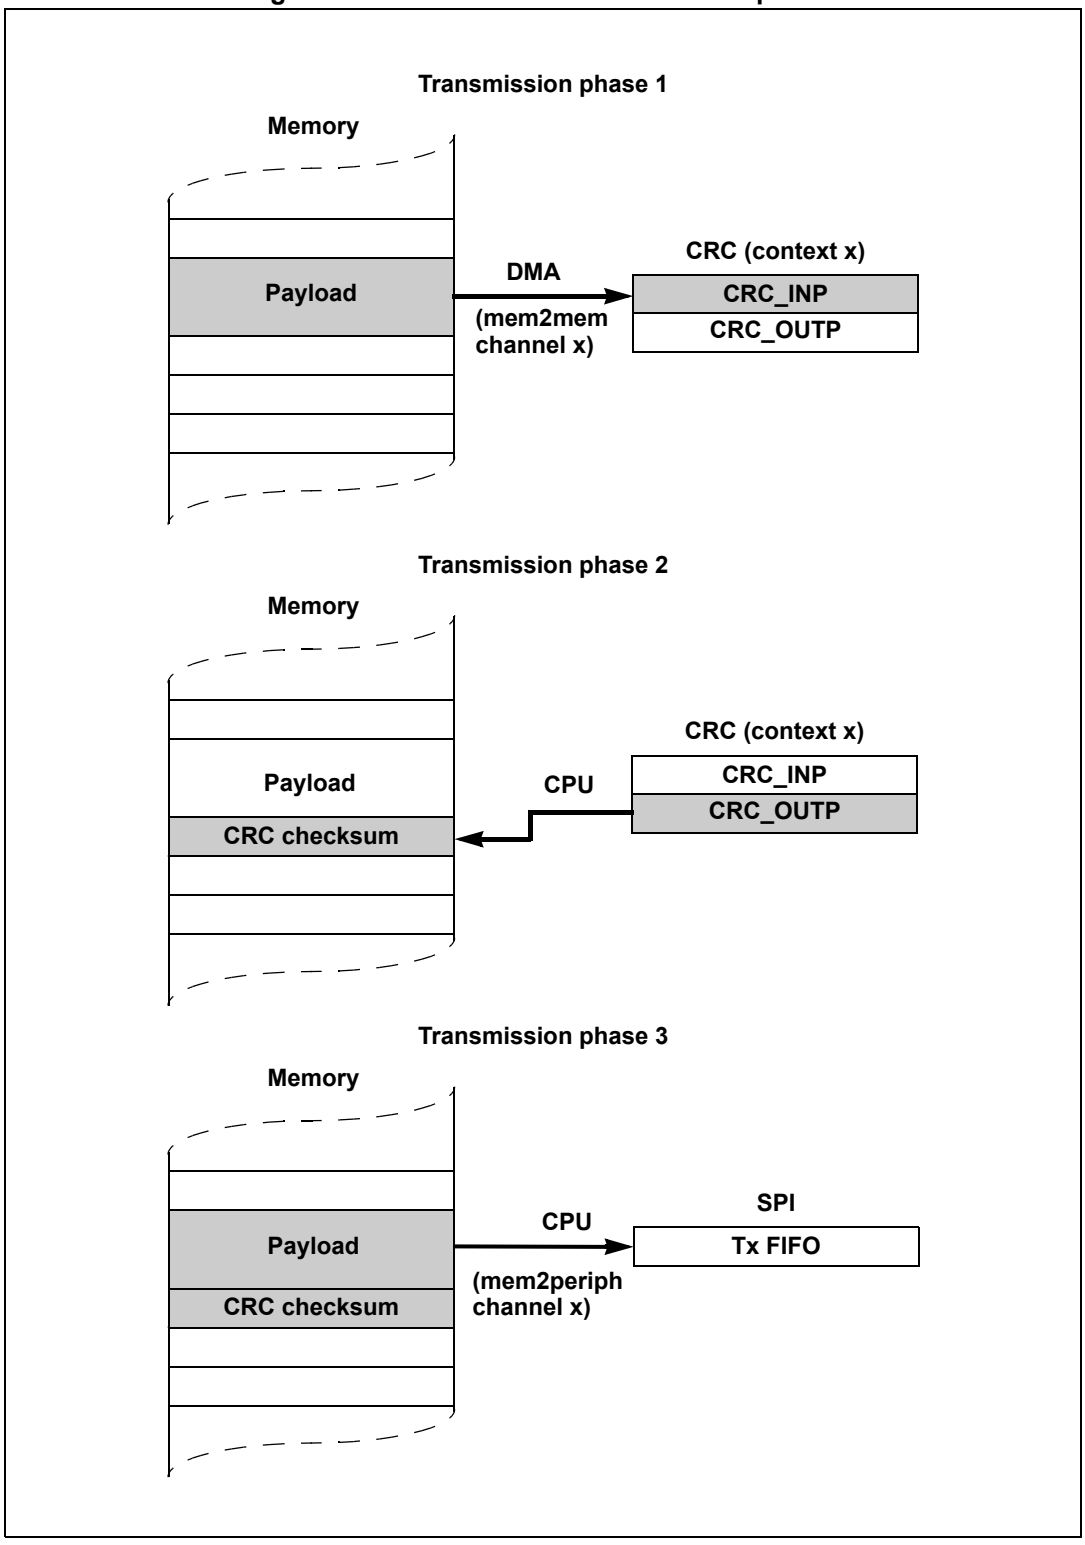
Use of the CRC module is summarized in the flow chart given in *Figure 1289*.

Figure 1289. CRC computation flow

63.7 Use cases

63.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:



- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer: mem2mem, periph2mem, mem2periph; then this sequence, as shown in *Figure 1290*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 1290. DMA-CRC transmission sequence

63.7.2 Register programming

- INV or SWAP, or both (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

64 Memory Error Management Unit (MEMU)

64.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- SRAM
- Peripheral RAM
- Flash memory.

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single/Double bit error in the data part that is detected via ECC for flash memory. Reporting of single/double bit error as correctable error depends on CTRL.FLASH_ERR_SELECT configuration.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Double/Multiple(more than two) bit error that is detected via ECC for Flash Memory. Reporting of double bit error as uncorrectable error depends on CTRL.FLASH_ERR_SELECTION configuration.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

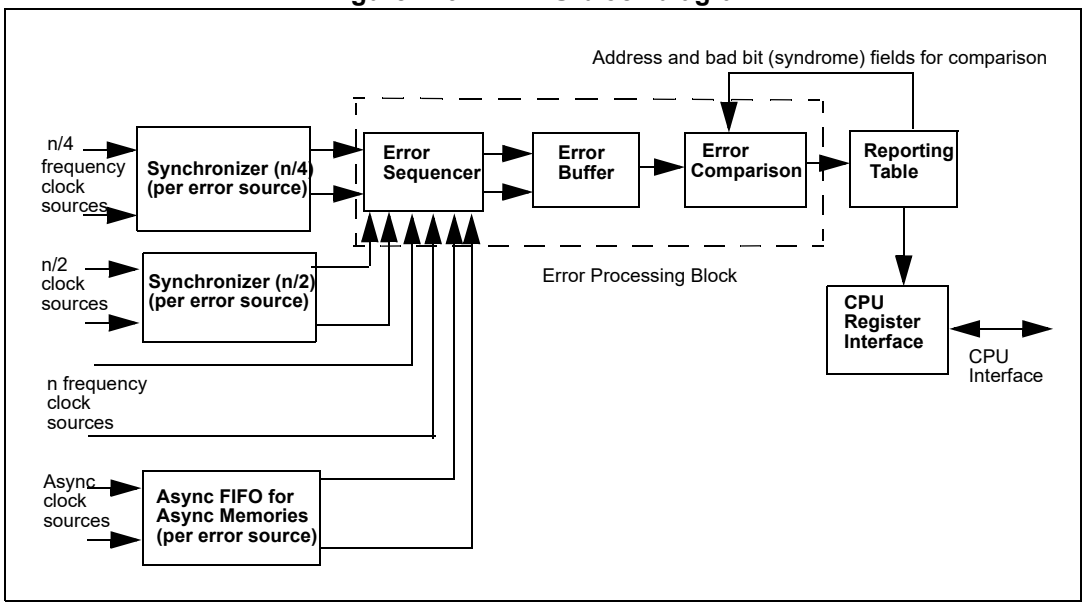
MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral SRAM ECC
- Flash memory ECC.

Each instance has two reporting tables–Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 64.4: Design overview* for the reporting block details.



64.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral SRAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

64.3 Block diagram

Figure 1291. MEMU block diagram

64.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 64.7.3: Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set, else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error (Correctable Error: CE or Uncorrectable Error: UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming

error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique

– Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)

– Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (*Section 64.6.2.4: System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *Section 64.6.2.6: System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS) on page 2203*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

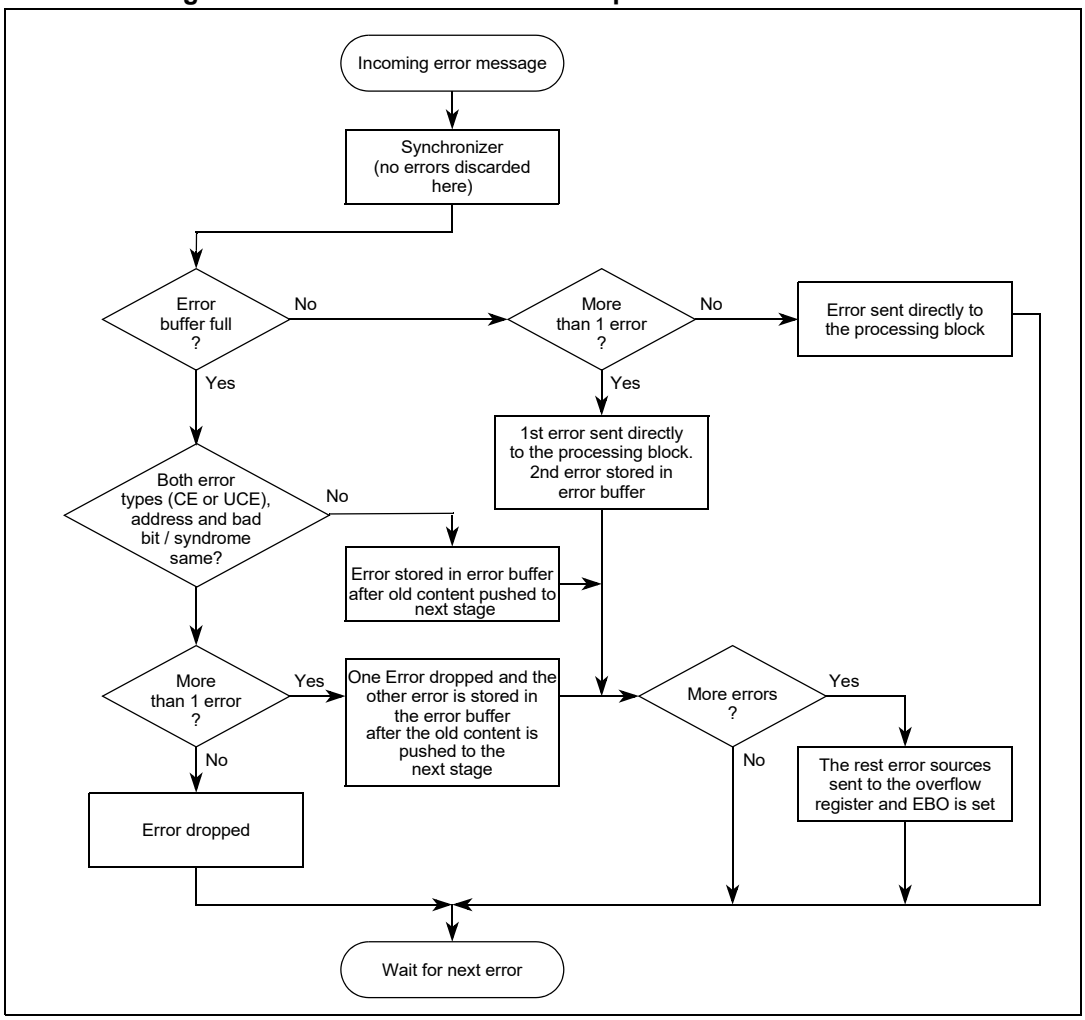
4. Register block

The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 1292. MEMU error buffer uniqueness check flow chart



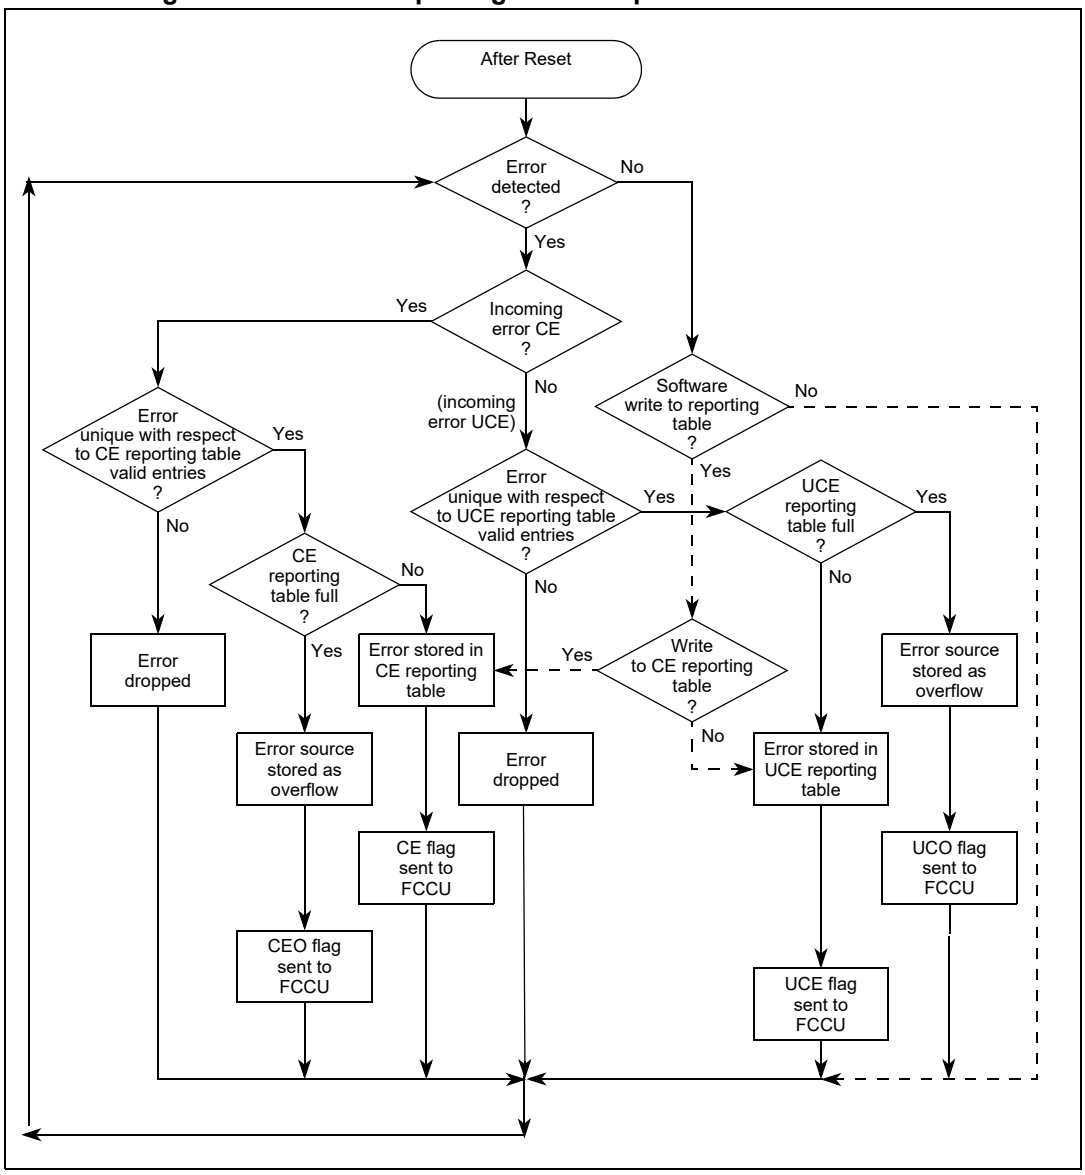


Figure 1293. MEMU reporting table uniqueness check flow chart

64.5 External signal description

MEMU has no external signals.

64.6 Memory map and register definition

64.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see Chapter 7: Device configuration that describes how modules are configured and connected.

Field	Description
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.

64.6.2.2 Error Flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 1295. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 1243. ERR_FLAG field descriptions

Field	Description
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table 1243. ERR_FLAG field descriptions (continued)

Field	Description
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.

Table 1243. ERR_FLAG field descriptions (continued)

Field	Description
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to '1' if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to '1' if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

64.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Field	Description
0:31 OFLW	Overflow Bit Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 64.7.3: Handling overflows (Multiple error reporting)* occurs.

64.7 Functional description

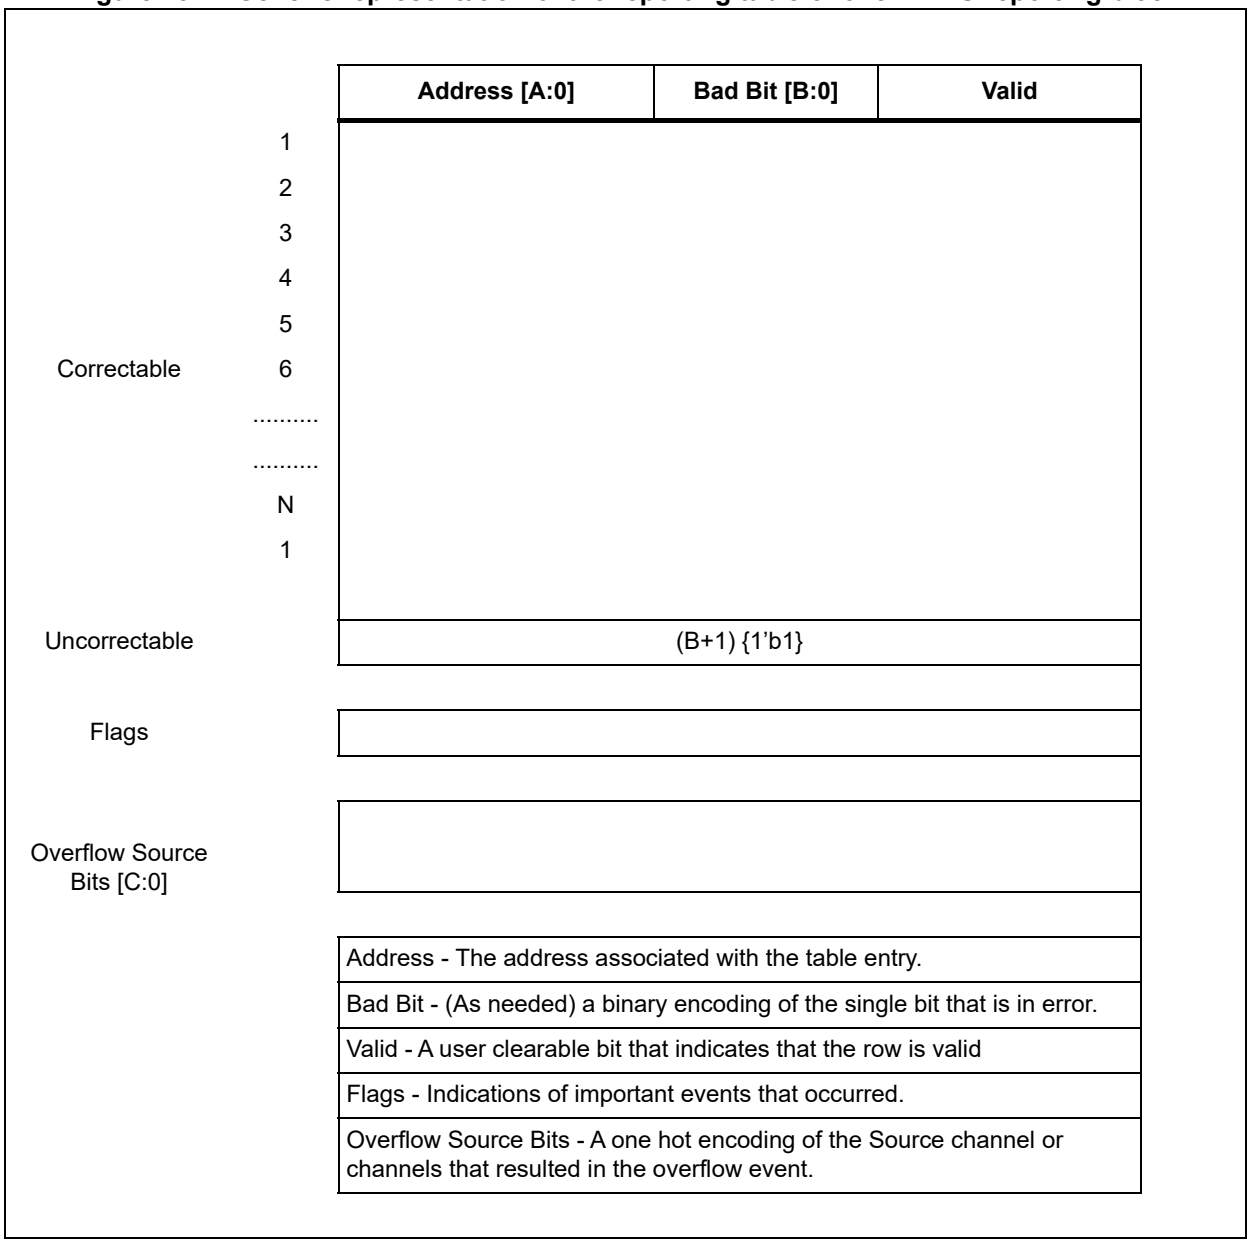
In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

64.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address.The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:



1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (duplicate entries).

64.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 1312. Generic representation of the reporting table of one MEMU reporting block

64.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
   - More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
   - An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order which means that if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

65 Fault Collection and Control Unit (FCCU)

65.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a systematic approach to fault detection and control.The FCCU provides a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

65.2 Features

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

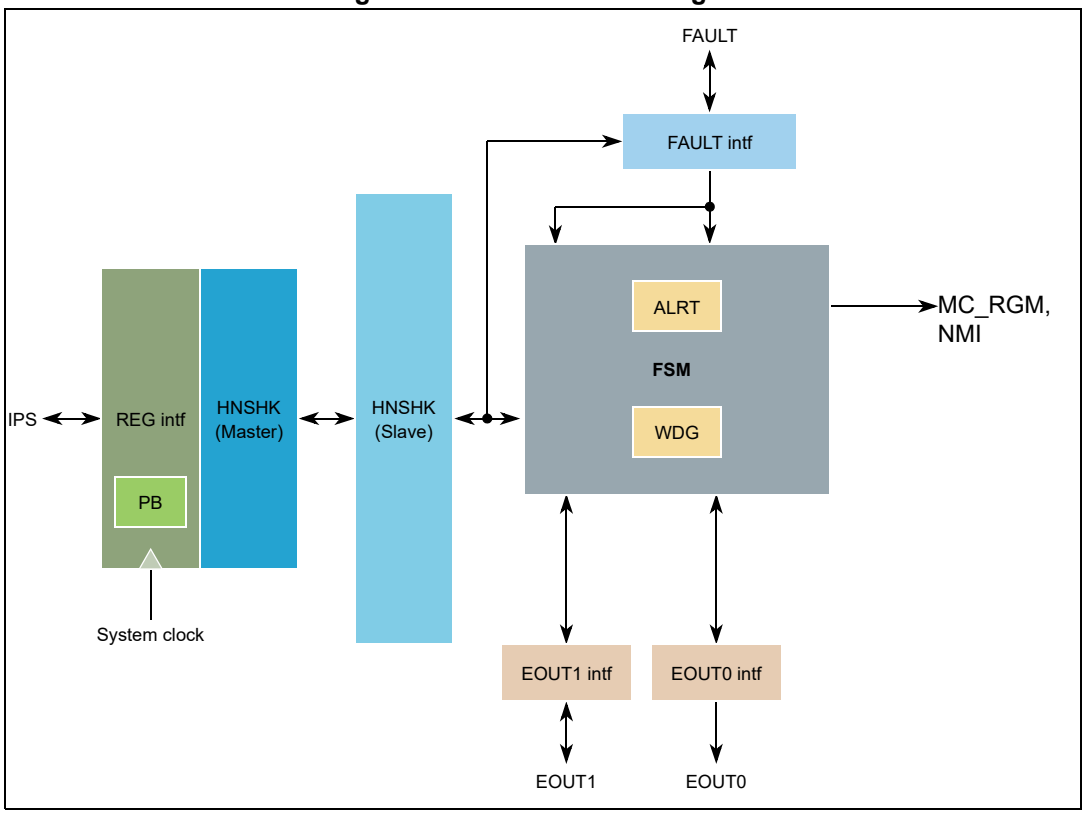
- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; see the implementation-specific details)
- Bi-stable, Dual Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Redundant collection of hardware checker (for example RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal (SoC) reactions
  - ALARM state: interrupt request
  - FAULT state: long functional reset request pulse, short functional reset request pulse, NMI
- Internal reactions (independently configurable for each RF)
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU
- Configuration lock: The FCCU’s configuration is lockable in two ways
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into

FCCU_TRANS_LOCK register (a value different to 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register

- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol that is dual rail and time switching
- After power-on the error out pins have high impedance[u]. FCCU goes to operational state only on software request
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms
- The overall error detection, processing and indication time is less than 10 ms
- The actual maximum time is five safe (IRCOSC) clock cycles

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster than the IRC clock.

65.2.1 Standard features



- IPS (slave bus signals) bus interface

65.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 1313*.

u. Actual value depends on the SoC settings at pad level

Figure 1313. FCCU block diagram

The FCCU module includes the submodules listed in *Table 1260*.

Table 1260. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of two asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: Watchdog timer (WDG) Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

65.4 Signal description

65.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 65.5.9*.

For the availability of these signals on a chip, see the device configuration chapter.

65.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers.
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0] data write/read operations to any registers.
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (for example FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Please see *Table 1269*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode.

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

65.5 Functional description

65.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization.
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization.
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

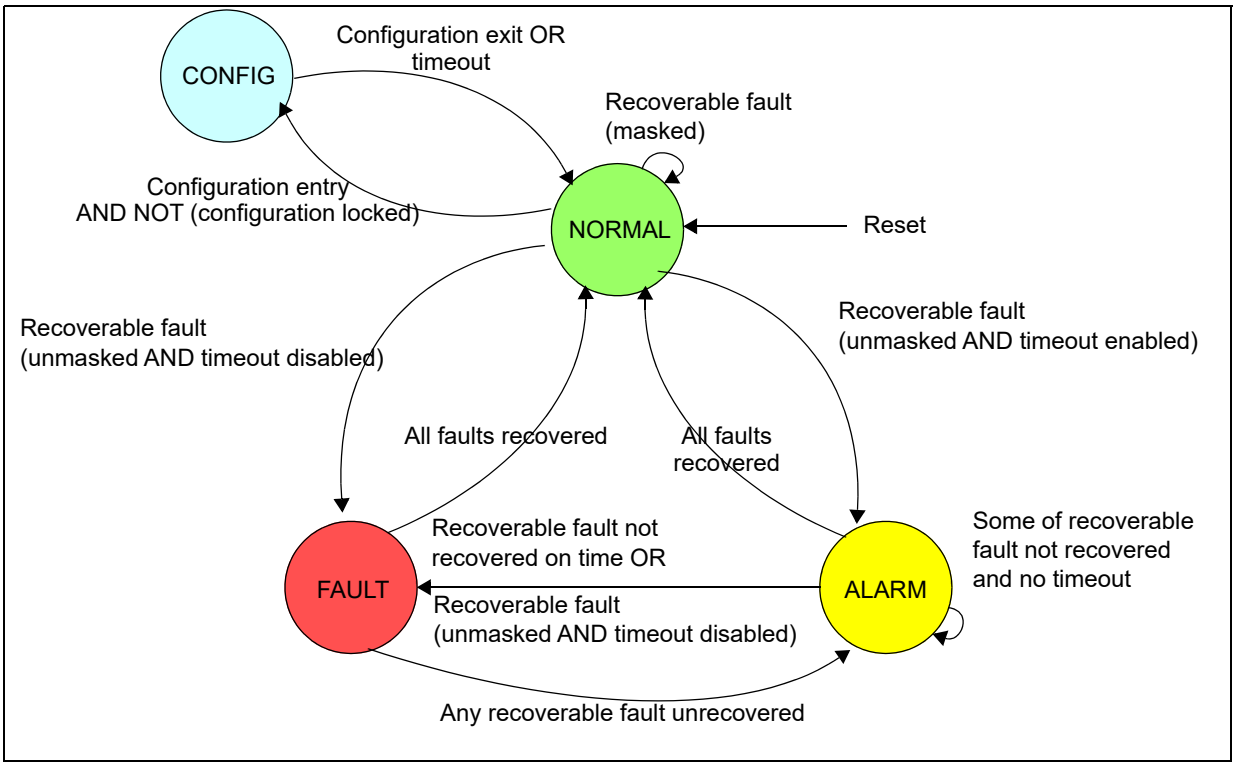
65.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 1314*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (a value different to 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Succeeding one of the following events:
  - unmasked recoverable faults with the timeout disabled → the FCCU moves to the FAULT state.
  - unmasked recoverable faults with the timeout enabled → the FCCU moves to the ALARM state.
  - masked recoverable faults → the FCCU stays in NORMAL state.
- ALARM: the FCCU moves into the ALARM state when a unmasked recoverable fault occurs and the timeout is enabled. The transition to the ALARM state goes along with an interrupt request (ALARM state), if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the

FAULT state. The timeout is re-initialized if the FCCU state moves to the NORMAL state. The timeout restarts following the recovery from the FAULT state.



- FAULT: the FCCU moves into the FAULT state when one of the following condition occurs:
  - timeout related to a recoverable fault when the FCCU is in the ALARM state.
  - unmasked recoverable faults with the timeout disabled.

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional).
- EOUT signaling (optional).
- SW option: Soft reaction (Short functional reset request pulse if configured).
- SW option: Hard reaction (Long functional reset request pulse if configured).

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 1314. FCCU state diagram

65.5.3 Reset interface

The FCCU has two input resets, as described in *Table 1261* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 1262* for each type of fault reaction (hard, soft or self-checking), the respective output reset (Long functional reset, Short functional reset) is activated. In *Table 1263* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit generates the corresponding input reset as described in *Table 1261*.

Table 1261. Input reset

Input reset	Description
System reset	Global reset of the FCCU synchronous to the system clock.
System reset (RC oscillator)	Global reset of the FCCU synchronous to the IRCOSC.

Table 1262 and *Table 1263* describe a typical reset strategy at system level.

Table 1262. Reset reactions

FAULT reaction	Active reset	System reset signal
Hard	Long functional reset	disabled
Soft	Short functional reset	disabled

Table 1263 shows the Reset sources.

Table 1263. Reset sources

Reset source	System reset signal
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 1264 summarizes the MC actions corresponding to each reset generated by FCCU.

Table 1264. MC actions

Active reset	MC action
Long functional reset	Reset FLASH and digital modules excluded FCCU, STCU
Short functional reset	Reset digital modules excluded FCCU, STCU

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for two IRCOSC clock periods.

65.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (possible for RFs only) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a RF (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any RF is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the RF that causes a ALARM to FAULT state transition. In this case the alarm timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

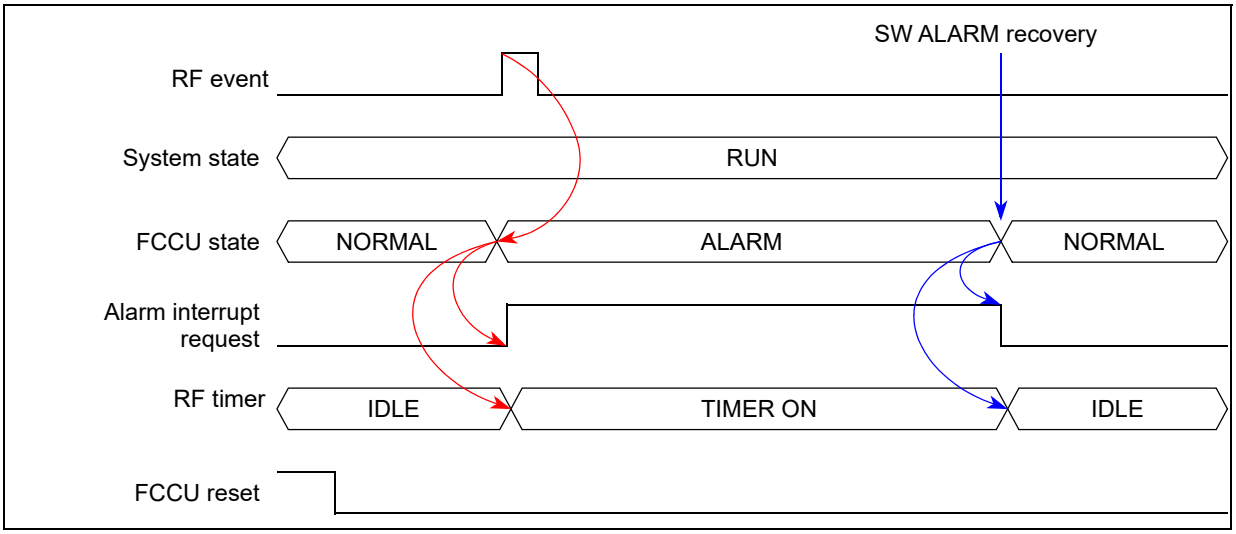
65.5.5 Fault recovery

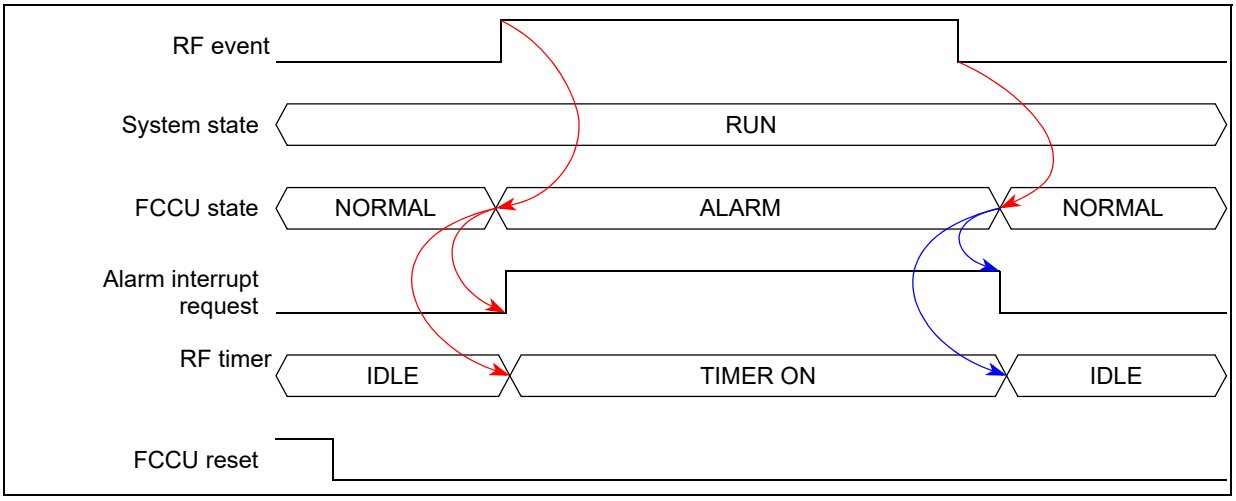
The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a RF management (ALARM state), see *Figure 1315* and *Figure 1316*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if configured)
  - timeout running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW): FCCU state transition ALARM → NORMAL

Figure 1315. RF (ALARM state) recovery (a)





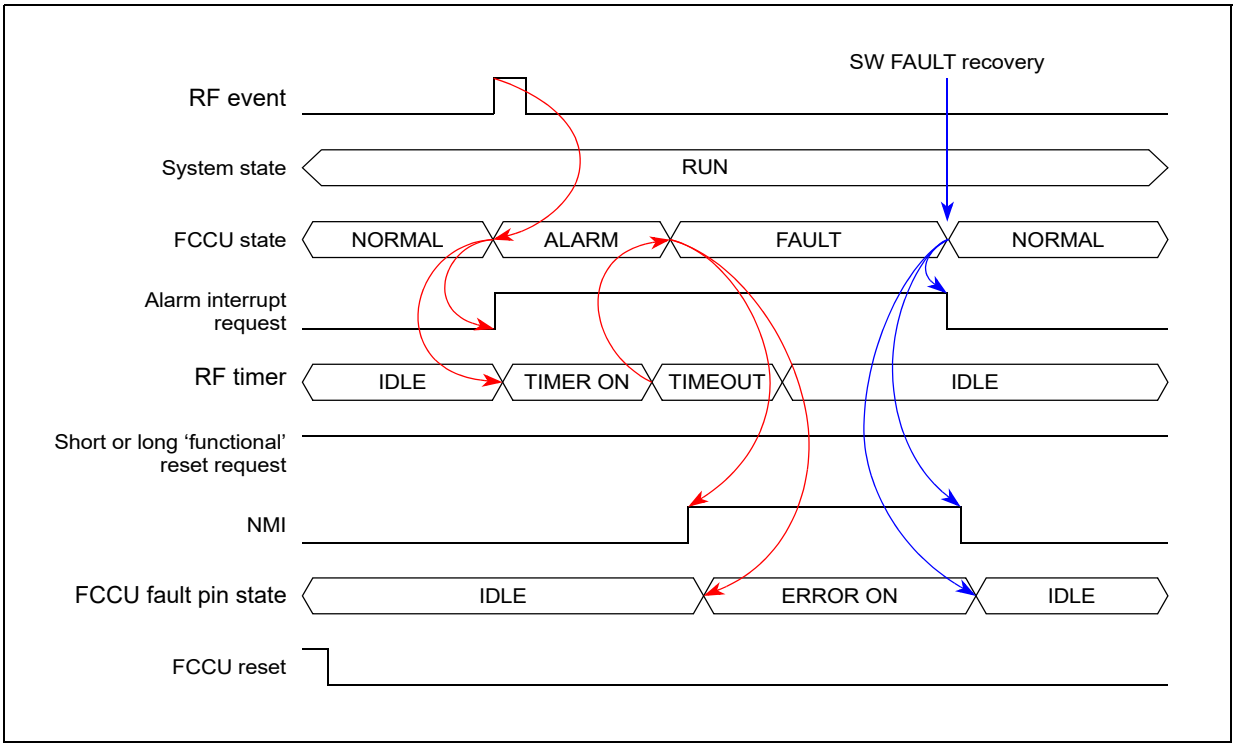


Figure 1316. RF (ALARM state) recovery (b)

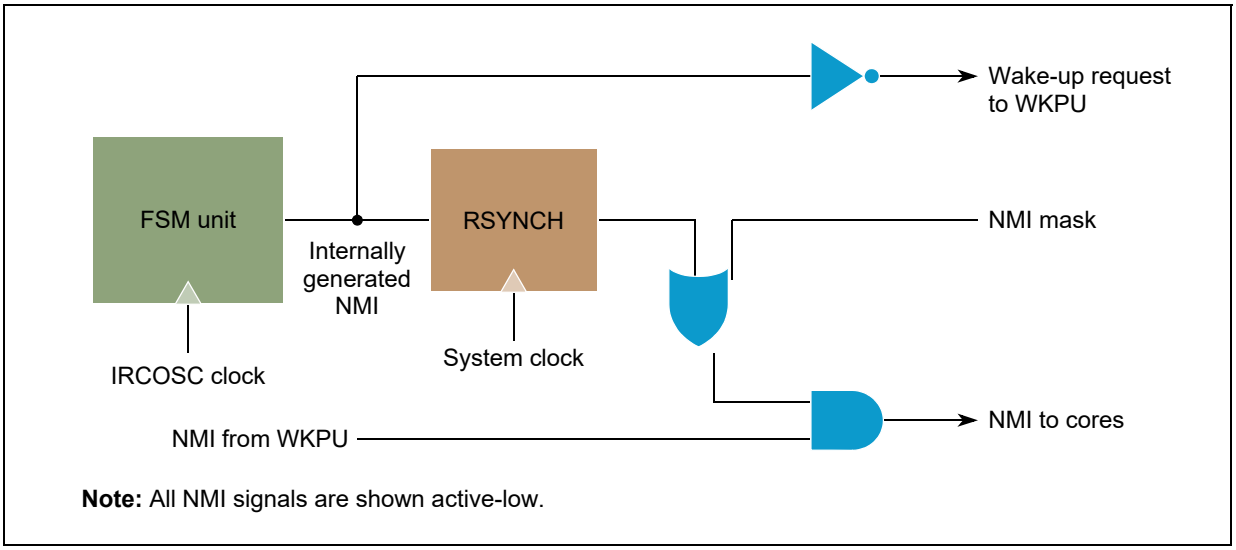
A typical sequence related to a RF management (ALARM → FAULT state), see *Figure 1317*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - timeout running
- FCCU state transition (following the timeout trigger): ALARM → FAULT: NMI assertion (if enabled)
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL

Figure 1317. RF(ALARM -> FAULT state) recovery

65.5.6 NMI/WKPU interface



The wake-up interface includes Nonmaskable interrupt: NMI interrupt source generated by the WKPU. It is synchronous with the system clock and active low. A logical AND interconnects the NMI sources (internally generated by FCCU and by WKPU) in order to provide a single NMI output.

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (MC state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (MC mode SW change request = 1).

Figure 1318. NMI/WKUP scheme

Note: All NMI signals are shown active-low.

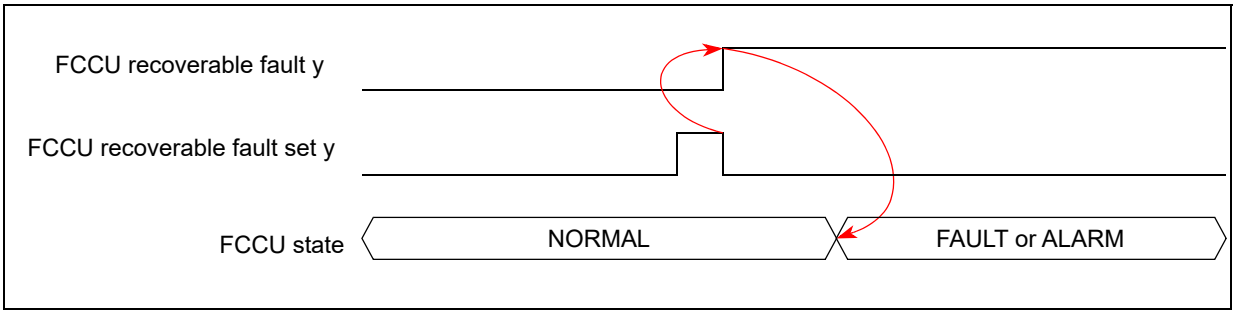
65.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple, programmable edge-sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1319*. The fault injection is executed by a write operation in the FCCU_RFF register.The reaction following a fake RF cannot be masked. The fault injection mechanism is optional; see the implementation-specific details. Refer to “FCCU failure inputs” table in Functional Safety chapter, for more details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (FCCU recoverable faults clear) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1320*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_S*n*. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 1319. FAULT injection



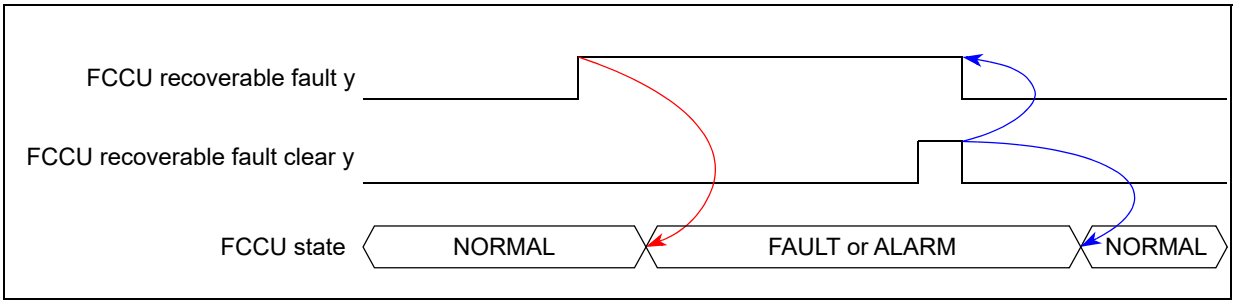


Figure 1320. FAULT clearing

65.5.8 STCU interface

The STCU interface includes:

- a set of signals resulting from the self-checking procedure connected externally at these FCCU faults:
  - Recoverable
- the STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- a mask (EOUT mask[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible to provide a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible to provide the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 1321. STCU-FCCU (case a)

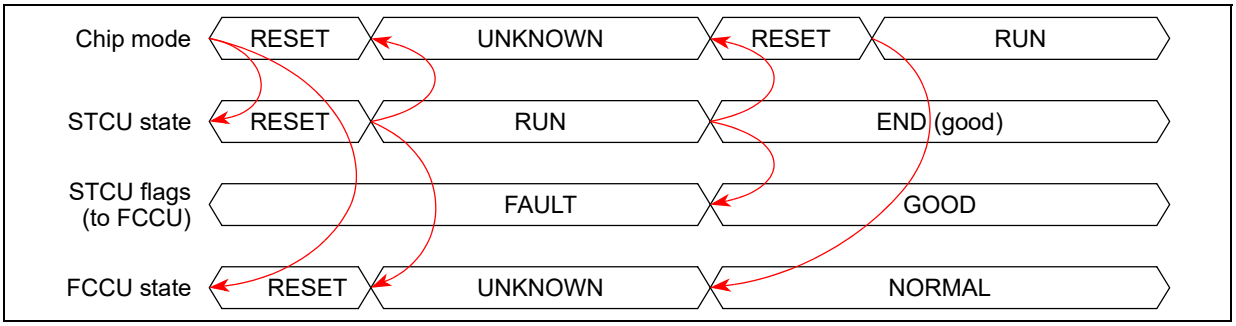

Figure 1322. STCU-FCCU (case b)

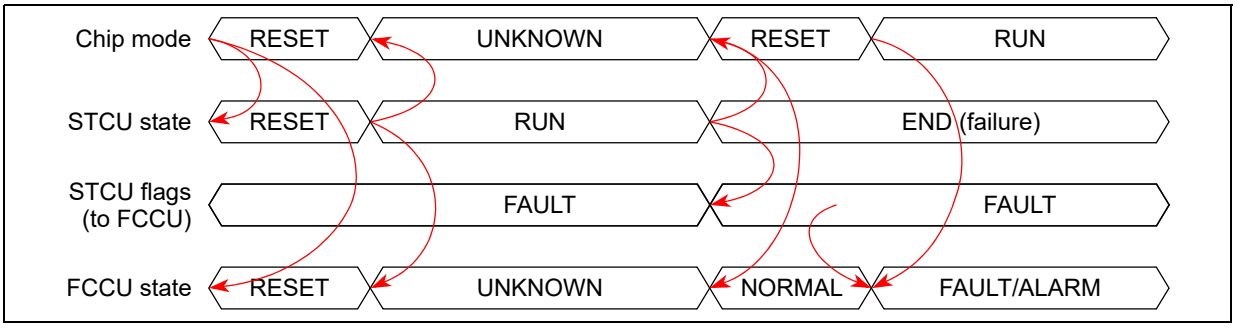

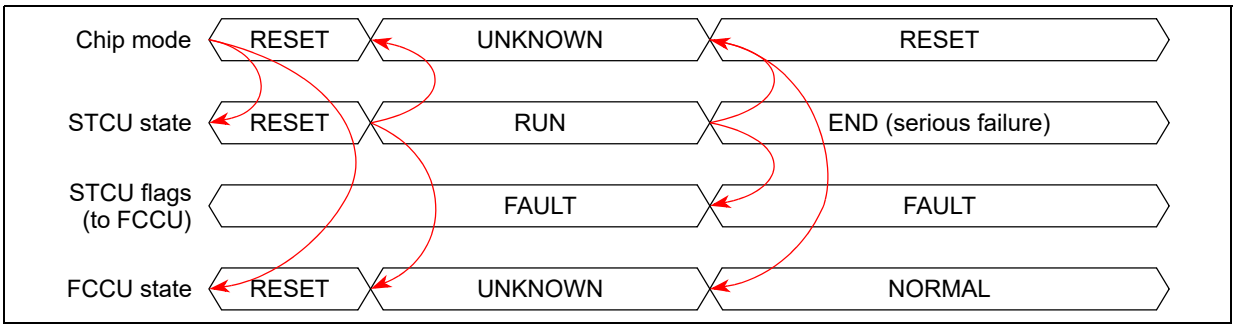

Figure 1323. STCU-FCCU (case c)

65.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (see table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS and FOP field in the FCCU_CFG register. For example, for PS = 0, FCCU Error output[0] = 0 and FCCU Error output[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection (FCCU_CFG.FOP = 0b): switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual rail or time switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or viceversa and CONFIG to NORMAL). The EOUT protocol

transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.

- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or viceversa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occurs in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by ((FOP + 1) * 2 * 2048) where FOP vary between 0 and 63. With an IRC clock of 16 MHz, this drives a signal between 61 and 3906 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual rail or time switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, that is an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset, and software bit FCCU_RST in RGM_PRST5) should not influence the state of the failure indication, pins.

Note: The transition from FAULT to CONFIG state is not possible but is shown to display the behavior in all four states: RESET, NORMAL, FAULT and CONFIG.

Table 1265. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written FCCU_SET_AFTER_RESET bit to 1.

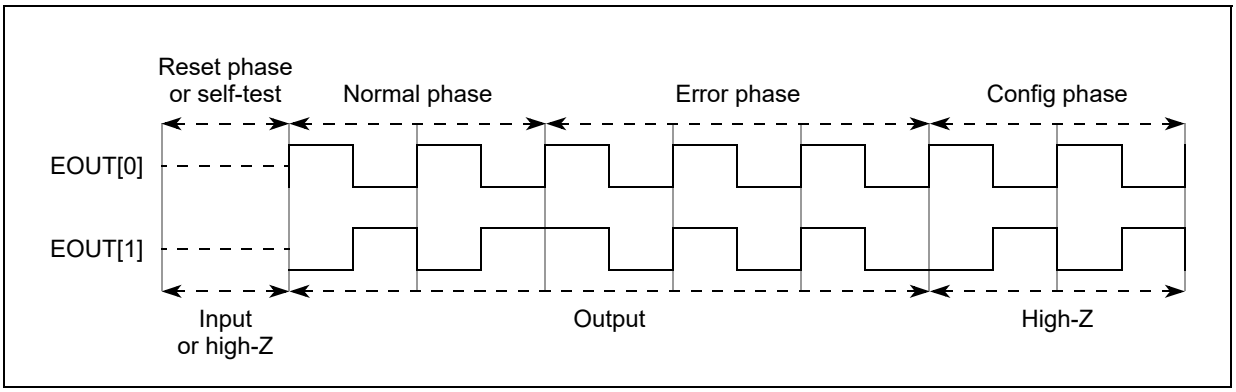
Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

65.5.9.1 Dual rail protocol

Dual rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual rail encoded circuits use two wires to carry each bit. The encoding scheme is given in *Table 1266* and the related timing diagram is given in *Figure 1324* and *Figure 1325*.

Table 1266. Dual rail encoding

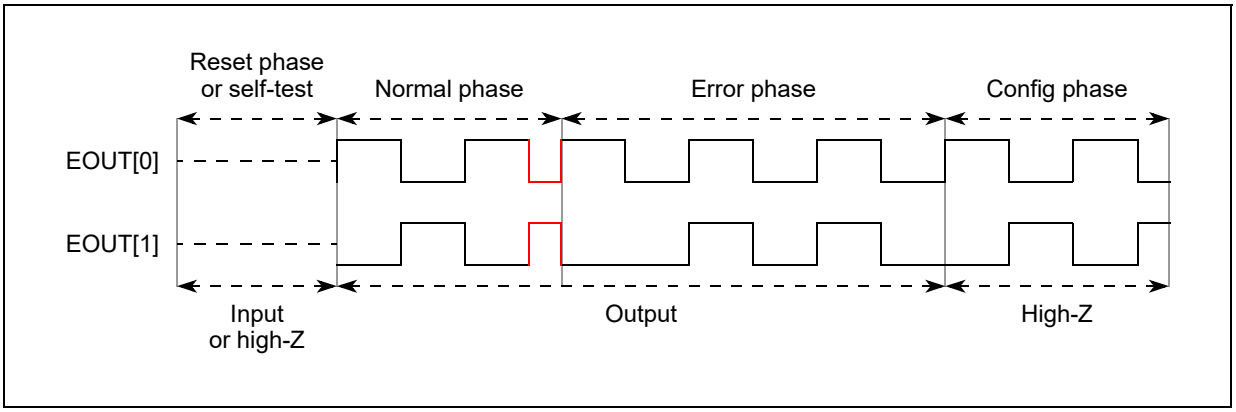
Logical state	Dual rail encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	00	toggling
faulty	11	
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling



1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the RESET phase the output pins are set as “high impedance”(v).



Note: Figure 1324 and Figure 1325 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 1324. Dual rail protocol (slow switching mode)

v. Actual value depends on the SOC settings at pad level

Figure 1325. Dual rail protocol (fast switching mode)

65.5.9.2 Time switching protocol

The encoding scheme is given in *Table 1267* and the related timing diagram is given in *Figure 1326*.

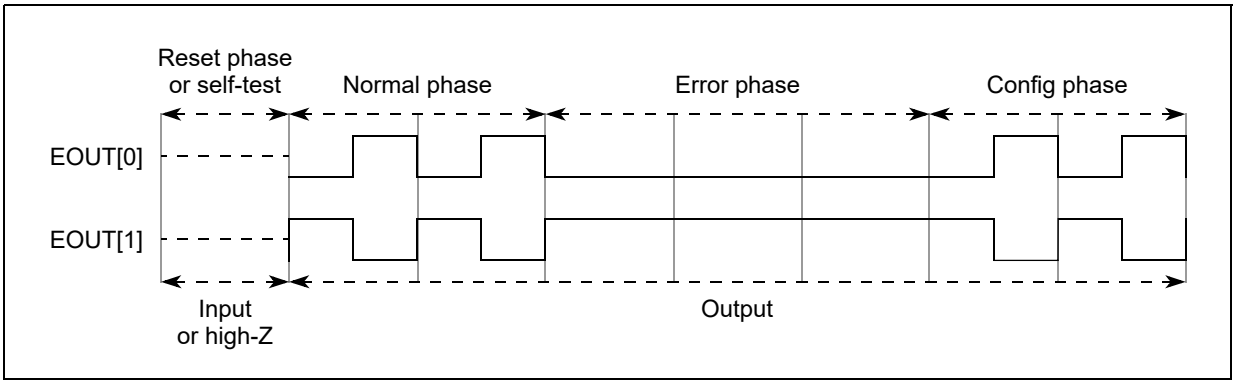
Table 1267. Time switching encoding

Logical state	Time switching encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the FAULT state, the output pin FCCU Error output pin[0] is set as low.



In Time Switching mode the second output (FCCU Error output pin[1]) is the inverted signal of first output (FCCU Error output pin[0]).

In the RESET phase the output pins are set as “high impedance”[w].

Note: Figure 1326 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

w. Actual value depends on the SOC settings at pad level

Figure 1326. Time switching protocol

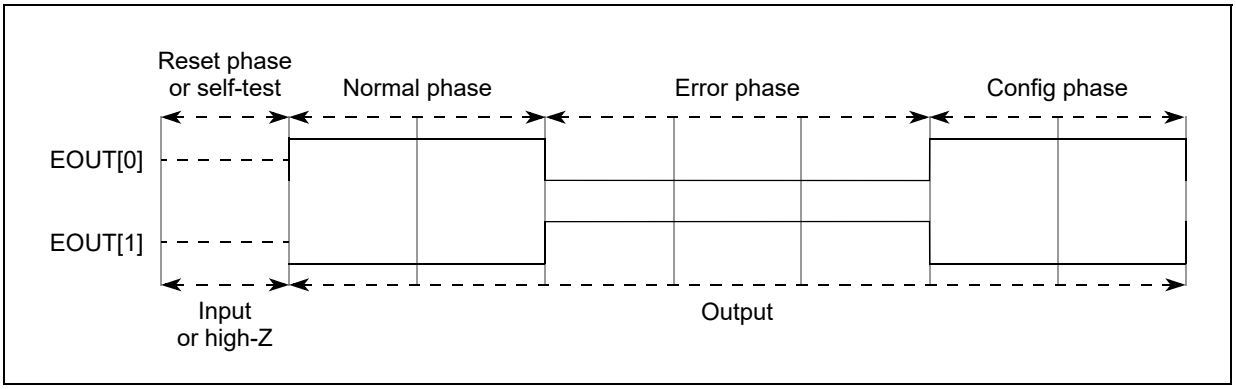
65.5.9.3 Bi-stable protocol

The encoding scheme is given in *Table 1268* and the related timing diagram is given in *Figure 1327*.

Table 1268. Bi-stable encoding

Logical state	Bi-stable encoding (FCCU Error output pins [1:0])	Note
nonfaulty	01	no toggling
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	no toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.



In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (FCCU Error output[1]) is the inverted signal of first output (FCCU Error output[0]).

In the RESET phase the output pins are set as “high impedance”(x).

Note: Figure 1327 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

x. Actual value depends on the SOC settings at pad level

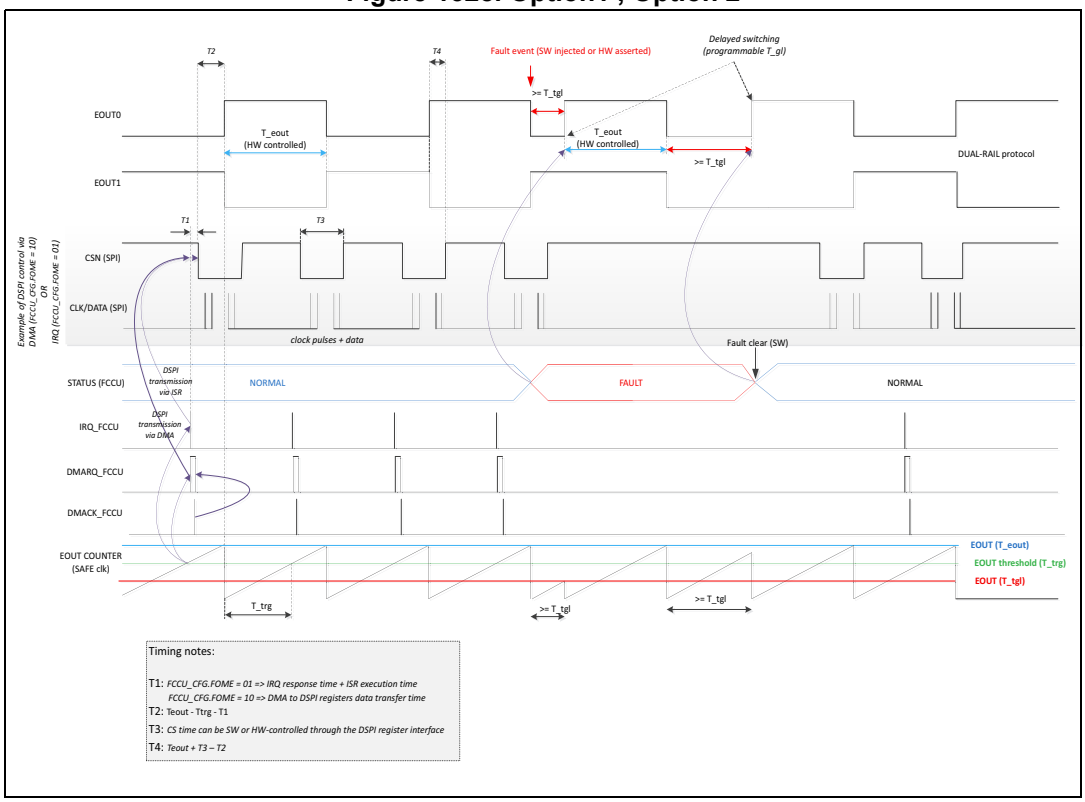


Figure 1327. Bi-stable protocol

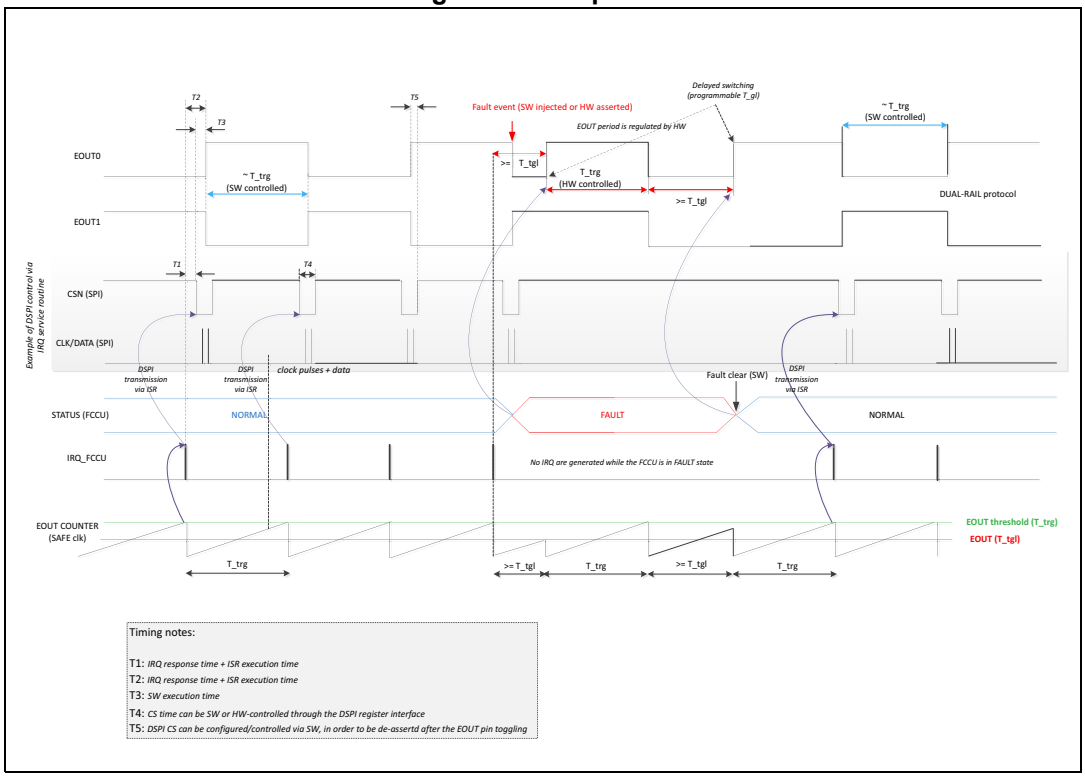
65.5.9.4 Option 1, Option 2

The internal counter used to generate the EOUT waveforms is used to control a IRQ or DMA trigger event. This event shall appear only when the FCCU is not in FAULT mode (see *Figure 1328*).

Figure 1328. Option1 , Option 2



65.5.9.5 Option 3

When FCCU_CFG. FOME = 11, the EOUT pin state is controlled by the application SW as far as the FCCU is in NORMAL or ALARM state. As soon as a the FCCU enters the FAULT state, both the EOUT pins are forced by the HW to the same level, which can be 0-0 or 1-1 depending on the polarity configuration. As far as the FCCU is in FAULT state, the SW has

no control over the EOUT pins. Once the error condition is recovered, the FCCU returns to the NORMAL state and the SW can take back the control of the EOUT pins. *Figure 1329* shows how this is accomplished. As far as the FCCU is not in FAULT mode, the IRQ interrupts are asserted when the FCCU internal timer reaches the programmed threshold. If needed, it is responsibility of the SW to toggle the EOUT pins within the ISR. The EOUT pin toggling period depends on the IRQ assertion frequency (controlled by the HW) plus the interrupt service time and SW execution. This period will be stable and close to the IRQ programmed period as far as the interrupt service routine can be serviced in a deterministic time frame and executed at the highest priority. During the ISR, additional operations can be done: the figure shows an example of a DSPI frame sent before every EOUT toggling, but with the DSPI CS being kept asserted for some time after the EOUT has toggled. When the FCCU enters into the FAULT state, no IRQ interrupt is fired anymore and the EOUT pins are controlled by the HW. During this time frame, the EOUT pin toggling is exactly matching the programmed period.

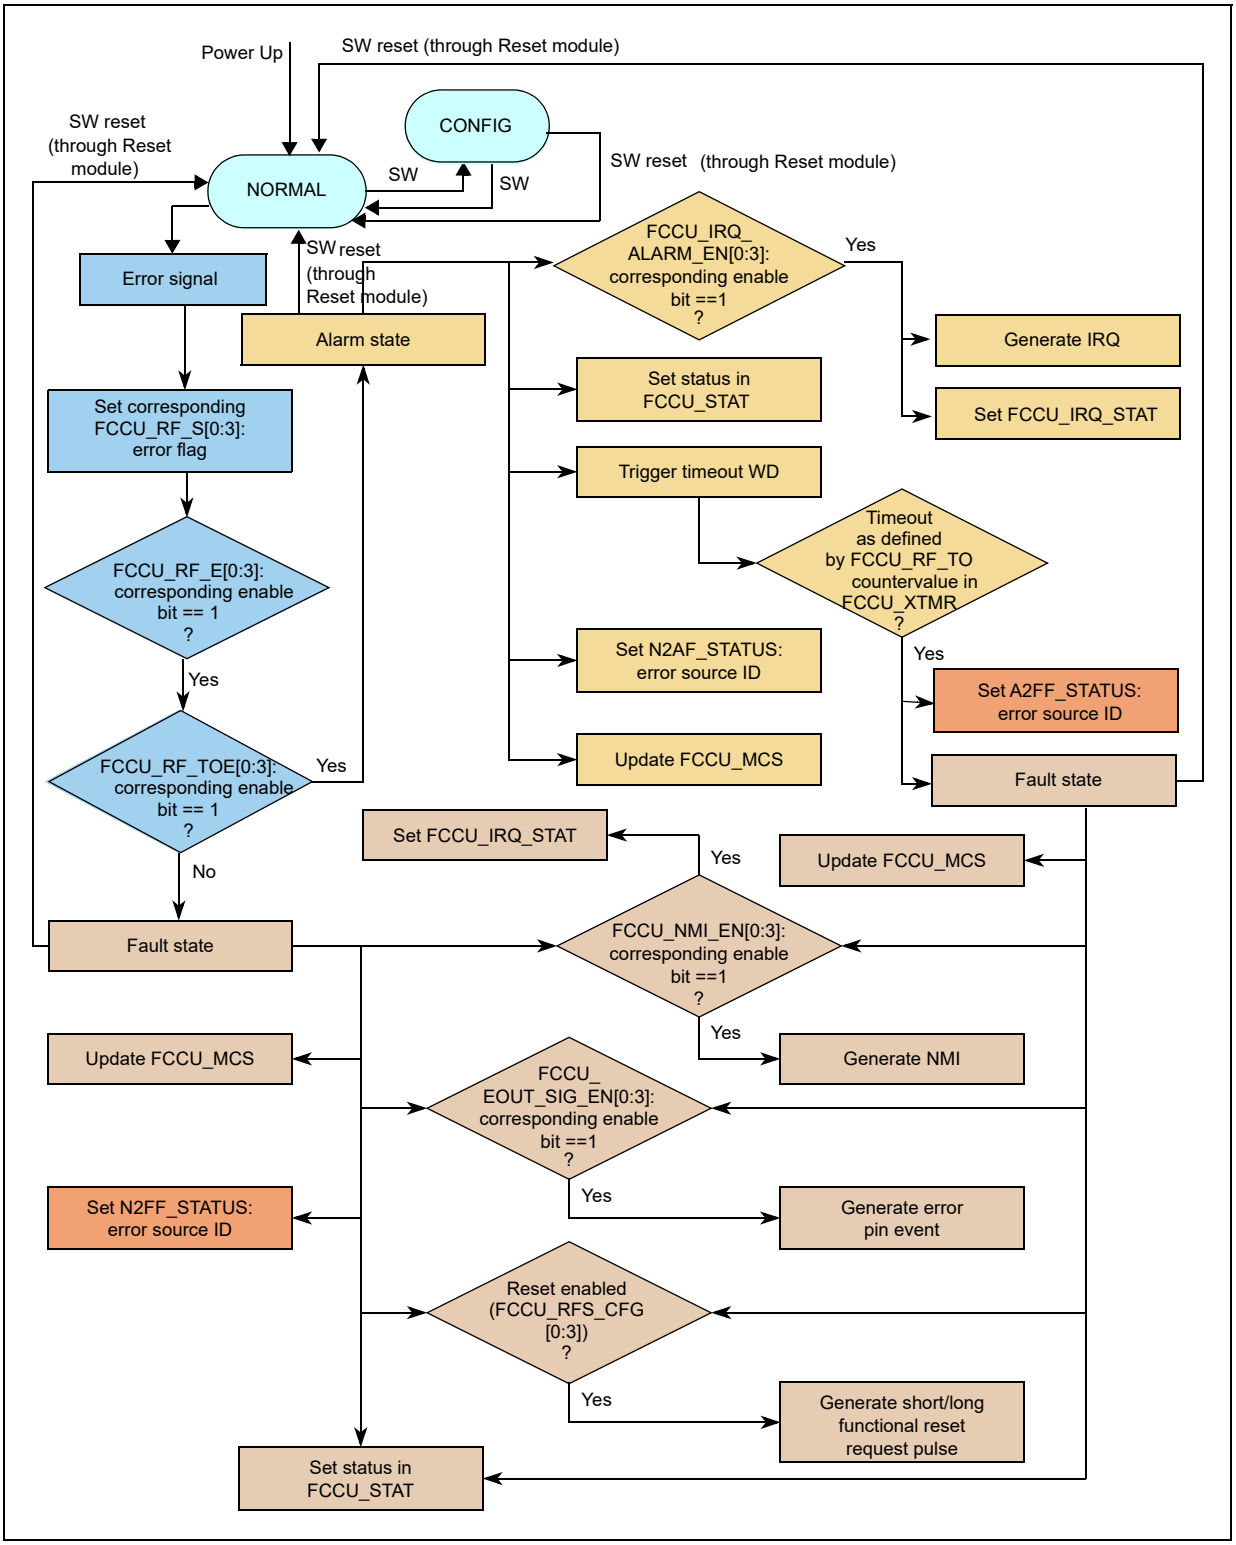


Figure 1329. Option 3

65.5.10 Error signal flow for RF case

On Power up, FCCU moves to NORMAL state. SW can configure it by moving it to CONFIG and back again. SW reset leads to movement back to NORMAL. On reaching ALARM state, depending on ALARM being enabled, FCCU generates IRQ(alarm) and the FCCU_IRQ_STAT's alarm status is also set. FSM status is set in FCCU_STAT along with N2AF_STATUS. If Error is enabled (FCCU_RF_E) and timeout disabled (FCCU_RF_TOE), FCCU moves straight to FAULT state and depending on FCCU_NMI_EN or FCCU_SIG_EN, or both, being set, it generates a NMI or signals error, or both, out to the external world. FCCU FSM status is also captured in FCCU_STAT.

Figure 1330. Error signal flow

65.6 Register description

The FCCU registers are listed in *Table 1269*. Any address offset not explicitly mentioned in *Table 1269* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 1269*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

2. No-Saf = Not Safety Relevant, Saf-Relv = Safety Relevant, Saf-Lat = Safety Latent

65.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state.
- moving the FCCU state from the CONFIG state into the NORMAL state.
- reading or to clear the RF status register.
- reading the FCCU FSM status register.
- reading or to clear the FCCU freeze registers.
- reading the ALARM timer.
- reading the Watchdog timer.

Some critical operations requires a key as defined in the FCCU_CTRLK register.

Offset: 0x000 Access: User read/write

Figure 1331. FCCU Control Register (FCCU_CTRL)

Table 1270. FCCU_CTRL field descriptions

Field	Description
DEBUG	Debug mode entry 0 Normal operation 1 Put FCCU into debug mode When Debug pin signal is asserted and this bit is set, FCCU moves into debug state and suspend the transition of the FSM by suspending timer elapse time effect.
OPS	Operation status 00 Idle 01 In progress 10 Aborted 11 Successful These bits can be read and cleared (via OP15 operation) by the software.

Table 1270. FCCU_CTRL field descriptions (continued)

Field	Description
OPR	Operation run 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (see the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (see the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (see the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (see the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (see the F2AF_STATUS register) [OP7] 01000 Reserved 01001 Reserved 01010 Read the RF status register (see the FCCU_RF_S register) [OP10] 01011 Reserved 01100 RF status clear operation in progress (see the FCCU_RF_S register) [OP12] 01101 Clear the freeze status registers (see the freeze registers) [OP13] 01110 CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111 Clear the operation status (OPS=Idle) [OP15] 10000 Reserved 10001 Read the ALARM timer (see the FCCU_XTMR register) [OP17] 10010 RESERVED 10011 Read the CFG timer (see the FCCU_XTMR register) [OP19] 10100 Read the Error Pin low counter value (see *Section 65.6.21*) [OP20] 10101–11111: Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution The max timing needed for ABORT/SUCCESS response is 12 IRC cycles

65.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There shall not be any other operation in between the above steps and the 32 bits need to be writed in one cycle. so store FCCU_CTRLK, merge with OP1 or OP2 then send it.

The FCCU_CTRLK register is not readable, a 0x0000_0000 value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Table 1271. FCCU_CTRLK field descriptions

Field	Description
0:31 CTRLK_VAL	Control register key 0x913756AF Key for the operation OP1 0x825A132B Key for the operation OP2

65.6.3 FCCU Configuration Register (FCCU_CFG)

The FCCU_CFG register defines the global configuration for the FCCU module.

This register is writable only in the CONFIG state.

1. Writable only in the CONFIG state.
2. After powerup, reset value will be 0. If configuration timeout occurs then default value will be changed to 1.

Figure 1333. FCCU Configuration Register (FCCU_CFG)

Table 1272. FCCU_CFG field descriptions

Field	Description
0:6 TGL	EOUT toggling time(3) Active only if CFG.SM = 0 (switch mode = slow transition) MIN duration of EOUT pulse during FAULT -> NORMAL/ALARM and NORMAL/ALARM -> FAULT transitions Min = 1 µs, Max = 128 µs, Resolution = 1 µs
7 FCCU_SET_ AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0 FCCU's Error indication stops functioning and error pins are in HI-Z state(1). 1 write to start FCCU functioning. After power-on the error out pins shall be in high impedance(1). They will go to normal state only on software request, this bit is set to '1'. It is SW's responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
8:9 FCCU_SET_ CLEAR	Error pin state can be controlled by these bits 01 Error Pin driven to logic 0. 11 Error Pin driven to logic 1 (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault). 00 FCCU acts independent of above SW control. 10 FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z(1). Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state. This bit feature may not work with toggling protocols for example say EOUT pins are set high by SW using this bit followed by switching to a toggling protocol after returning control to FCCU FSM via setting this bit to 2'b00 or 2'b10, the user may find that EOUT pins do not toggle as was being expected.
16 FOPE	Fault Output Prescaler Extension of CFG[FOP] [5:0] For toggling frequency formula, please see FOP field description.
17:18 FOME	Fault Output Mode Extension 00 current behave (default) 01 option #1(2) 10 option #2(3) 11 option #3 (only active if CFG.FOM = 000)(4) - 000 and option#3 disabled => Dual rail mode (current behave) - 000 and option#3 enabled => option #3 enabled (GPIO mode in NORMAL/ALARM mode and DUAL-RAIL in FAULT mode)
19 OD	Open Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s). 0 push-pull 1 OD
21 SM	Switching mode 0 EOUT protocol (dual rail, time switching) slow switching mode. 1 EOUT protocol (dual rail, time switching) fast switching mode. SM has no effect on the bi-stable protocol.

Table 1272. FCCU_CFG field descriptions (continued)

Field	Description
22 PS	Polarity selection 0 FCCU Error output[1] active high, FCCU Error output[0] active low. 1 FCCU Error output[1] active low, FCCU Error output[0] active high. This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are nontoggling in Error phase.
23:25 FOM	Fault Output Mode selection 000 Dual Rail (default state) [FCCU Error output[1:0]= outputs] 001 Time Switching [FCCU Error output[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [FCCU Error output[0]= input, FCCU Error output[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= input] **Note:** In Test mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.
26:31 FOP	Fault Output Prescaler FOP along with FOPE (FOPE being the MSB) defines the prescaler setting used to generate the EOUT protocol frequency. 0x00 Input clock frequency (RC oscillator clock) is divided by 2 x 2048 0x01 Input clock frequency (RC oscillator clock) is divided by 4 x 2048 0x02 Input clock frequency (RC oscillator clock) is divided by 6 x 2048 0x03 Input clock frequency (RC oscillator clock) is divided by 8 x 2048 0x04 Input clock frequency (RC oscillator clock) is divided by 10 x 2048 0x05 Input clock frequency (RC oscillator clock) is divided by 12 x 2048 0x06 Input clock frequency (RC oscillator clock) is divided by 14 x 2048 ... 0x7F Input clock frequency (RC oscillator clock) is divided by 256 x 2048 The equation below gives the EOUT frequency: EOUTfreq = RCOSCfreq / ((FOPe + 1) * 2 * 2048) where FOPe = {FOPE,FOP}

1. Actual value depends on the SOC settings at pad level.
2. SPI frame is SW controlled following a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state. For details, please refer to *Figure 1328*.
3. SPI frame is DMA controlled following a DMA request (DMARQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state. An interrupt by SPI/DMA engine is asserted in order to update the data packet for the next watchdog refresh SPI controlled only via DMA in time division mode. For details, please refer to *Figure 1328*.
4. EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. As alternative an external TMR can be optionally used. EOUT dual rail protocol:
-NORMAL/ALARM : for example 10 ms toggling in opposite phase
-FAULT : for example 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM=0)
-FAULT : fast switching mode (SM =1) in phase (no periodic toggling). For details, please refer to *Figure 1329*

65.6.4 FCCU RF Configuration Register *n* (FCCU_RF_CFG*n*)

The FCCU_RF_CFG*n* registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

65.6.6 FCCU RF Status register *n* (FCCU_RF_S*n*)

The FCCU_RF_S*n* register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for theRF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before to recovery the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_S*n* register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field
3. Wait for the completion of the operation (FCCU_CTRL.OPS field)
4. Read the FCCU_RF_S*n* register in order to verify the effective deletion and in case of failure to repeat the sequence

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (see *Section 65.5.7*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable

fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_S*n* read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_RF_S*n* register

In case of reconfiguration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_RF_S*n* must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

Offsets: 0x080 + *n**0x4 (*n*=0 to 3) Access: User read/write

0x08C	FCCU_RF_S3	RFS[127:96]

65.6.7 FCCU RF Key register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_S*n* register.

The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx

The key must be written for each FCCU_RF_S*n* clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0x0000_0000 value is always returned in case of read operation.

65.6.8 FCCU RF Enable Register *n* (FCCU_RF_E*n*)

The FCCU_RF_E*n* registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit

into the FCCU_RF_S*n* register is anyway set (for debugging purposes), only the reaction is masked.

These registers are writable only in the CONFIG state.

0x0A0	FCCU_RF_E3	RFE[127:96]

65.6.9 FCCU RF Timeout Enable Register *n* (FCCU_RF_TOE*n*)

The FCCU_RF_TOE*n* registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective timeout is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started

when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

0x0B0	FCCU_RF_TOE3	RFTOE[127:96]

65.6.10 FCCU RF Timeout Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state. The alarm timeouts value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU timeout.

This register is writable only in the CONFIG state.

Field	Description
0:31 TO	Recoverable fault timeout Timeout = (TO) x $T_{RC16MHz}$

65.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Please see *Table 1269*. The watchdog timeout is clocked with the RC oscillator clock (16 MHz). The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

65.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the FCCU Error output pin[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the FCCU Error output pin[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the FCCU Error inputs level

Table 1286 shows Bi-stable encoding.

Table 1286. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

1	1	1 xor PS	1 xor PS	In phase

65.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine (FSM) operates by the RC oscillator clock asynchronous with the System clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU status (FCCU_STAT register)

Table 1288. FCCU_STAT field descriptions

Field	Description
26:27 PhysicErrorPin	Physical Error Pin's state PhysicErrorPin[26] corresponds to error pin 0, PhysicErrorPin[27] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0 Error Pin is at logical 0 1 Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol.

Table 1288. FCCU_STAT field descriptions (continued)

Field	Description
28 ESTAT	Current Error Pin Status SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in nonfaulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state.This state is taken from the FCCU Eout logic (That is, as late as possible).
29:31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state Other: UNKNOWN state

65.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the recoverable source (FCCU recoverable fault x) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the N2AF_STATUS register

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation)

65.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the A2FF_STATUS register

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)

All the freeze registers are cleared by this operation.

65.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recoverable fault in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 65.5.7*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

65.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The external interrupt line (Interrupt request) is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

30 ALRM_STAT	Alarm Interrupt Status 0 Alarm interrupt is OFF 1 Alarm interrupt is ON
31 CFG_TO_STAT	Configuration Timeout Status 0 No configuration timeout error 1 Configuration timeout error

1. SPI frame is DMA controlled following a DMA request (DMARQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state. An interrupt by SPI/DMA engine is asserted in order to update the data packet for the next watchdog refresh SPI controlled only via DMA in time division mode. For details, please refer to *Figure 1328*.

65.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following events:

- Configuration timeout error

The external interrupt line “Interrupt request (miscellaneous conditions)” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

Field	Description
28 IRQ_EOUT_EN	It enables the FCCU_IRQ_STAT[IRQ_EOUT]. 0 IRQ_EOUT disabled. 1 RQ_EOUT enabled.
31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled. 1 Configuration timeout interrupt enabled.

65.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

EOUTMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it loads (a value corresponding to T_min = 250 µs + value programmed in FCCU_DELTA_T register) and then starts down-counting and becomes 0 on the expiry of T_min window. It reloads on occurrence of another fault event which has EOUT signaling enabled. T_min feature is available only in Bi-Stable

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   a) OP17
   b) OP19
   c) OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

Table 1297 shows Timer state/value.

65.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

1. EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. As alternative an external EOUTMR can be optionally used. EOUT dual rail protocol:
-NORMAL/ALARM : for example 10 ms toggling in opposite phase
-FAULT: for example 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM=0)
-FAULT: fast switching mode (SM =1) in phase (no periodic toggling). For details, please refer to *Figure 1329*

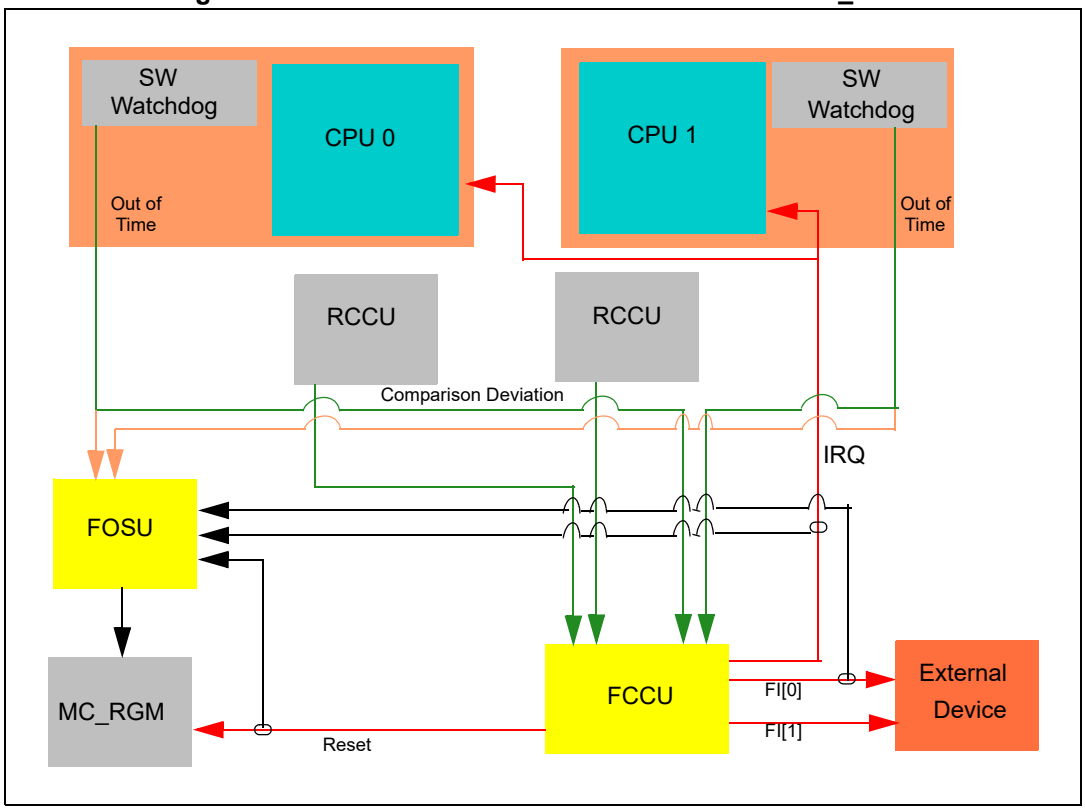
0x128	FCCU_EOUT_SIG_EN3	EOUTEN[127:96]

65.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (that is FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a "static" input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state.The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.



The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC.The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset.
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW).

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.
The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU (System reset), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 1359. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

65.8 Use cases and limitations

65.8.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.
   Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.
4. Software reset is optional.
5. The user must program the FCCU for a higher timeout value than the value hardcoded for FOSU. In this way FCCU reacts later than FOSU expects and as a result, FOSU generates a destructive reset request on its timeout, if a fault occurred when the FCCU was in CONFIG state.

65.8.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status.
   b) Verify FCCU is in NORMAL state, else repeat step(a) above.
   c) Configure FCCU.
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire.
   b) Check and clear fault status.
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires.
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state.
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU.
   f) Check and clear any new pending fault status until FCCU is in NORMAL state.
   g) Reconfigure FCCU.

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

66 Self-Test Control Unit (STCU2)

66.1 Introduction

The self-test control unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the offline and/or online conditions. The hardware can manage the logic built-in self-test (LBIST) and the SRAM or ROM built-in self-test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the self-test parameters (LBIST or MBIST scheduling activity, LBIST setup, unrecoverable faults (UF) or recoverable faults (RF) management, CRC and MISR expected values, PLL management, and so on) from flash memory during the offline self-test phase. This interface is only able to write the configuration parameters and start the self-test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the offline self-test and to load or check the execution of the online self-test.

The STCU2 includes:

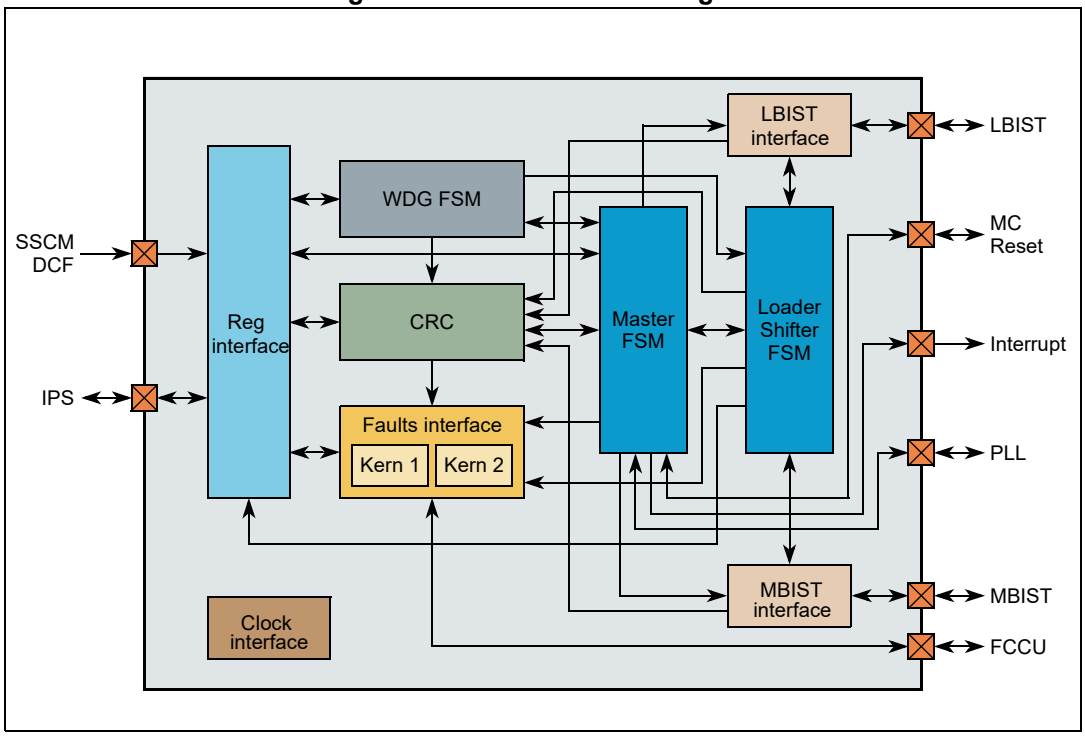
- A CRC block that can be optionally enabled to monitor the internal critical signals during the self-test run to increase the STCU2's self-checking capability.
- A programmable watchdog timer (WDG) to check the LBIST and MBIST self-test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before watchdog timeout.
- Direct PLL control during the offline self-test sequence.
- Two sets of registers to separately collect the LBIST or MBIST results during offline and online self-test.

To increase the security of this module, a different security key sequence is also required during offline and online self-test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after self-test sequence is completed.
- The register ITF clock when the WDG timeout is detected after a double security key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

66.2 Main features

- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG[WRP] bit) register interface.
- Programmable scheduler for LBIST or MBIST execution.
- LBIST concurrent/sequential execution.
- MBIST concurrent/sequential execution.
- Programmable LBIST delayed concurrent start.
- 32-bit CRC for STCU2 self-checking capability (enabled by STCU_CFG[CRCEN] bit)
- Online hardware self-test sequence abort capability.
- Programmable internal clock prescaler to reduce internal and MBIST or LBIST TCK clocks.
- Programmable PLL direct control during offline self-test sequence.
- PLL lock signal monitoring during offline and online self-test.
- Programmable WDG timer for self-check MBIST or LBIST time execution.
- Hard-coded WDG timeout to flag offline initialization errors.
- Hard-coded WDG timeout to auto-lock STCU2 write access after double key sequence.
- LBIST and SRAM or ROM MBIST offline status flags.
- STCU2 internal errors offline status flag.
- LBIST and SRAM or ROM MBIST online status flags
- STCU2 internal errors online status flag.
- Online hardware abort status flag
- LBIST and SRAM or ROM MBIST offline or online programmable failure severity (UF/RF).
- STCU2 internal errors offline or online programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software
- LBIST MISRE registers access to perform redundant software checks.
- Self-test bypass capability.
- Protection mechanism of the global write register based on double security key.
- STCU2 global auto power-saving when:
  - Self-test is completed.
  - bypass mode is selected.
  - WDT timeout is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).
- STCU2 ITF/WDG auto power-saving when hard-coded WDG timeout is detected after software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).



After completion of online self-test (MBIST or LBIST) a functional reset is generated.

So no partition level functional behavior is guaranteed once online self-test is triggered.

66.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 1360*.

Figure 1360. STCU2 block diagram

The STCU2 module includes the following submodules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- **CRC**: This module is the core of the self-checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface**: This module collects the error conditions respective to LBIST or MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages

the UF/RF fault lines and the set or clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.

- **Clock Block**: This module manages the internal and the LBIST or MBIST TCK clock prescaler, the internal clock gating power saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different watchdogs:
  - A hard-coded Watchdog used to auto-lock the STCU2 access, forcing a reset condition on the double security key registers.
  - A dual function watchdog:
  - After a reset event initializes the STCU2, it is used as a hard-coded watchdog timeout.
  - During LBIST or MBIST runs, it is used as a programmable watchdog timer to check the LBIST or MBIST have completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the self-test sequence.
- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the LBIST or MBIST registers and read back the data to be checked at the end of each self-test operation.
- **LBIST interface**: This module includes the interface between the LBIST engines and the STCU2 controllers of the device.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

66.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The self-test sequence parameters are loaded before offline self-test is executed.
- The IPS access on some specific registers (see *Section 66.5*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following R/W bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register.
- Any write operation on double security key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the double security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed offline on registers where writes are only allowed during the online self-test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on read only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 66.5*.

66.4 Functional description

66.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the self-test operations and the other state machines.
- Loader/Shifter State Machine: used to program the MBIST and the LBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the master state machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and LBIST and the timeouts in case of incorrect STCU2 programming.

66.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the offline self-test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the self-test execution phase depends on the self-test conditions reported in the following subsections.

66.4.2.1 Offline reset generation

At the end of the offline self-test execution, the STCU2 raises the global functional reset.

66.4.2.2 Online reset generation (only MBIST)

At the end of the execution, the online execution of the MBIST generates a global functional reset.

66.4.2.3 Online Reset generation (LBIST enabled)

At the end of the execution, the online execution of the LBIST generates a global functional reset.

66.4.3 LBIST and MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST or LBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 66.7.4*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first LBIST is mapped on 0x00, the second on 0x01, and so on. The first MBIST is mapped at the address 0x10, the second on 0x11 and so on. The additional pointers are in the bitfield STCU_LB_CTRL*x*[PTR] for LBIST*x* (where *x* is the selected LBIST) and STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_LB_CTRL[CSM] and STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the LBIST or MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 66.5.31* and *Section 66.5.43*.

66.4.4 ABORT management

The STCU2 module provides online self-test execution abort. When the abort is detected, the online self-test operation stops running and the status of the currently running MBIST or LBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run. For an LBIST run, see *Section 66.4.2*, regarding reset specific management when abort is detected.

66.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a functional reset that requires the self-test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the online self-test execution run.

66.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the offline self-test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 66.5.2*.

When STCU_RUN[RUN] is set to start the offline self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end

of the MBIST run, the clock source reverts to the original one. The same behavior applies when STCU_RUN[LBPLLEN] is active and LBIST is currently selected.

66.4.6 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an unrecoverable failure (UF) or a recoverable failure (RF) during the self-test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

66.4.7 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished on time.

66.4.7.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the self-test sequence (safety mode).
- Bypass the self-test sequence by setting the STCU_RUN[BYP] bit.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded watchdog timeout flags the incorrect behavior. See *Section 66.5.6* for more details.

66.4.7.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time is configured as described in *Section 66.5.6* to account for the overall execution time of the self-test sequence. If the selected LBISTs or MBISTs are not yet completed:

- During an offline self-test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBEL/M/H or STCU_LBE registers.
- During an online self-test, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBELSW/MSW/HSW or STCU_LBESW.

In case of multiple sequential runs in the same online or offline session and the timeout occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 66.4.2*.

66.4.7.3 Write access timeout

The access on the STCU2 registers during the self-test configuration phase (both online or offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware

watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software self-test configuration as the software application may enable write access to the STCU2 registers.

66.4.8 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomial to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the self-test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

66.4.9 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

66.5 Register description

The STCU2 registers are listed in *Table 1308*.

Table 1308. STCU2 register set

66.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the offline self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Figure 1361. STCU2 Run Register (STCU_RUN)

Table 1309. STCU_RUN field descriptions

Field	Description
21 BYP	Bypass mode 0 Offline self-test is active. If the STCU_RUN[RUN] bit is not set before the hard-coded WDG timeout, the WDTO error is generated in the STCU_ERR_STAT register. 1 Offline self-test is bypassed and access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
22 MBPLLEN	Offline MBIST with PLL enabled 0 Offline MBIST is executed without using the on-chip PLL. 1 Offline MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined in STCU_PLL_CFG register.
23 LBPLLEN	Offline LBIST with PLL enabled 0 Offline LBIST is executed without using the on-chip PLL. 1 Offline LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined in STCU_PLL_CFG register.
31 RUN	RUN The RUN bit is automatically cleared by the STCU2 when the offline self-test procedure has been completed. 0 Idle 1 Offline self-test procedure is running

66.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the online self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- Online self-test phase is active. The online condition starts when the offline condition finishes. In this condition, the system is alive and the SW can program the STCU.

Field	Description
22 MBSWPLLEN	Online MBIST with PLL enabled 0 Online MBIST is executed without using the on-chip PLL. 1 Online MBIST is executed using the PLL configuration provided by software. STCU2 does not take PLL control but monitors the PLL lock signal to check if PLL is working correctly.
23 LBSWPLLEN	Online LBIST with PLL enabled 0 Online LBIST is executed without using the on-chip PLL. 1 Online LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the online self-test procedure has been completed. 0 Idle 1 Online self-test procedure is running

66.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2

asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the offline or online test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: *Note that after the self-test sequence has been completed or the bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.*

In case of invalid access or sequence (Key1 and Key2 must be applied consecutively), a transfer error on the IPS or SSCM bus (causing SSCM.CER assertion) is asserted depending on the selected source.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG timeout, STCU2 write access is locked and the WDG and register ITF clocks are switched off. Also in this case the correct sequence (Key1 and Key2) must be applied in order to re-enable write access to the STCU2 and the WDG and register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG timeout expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus (causing SSCM[CER] assertion) is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 0x00000000.

66.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the offline and online test steps.

Access to this register is described in *Figure 1364*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the online self-test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Offset: 0x000C Access: User read/write

1. You can always read this field. In the offline self-test phase, you can always write to this field. In the online self-test phase, you can write to this field only when WRP = 0.

Figure 1364. STCU2 Configuration Register (STCU_CFG)

Table 1312. STCU_CFG field descriptions

Field	Description
1:7 PTR	LBIST or MBIST pointer. PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0, then the LBIST0 is initially scheduled. (0x00 to LBIST - 1) – pointer to LBIST (0x10 to 0x10 + MBIST - 1) – pointer to MBIST 0x7F – pointer to NIL. No BIST execution.
8:15 LB_DELAY	Delay LBIST run. LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. **Note:** if the frequency of the STCU2 core clock is 16 MHz, the delay parameters are expressed in microseconds. 0x00 No delay 0x01 001 * 16 STCU2 Core clock cycles 0x02 002 * 16 STCU2 Core clock cycles 0x03 003 * 16 STCU2 Core clock cycles … 0xFD 253 * 16 STCU2 Core clock cycles 0xFE 254 * 16 STCU2 Core clock cycles 0xFF 255 * 16 STCU2 Core clock cycles **Note:** STCU2 is being clocked from PBRIDGE clock. Please refer to Clocking chapter for PBRIDGE clock frequency value.
23 WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after offline self-test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after offline self-test sequence has completed, thus preventing any user application write operation.
26 CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values. 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS test is not enabled 1 MBIST PMOS test is enabled

Table 1312. STCU_CFG field descriptions (continued)

Field	Description
28 MBU	MBIST MBU Test Enabled. 0 MBIST full algorithm or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified multi-bit upset algorithm is used to check the RAM. If a ROM is selected, the applied algorithm will be the standard one without PMOS test. This bit overwrites the PMOSEN feature.
29:31 CLK_CFG	Logic, memory BIST and STCU2 core CLK clock configuration. CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 sys_clk 001 sys_clk/2 010 sys_clk/3 011 sys_clk/4 100 sys_clk/5 101 sys_clk/6 110 sys_clk/7 111 sys_clk/8

66.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the offline LBISTs or MBISTs are performed and STCU_RUN[MBPLLEN] = 1 or STCU_RUN[LBPLLEN] = 1.

In the online state, these bits are not effective. It is also possible to set the PLL during active online mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is active.

Figure 1365. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Table 1313. STCU_PLL_CFG field descriptions

Field	Description
2:7 PLLODF	PLL Output Division Factor. The value of this field drives the output division factor of the PLL embedded in the device. Refer to the RFDPHI field of the PLL0 divider register (PLL0DIV) in *Chapter 25: Dual PLL Digital Interface (PLLDIG)* to define the exact mapping between the PLLODF value and the respective PLL's output division factor.
13:15 PLLIDF	PLL Input Division Factor. The value of this field drives the input division factor of the PLL embedded in the device. Refer to the PREDIV field of the PLL0 divider register (PLL0DIV) in *Chapter 25: Dual PLL Digital Interface (PLLDIG)* to define the exact mapping between the PLLIDF value and the respective PLL's input division factor.
25:31 PLLLDF	PLL Loop Division Factor. The value of this field drives the loop division factor of the PLL embedded in the device. Refer to the MFD field of the PLL0 divider register (PLL0DIV) in *Chapter 25: Dual PLL Digital Interface (PLLDIG)* to define the exact mapping between the PLLLDF value and the respective PLL's loop division factor.

66.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for LBIST and MBIST execution, providing protection against dead-locks or infinite loop conditions during the self-test procedure. When the offline self-test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15…0 define the timeout before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the offline or online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active
- Online self-test phase is active and STCU_CFG[WRP] = 0

Offset: 0x0014 Access: User read/write

Figure 1366. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 1314. STCU_WDG field descriptions

Field	Description
0:31 WDGEOC	Watchdog End of Count Timer. This value must be set in order to define the time budget respective to the offline and online self-test execution and check that everything is working correctly in this timeslot. The allowed time delays are: 0x00000000 1 * 16 STCU2 core clock cycles 0x00000001 2 * 16 STCU2 core clock cycles 0x00000002 3 * 16 STCU2 core clock cycles … 0xFFFFFFFD 4294967294 * 16 STCU2 core clock cycles 0xFFFFFFFE 4294967295 * 16 STCU2 core clock cycles 0xFFFFFFFF 4294967296 * 16 STCU2 core clock cycles **Note:** STCU2 is being clocked from PBRIDGE clock. Please refer to Clocking chapter for PBRIDGE clock frequency value.

66.5.7 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the self check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

Equation 77 CRC-32 (ethernet protocol)

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

66.5.8 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the offline and online self-test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Field	Description
0:31 CRCR	Read CRC signature

66.5.9 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the online and offline self-test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 66.7.4*.

Access to this register is described in *Figure 1369* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

Figure 1369. STCU2 Error Register (STCU_ERR_STAT)

Table 1317. STCU_ERR_STAT field descriptions

Field	Description
6 ABORTHW	Online hardware abort flag. 0 No hardware abort was requested during the online self-test sequence 1 A hardware abort was detected during the online self-test sequence
11 LOCKESW	Online LOCK Error. 0 If PLL is enabled, it is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the online self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW[LBSWPLLEN] is set and/or during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1.

Table 1317. STCU_ERR_STAT field descriptions (continued)

Field	Description
12 WDTOSW	Online Watchdog timeout. 0 LBIST and MBIST time slots have completed within the assigned watchdog time. 1 LBIST and MBIST time slot have not completed in the assigned watchdog time or there are internal mismatches in the end of execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 CRCSSW	Online CRC Status. This flag is activated *only* when online self-test is performed and STCU_CFG[CRCEN] is set to '1', otherwise it is always forced to '0'. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to '0') 1 Failed CRC comparison
14 ENGESW	Online Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	Online Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the unrecoverable faults condition 1 There are errors that trigger the unrecoverable faults condition
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the recoverable faults condition 1 There are errors that trigger the recoverable faults condition
27 LOCKE	Offline LOCK Error 0 The PLL is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag signals an unexpected PLL unlock event during the offline self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLLEN] = 1 and/or during the MBIST run when STCU_RUN[MBPLLEN] = 1.

Table 1317. STCU_ERR_STAT field descriptions (continued)

Field	Description
28 WDTO	Offline Watchdog timeout. 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot have not been completed within the assigned watchdog time or there are internal mismatches among end of execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the watchdog reaches the end of count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Offline CRC status. This flag is activated *only* when offline self-test is performed STCU_CFG[CRCEN] is set to '1', otherwise it is always forced to '0'. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to '0') 1 Failed CRC comparison
30 ENGE	Offline Engine Error. 0 Valid engine execution 1 Invalid engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Offline Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)

66.5.10 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of unrecoverable or recoverable faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

66.5.31 STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

The STCU_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0100 + n * 0x40 (n = 0 to 3) Access: User read/write

Figure 1391. STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

Table 1339. STCU_LB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to '1', otherwise it is scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current LBIST has been completed. (0x00 to LBIST - 1) — pointer to LBIST (0x10 to 0x10 + MBIST - 1) — pointer to MBIST 0x7F — pointer to NIL. No BIST execution. others — invalid pointer, an error is set in the STCU_ERR register.
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
13:15 SHS	Shift speed 000 Shift at full rate (bist_clk) 001 Shift at 1/2 rate (bist_clk) 010 Shift at 1/3 rate (bist_clk) 011 Shift at 1/4 rate (bist_clk) 100 Shift at 1/5 rate (bist_clk) 101 Shift at 1/6 rate (bist_clk) 110 Shift at 1/7 rate (bist_clk) 111 Shift at 1/8 rate (bist_clk)

Table 1339. STCU_LB_CTRL*n* field descriptions (continued)

Field	Description
16:19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000 0 delay cycle 0001 1 delay cycle … 1111 15 delay cycles
20:23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000 0 delay cycle 0001 1 delay cycle … 1111 15 delay cycles
28 PFT	Past Flush Test The LBIST controller, by default apply 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence. 0 Apply flush test patterns 1 Skip flush test patterns
29:31 CWS	Capture window size 000 controller waits 16 shift cycles for capture to finish 001 controller waits 1 shift cycle for capture to finish 010 controller waits 2 shift cycles for capture to finish 011 controller waits 3 shift cycles for capture to finish 100 controller waits 4 shift cycles for capture to finish 101 controller waits 5 shift cycles for capture to finish 110 controller waits 6 shift cycles for capture to finish 111 controller waits 7 shift cycles for capture to finish

66.5.32 STCU2 LBIST PC Stop *n* Register (STCU_LB_PCS*n*)

The STCU_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0104 + n * 0x40 (n = 0 to 3) Access: User read/write

Field	Description
6:31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

66.5.33 STCU2 LBIST PRPG Low *n* Register (STCU_LB_PRPGL*n*)

The STCU_LB_PRPGL register defines the LSB part (31…0) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0108 + n * 0x40 (n = 0 to 3) Access: User read/write

Figure 1393. STCU2 LBIST PRPG Low *n* Register (STCU_LB_PRPGL*n*)

Table 1341. STCU_LB_PRPGL*n* field descriptions

Field	Description
0:31 PRPG[31:0]	PRPG LBIST low bits This field defines the low part (31…0) of the LBIST PRPG start value.

66.5.34 STCU2 LBIST PRPG High *n* Register (STCU_LB_PRPGH*n*)

The STCU_LB_PRPGH register defines the MSB part (63…32) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x010C + n * 0x40 (n = 0 to 3) Access: User read/write

Field	Description
0:31 PRPG[63:32]	PRPG LBIST high bits This field is the high part (63…32) of the LBIST PRPG start value.

66.5.35 STCU2 Offline LBIST MISR Expected Low *n* Register (STCU_LB_MISREL*n*)

The STCU_LB_MISREL register defines the LSB part (31…0) of the expected MISR of the offline LBIST controller. The size of the register depends on the number of MISR bits of the respective LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Offset: 0x0110 + n * 0x40 (n = 0 to 3) Access: User read/write

Figure 1403. STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

Table 1351. STCU_MB_CTRL*k* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to '1', otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current MBIST has been completed. (0x00 to LBIST - 1) — pointer to LBIST (0x10 to 0x10 + MBIST - 1) — pointer to MBIST 0x7F — pointer to NIL. No BIST execution. others — invalid pointer, an error is set in the STCU_ERR register.

66.6 Register map

The following STCU2 register map shows a full implementation case. If fewer LBISTs or MBISTs are implemented, note the following:

- The size of the STCU_LBS, STCU_LBSSW, STCU_LBE, STCU_LBESW, STCU_LBUFM depends on the number of LBIST.
- The size of STCU_MBSL, STCU_MBSLSW, STCU_MBEL, STCU_MBELSW, STCU_MBUFML depends on the amount of RAM or ROM subject to BIST.
- The size of STCU_MBSM, STCU_MBSMSW, STCU_MBEM, STCU_MBEMSW, STCU_MBUFMM depends on the amount of RAM or ROM subject to BIST only when the respective value is greater than 32, otherwise these registers are not implemented.
- The size of the STCU_MBSH, STCU_MBSHSW, STCU_MBEH, STCU_MBEHSW, STCU_MBUFMH depends on the amount of RAM or ROM subject to BIST only when the respective value is greater than 64, otherwise these registers are not implemented;
- The number of STCU_LB_CTRL, STCU_LB_PCS, STCU_LB_PRPGL, STCU_LB_PRPGH, STCU_LB_MISREL, STCU_LB_MISRELSW,

STCU_LB_MISREH, STCU_LB_MISREHSW, STCU_LB_MISRRL, STCU_LB_MISRRLSW, STCU_LB_MISRRH and STCU_LB_MISRRHSW depends on the number of LBISTs.

- The size of each STCU_LB_MISREL, STCU_LB_MISRELSW and STCU_LB_MISRRL, STCU_LB_MISRRLSW depends on the number of MISR bits of the respective LBIST.
- The size of each STCU_LB_MISREH, STCU_LB_MISREHSW, and STCU_LB_MISRRH, STCU_LB_MISRRHSW, depends on the number of MISR bits of the respective LBIST only when the respective value is greater than 32, otherwise the registers are not implemented.
- The size of STCU_LB_PRPGL and STCU_LB_PRPGH depends on the number of PRPG bits of the respective LBIST.
- The number of STCU_MB_CTRL depends on the amount of RAM or ROM subject to BIST.

66.7 Use cases and limitations

The STCU2 module is designed to give high flexibility during the online and offline self-test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Offline self-test sequence after a reset trigger event.
- Bypass mode of the self-test sequence after a reset trigger event.
- Online self-test sequence.

66.7.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and LBIST or MBIST execution parameters stored in the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the system RAM or ROM according to the system specifications. The sequence is the following:

- Unlock the offline STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFML/M/H registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, the STCU_LB_PRPGL/H can also be programmed to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the offline self-test sequence in the STCU_CRCE register
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.

- Program the RUN bit in the STCU_RUN register to enable the offline self-test execution and the L/MBPLLEN bits to enable the PLL during LBIST or MBIST execution according to STCU_PLL_CFG register content.
- Start the offline self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the self-test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBS flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBE flag register to check the LBIST still on-going when UF or RF are detected.
- The software application reads the STCU_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAM or ROM memory BIST when UF or RF are detected.
- The software application reads the STCU_MBEL/M/H flag registers, depending on the number of memories, to check the RAM or ROM memory BIST still running when UF or RF are detected.
- The software application reads the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- For each LBIST, the software application reads the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: The software application reads operations on the STCU2_CRC and LBIST_MISR registers after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

66.7.2 Online self-test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the LBIST or MBIST execution. Since the online operations clean up the content of the respective digital logic (LBIST) or RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the online STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 online self-test registers.
- The LBIST, MBIST and STCU2 internal fault reaction should already be programmed during the offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_LBUFM, STCU_MBUFML/M/H and STCU_ERR_FM.
- The STCU_LB_CTRL, STCU_LB_PCS should already be programmed during offline self-test sequence. If they have not been programmed or there is a need to change

them, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.

- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Overwrite/Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBISTs are running simultaneously to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the online self-test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the online self-test execution and the L/MBSWPLLEN bits to enable the PLL lock signal monitor during LBIST or MBIST execution.
- Start the online self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches off the core clock at the end of the self-test run.
- After online self-test completion, a functional reset is triggered in the SoC. In case core tries to access any peripheral/memory during online self test, access is not guaranteed.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBESW flag register to check the LBIST is still running when UFs or RFs are detected.
- The software application reads the STCU_MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAM/ROM memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBELSW/MSW/HSW flag registers, depending on the number of memories, to check the RAM/ROM memory BIST is still running when UFs or RFs are detected.
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.
- For each LBIST, the software application reads the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application reads operations on the STCU2 CRC and LBIST MISR registers after online self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in the STCU2.

66.7.3 Bypass USER Mode

In this mode, the user application parameters stored in Flash and read by SSCM are written to skip the self-test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the offline Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the self-test sequence is not applied and the system can wake up and start the user application.

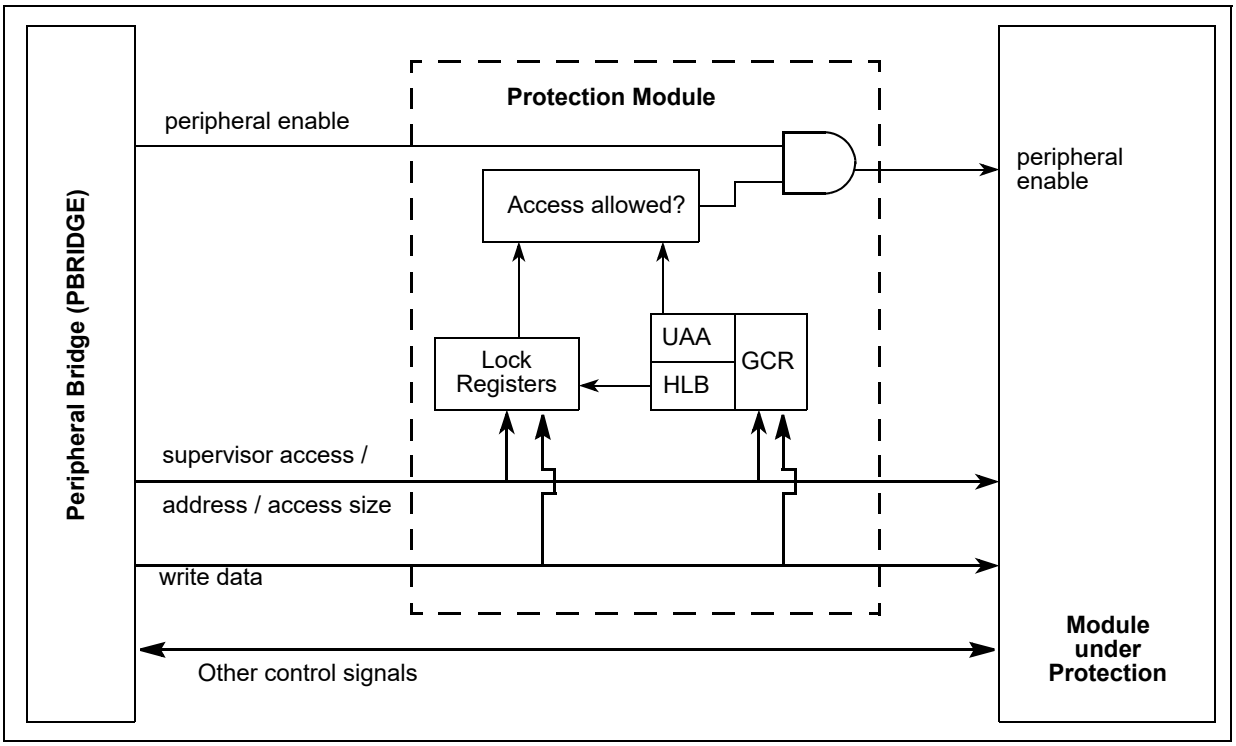
66.7.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the on/offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- As the software has full control of the system while applications are running during the online self-test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

67 Register Protection (REG_PROT)

67.1 Introduction



67.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Please see Chapter 7: Device configuration for device-specific details of the protected registers and bytes.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 1404*.

Figure 1404. REG_PROT Block Diagram

67.1.2 Features

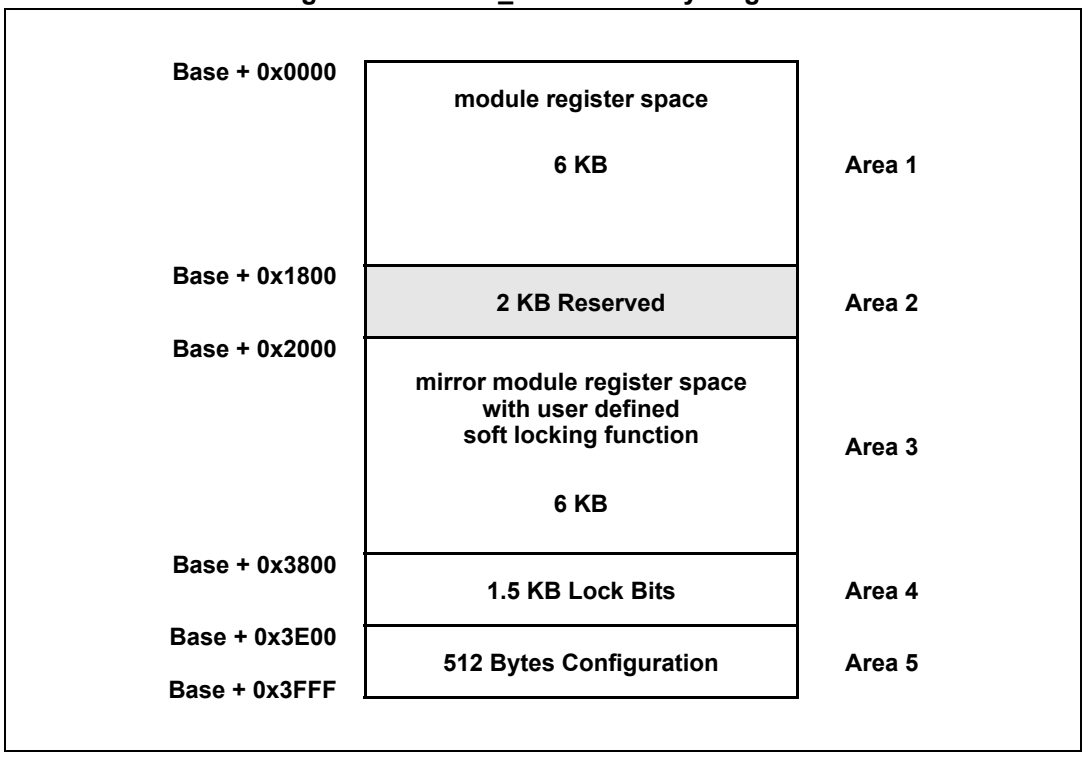
Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set.

67.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.



67.2 External signal description

There are no external signals.

67.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 1405*.

Figure 1405. REG_PROT memory diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated

Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

67.3.1 Memory map

Table 1353 shows the memory map for a module which is protected via a REG_PROT module.

Table 1353. REG_PROT memory map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*Section 67.3.2.1*
0x0001	Module Register 1 (MR1)	*Section 67.3.2.1*
0x0002	Module Register 2 (MR2)	*Section 67.3.2.1*
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	*Section 67.3.2.1*
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	*Section 67.3.2.2*
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	*Section 67.3.2.2*
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	*Section 67.3.2.2*
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3	*Section 67.3.2.3*
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	*Section 67.3.2.3*
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	*Section 67.3.2.3*
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	*Section 67.3.2.4*

Note: Reserved registers in area #1 will be handled as specified in the protected module's documentation.

67.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

67.3.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

67.3.2.2 Module Register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 1355*.

67.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 1354. Soft lock bits vs. protected address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

Note: As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3800-0x3DFF

Access: Read always
Supervisor write

	0	1	2	3	4	5	6	7
R	0	0	0	0	SLB0	SLB1	SLB2	SLB3
W	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

Figure 1406. Soft Lock Bit Register (SLBR*n*)

Table 1355. SLBR*n* field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR*n* register: SLB0 can block accesses to MR[*n* *4 + 0] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[*n* *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[*n* *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[*n* *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable

67.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3FFC

Access: Read Always
Supervisor write

Figure 1407. Global Configuration Register (GCR)

Table 1356. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register can not be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and can not be modified 0 All SLB bits are accessible and can be modified.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

67.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

67.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size is device and module specific, please refer to *Chapter 7: Device configuration for details.*

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

67.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

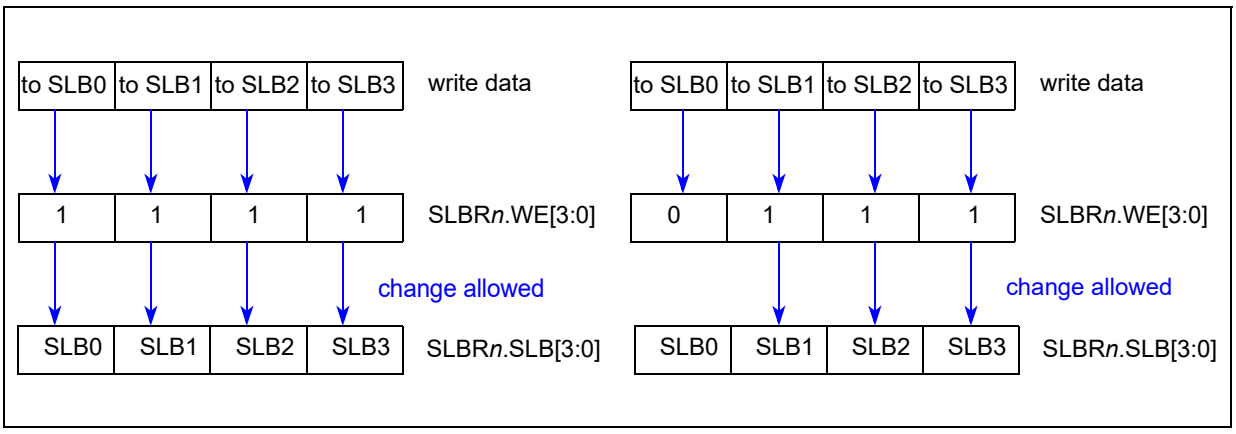
Both methods are explained in the following sections.

67.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 1408 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 1408. Change lock settings directly via Area #4



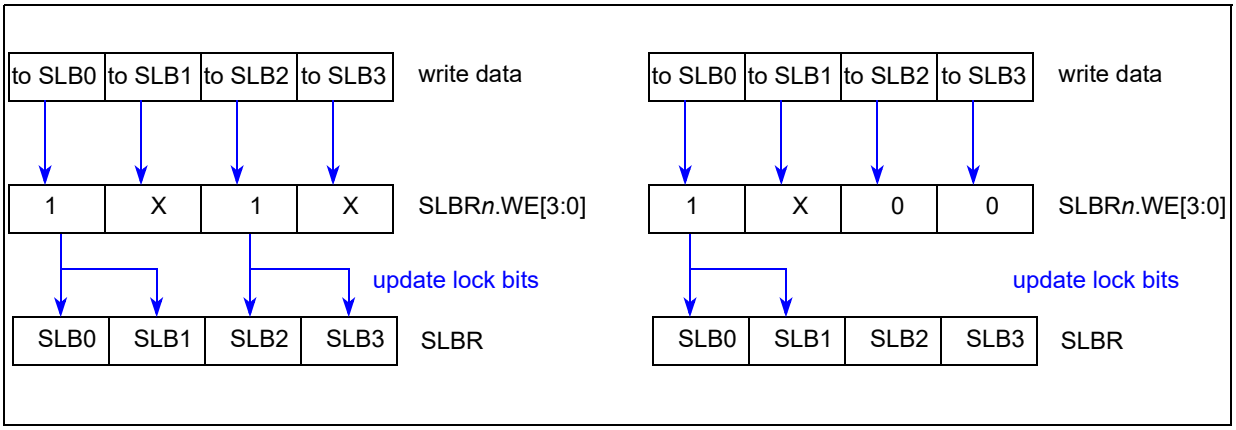


Figure 1408 shows four registers that can be protected 8-bit wise. In *Figure 1409* registers with 16-bit protection and in *Figure 1410* registers with 32-bit protection are shown:

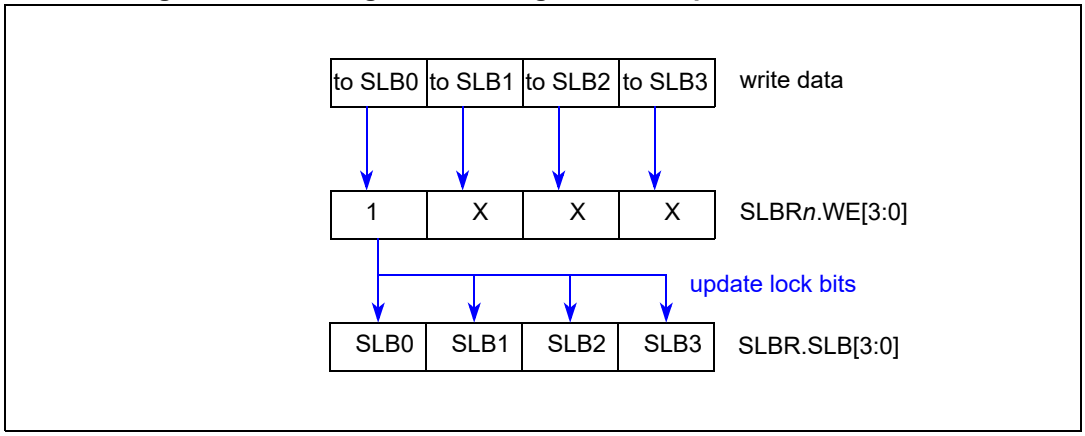
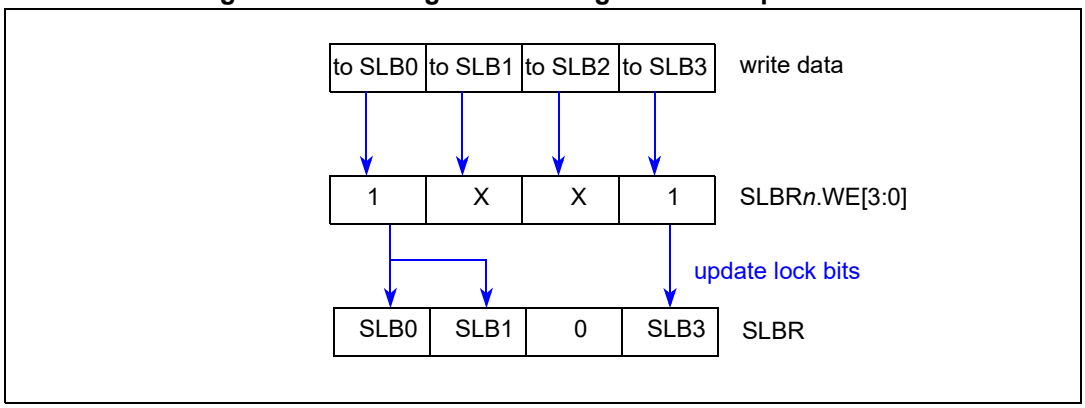
Figure 1409. Change lock settings for 16-bit protected addresses



On the right side of *Figure 1409* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 1409* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

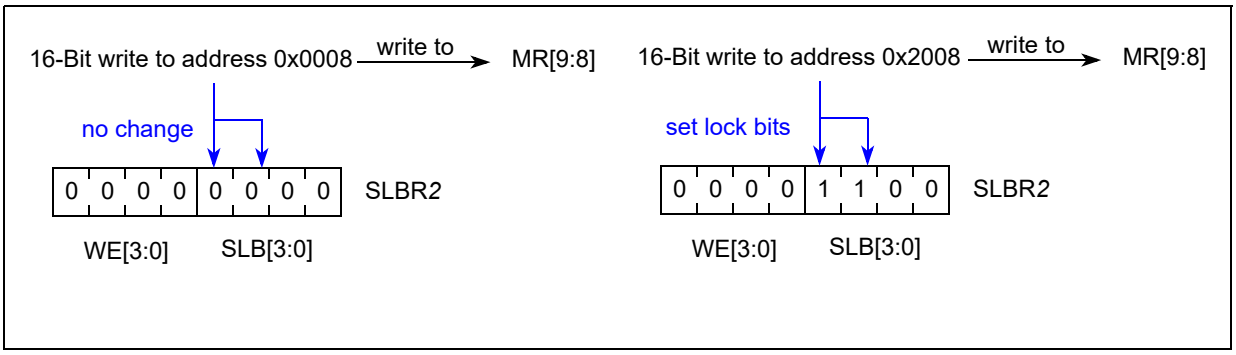


In *Figure 1410* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 1410. Change lock settings for 32-bit protected addresses

In *Figure 1411* an example is shown which has a mixed protection size configuration:

Figure 1411. Change lock settings for mixed protection

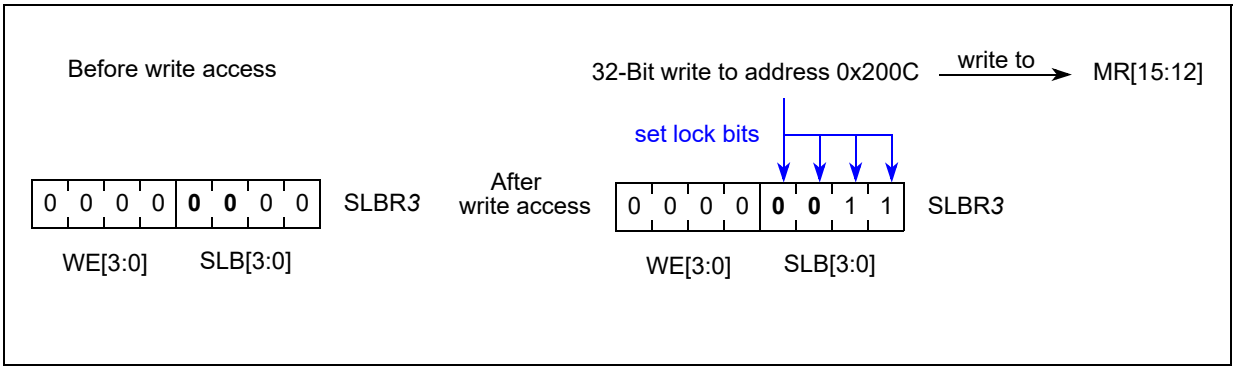


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

67.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 1412* shows one example:

Figure 1412. Enable Locking Via Mirror Module Space (Area #3)



When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 1409*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 1409*).

Figure 1413 shows an example where some addresses are protected and some are not:

Figure 1413. Enable locking for protected and unprotected addresses

In the example in *Figure 1413* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

67.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 67.4.2.1* and *Section 67.4.2.2* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

67.4.3 Access errors

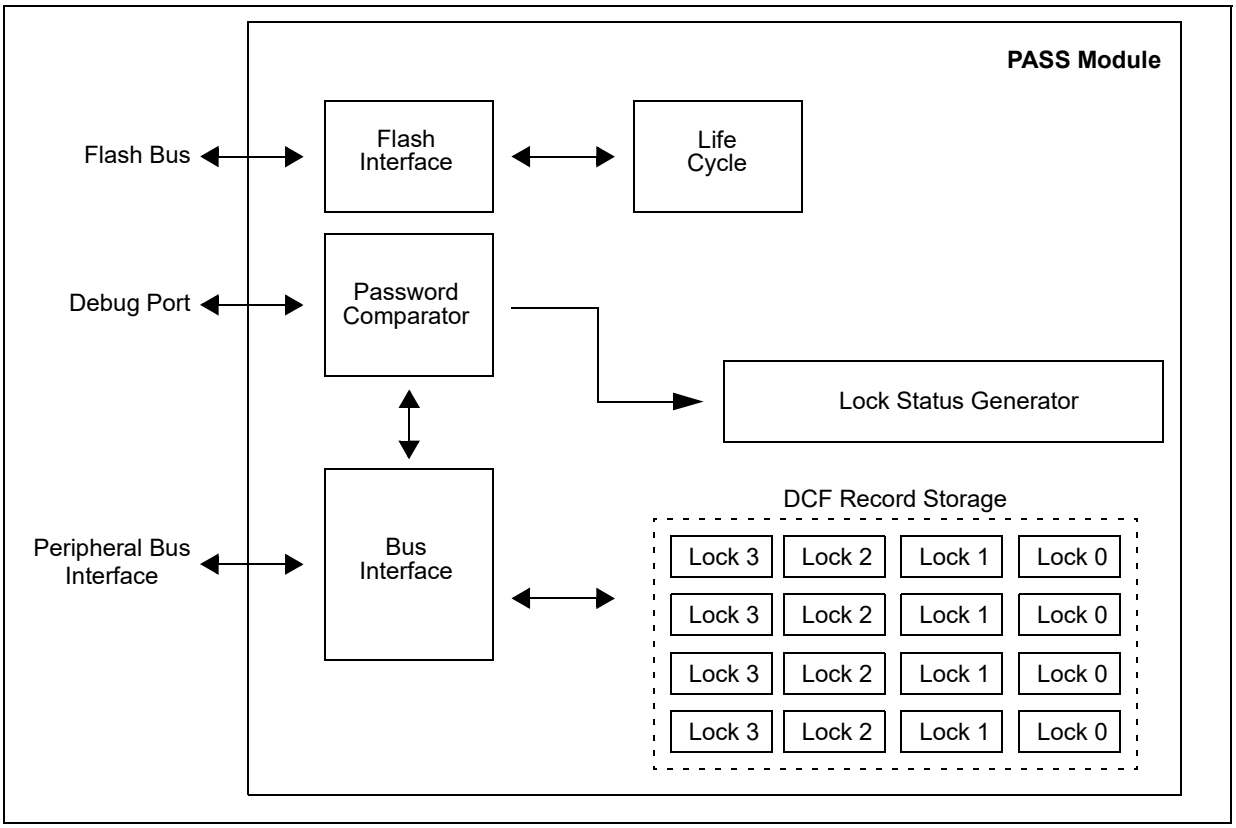
The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 1405*

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

67.5 Initialization/application information

67.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 67.3.2*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.



68 Password and Device Security Module (PASS)

68.1 Introduction

68.1.1 Overview

The Password and device security (PASS) module shown in *Figure 1414*, receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 1414. PASS module block diagram

68.1.2 Features

The PASS includes these distinctive features:

- Lifecycle status
- Password comparison
- JTAG password comparison
- Retest Password Comparison

68.1.3 Modes of operation

The PASS operates identically in all system modes.

68.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 68.3: DCF clients*.)

Table 1357 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

Table 1357. PASS memory map

Offset	Register	Access	Reset Value	DCF Client Address(1) (ADDR[14:0])	Section

1. DCF Client Address column shows what is the DCF used to pre-load the register value during reset. If the column value is "None", it means that the register value at reset is fixed in hardware.
2. Reset value depends on password group lock state

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

68.2.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

68.2.1.1 Lifecycle Status register (LCSTAT)

The Lifecycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device lifecycle forward), but never to revert the lifecycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external lifecycle management module (like SSCM). It is a 3-bit lifecycle. This register simply displays the lifecycle input from external blocks.

Offset: 0x0000 Access: Software Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	1	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	x(2)	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

2. Reset value depends on the Censorship DCF client

Figure 1415. Lifecycle Status register (LCSTAT)

PASS_LCSTAT register functions are as shown in *Table 1358*.

Table 1358. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the state of the Censorship DCF Client. The bit can be set (or cleared) via DCF Record in UTEST Flash. See *Section 68.5.3: Censoring and uncensoring the device*. 0 Device is uncensored 1 Device is censored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit. **Note:** Refer to the Security Reference Manual for details.
29:31 LIFE	The lifecycle setting is manipulated externally (SSCM). Pass displays a 3-bit input lifecycle. 000 Failure Analysis mode 001 Reserved 010 OEM Production 011 Customer Delivery 110 ST Production 111 In Field

68.2.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.

The ID of the accessing master sets the CMST field of the Challenge Status register.

Offset: 0x0008 Access: Software Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W	PW32															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

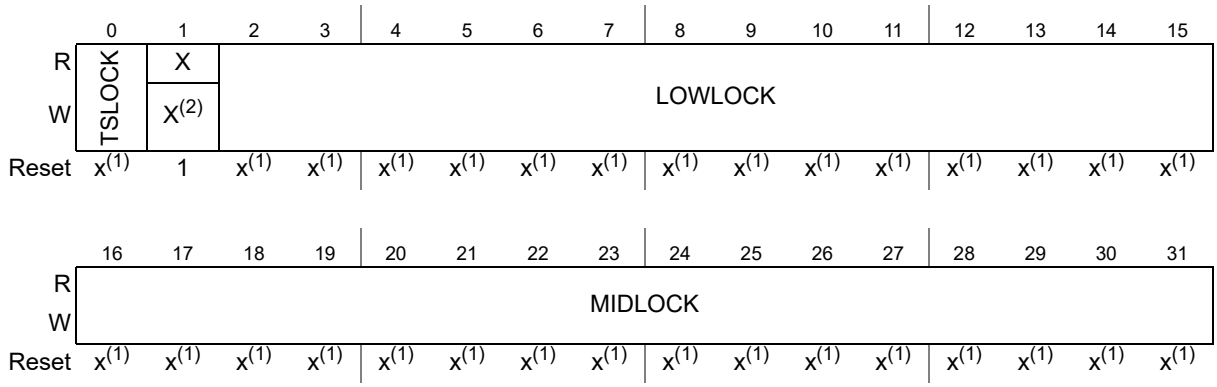
Figure 1418. Challenge Input register (CIN*n*)

CIN register functions are as shown in *Table 1361*.

Table 1361. CIN*n* register field descriptions

Field	Description
0:31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.



All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

68.2.1.5 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the lifecycle has matured to *OEM Production* or older.

Offset: 0x0100 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.
2. This bit is not implemented and its value has no impact on the system.

Figure 1419. Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

LOCK0_PG*n* register functions are as shown in *Table 1362*.

Table 1362. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
2:15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16:31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', indicating that a block is locked.

Warning: Failure to program valid passwords or DCF records for all password groups before the lifecycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is

older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

68.2.1.6 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x0104 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 1420. Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

LOCK1_PG*n* register functions are as shown in *Table 1363*.

Table 1363. LOCK1_PG*n* register field descriptions

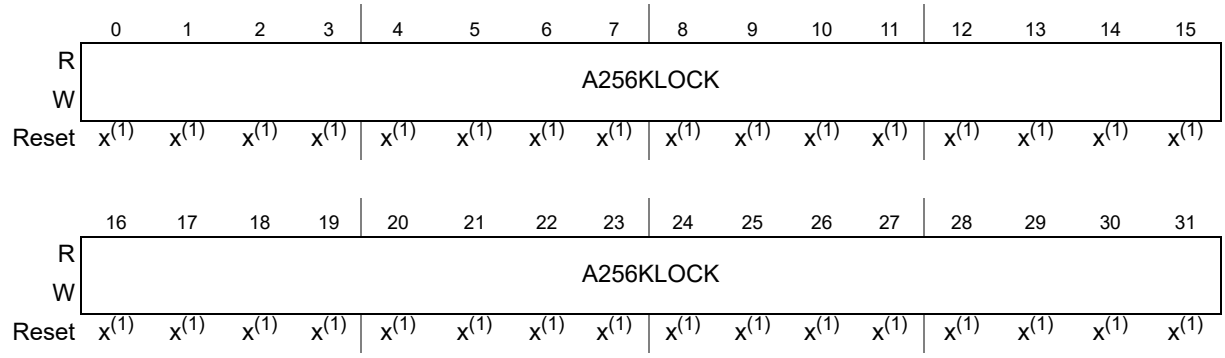
Field	Description
16:31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is ‘1’, which indicates a block is locked.

Warning: Failure to program valid passwords or DCF records for all password groups before the lifecycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.



The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

68.2.1.7 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle is matured to *OEM Production* or older.

Offset: 0x0108 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit resets to '1'.

Figure 1421. Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 1364*.

Table 1364. LOCK2_PG*n* register field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', which indicates a block is locked.

Warning: Failure to program valid passwords or DCF records for all password groups before the lifecycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

68.2.1.8 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x010C + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Not all devices include this field. See the device reference manual's chip configuration chapter for details.
2. Reset value depends on lifecycle. If lifecycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 1422. Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

LOCK3_PG*n* register functions are as shown in *Table 1365*.

Table 1365. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If lifecycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface Lock The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed. 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked.
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared. 1 Only the Master which unlocked the passgroup can change the passgroup settings.
4:7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
11 RL4	Read Lock Region 4 lock bit The default value of this bit would be '1' if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected.
12 RL3	Read Lock Region 3 lock bit The default value of this bit would be '1' if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected.
13 RL2	Read Lock Region 2 lock bit The default value of this bit would be '1' if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Read Lock Region 1 lock bit The default value of this bit would be '1' if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected.

Table 1365. LOCK3_PG*n* register field descriptions (continued)

Field	Description
15 RL0	Read Lock Region 0 lock bit The default value of this bit would be '1' if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected.
16:31 A256KLOCK	256K address space block lock A256KLOCK[47:32] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', which indicates a block is locked.

Warning: Failure to program valid passwords or DCF records for all password groups before the lifecycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to *Section 68.4.3: Flash Memory Read Protection*.

Once a censored device enters the *Failure Analysis* lifecycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. .

68.3 DCF clients

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

68.3.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Censorship DCF client defines whether the MCU is censored or not (see *Table 1357*).

DCF Client Address: 0x00B0 Censorship — Access: DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W																
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																
W	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 1423. Censorship register (not accessible)

Table 1366. Censorship register field descriptions

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored. If this value is anything other that 0x55AA, the MCU is censored.

68.4 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

68.4.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (See *Section 68.3.1: Censorship*).

68.4.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (See *68.2.1.8: Password Group n - Lock 3 status register*

(LOCK3_PGn)). Both of these debug enabling options are further conditioned by lifecycle and Production Disable.

The table below describes all options for enabling/blocking Debug Interface access.

Table 1367. Debug Interface Enable Truth Table

Input Conditions				Outcome
Lifecycle	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Not censored	Don't Care	Don't Care	Enabled
	Censored	Unlocked (DBL=0)	Don't Care	Enabled
		Locked (DBL=1)	Matched	Enabled
			Not Matched	Blocked
In Field	Not censored	Don't Care	Don't Care	Enabled
	Censored	Unlocked (DBL=0)	Don't Care	Enabled
		Locked (DBL=1)	Matched	Enabled
			Not Matched	Blocked
Failure Analysis	Don't Care	Don't Care	Don't Care	Enabled

If the device is censored, then access is possible via JTAG password.

68.4.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can to be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

68.4.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 1368: Flash Memory Read Protection Truth Table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The Flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (refer to *Chapter 7: Device configuration*, *Section 7.11.5: Password and Device Security Module (PASS) configuration*).

Table 1368. Flash Memory Read Protection Truth Table

INPUTS			OUTPUTS	
Lifecycle	**Censorship**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[2:1] (Other Regions)**
STMicroelectronics Production / Customer Delivery	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Readable	Readable
	Censored	Don't Care	Readable	Readable
		Locked (1)	Read Blocked	Read Blocked
		Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Readable	Readable

68.4.4 UTEST protection

During the *Customer Delivery* lifecycle, the user must program a valid password or a DCF record that writes LOCKm_PGn registers to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

68.4.5 Retest Password

Retest is the capability for STMicroelectronics to retest devices that have been returned to STMicroelectronics after being shipped to customers. Virgin devices are tested at STMicroelectronics in STMicroelectronics_Production lifecycle, the lifecyle is advanced to Customer_Delivery before shipping to the customer. Retest Password provides additional protection from entering Test mode while in Customer_Delivery lifecycle

68.4.5.1 Retest Password Implementation

The Retest Password is a password entered by the tester during retest to gain access to Flash Test Mode.

Note: This password is not required during normal production test until the lifecycle is advanced to Customer Delivery.

68.4.5.2 Retest Password Storage

The Retest password is 256 bits wide and is stored in Test Flash

68.4.5.3 Retest Password Challenge Entry

The Retest password challenge is entered via JTAG using the password register in the JTAGC.

JTAG password is not used in *Customer Delivery* lifecycle, so when the PASS module receives a request to perform a password compare from JTAGC while lifecycle = *Customer Delivery*, the password challenge is compared with Retest password.

68.4.5.4 Retest Password Compare

The Retest Password challenged, is compared against the password stored in Test Flash in the same way as in the PASS module for JTAG password. If the password matches, access to Flash Test Mode is granted and stays granted until the next destructive reset.

There are no passwords that the hardware detects as illegal. All 0's and all 1's are valid passwords.

68.5 Initialization/application information

68.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (see *Section 68.2.1*). However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

68.5.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 1369. CS/ADDR Values for Lock Registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xXXXX0100(1)
Lock1	0xXXXX0104(1)
Lock2	0xXXXX0108(1)
Lock3	0xXXXX010C(1)
PW Group 1	
Lock0	0xXXXX0110(1)
Lock1	0xXXXX0114(1)
Lock2	0xXXXX0118(1)
Lock3	0xXXXX011C(1)
PW Group 2	
Lock0	0xXXXX0120(1)
Lock1	0xXXXX0124(1)
Lock2	0xXXXX0128(1)
Lock3	0xXXXX012C(1)

Table 1369. CS/ADDR Values for Lock Registers (continued)

Register	DCF CS/ADDR
PW Group3	
Lock0	0xXXXX0130(1)
Lock1	0xXXXX0134(1)
Lock2	0xXXXX0138(1)
Lock3	0xXXXX013C(1)

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 1370*.

Table 1370. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA55AF	Start Record
0x04	0x00000000	
0x08	0x000000FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xXXXX0110(1)	
0x10	0xFFFFFFFF	Stop Record
0x14	0xFFFFFFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

68.5.3 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTEST Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS) and the address 0x00B0. Therefore 0xXXXX00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is censored.

Appendix A Acronyms and abbreviations

Table 1371 lists acronyms and abbreviations used in this document.

Table 1371. Acronyms and abbreviations

Term	Meaning
AC	Alternative current
ACIM	AC induction motor
AHB	Advanced high-performance bus
AIC	AIPS integrity checker
AIPS	AHB to IPS bridge
AMBA	Advanced microcontroller bus architecture
APU	– Advanced protocol unit – Auxiliary processing unit
ASILD	Automotive SIL D
AUTOSAR	Automotive open system architecture
BAF	Boot assist flash
BDC	Brush DC
BIST	Built-in self test
BIU	Bus interface unit
BLDC	Brushless DC
CAN	Controller area network
CF	Critical fault
CGM	Clock generation module
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check
CSI	Combined serial interface. DSPI configuration that alternates DSI and SPI frames.
CTU	Cross triggering unit
DC	Direct current
DCF	Device configuration format
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DSI	Deserial serial interface. DSPI configuration that serializes and deserializes registers or signals to allow for pin reduction.
ECC	Error correction code

Table 1371. Acronyms and abbreviations (continued)

Term	Meaning
ECSM	Error correction status module
EIM	Error injection module
EMI	Electromagnetic interference
EOUT	Error out
ESD	Electromagnetic static discharge
FCCU	Fault collection and control unit
FMPLL	Frequency-modulated phase-locked loop
FOC	Field oriented control
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
FTTI	Fault tolerant time interval
GPIO	General-purpose I/O
HVD	High voltage detector
HW	Hardware
ID	LIN identifier field
IEEE	Institute of electrical and electronics engineers
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety
IPS	– Internal peripheral system – IPI slave bus
IRQ	Interrupt request
ISR	Interrupt service routine
JDC	JTAG data communication
JEDEC	Joint electron device engineering council
JTAG	Joint test action group
LBIST	Logic built-in self test
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LVD	Low voltage detector
LWB	Late-write buffer
MB	Message buffer
MBIST	Memory built-in self test
MBM	Message buffer management

Table 1371. Acronyms and abbreviations (continued)

Term	Meaning
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit
MFD	Multiplication factor divider
Mux	Multiplex
NCF	Non-critical fault
NMI	Non-maskable interrupts
NVM	Non-volatile memory
OPP	Over-program protection
OSC	Oscillator
OTP	One time programmable
PASS	Password and device security module
PBRIDGE	Peripheral bridge
PCM	Platform configuration module
PCU	Power control unit
PFLASH	Platform flash controller
PIT	Periodic interrupt timer
PLL	Phase-locked loop
PMAC	Permanent magnet AC
PMC	Power management controller
PRAM	Platform RAM controller
PWD	Password
PWM	Pulse width modulation / modulator
RC	– Resistance-capacitance – Resistor-capacitor
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RTL	Register transfer language
RWW	Read-while-write
RX	Receive
SAG	Safety application guide

Table 1371. Acronyms and abbreviations (continued)

Term	Meaning
SAR ADC	Successive approximation register analog-to-digital converter
SIL	Safety integrity level
SIUL	System integration unit lite
SMPU	System memory protection unit
SoC	System-on-chip
SOR	Sphere of redundancy
SPI	Serial peripheral interface
SRM	Switched reluctance motor
SSCM	System status and configuration module
STCU	Self-test control unit
STM	System timer module
SW	Software
SWT	Software watchdog timer
TBD	To be defined
TCD	Transfer control descriptor
TSENS	Temperature sensor
TX	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault
VCO	Voltage controlled oscillator
VREG	Voltage regulator
VRM	Variable reluctance motor
WBBR	Write back bus register
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar
XBIC	XBAR integrity checker

Revision history

Table 1372. Document revision history

Date	Rev.	Changes
09-Sep-2014	1	Initial release
13-Apr-2015	2	*Chapter 2: Introduction* *Table 2: SPC574Sx device feature summary (superset configuration)*: – For SMPU, description updated to “Yes (8 Regions)” – Footnote 1 “SMPU with process ID support extension” removed Updated the description of LINFlexD from “2” to “4”. *Figure 2: Block Diagram*: INTC updated to INTC_0 *Chapter 3: System architecture* *Section 3.3: Motor control Architecture*: Replaced “PWM unit” by “FlexPWN unit”. *Table 7: ADC channels mapping description*: Added Column “PAD LFBGA244“ same as “PAD QFP144” except for row CADC1 - FCH5 that is “PAD[131]”. *Figure 7: Motor control architecture*:Updated picture at CH[32] input by added (except QFP144). *Chapter 4: Signal description* *Table 9: Power supply and reference pins*: – moved all “Exposed pad” rows at the end of the table. – updated footnote 2 with “PWMODE = 1” – Added column LFBGA244 – Added LFBGA244 pins “B16” and “F17” to pad “VDD_HV_IO1” row – Updated description of VDD_HV_IO0 and VDD_HV_OSC *Table 10: System pins*: row PWMODE: inverted “internal” and “external”. *Table 12: Pin multiplexing description*: Extensive updates throughout table. *Table 13: Peripheral multiplexing description*: row cansubsys_0, MSCR[512]: updated “M_CAN_1_RX” by “M_CAN_0_RX” in column “Functions”. *Table 14: Cross-mapping between pads and package pins*: – Removed rows: PAD_PWMODE, EXTAL, XTAL, PAD_TESTMODE, PAD_PORST – Added column LFBGA244 *Chapter 5: Memory map* Updated table name and content in *Table 17: Peripheral bridge 1 memory map* Replaced AIPS by PBRIDGE, AIPS 1 by PBRIDGE_1, RAM Controller by PRAM_0, MCAN 1 by CAN_SUB_1_M_CAN_1, CMU 2 (AIPS 0/1) by CMU 2 (PBRIDGE 0/1), Updated table name and content in *Table 18: Peripheral bridge 0 memory map* with following changes:

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	Replaced AIPS 0 by PBRIDGE_0, XBAR by XBAR_0, SMPU by SMPU_0, XBIC by XBIC_0, RAM controller by PRAM_0, Flash Memory Controller by PFLASH_0, INTC by INTC_0, SWT by SWT_0, STM by STM_0, DMA by eDMA_0, ADC 0 by SAR_ADC_12BIT_0, ADC 1 by SAR_ADC_12BIT_1, ADC 2 by SAR_ADC_12BIT_2, ADC Supervisor AIPS0 by SAR_ADC_12BIT_B0, ADC Supervisor AIPS0 seq by ADC Supervisor 0 seq, MCAN 0 by CAN_SUB_0_M_CAN_0, MCAN 2 by CAN_SUB_0_M_CAN_2, CRC by CRC_0, DMA Mux 0 by DMAMUX_0, DMA Mux 1by DMAMUX_1, PIT by PIT_0, Wakeup by WKPU, SUL by SIUL2. *Chapter 6: Functional safety* *Table 24: FCCU failure inputs*: – Re-ordered all FFCU inputs. – Input 41”PMC”: replaced “PMU6” and “PMU” by “PMC”. – Input 44 “DSMC”: removed complete row. – Input 44 “RCCU”: added “No reaction” to this fault. Updated failure sources in *Section 6.4.7: Failure handling* Added *Section 6.4.12: LBIST / MBIST architecture* *Chapter 7: Device configuration*, Extensive updates throughout chapter *Chapter 8: Reset and boot* *Section 8.7: System boot*: Rewrited first paragraph text to “After the reset phase is completed, the CPU starts executing at the start address provide by MC_ME peripheral,”. Removed signal p_rstbase *Section 8.8: HW boot record search (SSCM search)*: Removed list bullet 3. and Note: During ST production, till no valid...7 is programmed. Removed BAR execution paragraph. *Table 133: BAF boot record structure*: Sorted offsets from lowest (0x0) value to biggest value (0xC). *Table 134: BAF boot record search locations* , replaced “Flash 128 KB Code Block 0” with “Flash 256KB Code Block 0” *Section 8.5: ESR0 pin functionality*: Updated latest bullet. Updated *Figure 46: System boot sequence*. *Chapter 9: Device Configuration Format (DCF) Records* *Table 139: DCF client list*: STCU - Updated DCF client description: changed STCU_LBCFM to STCU_LBUFM *Figure 51: UTEST Miscellaneous DCF Client*: updated ‘Reset’ with ‘The reset value is described in *Table 139: DCF client list*.’ Added note “LVD11_C, LVD11_FL & LVD3_C monitors once enabled in DCF cannot be cleared by DCF record.” about *Figure 52: REE_BUS bits DCF Client* Added *Chapter 11: Security*

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Chapter 12: Core e200z420n3 Description* *Figure 63: e200z420n3 SUPERVISOR Mode Programmer's Model SPRs*: Updated figure with Local Memory Configuration registers. *Figure 64: e200z420n3 Supervisor Mode Programmer's Model DCRs and PMRs*: Updated figure with Local Memory registers. *Figure 67: EFPU Status and Control Register (SPEFSCR)*: changed OV bit-field 18 to reserved. *Section 12.7.5.13: System Reset Interrupt*: This section is moved after section "Embedded Floating-point Round Interrupt (offset 0xB0)". *Table 184: DMEMCTL0 field descriptions*: This section moved before section "System Call Interrupt (0x80)". *Table 184: DMEMCTL0 field descriptions*: Added this register table. *Section 12.9.2.1: DMEM Configuration Register 0 (DMEMCFG0)*, *Section 12.9.2.2: DMEM Control Register 0 (DMEMCTL0)* and *Section 12.9.2.3: DMEM Control Register 1 (DMEMCTL1)*: Added text note "These locations are accessible by S/W and will not result in error if accessed.". *Chapter 13: System Integration Unit Lite2 (SIUL2)* *Table 191: SIUL2 memory map*: Added table footnote about implemented MSCR registers. *Table 192: SIUL2_MIDR1 field descriptions*: Changed MAJOR_MASK field description to "Major Mask revision" and MINOR_MASK field description to "Minor Mask revision" (was "Silicon revision" for both). For field "PKG", configuration "11001 QFNmr152" changed to "01110 244 BGA". *Figure 98: SIUL2 MCU ID Register #1 (SIUL2_MIDR1)* and *Table 192: SIUL2_MIDR1 field descriptions*: Changed field bit 0:15 to PARTNUM and rewoked description with PARTNUM[15:8] asTechnology, PARTNUM[7:4] as Core and, PARTNUM[3:0] as Subfamily. *Chapter 14: Crossbar switch (XBAR)* *Table 211: XBAR memory map*: – Set address offsets (Was absolute adresses). – Changed register prefix from XBAR0 to XBAR. – Added subsection row named "SLAVE channel n (n=0 to 4)" *Figure 119: Priority Registers Slave (XBAR_PRSn)*: Changed offset format to "0x0000+n*0x100 (n=0 to 4)" *Figure 120: XBAR Control Register (XBAR_CRSn)*: Changed offset format to "0x0010+n*0x100 (n=0 to 4)" and set bit 29 as Reserved with figure footnote 1. "This bit is RW and must not be used". *Chapter 19: Interrupt Controller (INTC)* Removed "n" from field names in *Figure 149: INTC Priority Select Register n (INTC_PSRn)*, in *Figure 150: INTC Priority Select Register n (INTC_PSRn)*, in *Table 245: INTC_PSRn field descriptions* and in *Table 246: INTC_PSRn field descriptions*. *Chapter 20: Enhanced Direct Memory Access (eDMA)* Updated SSIZE field description in *Table 268: DMA_TCDn_ATTR field descriptions*

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Chapter 21: DMA channel multiplexer (DMACHMUX)* *Section 21.1.3: Modes of operation*: added text “for each DMACHMUX instances.” at the end of “Periodic Trigger Mode” bullet New *Figure 196: DMACHMUX triggered channels* Updated *Section 21.5.2: Enabling and configuring sources* *Chapter 24: Clocking* *Figure 203: Clock generation architecture*: Updated by moving XBAR to @140MHz (was @70MHz) Updated *Figure 204: SPC574Sx dual PLL digital interface block diagram* *Table 299: MC_CGM relationship to clocks*: Added following rows: – PLL0 max 120MHz – PLL0-PHI1 max 100MHz – PLL1 max 140MHz – CCCU max 120MHz Changed System clock from “PWM” to “FlexPWM” and “Etimer” to “eTimer” *Table 301: JTAG frequencies*, changed the “e200z0 max. internal JTAG frequency” from 140 MHz to 70 MHz *Section 24.3: System clock frequency limitations*: Changed “PBRIDGE_0 maximum frequency from 40 MHz to 70 MHz in text note. *Section 24.5.1.2.1: PLL1 input clocks*: Added “, PHI1 output clock from PLL0 divided by 2” after PLL0. *Section 24.6.1.1: System clock*: Changed paragraph text “The output clock from PLL0 and external oscillator (XOSC) can be selected for CLOCKOUT.” by “This is a divided version of device's system clock and can be observed outside the device by programming CGM_SC_DC2 register.” *Chapter 25: Dual PLL Digital Interface (PLLDIG)* *Section 25.3: Features*: Removed text in lastes bullet “User-selectable ability to generate a system reset upon loss of lock.” *Figure 210: PLL0 Control Register (PLL0CR)* and *Table 307: PLL0CR field descriptions*: removed field “LOLRE” at bit 29 *Figure 213: PLL1 Control Register (PLL1CR)* and *Table 310: PLL1CR field descriptions*: removed field “LOLRE” at bit 29 *Section 25.6.2: Clock configuration*: Updated the configuration example. *Chapter 26: Clock Monitor Unit (CMU)* *Section 26.5.3: CLKMN1 supervisor*, Updated the NOTE at end of section for clarity. *Section 26.4.1.5: CMU Interrupt Status Register (CMU_ISR)*:Added NOTE to the OLRI field description, "While entering STOP mode, OLRI may be triggered. To avoid this when the system is running on the PLL, disable the XOSC before entering STOP mode.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Chapter 27: Clock Generation Module (MC_CGM)* Added CGM_SC_DIV_RC; CGM_DIV_UPD_TYPE; CGM_DIV_UPD_TRIG; CGM_DIV_UPD_STAT registers *Table 323: MC_CGM register description*: Changed all offset addresses from 0x07xx to 0x00xx and from 0x08xx to 0x01xx *Section 27.3.1.16: System Clock Divider 0 Configuration Register (CGM_SC_DC0)*: Changed "...Fast XBAR" by "Core and XBAR." *Figure 241: System Clock Divider 0 Configuration Register (CGM_SC_DC0)* and *Table 339: CGM_SC_DC0 field descriptions*: Changed DIV field dimension to 13:15 (was 10:15), Divider 0 Enable (DE) and Divider 0 Division Value. *Section 27.3.1.17: System Clock Divider 1 Configuration Register (CGM_SC_DC1)*: Changed "...Slow XBAR" by "PBRIDGE." *Figure 242: System Clock Divider 1 Configuration Register (CGM_SC_DC1)* and *Table 340: CGM_SC_DC1 field descriptions*: Changed DIV field dimension to 12:15 (was 10:15). *Section 27.3.1.18: System Clock Divider 2 Configuration Register (CGM_SC_DC2)*: Changed "...PBRIDGE clock" by "...CLKOUT clock.". *Figure 243: System Clock Divider 2 Configuration Register (CGM_SC_DC2)* and *Table 341: CGM_SC_DC2 field descriptions*: Changed DIV field dimension to 7:15 (was 10:15), Divider 2 Enable (DE) field is writable (was read-only). *Section 27.3.1.19: System Clock Divider 3 Configuration Register (CGM_SC_DC3)*: Changed "...PBRIDGE clock" by "...DMA/INTC clock.". *Figure 244: System Clock Divider 3 Configuration Register (CGM_SC_DC3)* and *Table 342: CGM_SC_DC3 field descriptions*: Changed DIV field dimension to 12:15 (was 10:15), Divider 3 Enable (DE) and Divider 3 Division Value (DIV). *Figure 247: Auxiliary Clock 0 Divider 0 Configuration Register (CGM_AC0_DC0)* and *Table 345: CGM_AC0_DC0 field descriptions*: Changed DIV field dimension to 12:15 (was 9:15). *Figure 248: Auxiliary Clock 0 Divider 1 Configuration Register (CGM_AC0_DC1)* and *Table 346: CGM_AC0_DC1 field descriptions*: Changed DIV field dimension to 12:15 (was 9:15). *Figure 252: Auxiliary Clock 1 Divider 0 Configuration Register (CGM_AC1_DC0)* and *Table 350: CGM_AC1_DC0 field descriptions*: Changed DIV field dimension to 10:15 (was 9:15). *Figure 257: Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)* and *Table 355: CGM_AC4_SC field descriptions*: Changed SELCTL field value 0000 COSC to RCOSC. *Figure 259: Auxiliary Clock 4 Divider 0 Configuration Register (CGM_AC4_DC0)* and *Table 357: CGM_AC4_DC0 field descriptions*: Changed DIV field dimension to 12:15 (was 9:15). *Figure 265: Auxiliary Clock 5 Select Control Register (CGM_AC5_SC)* and *Table 363: CGM_AC5_SC field descriptions*: Changed first sentence to "This register is used to select the current clock source for the PLL1 reference clock.". *Figure 267: Auxiliary Clock 5 Divider 0 Configuration Register (CGM_AC5_DC0)* and *Table 365: CGM_AC5_DC0 field descriptions*: Changed DIV field dimension to 14:15 (was 9:15). *Section 27.4.1.2: Progressive System Clock Switching*: Added note. *Figure 275: MC_CGM Auxiliary Clock 4 Generation Overview*: Updated figure with input PLLPHI (was PLLPHI1). Deleted the whole sections: Divider Jitter Injection and Fractional Divider Details.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	Corrected some register accesses from “User read/write/write” to “User read/write” (such as *Figure 226* and *Figure 230*. *Chapter 29: IRCOSC digital interface* Added IRCOSC_NT and IRCOSC_TT register. *Section 29.1: Introduction*: added “, as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage” *Section 29.3.1.1: IRCOSC control register (IRCOSC_CTL)*: – Added note to register access. – Added bit10 to USER_TRIM bit field and set new description *Chapter 30: Platform RAM controller (PRAM)* *Figure 282: Platform RAM configuration register 1 (PRCR1)*: Changed reset bit 26 and 27 values to undefined (was 0) and add a figure footnote to them *Table 378: PRCR1 field descriptions*: Added note to field FT_DIS. *Table 377: PRAM controller memory map*: changed reset value to 0x000002X0 (was 0x0) with a table footnote to register section. Removed “Read-modify-write datapath” figure. – *Section 30.5.1.1: E2EECC considerations on less-than-64-bit write transactions*: Added “on a 32-bit write” to the first bullet. – Changed text “64-bit read from RAM array” in figure of second bullet (was “16 bit write request”) – Added “The PRAM controller” to the third bullet. *Section 30.5.2: Transaction monitor*, removed “RAM safety feature outputs” table *Chapter 31: Flash memory controller (PFLASH Controller)* Updated *Figure 288: Platform-centric block diagram with flash memory controller* *Chapter 32: Embedded Flash Memory* For registers SEL0, SEL1, and SEL2, updated all field descriptions to read “The select field must not be written when UT0[AIE] is high.“ (was “The select field is not writable...“). *Chapter 33: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface* *Table 437: CTR0–CTRL3 field descriptions*: Removed text “for most of the SARADC it is greater than 2” in PRECHG field description. *Chapter 34: Enhanced Cross Trigger Unit (ECTU)* *Figure 387: Commands list register n (CLRn)*: changed n values from 0 to 63 (was 1 to 64). *Table 472: CTU interrupt flags*: Added sub-row named “FIFO interrupt flags (i = 1 to 8)” and reworked FIFO_FULL[i], FIFO_EMPTY[i], FIFO_OVERFLOW[i] and FIFO_OVERRUN[i].

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	Added*Chapter 33: Decorated Storage Memory Controller (DSMC)* *Chapter 39: Software Watchdog Timer (SWT)* Updated reset value in *Figure 551: SWT Counter Output Register (SWT_CO)* *Chapter 40: Periodic Interrupt Timer (PIT)* Modified n value from 1 to 0 into *Table 623: PIT memory map* *Chapter 41: CAN Subsystem* *Section 41.1: Introduction*: added details of implemented CAN subsystems. *Section 41.7: External signal description*: Added 2 bullets - M_CAN_x_RXFD: M_CAN_x Receive Fast Data control signal - M_CAN_x_TXFD: M_CAN_x Transmit Fast Data control signal *Chapter 42: Deserial Serial Peripheral Interface (DSPI)* *Table 698: DSPI memory map*: Added “Reserved space for 0x4C - 0x78” *Figure 965: MC_RGM block diagram* changed ‘FCCU failure to react reset ‘ into ‘FCCU failure detected by FOSU’ *Table 937: Functional Event Status Register (RGM_FES) field descriptions* modified the description of F_SOFT_FUNC bit field *Table 938: RGM_FERD register field descriptions* modified the description of D_SOFT_FUNC bit field *Table 940: Functional Event Status Register (RGM_FBRE) field descriptions* modified the description of BE_SOFT_FUNC bit field *Table 941: RGM_FESS register field descriptions* modified the description of SS_SOFT_FUNC bit field *Chapter 43: LINFlexD* Updated baud rate calculation formula under conditional tag ‘Baud_rate_25=yes’ in *Section 43.2.1: LIN mode features* and *Section 43.2.2: UART mode features* Corrected the naming of LINIER register in the whole chapter Updated register offset of *Section 43.3.2.1: Operating modes* Updated bit field of *Section 43.4.2.25: DMA Tx Enable Register (DMATXE)* and *Section 43.4.2.26: DMA Rx Enable Register (DMARXE)* Removed” Register map” section *Table 738: LINFlexD memory map* : Note “In Master mode, ...would result in ips_xfer_err being flagged” updatd to read “In master mode, ...would result in bus transfer error” *Chapter 46: Reset Generation Module (MC_RGM)* *Table 932: MC_RGM memory map*: updated with new registers RGM_DBRE and RGM_FBRE. *Figure 966: Destructive Event Status Register (RGM_DES)*: moved F_SSCM from position 14 to 17. *Figure 967: Destructive Event Reset Disable Register (RGM_DERD)*: moved D_SSCM from position 14 to 17. *Table 937: Functional Event Status Register (RGM_FES) field descriptions*: updated description for F_SOFT_FUNC (bit 28) *Table 938: RGM_FERD register field descriptions*: updated description for D_SOFT_FUNC (bit 28)

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Table 941: RGM_FESS register field descriptions*: updated description for SS_SOFT_FUNC (bit 28) *Figure 972: Functional Event Alternate Request Register (RGM_FEAR)*: updated AR_FCCU_SOFT(bit 25) to RO and added '1' in AR_VOR_FUNC (bit 7) description. *Figure 979: Peripheral Reset Register 2 (RGM_PRST2)* and *Table 946: RGM_PRST2 register field descriptions*: added MCAN_0_2_RAM_RST (bit 21). *Figure 987: Peripheral Reset Status Register 2 (RGM_PSTAT2)* and *Table 954: RGM_PSTAT2 register field descriptions*: added MCAN_0_2_RAM_STAT (bit 21). *Chapter 47: Boot Assist Flash (BAF)* Removed CAN information *Table 964: BAF image version*: updated field "16:23" with Reserved. *Section 47.4: Resources accessed by BAF code execution*: – updated title (was "Resources") – added "The BAF code execution uses ...the main functions." – PFLASH: added "The two PFLASH are used".- *Table 963: BAF image header*: updated "Field Description" values for "Address offset" "0000h, 0004h, 0008h" *Chapter 48: System Status and Configuration Module (SSCM)* *Table 983: Resulting Life Cycle*: Removed the 3 latest rows including table footnote (1) and (3). Modified RAE bit field definition in *Table 977: ERROR field descriptions* Updated *Section 48.3.2: Boot mode functionality* and *Section 48.3.4.2: Reset Configuration Half-Word* *Chapter 49: Power management controller digital interface (PMC_Dig)* Extensive updates throughout chapter *Chapter 51: Mode Entry Module (MC_ME)* *Table 1031: MC_ME register description* and *Section 51.3.2.25: Peripheral Control Register n (ME_PCTLn)* added ME_PCTL15 register *Chapter 53: Debug and Calibration Interface (DCI)* *Section 53.1.3.1: Software enabled debug and calibration mode*, removed second paragraph in the note: "If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session." *Chapter 55: JTAG Controller (JTAGC)* *Table 1106: 6-bit JTAG instructions*: Added row "Reserved"

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Chapter 60: e200z420n3 Nexus 3 Module* *Section 60.4.2: Port Configuration Register - reference only (PCR)*: Added note after first paragraph. *Section 60.4.3: Nexus Development Control Register 1 (DC1)*: Added note after first paragraph. *Figure 1216: Development Status Register (DS)*: Changed register access to Read-only (was Read-write). *Figure 1228: Read/Write Access Control/Status register (RWCS)*: Changed bit field MAP access to Read-only (was Read-write). *Chapter 61: Nexus Crossbar Multi-Master Client (NXMC)* *Section 61.5: Programming considerations (RESET)*: Added text “after negation of TRST and should be programmed before deassertion of system reset” at the end. *Chapter 62: Cyclic Redundancy Check (CRC) Unit* Removed notes like "Refer to the chip configuration chapter for number of contexts used in this application." since the values are specified through the Chapter Specified the index “n” in all register definition section. *Chapter 64: Fault Collection and Control Unit (FCCU)* *Section 64.5.2: FSM description*, The key to lock the FCCU is written to FCCU_PERMNT_LOCK and not FCCU_TRANS_LOCK. Added footnote to “same as NORMAL” entries in *Table 1262: Dual rail encoding*, *Table 1263: Time switching encoding* and *Table 1264: Bi-stable encoding*. Replaced all occurrences of NCF with RF. Added missing bit numbers from field description tables. Added a footnote to the reset value of bit 28 in *Section 64.6.3: FCCU Configuration Register (FCCU_CFG)* *Table 1265: FCCU memory map*: Renamed table title (was “FCCU register set”). Removed Section “FCCU register map” Removed glitch filter related text of *Section 64.6.1: FCCU Control Register (FCCU_CTRL)* *Section 64.6.14: FCCU NA Freeze Status Register (N2AF_STATUS)* : – Footnote updated from “You can read the bits in this field”,.....Writing “1” has no effect” to “These are reserved bits. These bits are always read as ‘0’ and muist always be written with ‘0’. – The reset value of field NAFS[24:31] changed from “0” to “w1c”. *Section 64.6.16: FCCU NF Freeze Status Register (N2FF_STATUS)* : Footnote updated from “You can read the bits in this field”,.....Writing “1” has no effect” to “These are reserved bits. These bits are always read as ‘0’ and muist always be written with ‘0’. *Section 64.6.17: FCCU FA Freeze Status Register (F2A_STATUS)*: – Footnote updated from “You can read the bits in this field”,.....Writing “1” has no effect” to “These are reserved bits. These bits are always read as ‘0’ and muist always be written with ‘0’. – The reset value of field FAFS[24:31] changed from “0” to “w1c”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Chapter 65: Self-Test Control Unit (STCU2)* *Table 1304: STCU2 register set*, *Section 65.5.31: STCU2 LBIST Control n Register (STCU_LB_CTRLn)* to *Section 65.5.43: STCU2 MBIST Control k Register (STCU_MB_CTRLk)* and *Table 1348: STCU2 register map*: Updated Addresses and Register names for register STCU_LB_CTRL to STCU_MB_CTRL. Address was “0x0100+(NLBIST-1)*0x40h”, is now “0x0100+n*0x40 with n=0 to (NLBIST-1)”, same modification with NMCUT. Added ‘*n*’ to Register names. Updated FIELD*x* with FIELD[high_value:low_value]. *Table 1304: STCU2 register set*: Added table footnote and Reserved spaces at the following addresses: 0x0004-0x0007 0x0034-0x003B 0x005C-0x0073 0x0120-0x05FF *Table 1315: STCU_LBS field descriptions* to *Table 1319: STCU_LBUFM field descriptions*: Updated LBS*x*, LBE*x*, ... LBUFM*x* with LBS[(NLBIST-1):0], LBE[(NLBIST-1):0]... LBUFM[(NLBIST-1):0] *Table 1320: STCU_MBSL field descriptions* to *Table 1320: STCU_MBSL field descriptions*: Updated MBS*x*,... MBUFM*x with* MBS[(NMCUT-1):0]... MBUFM[(NMCUT-1):0] *Table 1321: STCU_MBSM field descriptions* to *Table 1333: STCU_MBUFMM field descriptions*: Updated MBS*x*,... MBUFM*x with* MBS[(NMCUT-1):32]... MBUFM[(NMCUT-1):32] *Table 1322: STCU_MBSH field descriptions* to *Table 1334: STCU_MBUFMH field descriptions*: Updated MBS*x*,... MBUFM*x with* MBS[(NMCUT-1):64]... MBUFM[(NMCUT-1):64] Fixed typos with Off:line and On:line. *Chapter 67: Password and Device Security Module (PASS)* *Table 1353: PASS memory map*: added some reserved spaces and added table footnotes to “DCF Client Address” column. *Figure 1415: Password Group n - Lock 3 status register (LOCK3_PGn)* and *Table 1361: LOCK3_PGn register field descriptions*: – Added RL4 and RL3 with same description as other RLn. – Deleted note in all RLn. – Changed footnote to (1) in reset value bits16:30 of field U_256CLK. *Section 67.2.1.5: Password Group n - Lock 0 Status register (LOCK0_PGn)* to *Section 67.2.1.8: Password Group n - Lock 3 status register (LOCK3_PGn)*: – Removed the sentence “The LOCK bits do not come into effect before the lifecycle matures to OEM Production or older.” – Removed the sentence “Each Password Group has one Lock 2 Status Register. This register ... refer to the Flash description.” and set this paragraph in a new section. Removed “Modifying Lifecycle (maturing the device)” section. Updated *Table 1363: Debug Interface Enable Truth Table*. Updated *Table 1364: Flash Memory Read Protection Truth Table*.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
13-Apr-2015	2	*Figure 1414: Password Group n - Lock 2 status register (LOCK2_PGn)* and *Figure 1415: Password Group n - Lock 3 status register (LOCK3_PGn)*: Replaced field L_256LCK by L_128LCK - Lower 128KByte Block Lock". *Figure 1415: Password Group n - Lock 3 status register (LOCK3_PGn)*: Added figure footnote to RL1-RL4 and U_256LCK. *Chapter 22: Wakeup unit (WKPU)* Renamed *NMI Configuration Register (NCR)* fields: NDSS3 → RDSS3 NWRE3 → RWRE3 NREE3 → RREE3 NFEE3 → RFEE3 NFE3 → RFE3 Updated *Figure 199: Wakeup unit Block Diagram*. *Section 22.1.1: Overview*: Added text "This NMI external source can also generate a functional reset event to the MC_RGM". Renamed *NMI Status Flag Register (NSR)* fields and updated their descriptions: NIF3 → RIF NOVF3 → ROVF Updated the reset conditions of *NMI Configuration Register (NCR)* fields and renamed fields and updated their descriptions as per: NLOCK3 → RLOCK RDSS3 → RDSS RWRE3 → RWRE RREE3 → RREE RFEE3 → RFEE RFE3 → RFE Removed the NMI pad diagram. *Chapter 44: SENT Receiver (SRX)* Extensive updates throughout chapter *Chapter 45: FlexRay Communication Controller (FlexRay)* *Section 45.5.2.66.23: Protocol Configuration Register 22 (FR_PCR22)*: Added footnote for bit 15 "Reserved bit or field. Application must not write any value different from the reset value." *Chapter 35: Motor Control Pulse Width Modulator Module (FlexPWM)* *Table 520: FlexPWM memory map*: – "CAPTCOMPAn" updated to "CAPTCMPAn" – "CAPTCOMPBn" updated to "CAPTCMPBn" – "CAPTCOMPXn" updated to "CAPTCMPXn" – "CVALxCn" updated to "CVALxCYCn", where x = 0 to 5. *Figure 462: Double Switching Output Example*: – "PWMA" updated to "Internal PWMA" – "PWMB" updated to "Internal PWMB" – "DBLPWM" updated to "PWMA & PWMB output"

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 2: Introduction* *Section 2.2: Features*: – Modified MPU into SMPU and replaced QFN package data by LFBGA ones – Increased ECC Flash memory size from 1.0 MB to 1.5 MB Code Flash *Table 2: SPC574Sx device feature summary (superset configuration)*: – Increased SRAM size from 64 KB to 96 KB – Increased ECC Flash memory size from 1.0 MB to 1.5 MB Code Flash – Changed the number of LinFlexD from 2 to 4 – Updated the table footnote for the number of MDO pins *Figure 2: Block Diagram*: – Replaced LINFlex by LINFlexD – added missing CMU4 – Added missing modules to block PBRIDGE_0: PASS, JDC, MC_PCU – Added LinFlexD_2 to block PBRIDGE_0, LinFlexD_3 to PBRIDGE_1 – Added a 2nd arrow between e200z420 and top side of XBAR, moved the arrow common to e200z420 & e200z419 to the bottom side of the XBAR. – Renamed AIPS instances by PBRIDGE, Wakeup by WKPU – Added missing modules to block PBRIDGE_0: PWMSync, CCCU_0 – Added missing modules to block PBRIDGE_1: PWMSync, CCCU_1 – Added block NPC next to SPU *Chapter 3: System architecture* *Section 3.1: Platform Architecture*: removed sentence “The blue blocks refer to ...”. *Figure 3: Platform block diagram*: – updated SRAM size by 96KB (was 64). Colored safety related blocks in brown, removed other colors. – updated FLASH size to 1,5MB (was 1MB) *Section 3.1.2.1: CPU exception system*: removed the last paragraph sentence “The figure also shows the HW vector mode...”. *Figure 4: CPU Exceptions vs. Interrupt Controller*: removed Note “Read only: Default to SW Mode” and updated reference to “z0h manual” by ““core manual”. *Section 3.2.1.1: System memory*: updated size by 96KB (was 64). *Figure 5: SPC574Sx flash memory block diagram*: updated Flash Memory Array size by 1632KB (was 1120). *Section 3.2.2.2: Flash memory array*: updated size by 1536KB (was 1024). *Section 3.2.2.2.1: Features*: updated 256KB blocks number by 5 (was 3). *Figure 6: Flash memory segmentation and read-while-write partitioning*: added 2 more blocks of 256KB (blocks 3 and 4). Replaced “AIPS” instances by “PBRIDGE”, “AIC” by “PBRIDGE Checker” through the chapter. *Figure 7: Motor control architecture*: updated figure title from “USE CASE for a two 3-phases motor” to “USE CASE for two 3-phase motors” *Table 7: ADC channels mapping description*, PAD[25], PAD[105] are no longer bonded in any package.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 4: Signal description* Updated *Table 8: Pin startup and reset states* Updated *Table 9: Power supply and reference pins* Updated *Table 12: Pin multiplexing description*: *Table 13: Peripheral multiplexing description*: Renamed MCAN_0 to MCAN_1 Updated *Table 14: Cross-mapping between pads and package pins* *Chapter 5: Memory map* *Table 17: Peripheral bridge 1 memory map*: – in the OPACR19 and OPACR112 entries, replaced AIPS by PBRIDGE – Added LinFlex_3 at start address 0xFBE9_0000 – Changed description “PRAM_1 (MCAN 1 Sub-system)” to “CAN_SUB_1 Message RAM” at start address 0xFBED_4000 *Table 18: Peripheral bridge 0 memory map*: – Added LinFlex_2 at start address 0xFFE9_0000 – Changed description “RAM controller for MCAN 0 and MCAN 2 subsystem” to “CAN_SUB_0 Message RAM” at start address 0xFFED_4000 – Changed description “RCOSC dig” to “RC16M_DIG (IRCOSC)” at start address 0xFFFE_0000 – Changed description “XOSC dig” to “OSC40M_DIG (XOSC)” at start address 0xFFFE_0000 – Changed description “Flash memory (registers) ” to “FLASH_0 (Flash memory registers)” at start address 0xFFFE_0000 *Table 16: Flash memory map*: added Flash 256 KB Code Blocks 3 and 4 *Table 15: Memory map (XBAR slave ports)*: – Changed End address of Flash memory to 0x0113_FFFF (was 0x3FFF_FFFF) – Added Reserved space at address 0x0114_0000-0x3FFF_FFFF – Changed System RAM (64KB) to (96KB) and its Start address to 0x4001_0000 and its End address to 0x4001_7FFF (was 0x4000_0000 / 0x4000_FFFF) *Chapter 6: Functional safety* *Table 24: FCCU failure inputs*: – Added columns “HW fault behaviour” and “Error reaction path check”. – Added footnote to FCCU input #51 (Lockstep Mode) – Added FCCU inputs #62 to #75 *Table 25: MBIST partitioning*: hanged sram end address from 0x4000_FFFF to 0x4001_7FFF *Section 6.4.7: Failure handling*: Updated failure sources – Added *Section 6.5: Register classifications* *Figure 22: ECC protection scheme for CAN subsystems*, exchanged MCAN 1 with MCAN 2

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 7: Device configuration*: Extensive updates throughout the chapter *Chapter 8: Reset and boot* *Table 125: Functional reset events*: – Modified signal description of F_SOFT_FUNC module – Modified footnote 5. *Table 127: Module status during the reset phase*: Updated P1, P2 an P3 for FCCU module *Table 134: BAF boot record search locations*: Updated line ‘Search order #6’ from 128KB to 256KB *Section 8.7: System boot*: Updated both text and *Figure 46: System boot sequence* *Section 8.8: HW boot record search (SSCM search)*: Updated both text and *Figure 47: Valid boot header search* Updated *Section 8.9: SW boot record search (BAF search)* *Chapter 9: Device Configuration Format (DCF) Records* *Figure 51: UTEST Miscellaneous DCF Client*: Renamed field “OSC_EN_40MHZ” to “XOSC_EN_40MHZ” *Table 140: UTEST Miscellaneous DCF Client field descriptions*: – In field description “XOSC LOAD CAP SEL”, note “Please refer to....Device Datasheet” added – Renamed field “OSC_EN_40MHZ” to “XOSC_EN_40MHZ” *Table 139: DCF client list*: – REE_BUS_UTEST: added a cross reference to the appropriate register – PNREG_ENB: added a cross reference to the appropriate register in PMC Digital chapter – ESR0_CFG: added a cross reference to the appropriate register PMC Digital chapter – Removed BBCTL – Removed CTL UPDATE – Added (NLBIST) and (NMCUT) to STCU subsection. – Renamed DCF client description “REE_BUS_UTEST” to “REE_BUS”. – Added cross-reference to PMC_DIG chapter to PMC_DIGITAL subsection – PNREG_ENB of DCF client description: added crossreference to Section IPS Regulator Monitor Register (IREGU_MON) – ESR0_CFG of DCF client description: added crossreference to Section ESR0 ConFiGuration Register (ESR0_CFG) *Figure 52: REE_BUS bits DCF Client* and *Table 141: REE_BUS bits DCF client field descriptions*: Renamed “REE_BUS bits DCF client” (was PMC_REE bits DCF client”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 10: Power management* *Section 10.2: Architecture*: Replaced QFN152 by BGA244 in introduction sentence *Figure 54: Power supply scheme BGA244 and QFP144(1)*: – Updated picture – Replaced QFN152 by BGA244 in the figure title – Replaced all EXP by GND – added a footnote to specify that only BGA244 is connected to ground balls (GND) *Figure 55: Power supply scheme QFP100*: Updated picture *Figure 58: Voltage monitor coverage*: Replaced LVD290_IOL0 by LVD290_XOSC *Figure 59: Monitor trigger and system reaction architecture*: Replaced FCCU_NCFS_CFGx by FCCU_RF_CFGx Added *Section 10.2.7: BIST details* *Table 148: Calculating the BIST_TIME values*: Added PBRIDGE clock frequency 70 MHz and BIST_TIME values *Section 10.2.3: Ballast*, replaced 250mA.with 325mA. *Section 10.2.7: BIST details*, replaced 25 MHz with 70 MHz *Figure 62: Monitor checking timing diagram* and *Table 147: Timing descriptions*, updated timing values *Table 148: Calculating the BIST_TIME values*, Updated values *Chapter 11: Security* *Section 11.1: Basic security*: Removed bullet “Secure watchdog timer Updated *Section 11.3: Detailed security information* *Chapter 12: Core e200z420n3 Description* Added *Section 12.8.2: Access Protection Operation* *Chapter 13: System Integration Unit Lite2 (SIUL2)* *Section 13.1.1: Overview*: Updated the number of DMA inputs from 16 to 6. *Section 13.1.2: Features*: Added bullet “Control of analog path switches” *Section 13.3.2: Pad control*: Added bullet “Control of analog path switches” *Table 191: SIUL2 memory map*: Changed field name “PARTNUM” by “FAMILYNUM” at bits 16:23 *Table 191: SIUL2 memory map*: Updated reset value to 0x0080_0000 *Figure 99: SIUL2 MCU ID Register #2 (SIUL2_MIDR2)* and *Table 193: SIUL2_MIDR2 field description*: – Replaced field name “PARTNUM” by “FAMILYNUM” – FAMILYNUM field description updated (SPC574Sxx instead of SPC570Sxx) – Updated footnote (1) to all bits 1:31 – Changed reset value of bits 28:31 to 0xF (was 0x0)

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Figure 109: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR0–SIUL2_MSCR511)* and *Table 202: SIUL2_MSCR0–SIUL2_MSCR511 field description*: – Removed APC field – Changed bit dimension of field ODC to bits 6:7 (was 5:7) – Updated OERC field description with “Specifies the output impedance, drive strength, and slew rate of the associated pin.” – Updated reset value to 0x0084_0000 *Table 203: I/O MSCR Reset State Exceptions*: Updated this table. *Chapter 16: Peripheral bridge* Replaced all occurences of AIPS with PBRIDGE *Table 221: Peripheral bridge memory map*: Removed registers PBRIDGE_PACRG and PBRIDGE_PACRH *Table 223: PACR memory map*: – Removed registers PACRG and PACRH – Set register PACRE to Reserved. *Section 16.1.1: Features*: Feature “Supports a pair...memory accesses” updated to “Supports 32 bit transaction”. *Section 16.3.1: Access support*: Removed text “The peripheral bridge performs...single transfer” *Figure 129: Peripheral Access Control Registers (PBRIDGE_PACRx)*: – Removed offset address for registers PACRG and PACRH – Removed PACRE register offset (was 0x100) Corrected offset values from OPACRQ to OPACRAE registers (was 0x140) *Chapter 17: System Memory Protection Unit (SMPU)* *Table 227: SMPU memory map* and *Figure 138: Region Descriptor n, Word 0 (RGDn_WORD0)* to *Figure 141: Region Descriptor n, Word 3 (RGDn_WORD3)*: Corrected all RGD register occurences to n=0 to 11. *Chapter 19: Interrupt Controller (INTC)* Extensive modifications to clarify text and register naming for a single processor device Removed all references to the INTC_MPROT register throughout the chapter *Table 245: INTC_PSRn field descriptions*: Updated bit field description of PRC_SEL0 *Section 19.4: Modes of operation*: removed note about *n* = 0 to avoid confusion. *Section 19.4.1: Software vector mode*: “HVEN_PRCn bit” updated to “HVENn bit”. *Chapter 20: Enhanced Direct Memory Access (eDMA)* *Figure 157: Control Register (DMA_CR)*: – Reset Value of bit “GRP1PRI” (Bit 20-21) changed from “00” to “01”. – For bit “GRP1PRI”, added footnote “Bit 20 is always set to 0 and not writable” – For bit “GRP0PRI”, added footnote “Bit 22 is always set to 0 and not writable” – Bit 31 changed from “Reserved” to “EBW” *Table 250: DMA_CR field descriptions*: Added EBW bit field description

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 21: DMA channel multiplexer (DMACHMUX)* Updated register name to CHCFG (was CHCONFIG) throughout the chapter. *Table 292: DMACHMUX memory map*: Corrected register name to CHCFG (was CHCNFG) Updated *Section 21.1.2: Features* *Chapter 22: Wakeup unit (WKPU)* Updated *Figure 199: Wakeup unit Block Diagram* and “AIPS” renamed to “PBRIDGE” *Section 22.1.1: Overview*: Added text “This NMI external source can also generate a functional reset event to the MC_RGM”. *Section 22.2.2.1: NMI Status Flag Register (NSR)*: Renamed fields and updated their descriptions (NIF3 → RIF and NOVF3 → ROVF) *Section 22.2.2.2: NMI Configuration Register (NCR)*: – Renamed fields and updated their descriptions (NLOCK3 → RLOCK, RDSS3 → RDSS, RWRE3 → RWRE, RREE3 → RREE, RFEE3 → RFEE and RFE3 → RFE) – Removed the NMI pad diagram *Table 295: WKPU Memory Map*: – deleted Size column – renamed Use column to Register – deleted the Abbreviation column and moved the abbreviation into the Register column *Chapter 23: Temperature sensor (TSENS)* *Section 23.4: TSENS outputs*: Replaced P1, P2, C1, and C2 with P2, C2, P1, and C1 respectivety in note below the table and appended for Temperature Sensor 0. Added Flash locations for Temperature Sensor 1. *Chapter 24: Clocking* Updated *Figure 204: SPC574Sx dual PLL digital interface block diagram* *Table 300: Maximum system level clock frequencies*: added 2 rows TCK (JTAGM/PAD) *Table 301: JTAG frequencies*: updated “e200z0” by “e200z420n3” *Section 24.3: System clock frequency limitations*: Reworded the sentence in the Note “In order to... dividers” *Chapter 25: Dual PLL Digital Interface (PLLDIG)* *Section 25.3: Features*: – Added “The frequency range after the prescaler is required to be 8-20Mhz” – Removed the information about inout and output clock frequency range. Added a note to consult the Device data sheet for the same *Table 306: Dual PLL Digital Interface memory map*: – Removed “Access” and “Reset Value (hex)” columns. – Reformated all end address of reserved spaces *Figure 212: PLL0 Divider Register (PLL0DV)* and *Figure 215: PLL1 Divider Register (PLL1DV)*: added “default” to figure footnote. *Figure 211: PLL0 Status Register (PLL0SR)*: Updated reset value

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 27: Clock Generation Module (MC_CGM)* *Section 27.3.1.18: System Clock Divider 2 Configuration Register (CGM_SC_DC2)*: Changed sentence from “This register relates to PBRIDGE clock.” to “This register relates to CLKOUT clock.” *Section 27.3.1.12: Divider Update Type Register (CGM_DIV_UPD_TYPE)*: added bit fields AUX5_UPD_TYPE and AUX4_UPD_TYPE *Section 27.3.1.14: Divider Update Status Register (CGM_DIV_UPD_STAT)*: added AUX5_UPD_STAT and AUX4_UPD_STAT and set description as AUXn_UPD_STAT *Section 27.4.1.4.2: System Clock Divider Update Triggering*: Removed text in bracket: “(This is applicable to auxilliary mux 4 as well)’ *Chapter 29: IRCOSC digital interface* Updated *Section 29.3.1.2: IRCOSC Native Trimming register (IRCOSC_NT)* and *Section 29.3.1.3: IRCOSC Temperature Trimming register (IRCOSC_TT)* *Chapter 30: Platform RAM controller (PRAM)* *Section 30.1: Introduction*: Reworked the sentence “The read data is the result of a RAM access” *Figure 282: Platform RAM configuration register 1 (PRCR1)*: Reset value changed to 0 for bits 26 and 27 *Table 377: PRAM controller memory map*: – Removed “Width” and “Access” columns. – Changed PRCR1 register reset value to 0x0000_0200 (was 0x000002X0). *Section 30.3.1.2: Optional read wait-state*: Removed note. *Section 30.5.2: Transaction monitor*: Removed text from “As a countermeasure against false misses to the late-write buffer on reads,” to “the RAM or from the late-write buffer.” *Chapter 31: Flash memory controller (PFLASH Controller)* *Table 380: Flash memory controller memory map*: – updated table footnotes – removed Access and Reset value columns *Section 31.5.7: Censorship*: Replaced “TEST flash” by “UTEST flash” *Section 31.5.13.1.1: e2eEDC and flash accesses*: Updated fl_data value *Section 31.5.13.1.2: ECC and data flash accesses*: Replaced “illegal code value” by the value itself, “FFFF” *Section 31.5.13.2: Flash address generation check*: Replaced “fl_enc_addr [23:2]” by “encoded address as received by flash memory” and “fl_enc_error” by “address encoding error provided by flash memory” *Section 31.5.14: Array integrity considerations*: Removed internal naming “fl_aid” *Chapter 32: Embedded Flash Memory* *Section 32.3.2.9: Address register (ADR)*: Added Flash format addresses mapping with Absolute addresses *Table 413: UM9 field descriptions*: Reformated MISR[288] to MISR288 and corrected its bit-field value to 31 (was 0:31)

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 34: Enhanced Cross Trigger Unit (ECTU)* *Section 34.2: Main features*: Number of triggers updated to 8 *Table 477: TGS registers*: Removed TCR8–15 registers *Table 478: SU registers* : Commands List Register updated from “CLR1-CLR128” to “CLR0-CLR63” *Table 481: TGSISR field descriptions*: Added note “See figure: Module to module connections in Device Configuration chapter. *Table 510: CTUCR field descriptions*: Added sentence “It is set by the user and automatically reset when it is reloaded in MT_clk domain. The reloaded bit in MT_clk domain gets reset by MRS.“ to FILTER_enable bit field. *Section 34.10.26: Status register 1 (ST1)*: Name updated from “SR1” to “ST1” *Section 34.10.27: Status register 2 (ST2)*: Name updated from “SR2” to “ST2” Added *Section 34.10.40: CTU expected CRC register (CTU_EXP_CRC_VAL)* and *Section 34.10.41: CTU computed CRC register (CTU_COMP_CRC_VAL)* *Section 34.10.42: CTU Mask CRC computation register (CTU_MASK_CRC_VAL)*: added additional bits *Figure 406: CTU_CFGSR2 register* : Footnote added “The reset value is device dependent. Please see the Chapter: Device configuration for details.” *Chapter 35: Motor Control Pulse Width Modulator Module (FlexPWM)* *Section 35.3.31: Capture Value 2 Cycle register n (CVAL2CYCn)*: Updated the width of field “CVAL2CYC” from “3:0” to “2:0” *Section 35.3.33: Capture Value 3 Cycle register n (CVAL3CYCn)*: Updated the width of field “CVAL3CYC” from “3:0” to “2:0” *Section 35.3.38.1: Output Enable register (OUTEN)*: removed index n in the title and in the offset address, now it is 0x0140 instead of BASE + 0x50*n+0x0140(n=0 to 3) *Section 35.3.38.5: Master Control register (MCTRL)*: Added note “The relationship between the fields of MCTRL and the submodules is as follows:...” *Section 35.4.2.6: Enhanced Capture Capabilities (E-Capture)*: Added note “CVAL0-CVAL1 are used for PWMx, CVAL2 and CVAL3 are used for PWMA and finally, VAL4 and CVAL5 are used for PWMB.” *Chapter 36: PWM Synchronizer* *Section 36.5: Functional description*: Added cross-references to *Figure 505: PWM synchronizer (full sync mode)* and *Figure 506: PWM synchronizer (half sync mode)* *Section 36.3.1: Memory map*: Added *Table 571: PWM synchronizer memory map* *Chapter 37: Enhanced Motor Control Timer (eTimer)* *Section 37.2: External signal descriptions*: Removed fault inputs references *Section 37.4.1: Overview*: Added note “The actual availability...” *Section 37.7: Interrupts*: Removed fault inputs references Removed Section 1.2.3: FAULT[n:0] - Fault Inputs *Figure 527: Control Register 1n (CTRL1n)*: Change offset formula to 0x000E + n*0x20 (n=0 to 5) (was n=0 tn 5) *Chapter 38: System Timer Module (STM)* Replaced "system clock" instances by "PBRIDGE clock" throughout the chapter

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 39: Software Watchdog Timer (SWT)* *Section 39.1: Introduction*: Added Note “For chip-specific implementation...” *Table 616: SWT_CR field descriptions*: updated description of bit fields MAP[0:7]. *Chapter 40: Periodic Interrupt Timer (PIT)* *Section 40.4: Initialization and application information*: Updated example with device specific values *Chapter 41: CAN Subsystem* *Section 41.3.12: Debug on CAN Support*: Removed Note “To use full ‘Debug on CAN Support’ feature on a M_(TT)CAN instance a DMA channel is required. Please refer to device DMA map to see which M_(TT)CAN instances has got an assigned DMA channel.” *Section 41.3.15: Clock Calibration on M_CAN*: Removed Caution note Removed Section 1.8.1: Shared memory *Figure 566: Data Bit Timing and Prescaler Register (DBTP)* and *Table 633: DBTP Register field descriptions*: Renamed (was FBTP), Moved TCDO bit field to *Section 41.3.5.2.14: Transmitter Delay compensation Register (TDCR)* *Figure 567: Test Register (TEST)* and *Table 634: TEST register field descriptions*: Moved TDCV bit field to *Section 41.3.5.2.13: Protocol Status Register (PSR)*. *Figure 569: CC Control register (CCCR)* and *Table 636: CCCR Register field descriptions*: Added 1 bit field NISO, Removed fields FDBS and FDO, Replaced field FBDS by EFBI, Replaced field FDO by PXHD, Removed CMR, Replaced CME by FDOE and BRSE. *Figure 570: Nominal Bit Timing and Prescaler Register (NBTP)* and *Table 637: NBTP field descriptions*: Renamed (was BTP), renamed field BRP to NBRP, TGSEG1/2 to NTSEG1/2 and SJW to NSJW. *Figure 576: Protocol Status Register (PSR)* and *Table 643: PSR field descriptions*: Moved TDCV bit field to *Section 41.3.5.2.4: Test Register (TEST)* with range increased, added status flag PXE, and renamed field FLEC to DLEC Added *Section 41.3.5.2.14: Transmitter Delay compensation Register (TDCR)* *Figure 578: Interrupt Register (IR)* and *Table 645: IR field descriptions*: Replaced fields STE, FOE, ACKE, BE, CRCE by ARA, PED, PEA *Figure 579: Interrupt Enable Register (IE)* and *Table 646: IE Register field descriptions*: Replaced fields STEE, FOEE, ACKEE, BEE, CRCEE by ARAE, PEDE, PEAE *Figure 580: Interrupt Line Select Register (ILS)* and *Table 647: ILS field descriptions*: Replaced STEL, FOEL, ACKEL, BEL, CRCEL by ARAL, PEDL, PEAL *Figure 611: Rx FIFO Element* and *Table 677: Rx FIFO Element descriptions*: Renamed bit ELD to FDF *Figure 612: Tx Buffer Element* and *Table 678: Tx Buffer Element descriptions*: Added bit ESI (Error State Indicator), bit FDF (FD format) and bit BRS (Bit Rate Switching) Updated text in *Section 41.3.7.3: CAN FD Operation* and in *Section 41.3.7.4: Transceiver Delay Compensation*

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Figure 631: Calibration Configuration Register (CCFG)* and *Table 690: CCFG Register field descriptions*: Changed SWR field access to RW (was R only). Added values 0x00–0xFF to OPCM field description. Added values 0x04–0x19 to TQBT field description *Section 41.3: Modular CAN (M_CAN) cores*: Added year 2015 to ISO11898-1 *Section 41.8.1: Shared memory map*: Removed note “triggers” in the third sentence *Table 629: IP user manual versions* : Renamed (was “References”) *Figure 572: Timestamp Counter Value Register (TSCV)*, *Figure 574: Timeout Counter Value Register (TOCV)*, *Figure 578: Interrupt Register (IR)*, *Figure 572: Timestamp Counter Value Register (TSCV)* and *Figure 574: Timeout Counter Value Register (TOCV)*: Changed register access to R/W (was w1c) *Figure 578: Interrupt Register (IR)*: Applied w1c to all register fields *Section 41.3.6: Message RAM*: Added note after the first sentence *Table 643: PSR field descriptions*: Updated RFDF field description *Chapter 42: Deserial Serial Peripheral Interface (DSPI)* *Figure 638: DSPI block diagram (1)*: – removed ‘Slave Bus Interface’ and ‘Clock/Reset’ – added footnote “CSI and DSI features are not supported”. *Table 698: DSPI memory map* : – Added Reserved space for ‘0x0004-0x0007’ – Added “Reserved space for 0x4C - 0x7B” *Section 42.3: Register classification for safety*: bullet ‘Safety Latent’ removed footnote “LBIST **not** supported on this device”. *Section 42.4: Functional description*: Added the sentence “SPI — DSPI operates as a basic SPI or a queued SPI.” *Chapter 43: LINFlexD* Updated *Section 43.1: Introduction* with “2.2” version at the end of sentence starting with: “The LINFlexD supports LIN protocol version...”. Updated *Section 43.3.3: Timer* *Table 738: LINFlexD memory map*: removed table footnote (3). *Figure 732: Global Control Register (GCR)*, *Figure 733: UART Preset Timeout Register (UARTPTO)*, *Figure 734: UART Current Timeout Register (UARTCTO)*, *Figure 735: DMA Tx Enable Register (DMATXE)*: Change main address to 0x8C (was 0x4C). *Table 764: DMARXE field descriptions*: Changed TX_CH_NUM to RX_CH_NUM in field column.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 44: SENT Receiver (SRX)* *Section 44.4.2.1: DMA request for Fast Message reading*: Added Note “The data buffer related to the SENT data transferred...” *Table 789: CHn_FMSG_TS field descriptions*: Changed register name to CHn_FMSG_TS (was DMA_FMSG_TS). *Figure 794: Enhanced Serial Message with 8-bit ID field*, *Figure 795: Enhanced Serial Message with 4-bit ID field* and *Figure 796: Short serial message*: Reordered bit numbering from 0 to 31 (was 31 to 0) *Section 44.3.2.20: Channel n Configuration Register (CHn_CONFIG)*: the description for FIL_CNT field has been changed from "This indicates the number" to "This indicates twice the number" *Section 44.4.8: Time stamp logic*: Changed the sentence “For example, if the high frequency receiver clock is 60 MHz, the required prescaler value [...] is 60.” to “For example, if the high frequency receiver clock is 60 MHz, the required prescaler value [...] is 59...” *Section 44.3.2.1: Global Control Register (GBL_CTRL)*: – updated description of Time Stamp Prescaler Value (GBL_CTRL[TSPRSC]). – updated TSPRSC field from value from [1 to 255] to [0 to 255] Added note to *Section 44.3.2.6: Data Control Register 1 (DATA_CTRL1)* and *Section 44.3.2.7: Data Control Register 2 (DATA_CTRL2)* Added two notes in *Section 44.1.2.2: Low power modes* *Section 44.3.2.4: Fast Message Ready Status Register (FMSG_RDY)*: updated note “Reads of bits beyond those for the supported number of channels should be ignored...” *Section 44.4.7.6: Pause pulse diagnostic*: added details as a workaround for unexpected behavior of SENT Calibration equal to pause pulse. Added new paragraphs and tables. *Figure 795: Enhanced Serial Message with 4-bit ID field*: Data [15:12] changed to Data Field [15:12]. *Section 44.1.1: Features*: – changed sentence from "Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift and jitter in the Transmr clocks per channel" to "Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel". – changed the maximum supported bit rate from 36µs to 90µs *Section 44.3.2.5: Slow Serial Message Ready Status Register (SMSG_RDY)*: Note changed to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver". *Table 784: CHn_CLK_CTRL field descriptions*: added a note to the field CM_PRSC. *Section 44.4.6: Input programmable filter*: added value of FIL_CNT in sentence "A timing diagram of the input filter when FIL_CNT is 4 …" *Section 44.3.2.1: Global Control Register (GBL_CTRL)*: NIB_LEN_VAR_LIMIT field is added. *Table 766: SENT memory map*: – updated appearance of register names, and removed “Reserved” rows. – added subtitle rows “CH registers (n = 0 to (CH-1))” and “CH_MSG registers (n = 0 to (CH-1))”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Section 44.3.2.4: Fast Message Ready Status Register (FMSG_RDY)*: added note “Under certain conditions, the Single Edge Nibble Transmission (SENT)...“ *Table 770: FMSG_RDY field descriptions*: Added note “These bits are either "write 1 to clear" (w1c) or self-clearing *Table 785: CHn_STATUS field descriptions*: split field description relative to bits 9–15 (MSB=0) into individual field descriptions *Table 786: CHn_CONFIG field descriptions*: split field description relative to bits 9–15 (MSB=0) into individual field descriptions *Section 44.4.1: Initialization sequence*: added notes “When configuring the Single Edge Nibble Transmission (SENT)...“ and “The Successive Calibration Pulse Check Method...” *Section 44.4.5: Adjustment for variation in sensor (Tx) clock*: added note “At ambient temperatures above 114 degree C...”. *Section 44.4.7.5: CRC check*: added note “The Single Edge Nibble Transmitter (SENT) Receiver...” *Section 44.3.2.16: DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*: Replaced field "DATA[11:8]" with "ID3_0_DATA11_8” in register figure and updated field description table accordingly. *Section 44.3.2.25: Channel n Serial Message Bit2 Read Register (CHn_SMSG_BIT2)*: Replaced field "DATA[11:8]" with "ID3_0_DATA11_8” in register figure and updated field description table accordingly. *Figure 788: Channel n Slow Serial Message Bit3 Read Register (CHn_SMSG_BIT3)*: Updated the Offset address. *Figure 767: Global Status Register (GBL_STATUS)* and *Figure 783: Channel n Status Register (CHn_STATUS)*: changed register access to R/W (was w1c). *Section 44.5.3: High frequency receiver clock (protocol clock) requirements*: Added this section. *Figure 765: Global Control Register (GBL_CTRL)*: changed offset to 0x0000 as per value in SENT memory map *Figure 779: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)*: – updated field named “ID7_4_ID3_0” to 2 fields named “ID7_6/ID3_2“ and “ID5_4/ID1_0” – updated field named “ID3_0_DATA15_12” to “ID3_0/DATA15_12” *Figure 780: DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*: – Updated field named “ID[7:6] / ID[3:2]” to “ID3_0/DATA11_8” – Updated field named “DATA[7:0]” to “DATA7_0” *Figure 788: Channel n Slow Serial Message Bit3 Read Register (CHn_SMSG_BIT3)*: – Updated field named “ID[7:6] / ID[3:2]” to “ID7_6/ID3_2” Updated field named “ID[5:4] / ID[1:0]” to “ID5_4/ID1_0” – Updated field named “ID[3:0] / DATA[15:12]” to “ID3_0/DATA15_12” *Figure 789: Channel n Slow Serial Message Bit2 Read Register (CHn_SMSG_BIT2)*: – Updated field named “ID3_0_DATA11_8” to “ID3_0/DATA11_8” – Updated field named “DATA[7:0]” to “DATA7_0” *Figure 778: DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)* and *Figure 787: Channel n Fast Message Time Stamp Read Register (CHn_FMSG_TS)*: Changed register access from R/W to Read-only.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 45: FlexRay Communication Controller (FlexRay)* Reordered the registers according to the offset address *Section 45.5.2.66.23: Protocol Configuration Register 22 (FR_PCR22)* : Added footnote for bit 15 “Reserved bit or field. Application must not write any value different from the reset value.” *Table 830: FR_SFCNTR field descriptions*: Renamed the bit field Sync Frames Channel A, even cycle from SFEVB to SFEVA *Chapter 46: Reset Generation Module (MC_RGM)* *Figure 965: MC_RGM block diagram*. changed ‘FCCU failure to react reset ‘ into ‘FCCU failure detected by FOSU’ *Table 940: Functional Event Status Register (RGM_FBRE) field descriptions*: modified the description of BE_SOFT_FUNC bit field *Figure 979: Peripheral Reset Register 2 (RGM_PRST2)* and *Table 946: RGM_PRST2 register field descriptions*: Added register field LINFlexD_2_RST at bit 4. *Figure 983: Peripheral Reset Register 6 (RGM_PRST6)* and *Table 950: RGM_PRST6 register field descriptions*: Added register field LINFlexD_3_RST at bit 4. *Figure 987: Peripheral Reset Status Register 2 (RGM_PSTAT2)* and *Table 954: RGM_PSTAT2 register field descriptions*: Added register field LINFlexD_2_STAT at bit 4. *Figure 991: Peripheral Reset Status Register 6 (RGM_PSTAT6)* and *Table 958: RGM_PSTAT6) register field descriptions*: Added register field LINFlexD_3_STAT at bit 4. *Figure 966: Destructive Event Status Register (RGM_DES)* and *Figure 970: Functional Event Status Register (RGM_FES)*: Added footnote “HVD6 occurence will not...”. *Figure 979: Peripheral Reset Register 2 (RGM_PRST2)* and *Figure 983: Peripheral Reset Register 6 (RGM_PRST6)*: Added footnote “RGM is able to reset CAN RAM controller...” *Chapter 47: Boot Assist Flash (BAF)* Inserted CAN information *Section 47.3.4.1: ‘Soft’ DCF clients*: Added Note “*BAF boots with a watchdog timeout window...”* *Section 47.3.4.3: BAF DCF client - DATAX*: added Caution text. Added *Table 967: DATA32 DCF client configuration* Added *Table 968: DATA16 DCF client configuration* and *Table 969: DATA8 DCF client configuration* Added text about “NO_ECHO bit” in sections: – *Section 47.3.5.1: Serial boot mode protocol*:in bullet 2 – *Section 47.3.5.2: LINFlexD download protocol*: in bullet 3 – *Section 47.3.5.5: Download start address, VLE bit, NO_ECHO bit and code size* – *Figure 1001: VLE bit, NO_ECHO bit and code size*: bit NO_ECHO position 30 – *Table 972: LINFlexD serial boot mode download protocol* – *Table 973: CAN serial boot mode download protocol* Updated *Figure 994: Flow of control*

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	Updated *Section 47.1: Introduction* *Section 47.4: Resources accessed by BAF code execution*: – Renamed “clocks” to “magic carpet” – Added SSCM to ressource list *Section 47.2: Memory map*: replaced the sentence “The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block“ by “For the BAF location in flash, refer to the Embedded memories chapter” *Section 47.3.1: Boot modes*: in the bullet “Application code execution”, deleted the sentence “The boot header contains flags that enable/disable individual cores and their reset vectors”. Updated *Section 47.3.2: Device initialization* *Section 47.3.5: Optionally perform a serial boot*: Added the sentence “The BAF is executed via the XOSC as clock source” Replaced all LINFlex occurences by LINFlexD. *Chapter 48: System Status and Configuration Module (SSCM)* Renamed *Table 983: Resulting Life Cycle* and added two rows to this table. *Section 48.3.1: DCF mechanism*: Added Footnote “Refer to the Device Configuration chapter for UTEST_OFFSET value” *Chapter 49: Power management controller digital interface (PMC_Dig)* *Section 49.1: Introduction*: – Removed the following text: “The PMU digital logic.....with the ADC module” – “There is also a custom interface... during initial POR” updated to “There is also a custom interface... to load the trim values” *Section 49.3: IPS bus interface* – “byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers”, edited to add “except BIST TIME registers (BIST_TIME10, BIST_TIME32, and BIST_TIME65)” – “STA1_PMUCTR_IPS macrocell” updated to “PMC_DIG block” – Instance of “MREG” removed *Section 49.5.1: Event Pending Register (EPR_LV0)*: Removed text “Since the MVD.....disable these UCDs/MVDs/POR” *Figure 1017: Event Pending Register (EPR_LV0)* and *Table 987: EPR_LV0 field descriptions*: bit fields MVD2_FL (bit 11), MVD2_C (bit 15), MVD1_C (bit 23) and PVD0_C (bit 31) made reserved. *Figure 1022: Event Pending Register (EPR_LV1)*: bit fields UVD7_FL (bit 3) and UVD7_C (bit 7) made reserved. *Section 49.5.11: Event Pending Register (EPR_HV0)*: Removed text “Since the MVD.....disable these UCDs/MVDs/POR” *Figure 1027: Event Pending Register (EPR_HV0)*: bit fields MVD10_FL (bit 11), MVD10_C (bit 15), MVD9_C (bit 23) and PVD8_C (bit 31) made reserved. *Section 49.5.16: Event Pending Register (EPR_HV1)*: Removed text “Since the MVD.....disable these UCDs/MVDs/POR” *Figure 1032: Event Pending Register (EPR_HV1)* and *Table 1002: EPR_HV1 field descriptions*: bit field UVD15_C (bit 7) made reserved.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Figure 1037: Supply Gauge Status Register (GR_S)* and *Table 1007: GR_S field descriptions*: bit fields VD15_C (bit 0), VD10_FL (bit 12), VD10_C (bit 13), VD9_C (bit 14), VD8_C (bit 15), VD7_FL (bit 16), VD7_C (bit 17), VD2_FL (bit 26), VD2_C (bit 27), VD1_C (bit 29) and VD0_C (bit 31) made reserved. *Table 1007: GR_S field descriptions*: In field “VD6_C” (Bit 19) description, “hvd145_c” updated to “hvd140_c” *Figure 1038: Pending Gauge Status Register (GR_P)* and *Table 1008: GR_P field descriptions*: bit fields VD15_C (bit 0), VD10_FL (bit 12), VD10_C (bit 13), VD9_C (bit 14), VD8_C (bit 15), VD7_FL (bit 16), VD7_C (bit 17), VD2_FL (bit 26), VD2_C (bit 27), VD1_C (bit 29), VD0_C (bit 31) made reserved. *Table 1013: EPR_TD field descriptions* – For field “TEMP1_2” and “TEMP0_2”, Temperature sensor point updated from “150 °C“ to “165 °C” – For field “TEMP1_0”, Temperature sensor point added “-40 °C” *Section 49.7: FCCU Interface*: – “dpmc_fccu_hvd” updated to “HVD_ERROR” – “dpmc_fccu_lvd” updated to “LVD_ERROR” – “dpmc_fccu_tmpsns” updated to “TEMP_ERROR” – “dpmc_ncf” updated to “PMC VD BIST” – “dpmc_safety_error” updated to “DPMC_DCF_SAFETY_ERR” *Figure 1045: Temperature Sensor Configuration register (CTL_TD)*: – bit fields TRIM_ADJ_OVER1[3:0] (bits 4:7), TRIM_ADJ_UNDER1[3:0] (bits 10:13), TRIM_ADJ_OVER0[3:0] (bits 20:23) and TRIM_ADJ_UNDER0[3:0] (bits 26:29) made reserved. – added footnote for bits 19-29: “These bits should not be written” *Table 984: Power Management Controller Memory Map*: – Removed the following registers and their instances, IREGU_CTL_BB, IREGU__DELAY_2_1, IREGU_CTL_SLOPE0....IREGU_CTL_SLOPE10 and IREGU_CTL_UPDATE. – Added register “Voltage selection of IO (VSIO) at offset address 0x0104 – Removed register “IPS Regulator QVF Status register (IREGU_QVF_STATUS) at offset address 0x036C (set to “non_cust” cond. text tag) *Section 49.5.26: Event Pending Register (EPR_TD)*: Removed fields TEMP1_2 and TEMP0_2 and set them to Reserved *Section 49.5.27: Reset Event Enable Register (REE_TD)*: Removed fields TEMP1_2 and TEMP0_2 and set them to Reserved. *Section 49.5.28: Reset Event Select Register (RES_TD)*: Removed fields TEMP1_2 and TEMP0_2 and set them to Reserved. *Section 49.5.30: Temperature Sensor FCCU Event Enable Register (FEE_TD)*: Removed fields FEE1_TS2 and FEE0_TS2 and set them to Reserved. *Section 49.5.34: User BIST Flags Register (BIST_FLAGS)*: Added note with crossreference to Power Managment. *Section 49.5.36: User BIST Time1 and Time0 Register (BIST_TIME10)*, *Section 49.5.37: User BIST Time3 and Time2 Register (BIST_TIME32)* and *Section 49.5.38: User BIST Time6 and Time5 Register (BIST_TIME65)*: – Added a cross-reference to Power Management – Added the sentence “The reset value is calculated based on 70MHz.”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Table 1023: BIST_TIME10 field descriptions*, *Table 1024: BIST_TIME32 field descriptions* and *Table 1025: BIST_TIME65 field descriptions*: Added the correspondent timing of reset values for each TIME_*x* field. Added register at *Section 49.5.24: Voltage Selection of IO (VSIO)* with *Figure 1040: Voltage Selection of IO (VSIO)* and *Table 1010: VSIO field descriptions* *Section 49.5.29: Temperature Sensor Configuration register (CTL_TD)*: Removed fields TS2IE1 and TS2IE0 and set bit 0 and bit 16 to Reserved. *Section 49.5.12: Reset Event Enable Register (REE_HV0)*: Removed bit fields REE11_FL and REE11_C. *Section 49.5.13: Reset Event Select Register (RES_HV0)*: Removed bit fields RES11_FL and REE11_C. *Section 49.5.14: Interrupt Enable (IE_HV0)*: Removed bit fields LVD11E_FL and LVD11E_C. *Table 985: 32-bit registers LV0, LV1, HV0, HV1 arrangement table*: Change HV0 / BYTE3 to “VD11=lvd290_adl1_adl0_fl_iol1_osc_c” *Table 986: VD number versus VD name table*: Changed VD11-LVD290_XOSC / VD Meanning to “HV detector asserts when XOSC supply < 2.90V”. *Table 998: REE_HV0 field descriptions*: Removed “PMU” in REE11_OSC field description. *Table 1001: FEE_HV0 field descriptions*: Changed “IO0 PMU” to “XOSC” in REE11_OSC field description. *Figure 1038: Pending Gauge Status Register (GR_P)* and *Table 1008: GR_P field descriptions*: Changed field “VD11_IOL0” to “VD11_OSC” at bit 10. *Figure 1039: Interrupt Enable Global Register (IE_G)* and *Table 1009: IE_G field descriptions*: Changed field “VD11_IOL0” to “VD11_OSC” at bit 11. *Chapter 51: Mode Entry Module (MC_ME)* *Table 1031: MC_ME register description*: added ME_PCTL91 register for LINFlex_2 and ME_PCTL219 register for LINFlex_3 *Figure 1075: Peripheral Status Register 2 (ME_PS2)*, added bit field S_LINFlex_2 *Figure 1079: Peripheral Status Register 6 (ME_PS6)*, added bit field S_LINFlex_3 *Figure 1083: Peripheral Control Register n (ME_PCTLn)*: Address updated to “0x0C0 +n*0x1 (n=0 to 255)”. Updated *Figure 1088: MC_ME transition diagram* *Table 1031: MC_ME register description*: and *Section 51.3.2.26: Core Status Register (ME_CS)*: Renamed register to CS at 0x1C0 (was CS0). *Chapter 52: e200z420n3 Core Debug Support* *Figure 1111: OnCE controller implementation*: added figure title. *Chapter 53: Debug and Calibration Interface (DCI)* Splitted table into *Table 1083: DCI JTAG source selection* and *Table 1083: DCI JTAG source selection* *Section 53.3.2: DCI EVTx pin multiplexing control register (DCI_PINCR)*: Changed the sentence “The DCI_PINCR is a 32-bit data register” into “The DCI_PINCR is a 64-bit data register”.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	*Chapter 56: JTAG Data Communication (JDC)* *Section 56.2: Overview*: removed sentence “The JTAG accessible registers...“ *Section 56.3.1.2: Module status register (JDC_MSR)*: Changed access type of register JDC_MSR to w1c (was RW) *Section 56.3.1.3: JTAG output IPS data register (JDC_JOUT_IPS)*: renamed field “JOUT_IPS Data“ to “DATA“ *Section 56.3.1.4: JTAG input IPS data register (JDC_JIN_IPS)*: renamed field “JIN_IPS Data“ to “DATA“ *Chapter 58: Nexus Port Controller (NPC)* *Section 58.1.2: Features*: Removed bullet “System clock locked status indication via MDO[0] following power-on reset”. *Table 1124: NPC Signal Properties*: Removed table footnote on MDO signal. Removed Section named “System clock locked indication. *Table 1127: PCR field descriptions*: Removed EVT_EN bit field description. *Chapter 61: Nexus Crossbar Multi-Master Client (NXMC)* *Figure 1260: Development control register 2 (DC2)*: Added footnote “This bit is not implemented and it’s value has no impact on the system” to bit 31. *Chapter 62: Cyclic Redundancy Check (CRC) Unit* *Table 1232: CRC unit memory map*: Changed CRC registers per context from (n=1 to 4) to (n=0 to CRC_CNTX_NUM - 1 with CRC_CNTX_NUM = 4). *Figure 1282: CRC computation flow*: Reworked picture (context values) [CRC_COMP_YES] *Section 62.5.1.4: CRC Output Register n (CRC_OUTPn)*: Renamed CRC_OUTP_CHK to CRC_OUTP_CHK*n* *Chapter 63: Memory Error Management Unit (MEMU)* *Table 1251: FLASH_CERR_STSn register field descriptions*: in [BAD_BIT] description, “RAM” replaced by “FLASH”. *Section 63.6.2.14: Flash memory correctable error reporting table status register (FLASH_CERR_STSn)*: Added Note “MEMU captures flash ecc error address on 64bit boundary”. *Chapter 64: Fault Collection and Control Unit (FCCU)* *Section 64.5.2: FSM description*: Updated with “Also, FCCU_CFG_TO ... a configuration register.” *Section 64.7: FCCU Output Supervision Unit*: Updayed with “This signal is automatically de-asserted ...in CONFIG state.” Removed all text referring to SMRT (Safe mode request timer) throughout the chapter. *Section 64.6.21: FCCU XTMR Register (FCCU_XTMR)*: – Updated the second sentence – Updated with “loads (a value corresponding to T_min=250 us + value programmed in FCCU_DELTA_T register) ...which has EOUT signaling enabled.”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-May-2016	3	All signal names (such as ipg_clk) are replaced by thier respectives description names (System clock) throughout the chapter. Changed “eTMR” and “ETMR” to “EOUTMR” throughout the chapter. Changed register names from NCF/UF (Noncritical / Unrecovarable Faults) to CF/RF (Critical / Recoverable Faults). *Figure 1329: FCCU RF Status register n (FCCU_RF_Sn)*: Changed reset value from 0x0 to note “The reset value is chip-specific; see the chapter that describes how modules are configured and connected.” *Figure 1330: FCCU RF Key register (FCCU_RFK)* and *Figure 1341: FCCU RF Fake Register (FCCU_RFF)*: Replaced access “Write” by “Write-only”. *Figure 1347: FCCU Permanent Lock Register (FCCU_PERMNT_LOCK)*: Corrected the figure title. *Section 64.5.9: EOUT interface*: Changed sentence “The EOUT frequency is generated ... drives a signal of 61 Hz on EOUT.” by sentence “The EOUT frequency is generated by dividing IRCOSC clock by ((FOP + 1) * 2 * 2048) where FOP vary between 0 and 63. With an IRC clock of 16 MHz, this drives...” *Chapter 65: Self-Test Control Unit (STCU2)* *Table 1335: STCU_LB_CTRLn field descriptions*: For bit CWS, configuration “000”, description changed from “illegal” to “controller waits 16 shift cycles for capture to finish” *Table 1309: STCU_PLL_CFG field descriptions* : – For bit field PLLODF, description updated to add “Refer to the RFDPHI field of the PLL0 Divider Register (PLL0DIV)….” – For bit field PLLIDF, description updated to add “Refer to the PREDIV field of the PLL0 Divider Register (PLL0DIV)….” – For bit field PLLLDF, description updated to add “Refer to the MFD field of the PLL0 Divider Register (PLL0DIV)….” Updated *Section 65.5.3: STCU2 SK Code Register (STCU_SKC)* Renamed all instantiated register headings to the format: STCU2 <description> *n* Register (<reg_abbr>*n*) *Chapter 67: Password and Device Security Module (PASS)* Added new *Table 1363: Debug Interface Enable Truth Table* *Section 67.2.1.7: Password Group n - Lock 2 status register (LOCK2_PGn)*: Renamed bit field into A256KLOCK. *Section 67.2.1.8: Password Group n - Lock 3 status register (LOCK3_PGn)*: Renamed bit field into A256KLOCK. *Table 1353: PASS memory map*: – Changed LOCK3_PG*n* reset values to 0xXFXXXXXX (was 0xXXXXXXXX). – Changed LCSTAT reset value to 0xX0000007 (was 0x000000XX). *Chapter Appendix A: Acronyms and abbreviations* Added Terms: BLDC, FOC, WBBR, AC, ACIM, BDC, DC, PMAC, PWM, SRM and VRM

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4	*Chapter 2: Introduction* *Section 2.2: Features* – “Up to -40 °C to 130 °C ambient .....range” updated to “Up to -40 °C to 150 °C junction....range” – “Supports internal flash...(UART)” updated to “Supports internal flash...(UART and MCAN)” *Table 2: SPC574Sx device feature summary (superset configuration)* – Instances of LFBGA244 conditioned with “non_cust” – Table footnote updated from “Including trace for the crossbar masters (data & instruction trace on core and data trace on eDMA).10 MDO pin Nexus..... and LFBGA244” to “Including trace for the crossbar masters (data & instruction trace on core and data trace on eDMA). 4 MDO pin Nexus..... for QFP144.” *Section 2.4: Packages* – Remove LFBGA244 *Chapter 3: System architecture* *Figure 4: CPU Exceptions vs. Interrupt Controller* – Updated bitline by 14 (was 13). – Added a new note “Note5: IVPR[16:0] + p_voffset[13:0]+2'b00”. Updated the CPU address of HW mode “ IVPR[15:0] + p_voffset[12:0] + 00b” to “ IVPR[23:0] + 0x00001000 + IACKR[31:20] *Section 3.3: Motor control Architecture* – Updated by adding a new point “For each ADC: 4 configurable analog watchdogs.” – Replaced “Resolution: 12 bit, ENOB: 10 bit” by “Resolution: 12 bit.” *Figure 7: Motor control architecture* – DFT, PTCH blocks, and their connections are removed. *Table 7: ADC channels mapping description* – Column PADLBFGA244 deleted. *Chapter 4: Signal description* *Table 9: Power supply and reference pins* – Removed column “LFBGA244”, and remove pin no. 77 from eTQFP144 for VDD_LV pad. *Table 10: System pins* – Removed column “LFBGA244”. *Table 11: Debug and trace pins* – Removed column “LFBGA244”. *Table 12: Pin multiplexing table description* – Table footnote is updated from “ This is..... for eTQFP144 and LFBGA244.” to This is..... for eTQFP144 only”. *Table 13: Peripheral multiplexing table description* – Added linflex_2 and linnflex_3 value in the table. *Table 14: Cross-mapping between pads and package pins* – Removed column “LFBGA244”.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 5: Memory map* *Table 15: Memory map (XBAR slave ports)* – Updated System RAM from 96 KB RAM to 128 MB RAM for 0x4000_0000 (Start address) and 0x4001_7FFF (End address). – Updated table footnote, “In order to avoid ECC errors.....address within the upper DMEM window” to “In order to avoid ECC errors..... whenever there is an access to the DMEM mirrored space, the address feedback alarm gets set. It will be reported to FCCU as ncf[70].” *Table 18: Peripheral bridge 0 memory map* – Updated End address from 0xFFED_FFFF to 0xFFED_3FFF. *Chapter 6: Functional safety* *Table 22: ECC Engine Summary* – Updated the value of FlexRay CHI RAM I/F for Correction and Detection column. *Table 26: LBIST / MBIST configurations* – Updated the table. *Chapter 7: Device configuration* Created *Section 7.5.2: Decorated Storage Memory Controller (DSMC)*. – Extensive changes are made throughout the chapter. *Chapter 9: Device Configuration Format (DCF) Records* – Editorial and formatting changes. – *Figure 51: Appending DCF records*, editting done in the diagram from”Data Record - CS2, Ad = 1” to “Data Record - CS2, Ad = 0” *Chapter 14: System Integration Unit Lite2 (SIUL2)* *Figure 98: SIUL2 MCU ID Register #1 (SIUL2_MIDR1)*: – In the footnote removed the default value of PKG bit field. *Table 240: SIUL input trigger connections to the INTC channels*: – Updated external interrupt number column from “0 to 3, 4 to 7, 8 to 11, 12 to 15, 16 to 19, 20 to 23, 24 to 27, 28 to 31” to “0 to 7, 8 to 15, 16 to 23, 24 to 31”. *Chapter 21: DMA channel multiplexer (DMACHMUX)* – Updated *Figure 194: DMACHMUX triggered channels* *Chapter 22: Wakeup unit (WKPU)* – Updated *Figure 197: Wakeup unit Block Diagram* – *Section 22.3.2.1: NMI Management*: Removed Note “An edge enable for a given input must be asserted before the NMI/external interrupt edge in order for a system wakeup or interrupt to be generated.”

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 24: Clocking* *Figure 201: Clock generation architecture*: – Removed the block of Re-sync stage. – Added two blocks linflex2_clk and linflex3_clk in periph clock for DIV1-16 *Table 299: Maximum system level clock frequencies*: – Added the value of Max protocol clock 40 MHz. – Added the value of Max host clock 70 MHz. *Section 24.5.2: External oscillator (XOSC)*: – “The XOSC provides support for 8 – 44 MHz crystal....resistor.” updated to “The XOSC provides support for 8 – 40 MHz crystal....resistor.” – Added a note, “The user must take care when using 16 MHz crystals or lower, because the S_XOSC flag in the ME_GS register will not be set if the CMU_PLL (CMU 0) default configuration is used. Indeed CMU_PLL (CMU 0) is programmed by default to use crystal frequencies greater than IRC (16 MHz) + 0.5 MHz and this condition is no longer valid with XOSC <= 16 MHz. In this case, to use an XOSC frequency less than or equal to 16 MHz, an RCDIV value (CMU_0.CSR register) that respects the previous formula (CMU_CSR.B.RCDIV = 3) must be used. This setting has to be done before enabling XOSC in the user code.” *Section 24.5.2.1: XOSC startup*: – “The XOSC.....or 40 MHz to 44 MHz crystal. The XOSC EN_40 MHz.....crystal (UTEST Misc bit 21 = 0).” updated to “The XOSC.....or 40 MHz crystal. The XOSC EN_40 MHz.....crystal (UTEST Misc bit 21 = 0).” *Figure 205: CMU_0 block diagram* and *Figure 206: CMU[1:4] block diagram*: – Deleted “$f_{CLKMN1} < f_{CLKMT0_RMN} / 4$” from CLKMN1 Supervisor part. *Chapter 25: Dual PLL Digital Interface (PLLDIG)* *Table 308: PLL0DV field descriptions* and *Table 311: PLL1DV field descriptions*: – Updated division factors of RFDPHI. *Table 312: PLL1FM field descriptions*: – Added a cross-reference to Frequency modulation section for MODPRD and INCSTP field descriptions. *Table 313: PLL1FD field descriptions*: – Added a cross-reference to Clock configuration section for FRCDIV field description. – Updated DTHDIS field description. – Added note to FRCDIV field description. *Section 25.6.2: Clock configuration*: – Added text “refer to the device datasheet” – Added two notes. *Section 25.6.4: Frequency modulation*: – Changed feedback divider f_{ref} by $f_{pll1ref}$ – Move text “PLLFM[MODPRD] and PLLFM[INCSTP] are subject to the following restriction:” to next equation. – Replaced PLLnCR[MFD] with PLL1DV[MFD].

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 26: Clock Monitor Unit (CMU)* *Table 316: CMU_CSR field descriptions* – SFM: added sentences “MDR[MD] ... CSR[SFM]=1” and “Software ... bit” – RCDIV: added sentence “Ensure ... [RCDIV]” – CME: added sentence “CMU_HFREF ... (CSR[CME=1])” *Section 26.5.2: CLKMN0_RMT supervisor*: – Deleted Note “f_{CLKMN0_RMT} ... *monitoring.*” *Chapter 27: Clock Generation Module (MC_CGM)* *Table 322: MC_CGM register description*: – Updated offset address for PCS Divider Start for XOSC (CGM_PCS_DIVE1), PCS Divider Start for XOSC (CGM_PCS_DIVS1), PCS Divider Start for XOSC (CGM_PCS_DIVE2), PCS Divider Start for XOSC (CGM_PCS_DIVS2), PCS Divider Start for XOSC (CGM_PCS_DIVE4), PCS Divider Start for XOSC (CGM_PCS_DIVS4). – Updated offset address in *Section 27.3.1.3: PCS Divider End 1 Register (CGM_PCS_DIVE1)*, *Section 27.3.1.4: PCS Divider Start 1 Register (CGM_PCS_DIVS1)*, *Section 27.3.1.6: PCS Divider End 2 Register (CGM_PCS_DIVE2)*, *Section 27.3.1.7: PCS Divider Start 2 Register (CGM_PCS_DIVS2)*, *Section 27.3.1.9: PCS Divider End 4 Register (CGM_PCS_DIVE4)*, *Section 27.3.1.10: PCS Divider Start 4 Register (CGM_PCS_DIVS4)*. *Chapter 32: Embedded Flash Memory* *Section 32.3.2.13: Test Mode Disable Password Check register (TMD)*: – Deleted text between brackets “Test Mode Disable Override Passcode at address offset 0x3DC8” *Table 416: TDM field descriptions*: – Added Note “PWD bitfield is byte-reversed...” Added *Chapter 33: Decorated Storage Memory Controller (DSMC)*. *Chapter 34: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Section 34.4.5.1: CTU trigger mode*: – Replaced JABORT by JABORTCHAIN (was a typo) *Table 423: MCR field descriptions*: – Added note in the description of CTUEN – Removed note in CTUEN bitfield Replaced SDADC by SARADC in FRZ bitfield description (was a typo)

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 35: Enhanced Cross Trigger Unit (ECTU)* *Section 35.1: Introduction*: – "The ECTU...command to the ADC, trigger signals to other IPs and external trigger...lost." updated to "The ECTU ...commands to the ADCs, start/stop trigger signals to other IPs and external trigger to the pad...lost. *Section 35.2: Main features*: – Added "Receives up to 8 trigger events from other IPs such as PWM, Timers, external pins" to "Receives up to 16 input trigger events from other IPs such as PWM, Timers, external pins . For mapping details, refer to *Figure 33: Module to module connections* and *Table 13: Peripheral multiplexing table description*" – "Generates.....8 trigger events" updated to "Generates..8 internal events to trigger ADC sequences" – "Each trigger...conversion" updated to "Each internal trigger...conversion" Multiple Conversion Mode of *Section 35.6.1: ADC commands list format* : – Updated the description from "Maximum...CLR_0 will.....CLR_1 and so on..FIFO." to "Maximum...CLR_1 will.....CLR_2 and so on...FIFO." Updated *Section 35.10.18: Commands list register n (CLRn)*: – Offset: 0x120 +n*0x4 (n=0 to 63)" to " Offset: 0x11C +n*0x4 (n=1 to 64)." *Table 477: SU registers*: – Updated Register section of Address offset 0x0120- 0x02AC from "Commands List Register 0–63 (CLR0–CLR63)" to "Commands List Register 1–64 (CLR1–CLR64)". *Table 481: TGSCR field descriptions*: – Updated the descriptive section of MRS_SM field from " MRS...(5 bits to select one of 32 inputs)." to "MRS...(4-bits to select one of 16 input trigger signals)." *Figure 414: Cross triggering unit expected value n (CTU_EXPECTEDn)*: – Changed constant offset address to 0x051C (was 0x0520) *Figure 415: Cross triggering unit counter range (CTU_CNT_RANGEn)*: – Changed constant offset address to 0x052C (was 0x0530)

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 42: CAN Subsystem* *Table 637: CCCR field descriptions*: – Removed note in NISO register field and added notes to PXHD and BRSE register fields. *Figure 569: CAN subsystem generic block diagram*: – Rewrite figure note 1. *Figure 579: Timestamp Counter Value Register (TSCV)* and *Figure 581: Timeout Counter Value Register (TOCV)*: – Changed TSC/TOC field access to R/W (was R/w1c). *Section 42.3.15: Clock Calibration on CAN Unit (CCCU)*: – Added note. *Section 42.3.6: Message RAM* and *Figure 617: Message RAM Configuration*: – Set Message RAM to maximum value of 4352 words and added reference to specific device configuration. *Section 42.5: SRAM interface and memory organization*: – Added cross- reference to Shared memory map section. *Chapter 48: Boot Assist Flash (BAF)* *Section 48.2: Memory map*: – Added a note (removed from the PASS chapter's Clock Jitter activation section and copied here) Updated *Table 964: BAF memory organization*: – Updated the value of BAF_data_area_and_stack. Updated *Table 965: BAF image header* – Updated the value of address offset from 0010h to 0x0008 for the field BAF version number. *Chapter 49: System Status and Configuration Module (SSCM)* *Section 49.3.5: Life Cycle*: – Changed the sentence starting with "The LC is written into 5 slots, 128 bits each,..." by "The LC is written into 5 slots, 256 bits each,..." – Changed the sentence ending with "each LC slot can have one of the possible 4 status:" by "each LC slot can have one of the possible 3 status:" – Updated *Table 983: Life Cycle slots* and *Table 984: Life Cycle Slots in Memory* – Updated *Figure 1020: Appending DCF records* – *Table 985: Resulting Life Cycle*, changed back the title.

Table 1372. Document revision history (continued)

Date	Rev.	Changes
12-Jun-2018	4 (cont'd)	*Chapter 55: Debug and Trace* *Table 1100: Nexus signals*: – Updated the footnote. *Chapter 59: Nexus Port Controller (NPC)* Updated *Section 59.1.3.4: Reduced-Port Mode* – Added “All MSEO signals need to be connected” to the content. *Chapter 65: Fault Collection and Control Unit (FCCU)* *Table 1272: FCCU_CFG field descriptions*: – Updated description of bitfield FCCU_SET_CLEAR *Chapter 66: Self-Test Control Unit (STCU2)* *Table 1310: STCU_RUNSW field descriptions*: – Moved this table to above section. *Table 1312: STCU_CFG field descriptions*: – Added note “STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE Clock Frequency value” for “LB_DELAY” field. *Table 1314: STCU_WDG field descriptions*: – Replaced table footnote by table note for “STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE Clock Frequency value.” *Chapter 68: Password and Device Security Module (PASS)* *Table 1358: LCSTAT register field descriptions*: – Updated description of LIFE bitfield with value 110 (ST production)
