The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

71.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the

external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

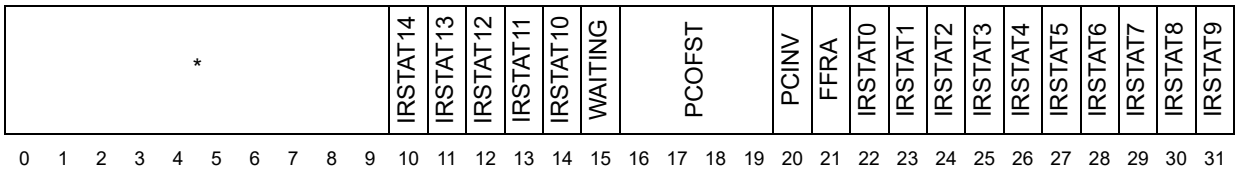

Figure 1943. Control State Register (CTL)

Table 1876. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. Refer to *Section 71.5.5.3, OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered

Table 1876. CTL field descriptions (continued)

Bit	Name	Description
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (Refer to PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of $WBBR_{lo}$ used as operand value.
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.

Table 1876. CTL field descriptions (continued)

Bit	Name	Description
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to ‘0’, and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU,

the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

71.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

71.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 71.5.9.2, Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

71.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

71.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

71.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device or system damage, or both, these registers should not be accessed.

71.6 Watchpoint support

e200z420n3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes (refer to the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter).

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1877 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1877. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]

Table 1877. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.

Table 1877. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

71.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR *Section 71.5.6.3, OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 71.5.6.3, OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

71.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

71.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 71.5.9.2, Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 71.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 71.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

72 Debug and Calibration Interface (DCI)

72.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

72.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

72.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

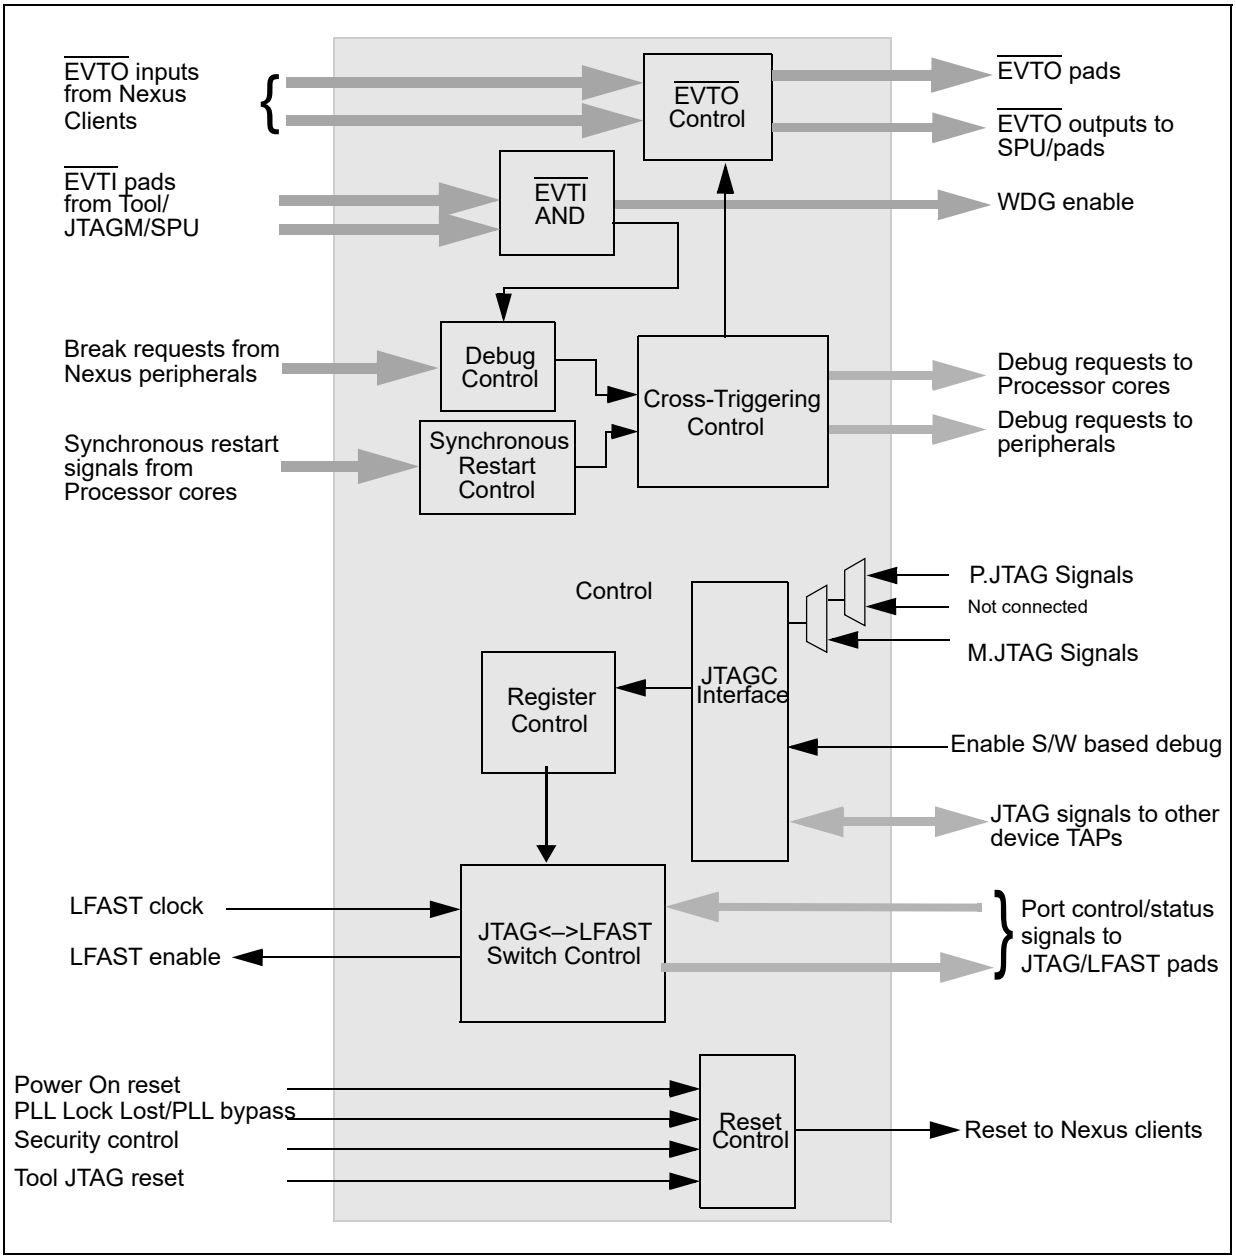
When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

Figure 1944 shows the DCI block diagram.

Figure 1944. DCI block diagram



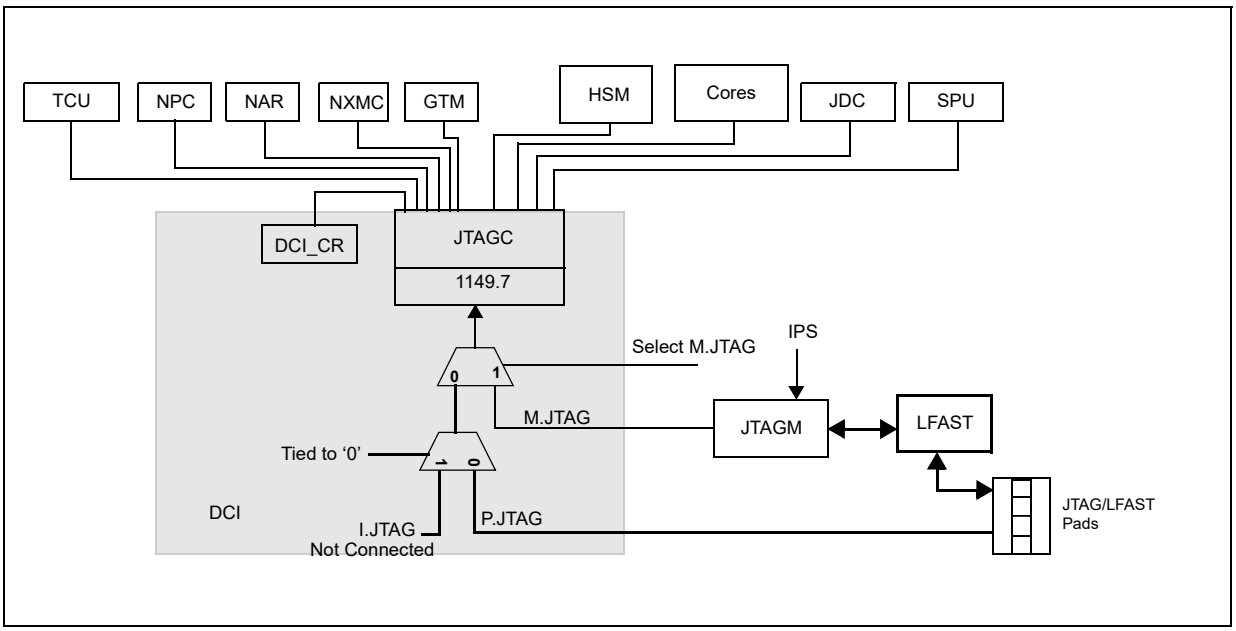


Figure 1945 shows the DCI configuration for the standard production package.

Figure 1945. DCI in a standard configuration

72.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 1878 shows a summary of the configuration options.

Table 1878. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

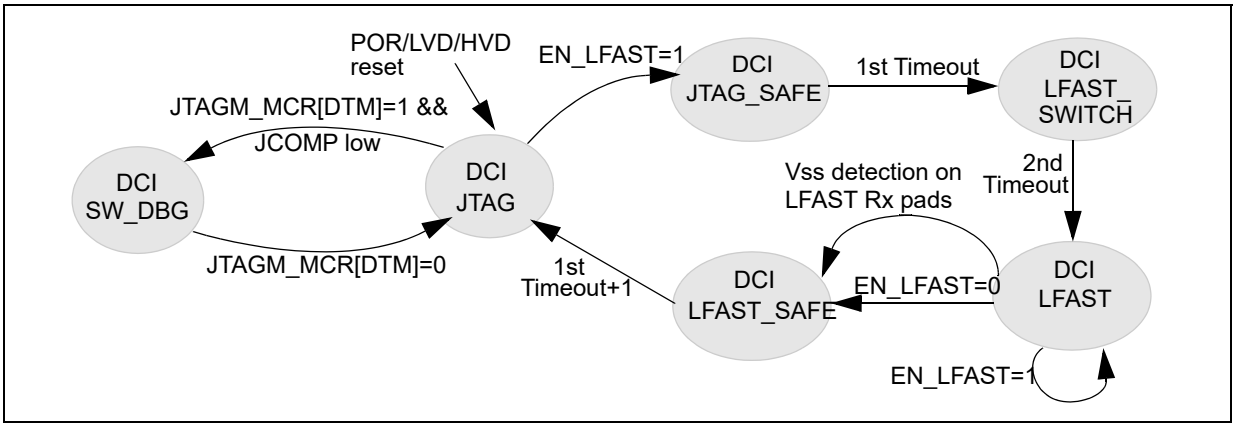
The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the

JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 72.1.3.1: Port sharing between JTAG and LFAST modes*. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 1879* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1879. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

Figure 1946 shows the DCI mode switching operation.

Figure 1946. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

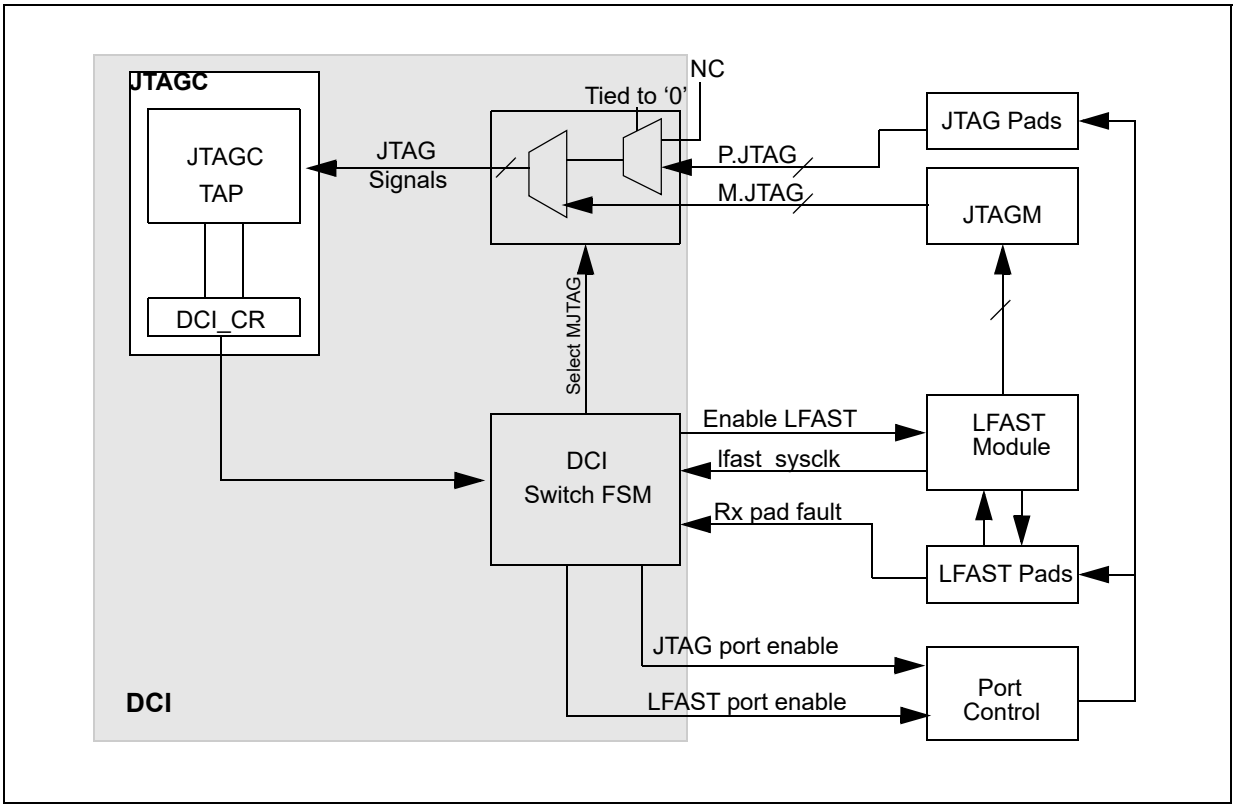


Table 1880 contains the operating mode descriptions.

Table 1880. DCI operating modes

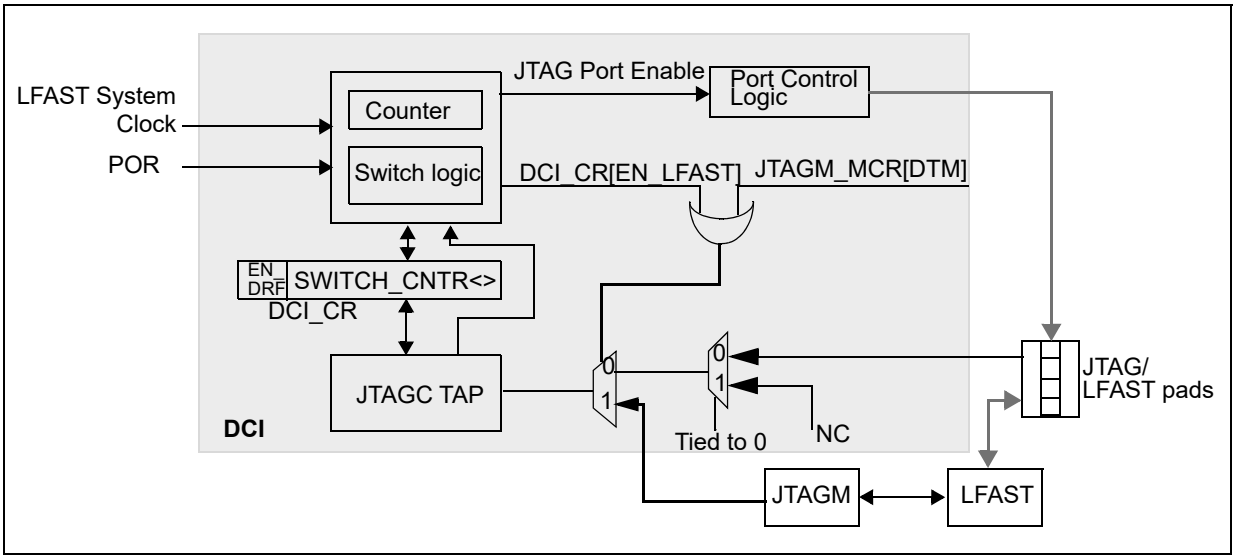
Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

Figure 1947 shows a block diagram of the JTAG/LFAST connections.

Figure 1947. DCI JTAG/LFAST switch integration

72.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):



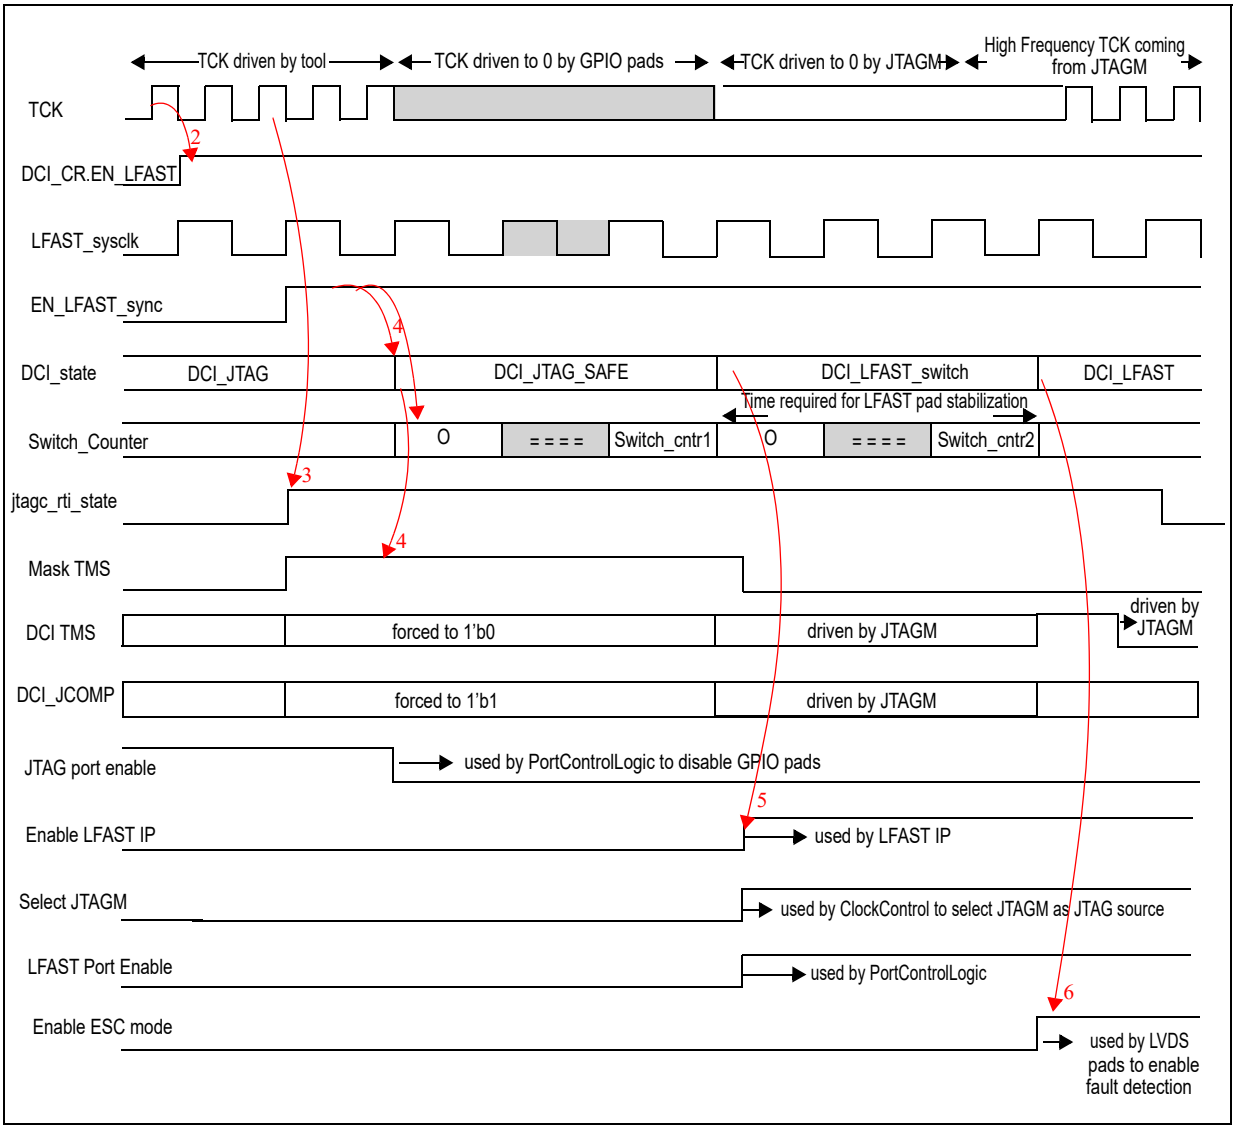
- EN_LFAST – Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2 – Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 1948*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 1948. DCI switching between JTAG and LFAST modes



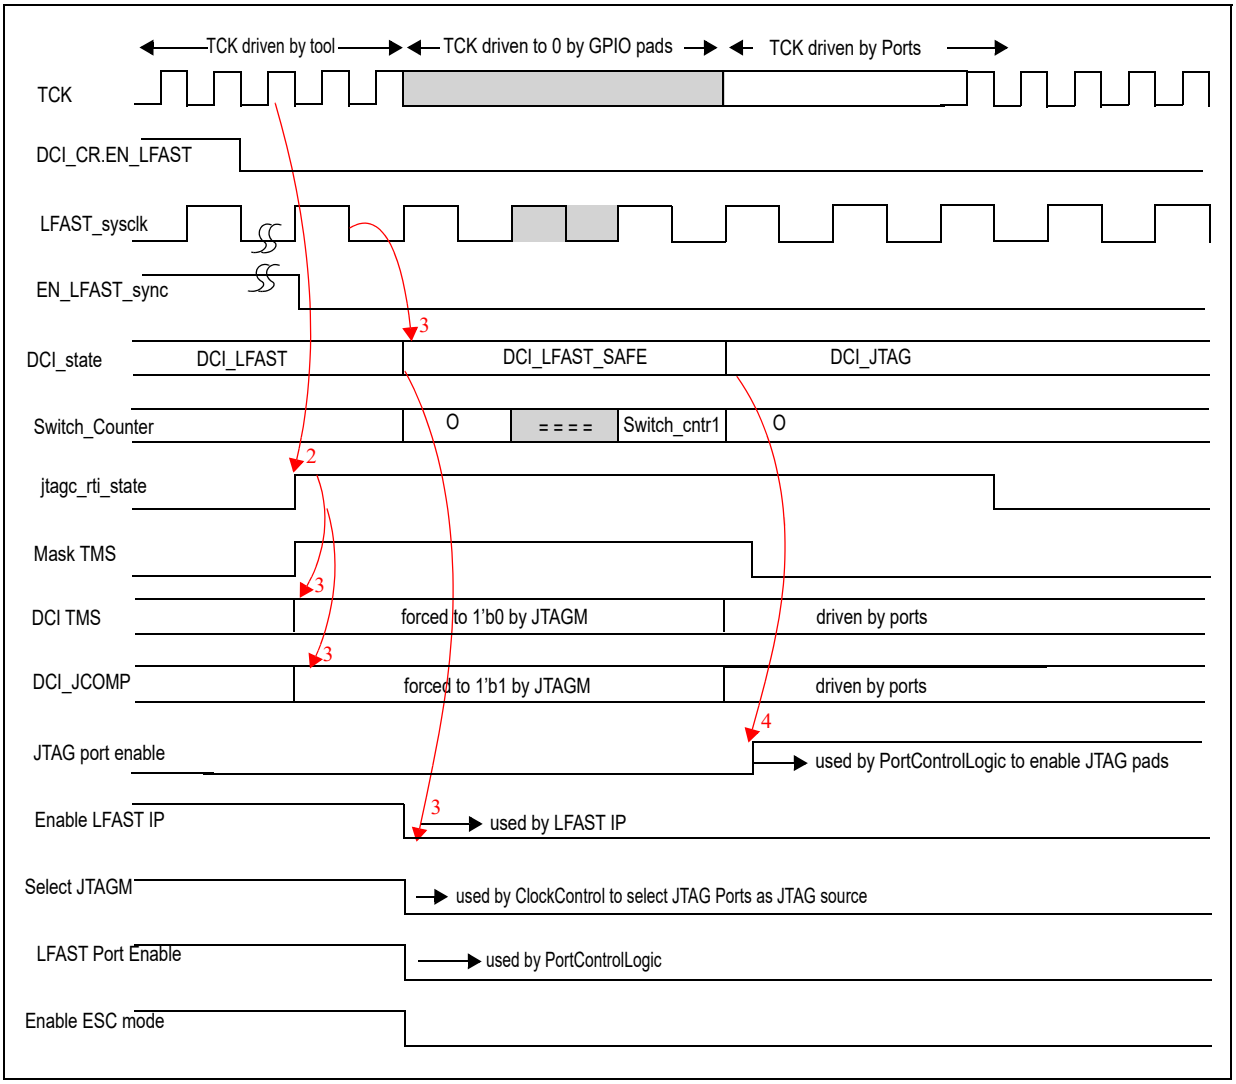
72.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 1949 shows the timing sequence.

Figure 1949. DCI JTAG to LFAST switching diagram



72.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 1884 and *Table 1886* summarize the MCU and tool behaviors. *Figure 1950* shows the timing sequence.

Figure 1950. DCI LFAST to JTAG switching diagram

72.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

72.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

72.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1881. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

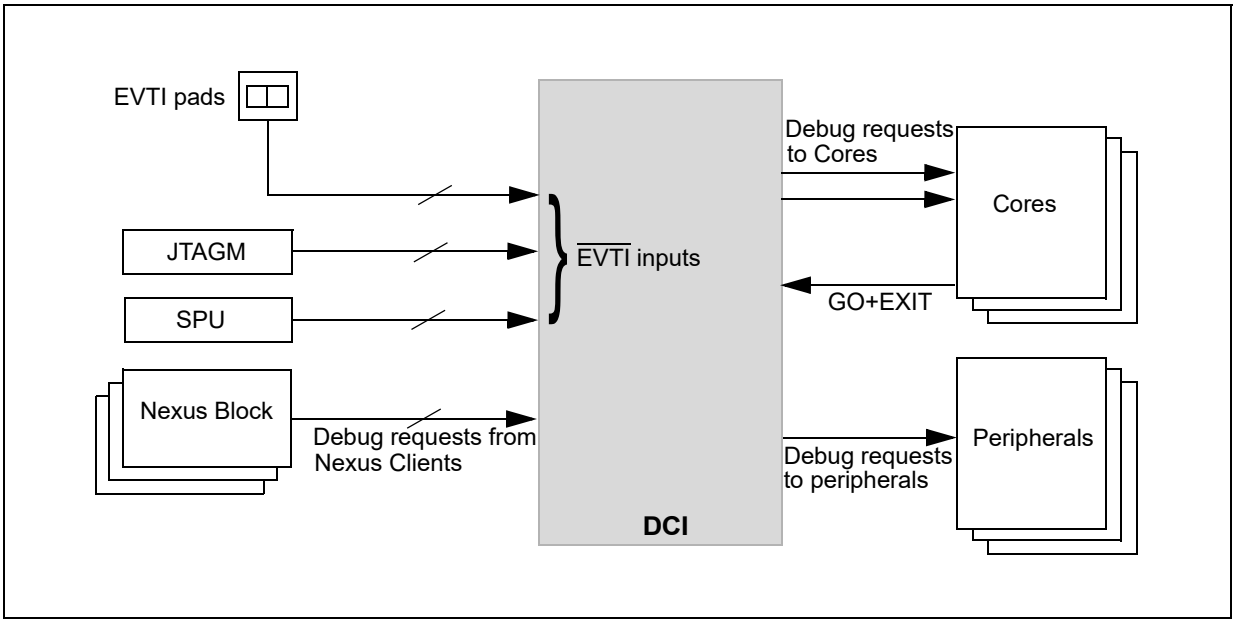
72.1.3.5 System watchdog control

he DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

Note: Debugger should check the SWT counter to confirm if SWT has actually stopped or not, otherwise repeat the sequence mentioned above to disable the SWT.

72.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.



There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[1:0] signals from EVTI pads
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

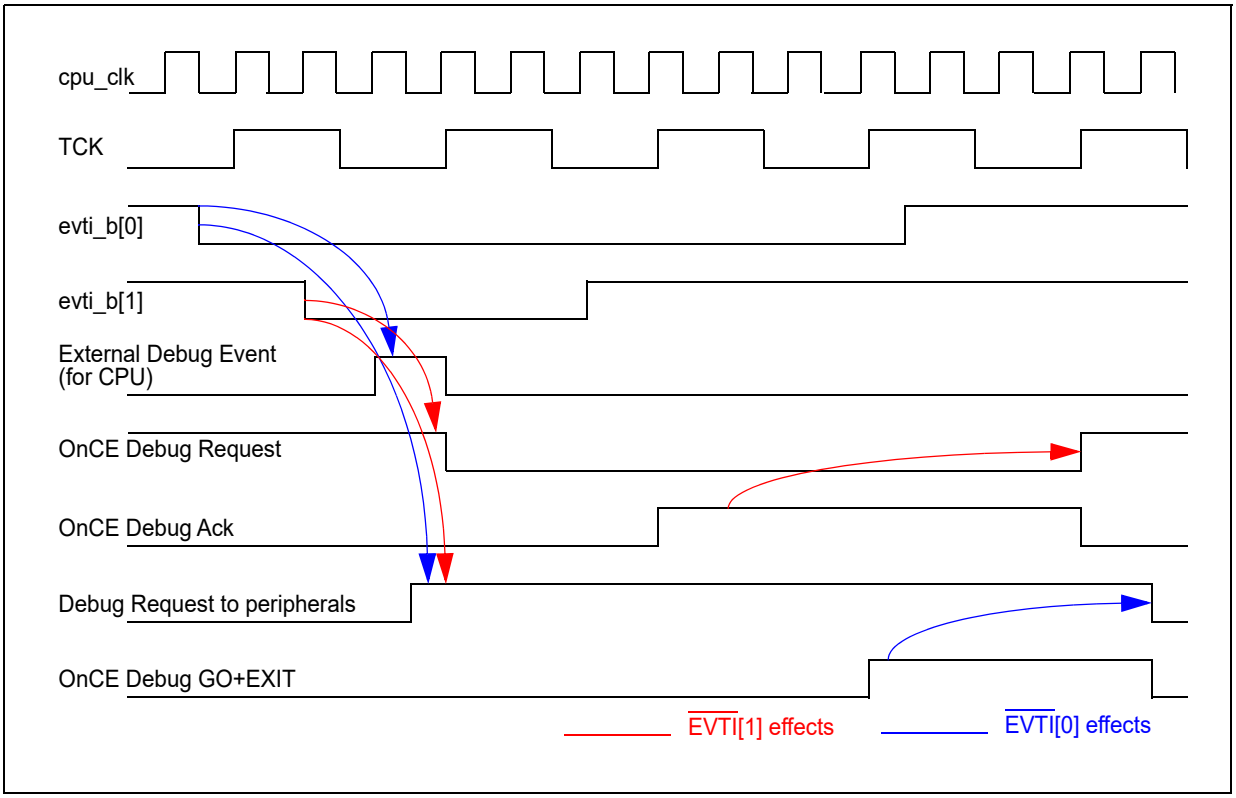
The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1951. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$ inputs are synchronized and logically ANDed in the DCI to generate the following:

- debug requests for each processor core
- external debug requests for each processor core
- debug request for all non-CPU peripherals



The $\overline{\text{EVTI}}$[0] from the EVTI pads, SPU and JTAGM are used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The $\overline{\text{EVTI}}$[1] from the SPU and JTAGM, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 1952 shows the timing sequence.

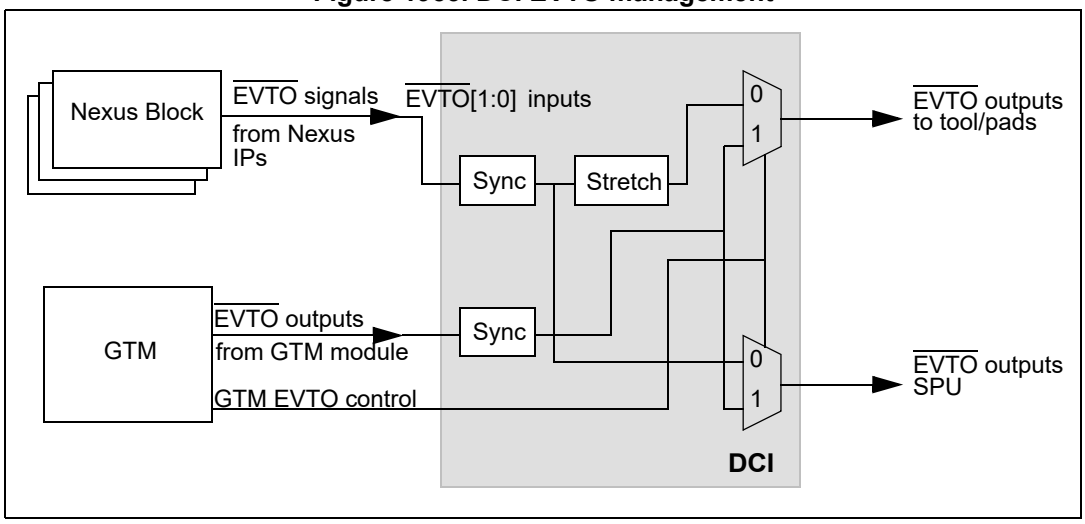
Figure 1952. DCI debug signal generation

72.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

72.1.3.8 Synchronous restart control



The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (that is set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

72.1.3.9 EVTO management

The EVTO management block diagram is presented in *Figure 1953*.

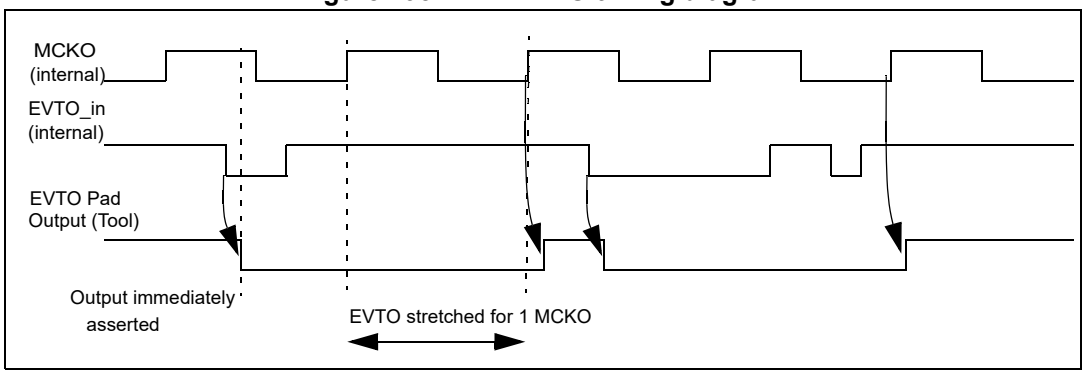


Figure 1953. DCI EVTO management

The DCI module controls distribution of the EVTO outputs from all Nexus Clients including the cores that produce EVTO[1:0] signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[1:0] signals from any Nexus client, the DCI immediately asserts EVTO[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool (*Figure 1954*). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 1954. DCI EVTO timing diagram

72.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

72.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

72.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

72.3 Register description

The DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

72.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 1955* shows the format of the DCI_CR.

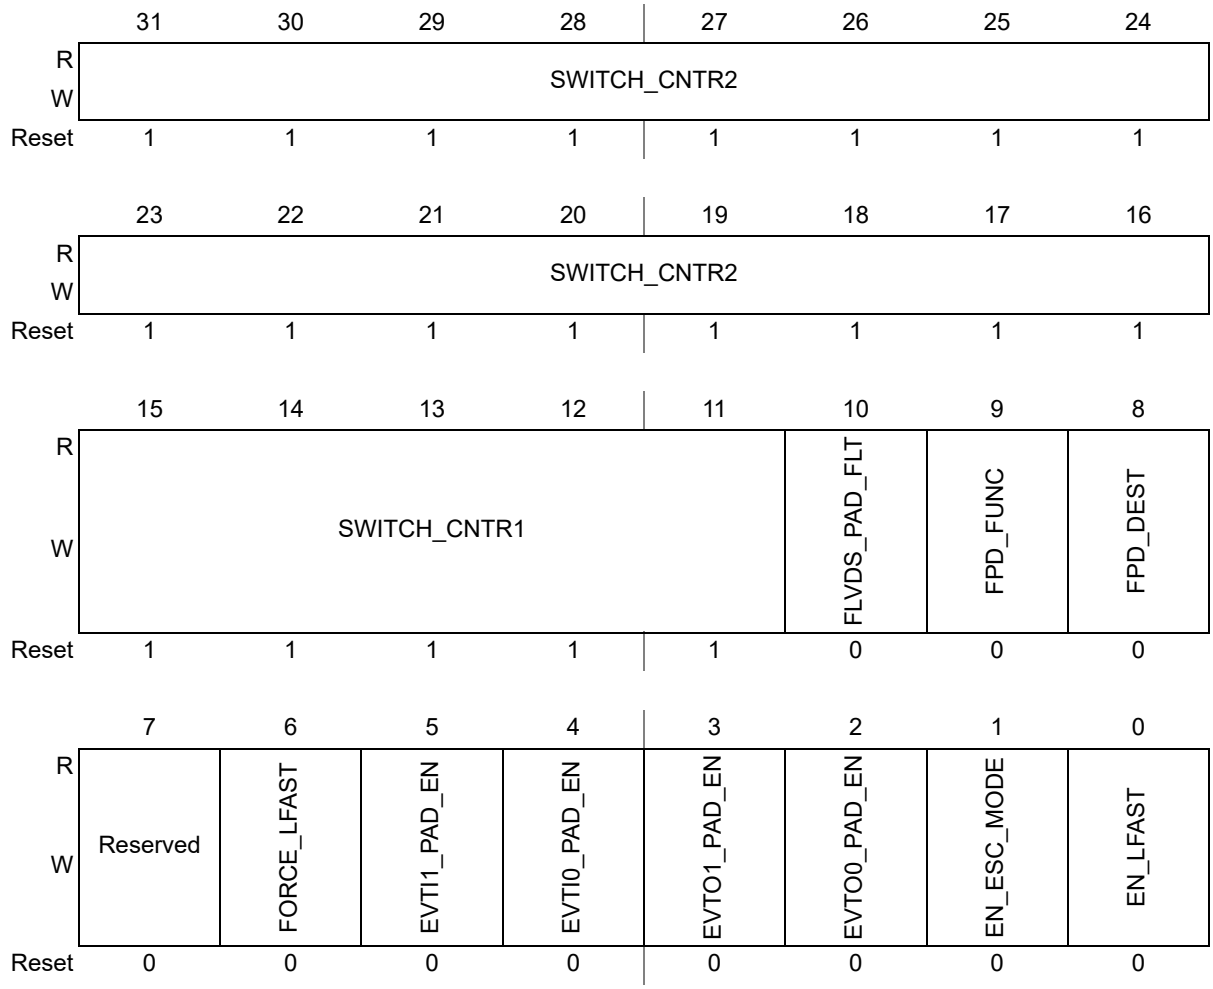

Figure 1955. DCI control register (DCI_CR)

The DCI_CR is described in *Table 1882*.

Table 1882. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2 Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1 Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}

Table 1882. DCI_CR field descriptions (continued)

Field	Description
10 FLVDS_PAD_FLT	Force LVDS Pad Fault Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN(1)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}$[1] pad 0 $\overline{\text{EVTO}}$[1] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[1] pad output enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled
1 EN_ESC_MODE	Enable Escape Mode Fault detect feature enable for LFAST Rx pads. 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(1)	Enable for LFAST-based tool selection This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

72.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter, ENABLE_DATA2. For

a description of the DCI_PINCR functionality, refer to Calibration and Debug configuration chapter (or the Debug and Trace chapter) which describes how the modules are configured.

72.4 Functional description

72.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 1883* and *Table 1884* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 1885* and *Table 1886* contain the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1883. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received

TCK	Logic Input	Logic Input	Logic Output	Logic Output

72.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 1887* and *Table 1888* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 1887. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input

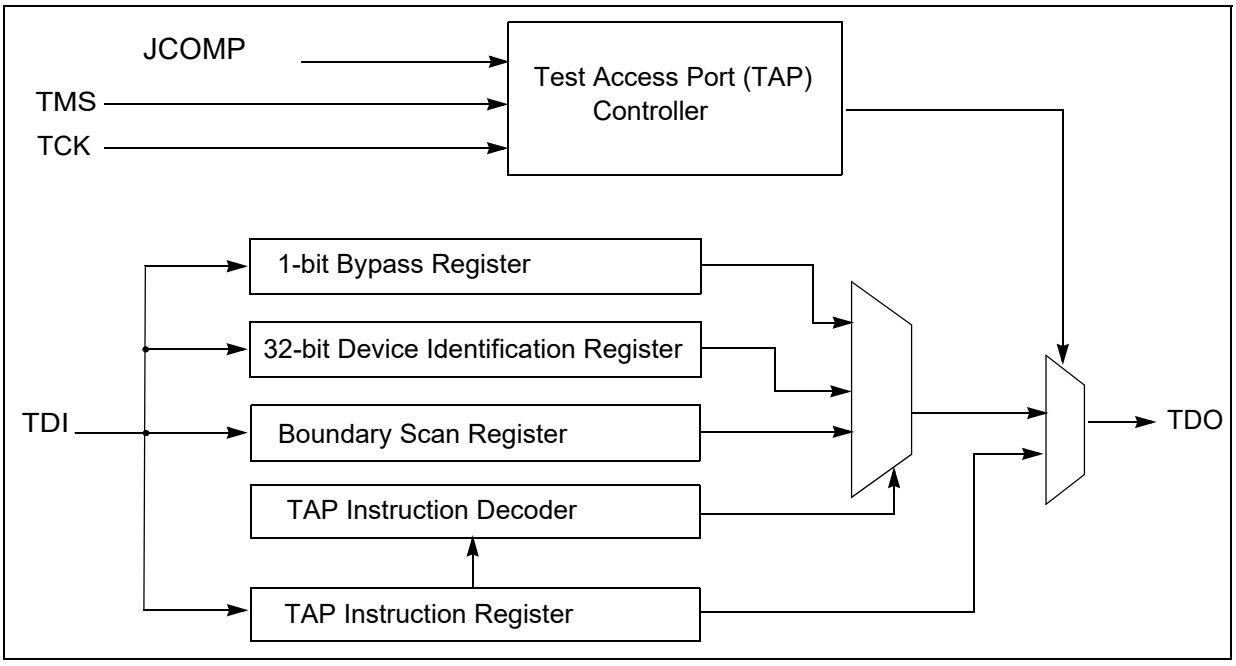
73 JTAG Controller (JTAGC)



73.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

73.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1956. JTAG (IEEE 1149.1) block diagram

73.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1892* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

73.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

73.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

73.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 73.4.4*.

73.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

73.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1889. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

73.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

73.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

73.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 73.4.3*.

73.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

73.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

73.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

73.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

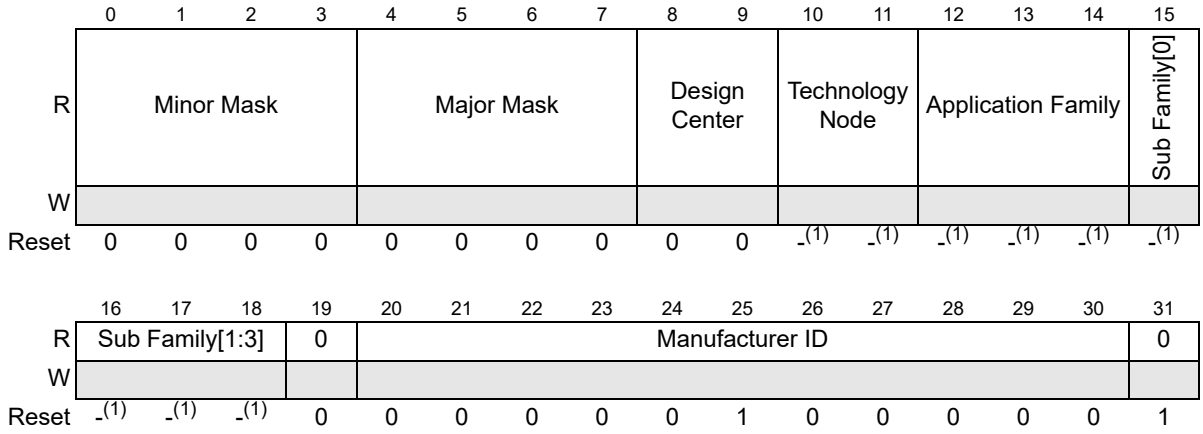


Figure 1957. 6-bit instruction register

73.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

73.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 1890*

Figure 1958. Device identification register

The following table describes the device identification register functions.

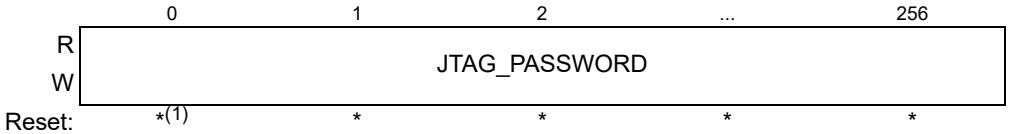

Table 1890. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 01 40nm
12:14 Application Family	Application Family These bits indicate the device application family 000 SPC58N - Powertrain 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 1000 SPC58NE84C3 , SPC58NE84E7
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

73.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine

is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1959. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1891. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

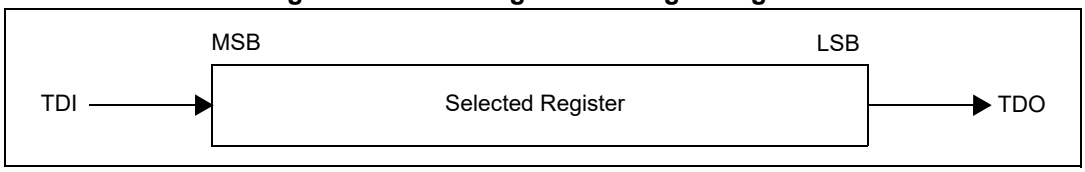
73.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 73.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

73.4 Functional description

This section explains the JTAGC functional description.

73.4.1 JTAGC reset configuration



While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

73.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 73.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

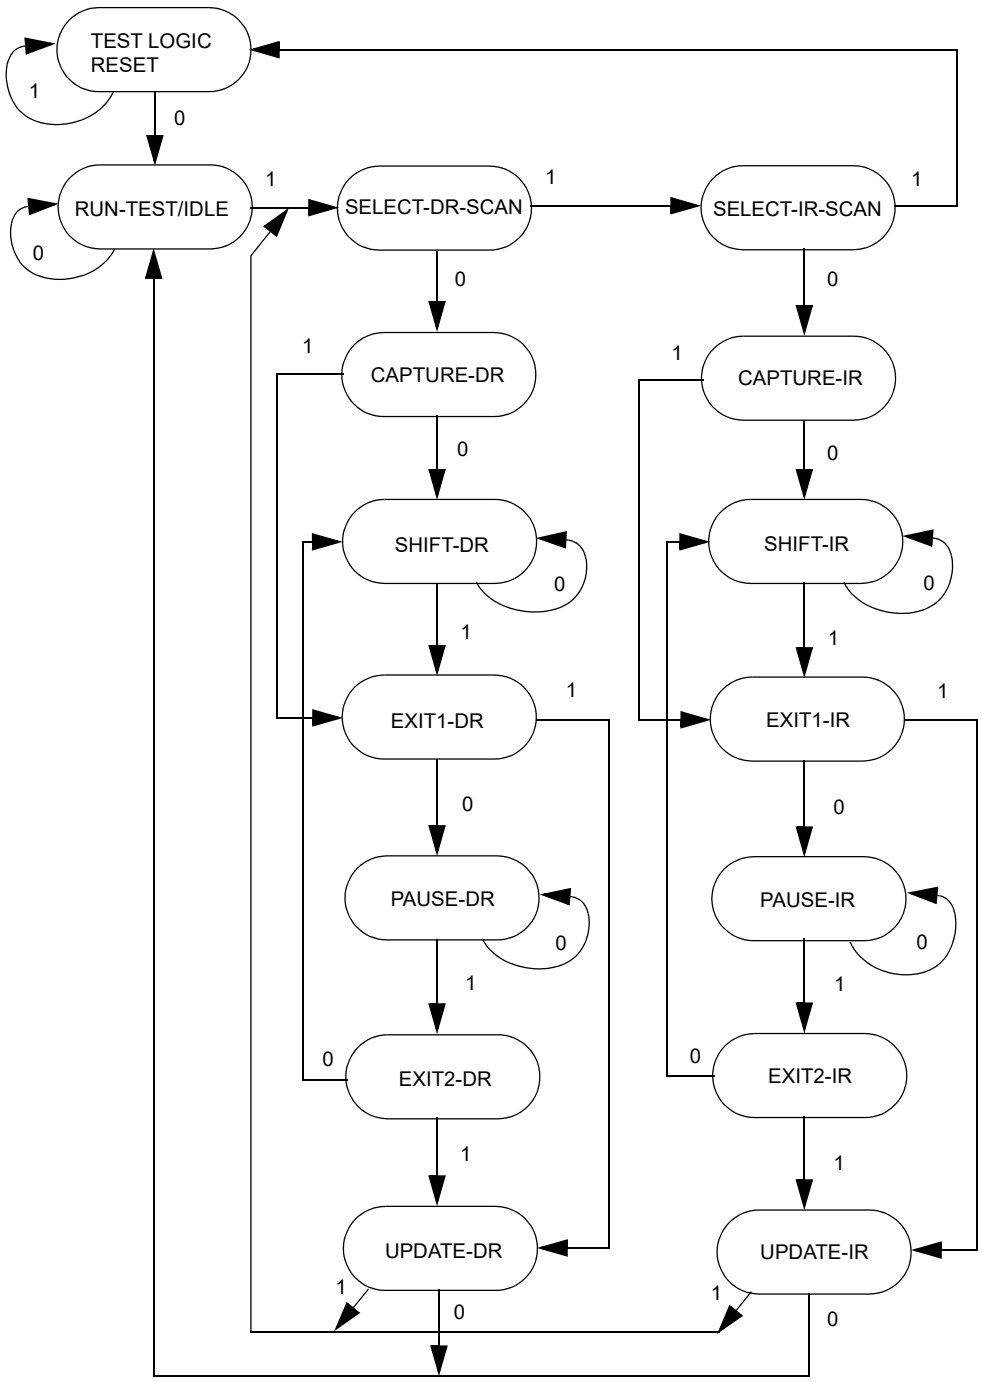


Figure 1960. Shifting data through a register

73.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 1961. IEEE 1149.1-2001 TAP controller finite state machine

Note:

1. The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

73.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

73.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

73.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1892. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NR_PD	100001	Enables access to the NAR TAP controller on production device

Table 1892. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100010	Reserved
Reserved	100011	Reserved
Reserved	100100	Reserved
Reserved	100101	Reserved
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller, to access the HSM challenge and response registers
ACCESS_AUX_HSM	100111	Enables access to the HSM core TAP controller
ACCESS_AUX_CORE_0	101000	Enabled access to E200 Core 0
ACCESS_AUX_CORE_1	101001	Enables access to E200 Core 1
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
ACCESS_AUX_GTM	110011	Enables access to GTM TAP controller
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
ACCESS_AUX_BUS_MON_2	110110	Enables access to NXMC Client 2 TAP controller
ACCESS_AUX_BUS_MON_3	110111	Enables access to NXMC Client 3 TAP controller
ACCESS_AUX_BUS_MON_4	111000	Enables access to NXMC Client 4 TAP controller
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

73.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

73.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

73.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

73.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

73.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

73.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (for example high impedance).

HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

73.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

73.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

73.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

73.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

73.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, must be loaded the appropriate instruction for the test or action to be performed.

74 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

74.1 References

- IEEE Std 1149.1-2001 (R2008), Standard Test Access Port and Boundary-Scan Architecture
- IEEE Std 1149.7, Standard for Reduced-Pin and Enhanced-Functionality Test Access Port and Boundary-Scan Architecture

74.2 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backward compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

74.2.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- Compliant
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- Extended
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- Advanced
  - Two-pin operation using the “Advanced Protocol” – signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

74.2.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

74.2.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in *Table 1893*. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

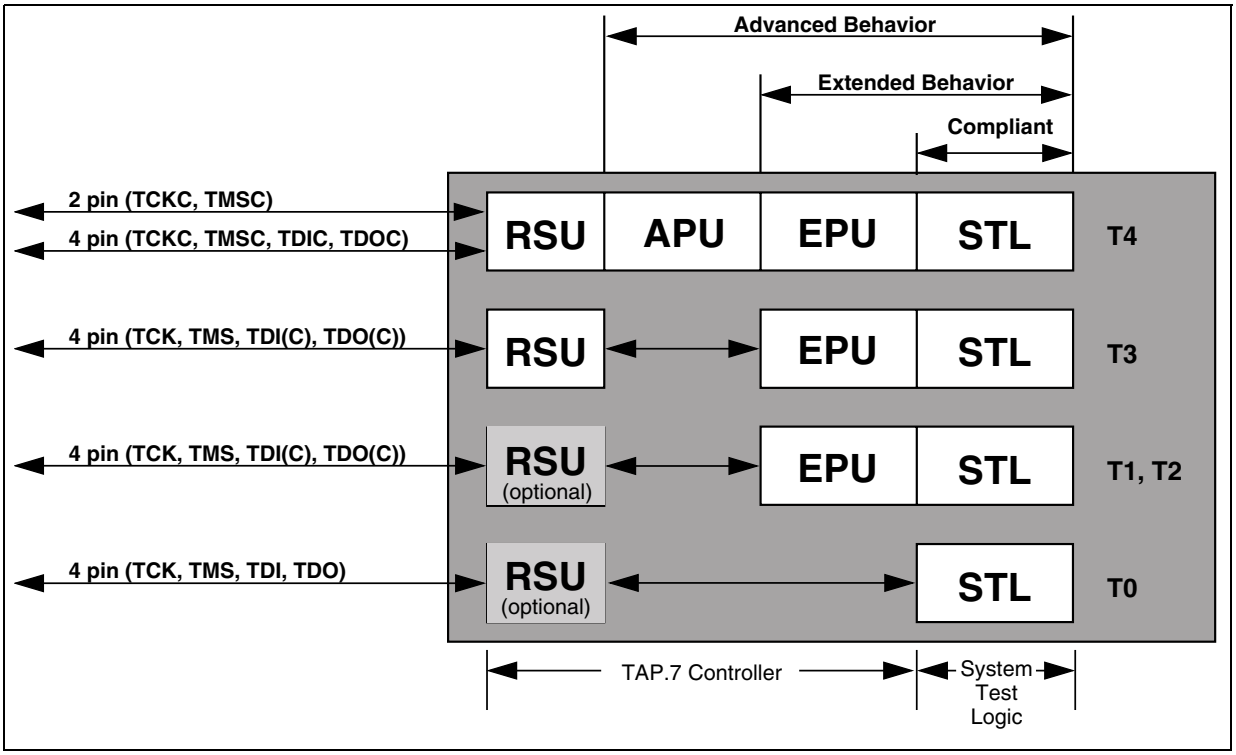
The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC, and nTRST pins.

Table 1893. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4



74.2.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in *Figure 1962*. It is described with the hardware layers listed below:

- **STL System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

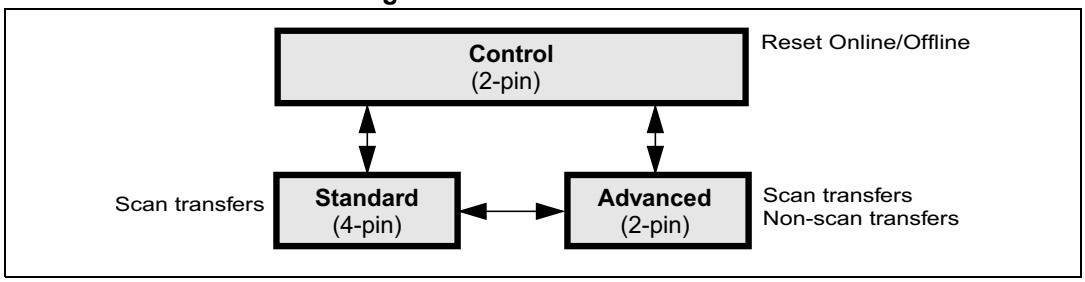


Figure 1962. TAP.7 Controller Architecture

74.2.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in *Figure 1963*.

Figure 1963. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in *Table 1894*.

Table 1894. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

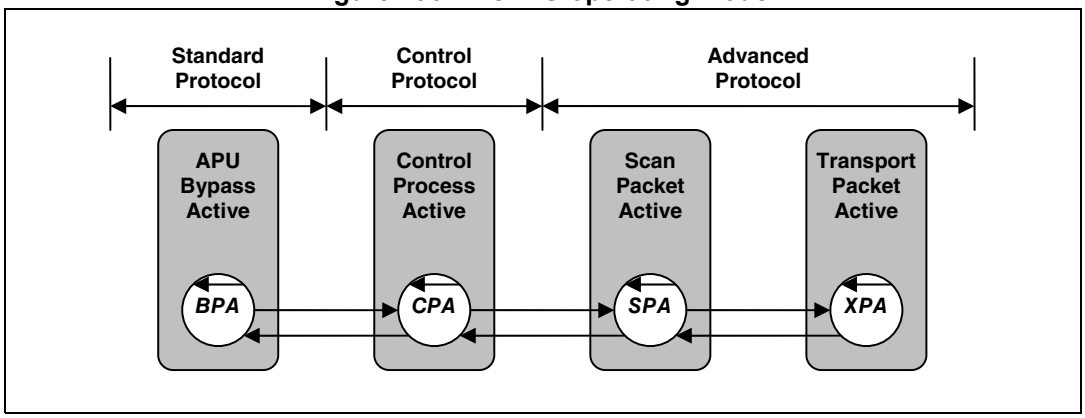
The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

74.2.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

74.2.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.



74.2.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

74.3 Operating models

Figure 1964 illustrates a simplified view of the CJTAG operating model.

Figure 1964. CJTAG operating model

74.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

74.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

74.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

74.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

74.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

74.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

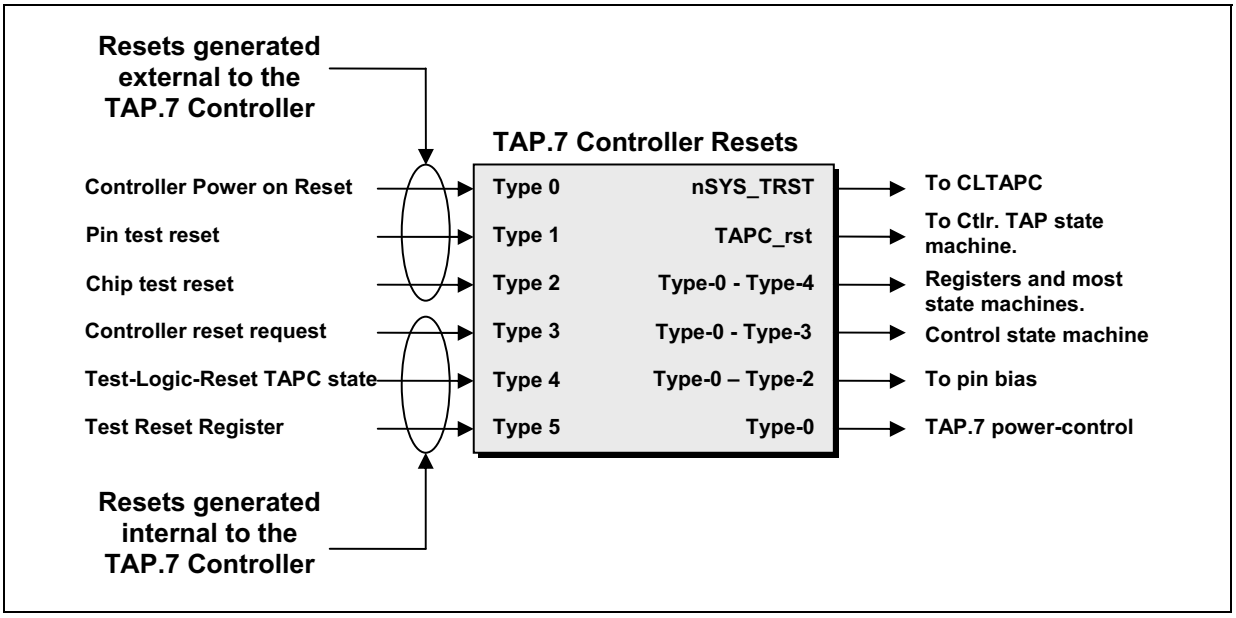
74.5 Ancillary services

74.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine



74.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 1965. Conceptual view of the EPU reset logic and state machines

74.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

74.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

74.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

74.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

74.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

74.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

74.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 1966. Reset state machine

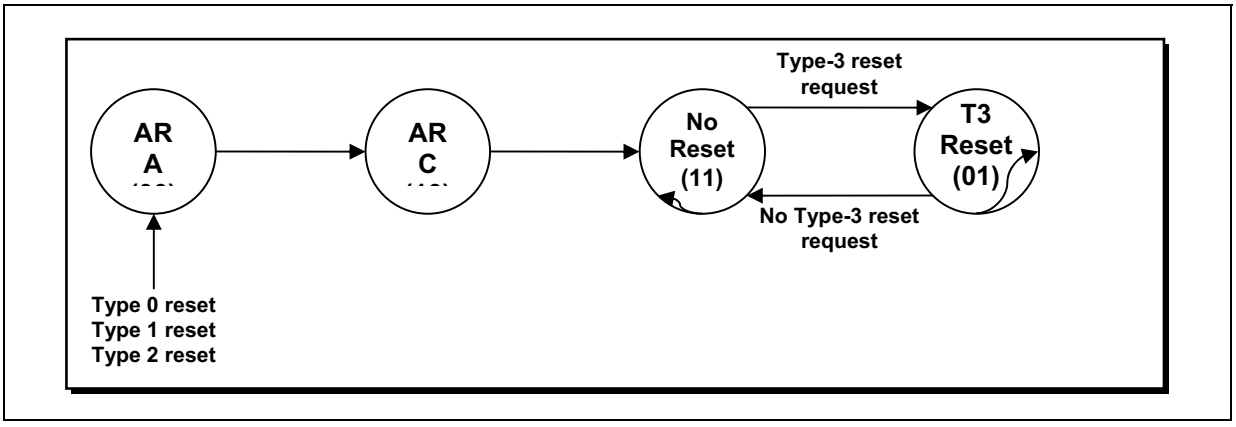


Table 1895. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in *Table 1896*.

Table 1896. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

74.5.3 Start-up Options

74.5.3.1 Overview

The TAP.7 start-up options are shown in *Table 1897*. The only startup option currently supported by the CJTAG module is 1149.1 compliant.

Table 1897. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

74.5.3.2 1149.1 Compliant start-up

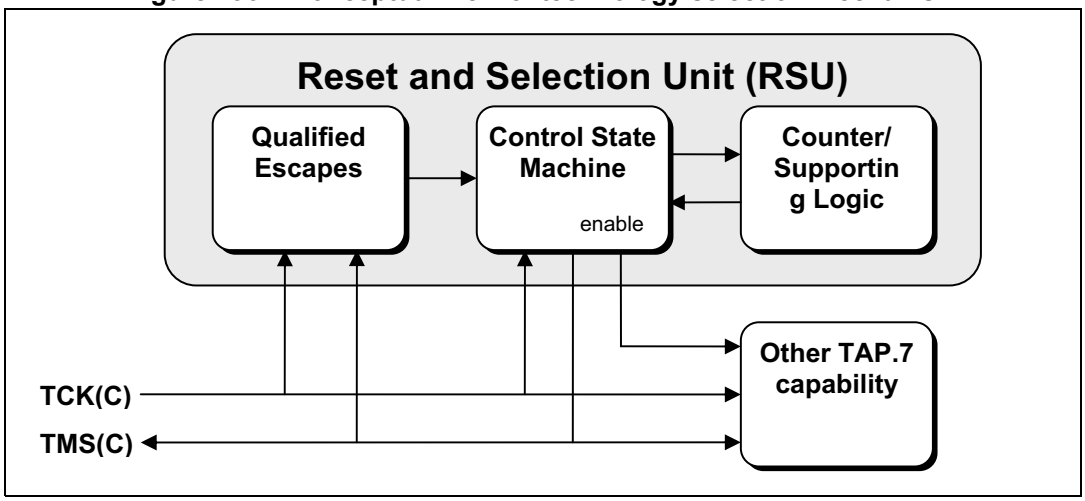
Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine
- The TDIC and TDOC pins are present and provide the TDI and TDO function
- The CLTAPC is coupled at start-up

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 1898. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU



74.5.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

74.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in *Figure 1967*.

Figure 1967. Conceptual view of technology selection mechanism

74.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

74.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset).

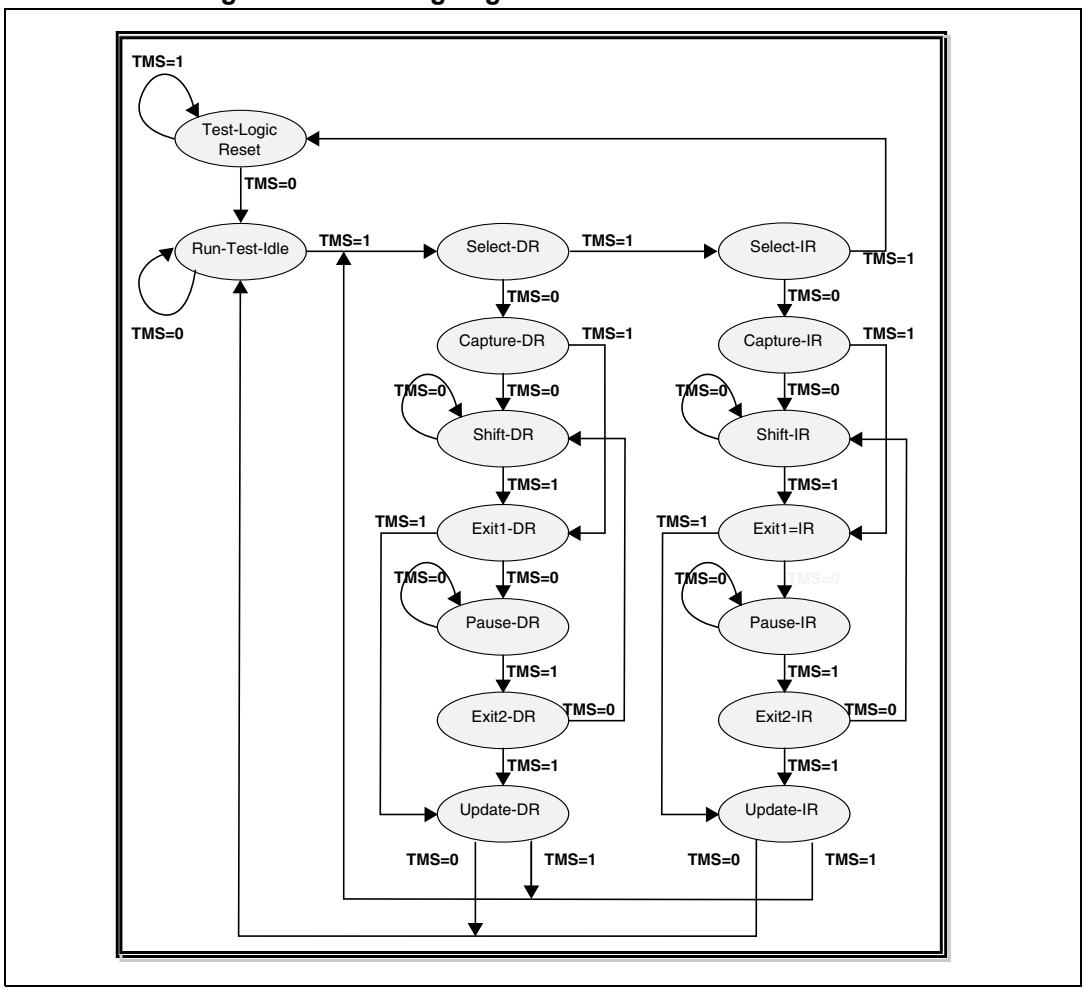
The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

74.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.



74.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occurs with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

74.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 1968. Falling edge TAP controller state machine

74.6 EPU (Extended Protocol Unit) Operation

74.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

74.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

74.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be

incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

74.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

74.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

74.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

74.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

74.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created.
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

74.6.2 EPU Registers

74.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose.

These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

74.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back.

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 1899. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
		1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Options Select	Local Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge

Table 1899. TAP.7 controller register list (managed with commands) (continued)

Register type	Global/ local	Width	Register mnemonic	Name
		32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
Read-only	Local	M = Mandatory register O = Optional register		

74.6.2.3 Registers

74.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

74.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the “System Path” (STL) is used.

- **1** – Suspend use of control levels. Enables “System Path.”
- **0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

74.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- **1** – Inhibit ZBS detection.
- **0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

74.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 1900. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state

Table 1900. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

74.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

74.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance

the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the “Global Register.”

74.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

74.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

74.6.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0x** – TDI and TDO have JTAG function.
- **1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

74.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

74.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

74.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0.

74.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 1901. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format
6:5	2	PWRMODE	Power-control Modes
7	1	FRESET	Functional Reset
8	1	TRESET	Test Reset

Table 1901. RDBACK register format (continued)

Bit	Width	Register Mnemonic	Name
9	1	SGC	Scan Group Candidate
		CGM	Conditional Group Member
11	1	SSDE	Scan Selection Directive Enable
13:12	2	TOPOL	Topology
14	1	SREDGE	Sampling Edge
16:15	2	DLYC	Delay Control
18:17	2	RDYC	Ready Control
20:19	2	APFC	Auxiliary Pin Functional Control
22:21	2	STCKDC	SYS_TCK Duty Cycle
31:23	11	Reserved	Read as a logic 0

74.6.2.3.14 Configuration Register 0 (CNFG0)

Table 1902. Configuration Register 0 Format

Field	Bit #	Width	Name	Description
CNFG (Class)	3:0	4	CLASS[3:0]	TAP.7 Class
				0000 – TAP.1 or TAP.7 Class T0

Field	Bit #	Width	Name	Description
T4 Options	21:20	2	SSCANS[1:0]	x0 – SScan1:0 Unsupported
				x1 – SScan1:0 Supported
				0x – SScan3:2 Unsupported
				1x – SScan3:2 Supported
	24:22	3	OSCANS[2:0]	xx0 – OScan3:2 Unsupported
				xx1 – OScan3:2 Supported
				x0x – OScan5:4 Unsupported
				x1x – OScan5:4 Supported
				0xx – OScan7:6 Unsupported
				1xx – OScan7:6 Supported
	25	1	APFCS	Auxiliary Pin Function Control supported
				0 – Unsupported
				1 – Supported
	26	1	TAPWIDS	TAP Width Default
				0 – 2-pin supported
				1 – 4-pin supported
	27	1	TAPWLCK	TAP Width Locked
				0 – Not locked
				1 – Locked
	28	1	STCKDCS	SYS_TCK Duty Cycle supported
				0 – Unsupported
				1 – Supported
Reserved	31:29	3	Reserved	Reserved, read as zero

74.6.2.3.15 Register reset values

Table 1903. Reset values of TAP.7 controller registers managed with commands

Register type	Width	Register mnemonic	Name	Values for reset type			
				0	1 – 3	4	5
Control	1	ECL	Exit Control Level	0	0	0	NC
	1	SUSPEND	Suspend	0	0	0	
	1	ZBSINH	ZBS Detect Inhibit	0	0	0	
	5	SCNFMT	Scan Format	DF	DF	DF	
	1	SSDE	SSD Enable	0	0	0	
	2	DLYC	Delay control	00	00	00	
	2	RDYC	Ready Control	00	00	00	
Options	1	TRESET	Test Reset	0	0	0	NC
	2	APFC	Aux. Pin Functional Cntl.	DP	DP	NC	
Select	1	CGM	Conditional Group Member	0	0	0	NC
	1	SGC	Scan Group Candidate	DSGM	DSGM	DSGM	
	1	SREDGE	Sampling Rising Edge	0	0	0	
Read-only	32	RDBACK0	Read-back 0	N/A	N/A	N/A	N/A
	32	CNFG0	Configuration Register 0				

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

74.6.3 EPU Commands

There are two command types:

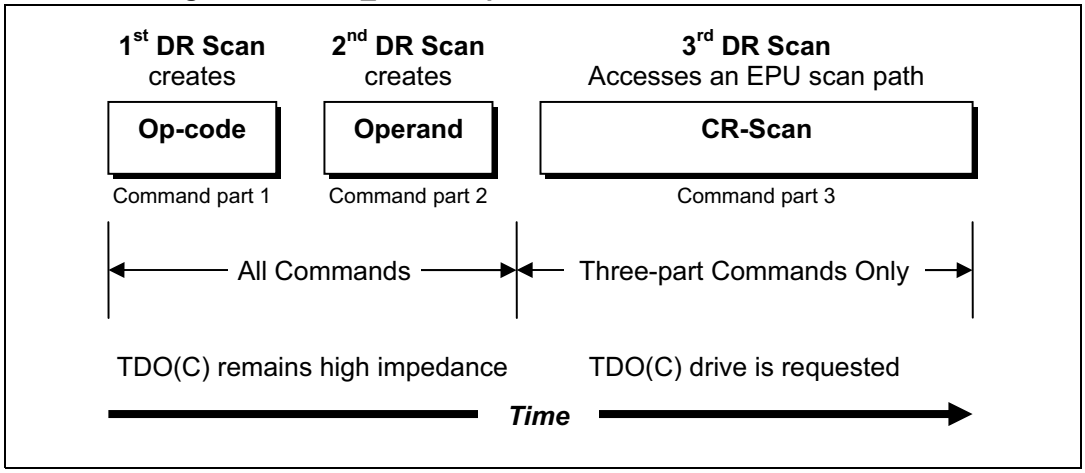
- Two-Part Commands
- Three-Part Commands

Any number of two-part and three-part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

74.6.3.1 Two-Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two).

The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.



74.6.3.2 Three-Part Commands

Some commands are used to send or receive, or both, data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

74.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in *Figure 1969*.

Figure 1969. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two-part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two-part commands, but only 3 three-part commands, each having a special purpose.

74.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in *Table 1904*.

Table 1904. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate(1)	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

74.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

74.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

74.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

74.6.3.5 Command Definitions

74.6.3.5.1 Store Commands

74.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 1905. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	Operand	bbb		x	y	Description
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	—	SGC = y
				1	—	CGM = y
		010	RdyCtl	-	—	RDYC = xy
		011	DlyCtl	-	—	DLYC = xy
		100	ScnFunc	0	—	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	—	—	Reserved
		110		—	—	
		111		—	—	

74.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 1906. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	—	SREDGE = v
			001	—	Reserved
			010	—	TRESET = v
			011 – 111	—	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

74.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 1907. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	Operand	c	bb	CAPE	Description
00010	c bb vv	0	00	—	Reserved
			01	—	STCKDC = vv
			10	—	APFC = vv
			11	—	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

74.6.3.5.1.4 Store Scan Format (STFMT)

Table 1908. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

74.6.3.5.2 Select Commands

74.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 1909. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

74.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 1910. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

74.6.3.5.3 Scan Commands

74.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 1911. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

74.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

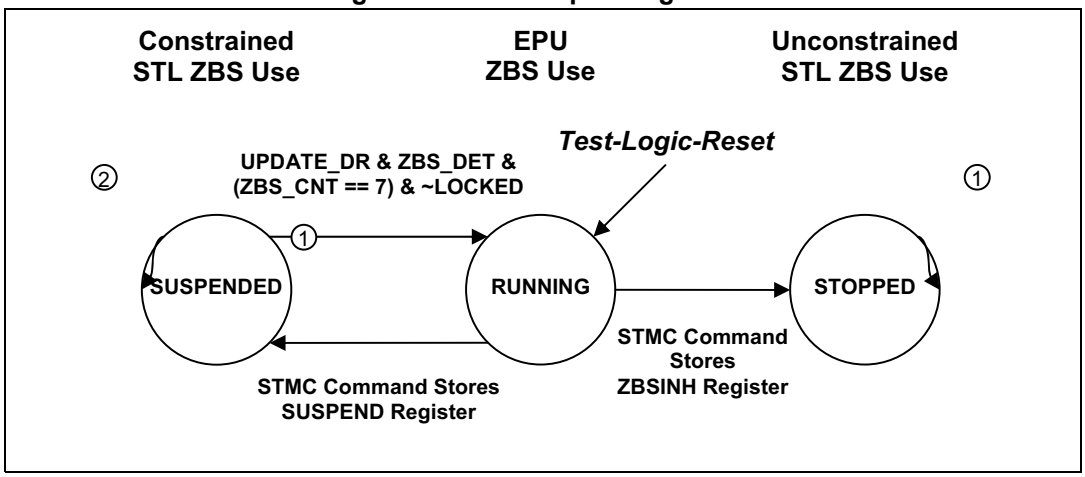


Table 1912. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

74.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in *Figure 1970*.

Figure 1970. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in *Table 1913*. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 1913. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

74.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path.
- **Bit** – Supports set and test bit operations (a 1-bit shift register).
- **String** – Support 32-bit reads or 32-bit writes.
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s.
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

74.7 APU (Advanced Protocol Unit) Operation

74.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

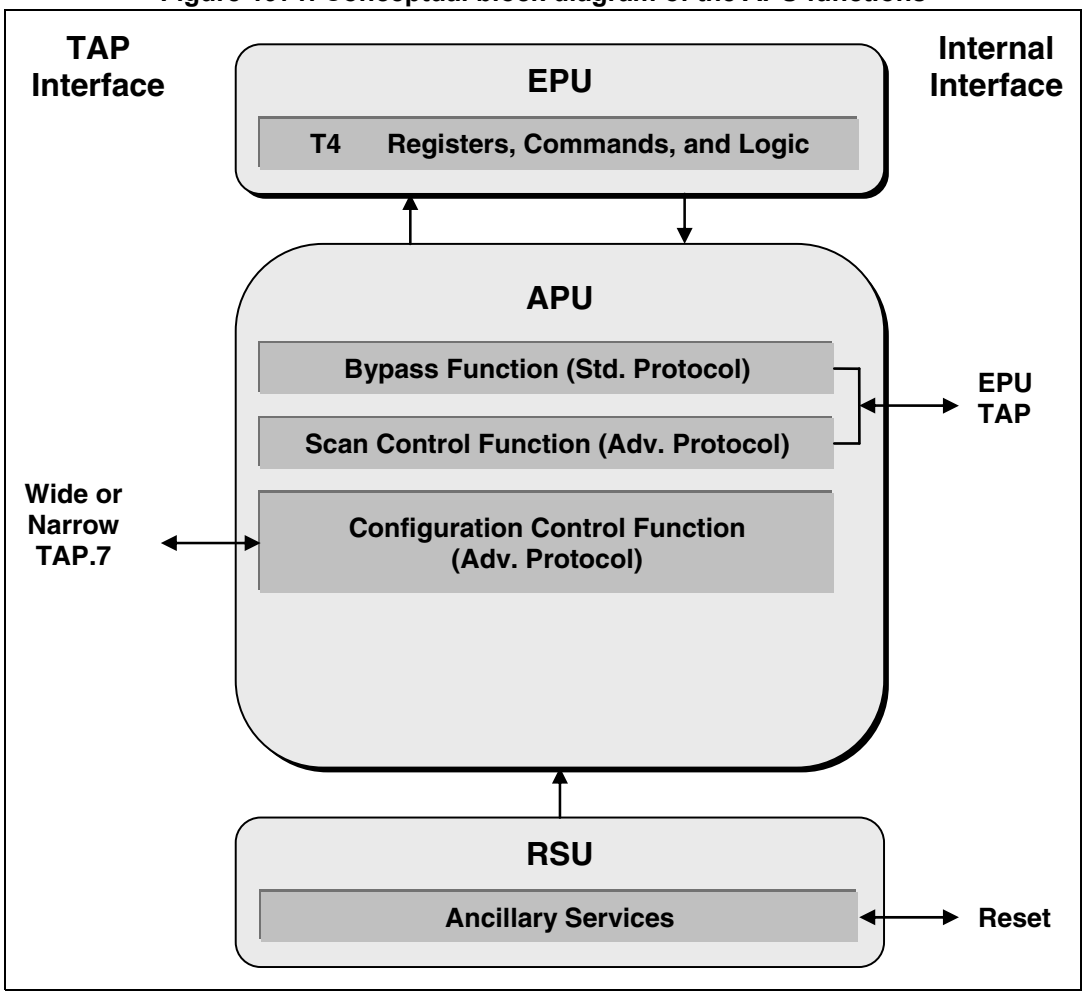
The entire EPU infrastructure (that is, ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.



The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

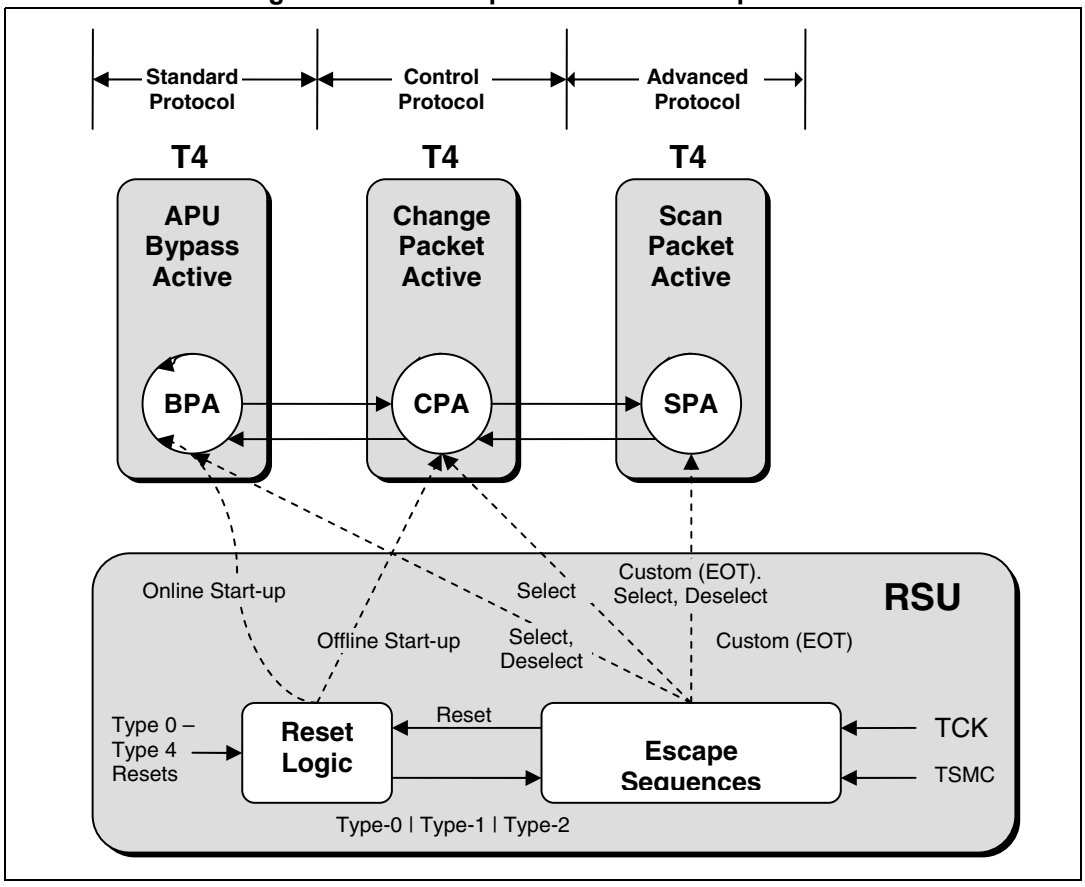
- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 1971. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function



When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

74.7.2 Operation

The conceptual view of the APU operation is shown in *Figure 1972*.

Figure 1972. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

74.7.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

74.7.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

74.7.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

74.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

74.7.4 Signal behaviors

The TCKC signal:

- The test clock

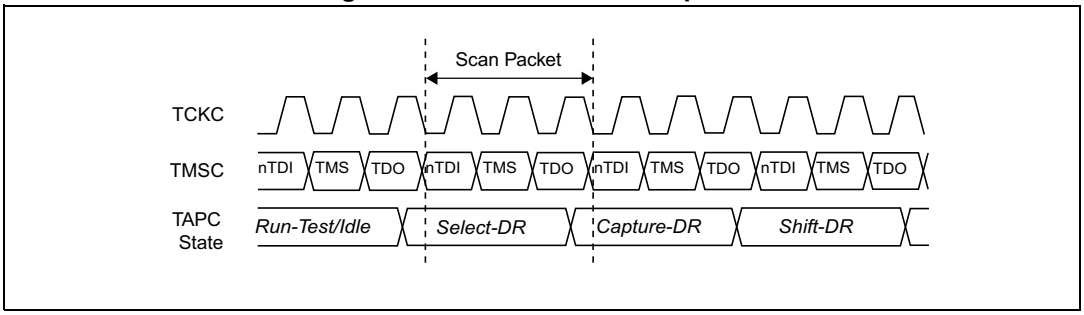
The TMSC signal:

- An input when the Standard Protocol is used
- Bidirectional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

74.7.5 APU Functions



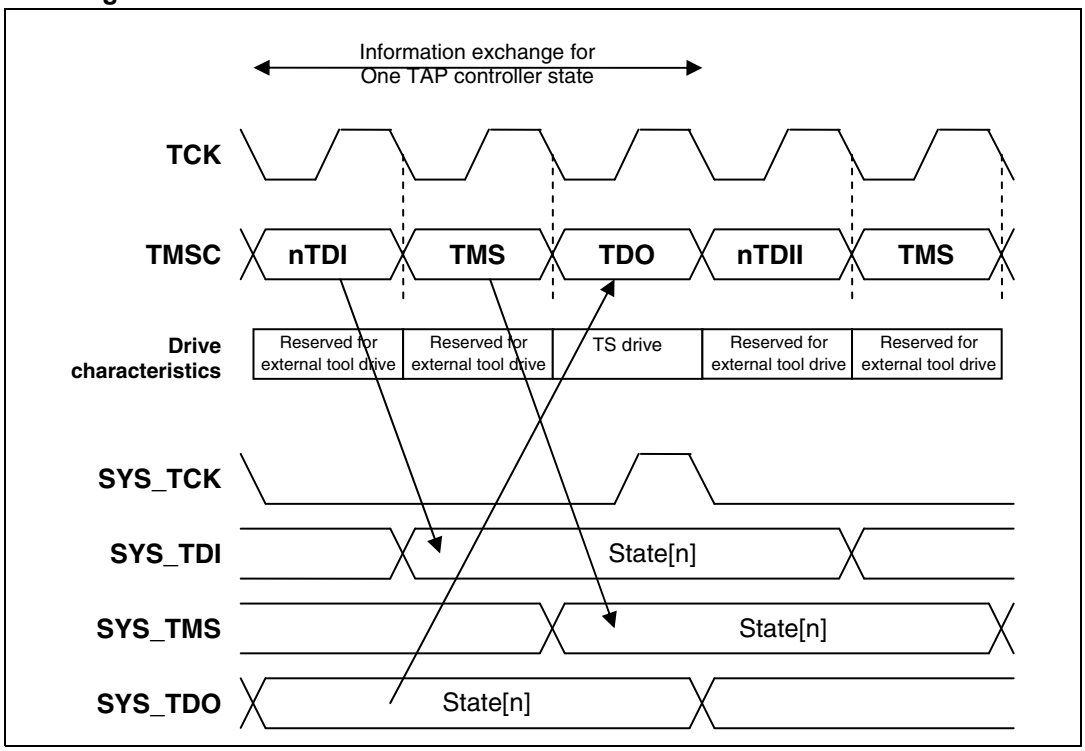
74.7.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (for example, a narrow TAP.7, or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

74.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in *Figure 1973*. There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 1973. Scan Packet sequence



A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

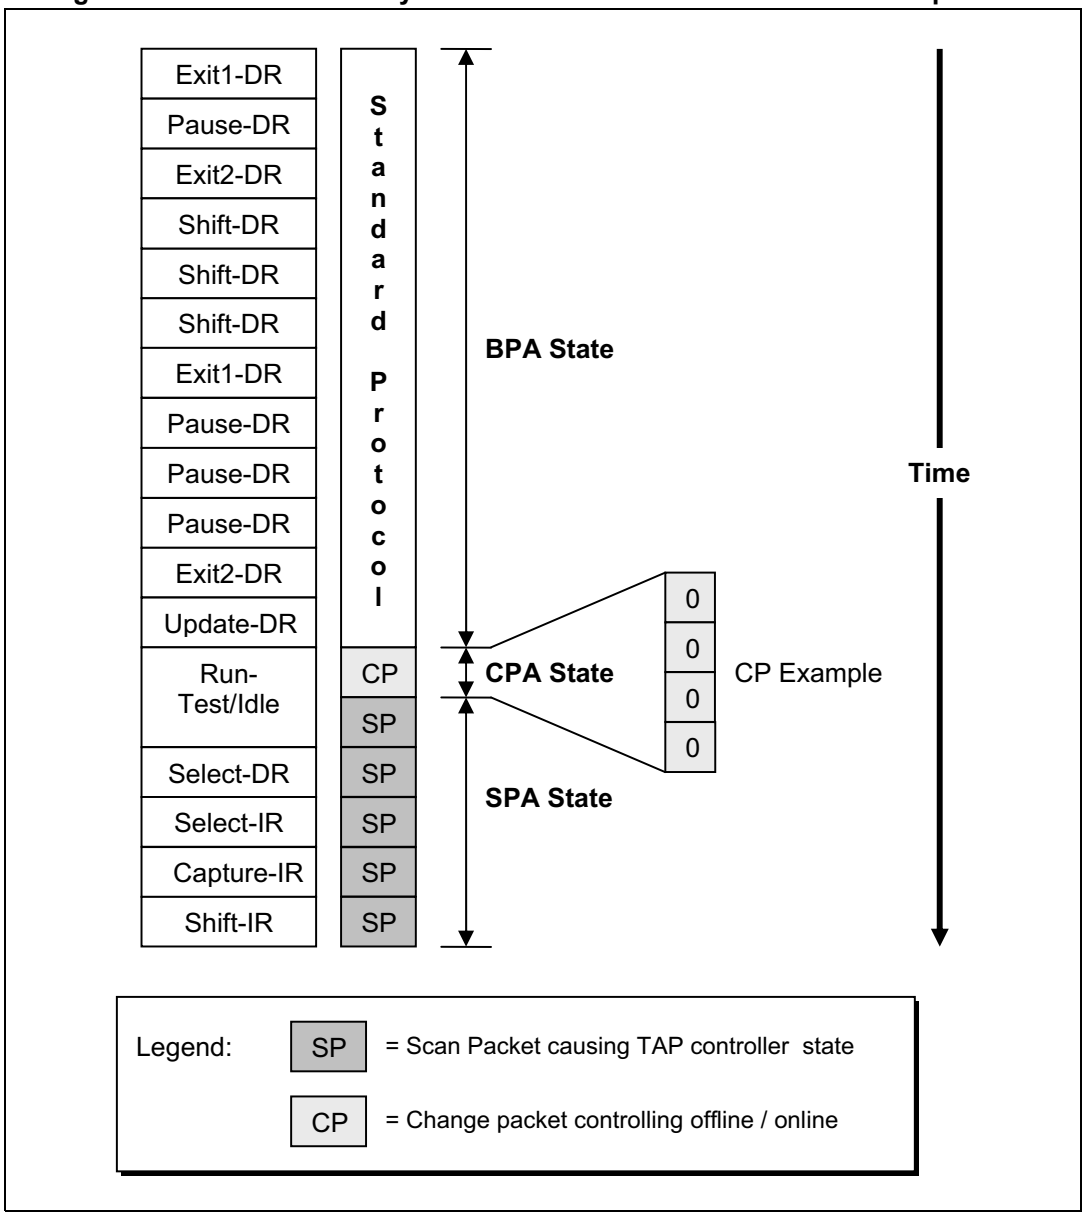
Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 1974. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats).

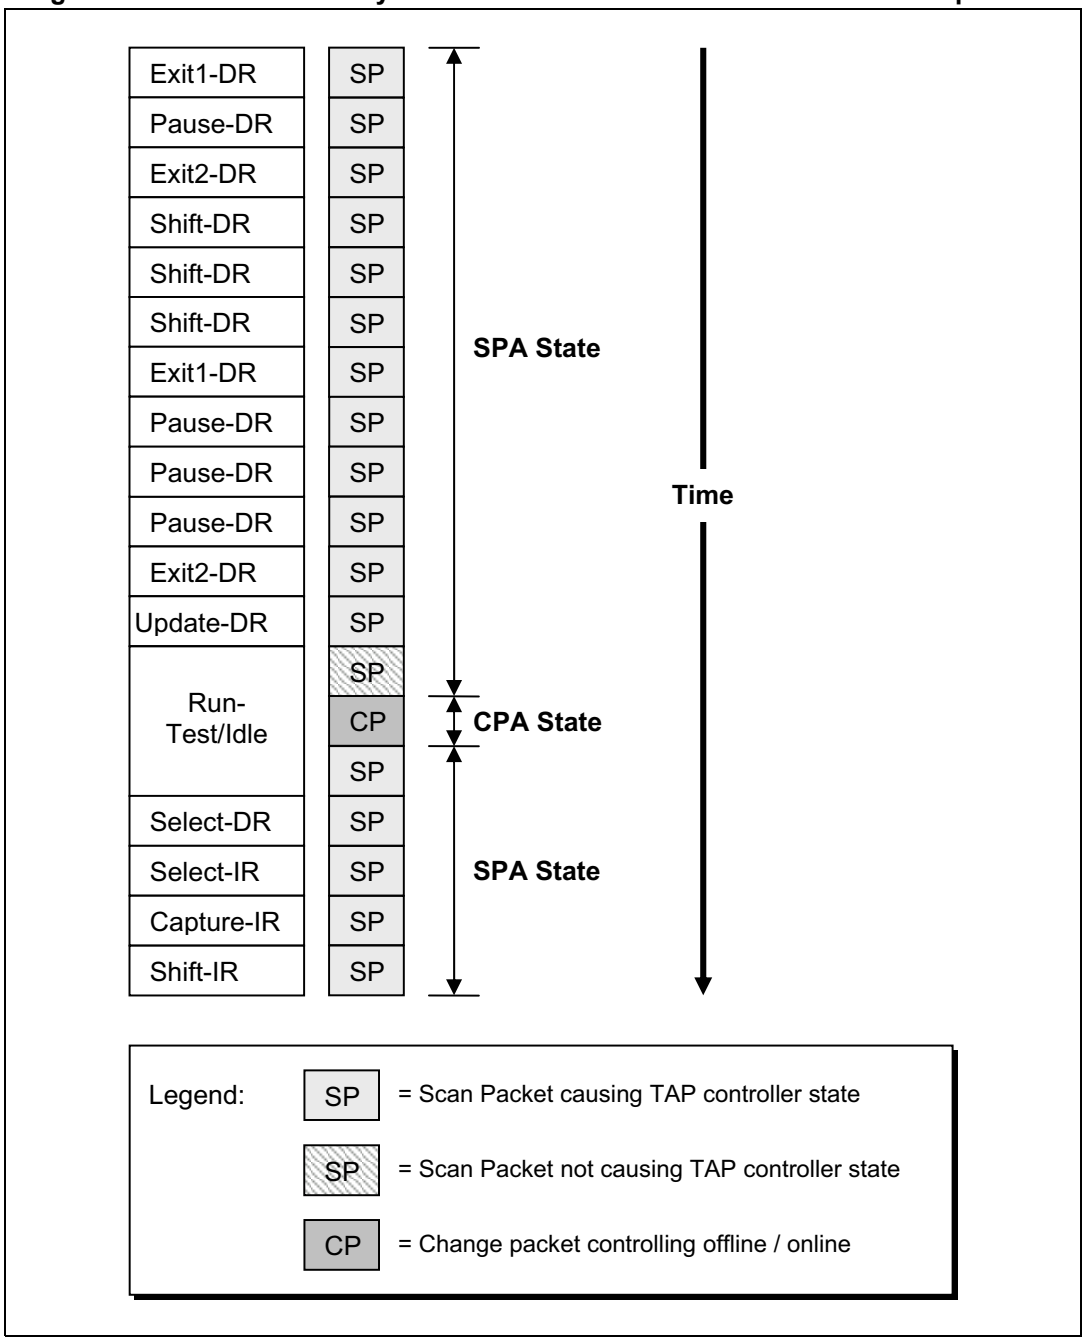
The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.



With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

74.7.5.3 Control Process Active (CPA) Function



While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

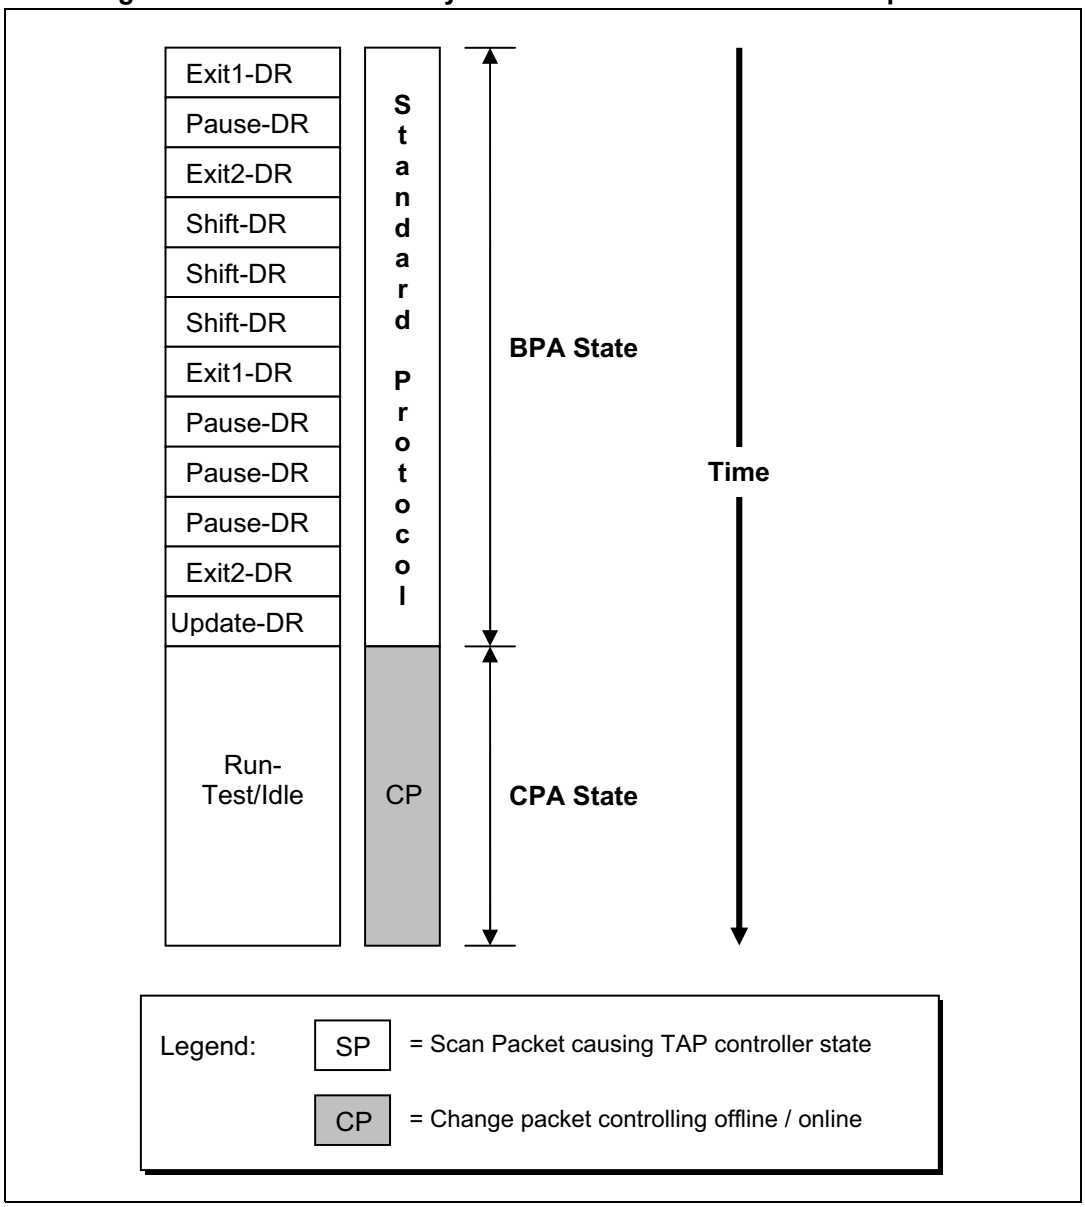
Figure 1975. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 1976. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 1977. CPA State Entry from the BPA State with Offline Operation



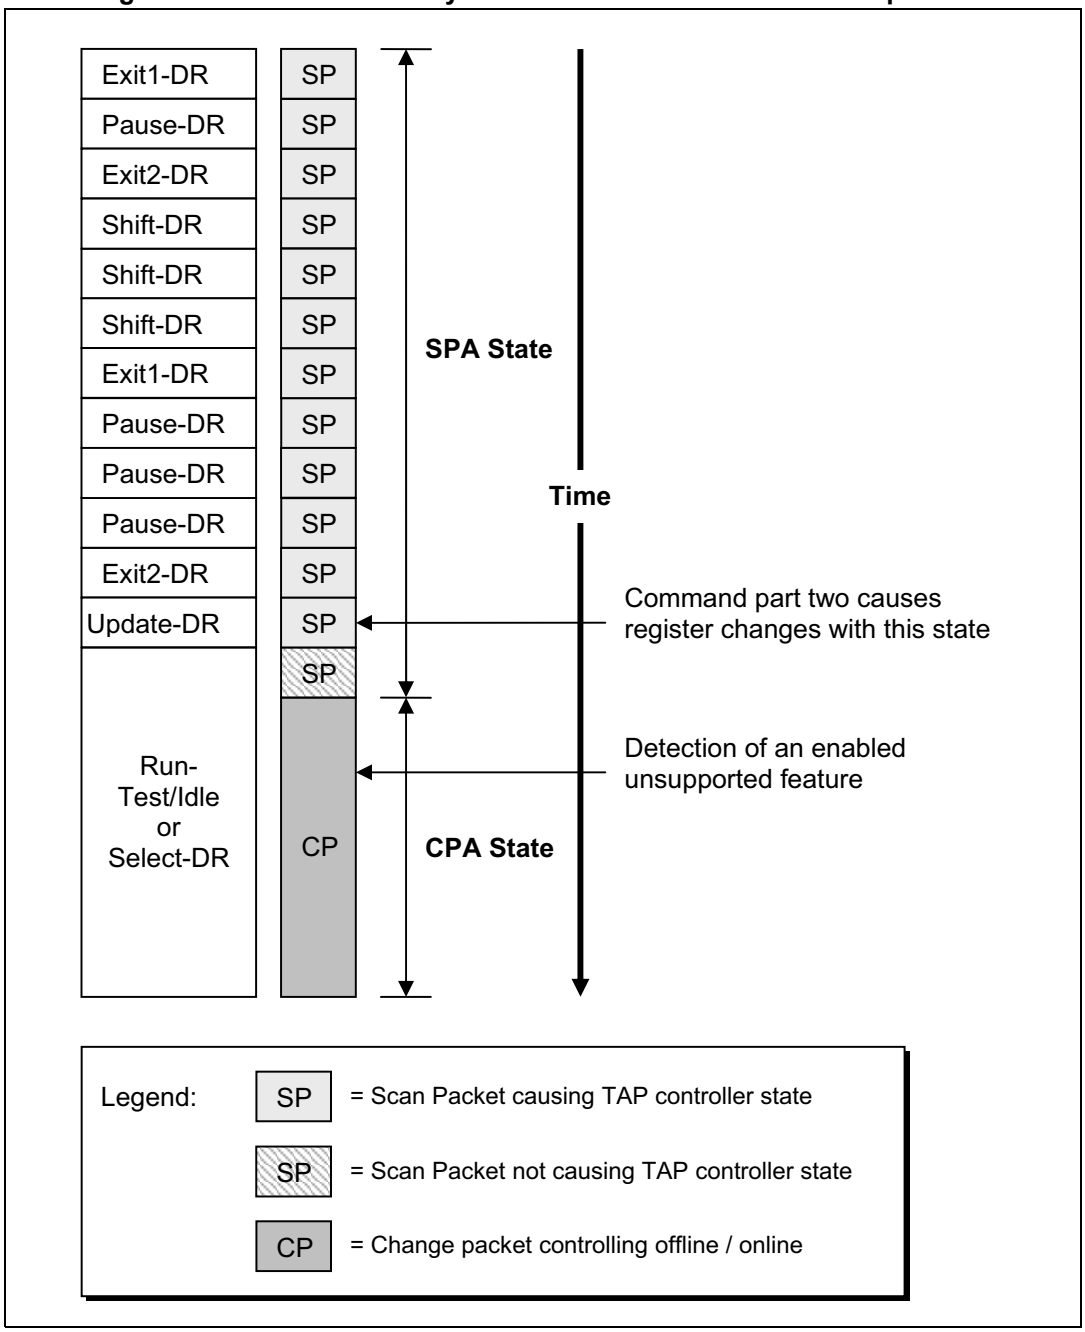


Figure 1978. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

74.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives:
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit)
- **Post amble** – A 1-bit value that is a don't care. This bi t facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

74.7.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof).
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

74.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

74.7.8.1 Payload Element Content

74.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

74.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in *Table 1914*.

Table 1914. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

74.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

74.7.8.3 Scan Formats

74.7.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in *Table 1915* and *Table 1917*, respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

74.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

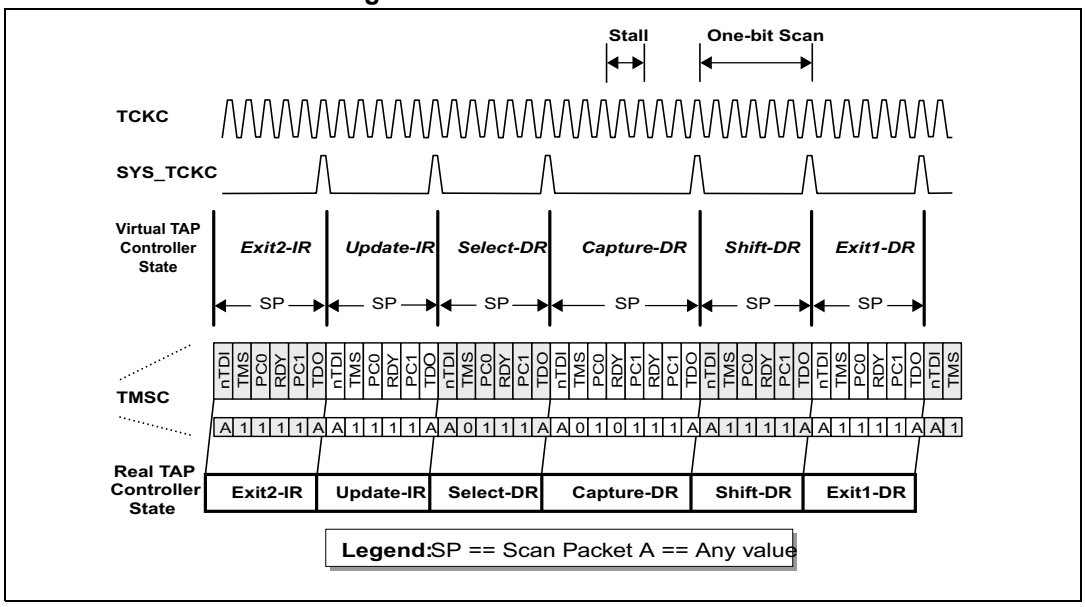

Table 1915. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 1916. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

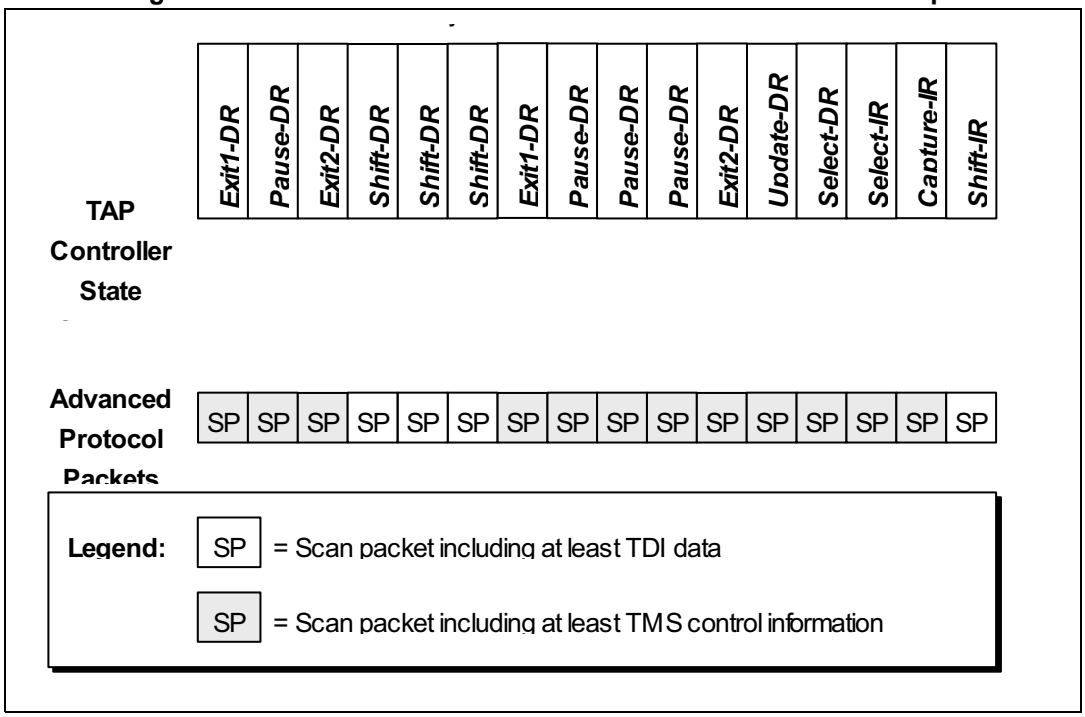

Figure 1979. MScan Transaction

74.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 1980. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in *Table 1917*.

Table 1917. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 1918. OScan Scan Format "Payload"

74.8 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

74.8.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in *Section 74.6.1.4: Control levels*.

After the control level is set to control level 2, TAP.7 commands can be executed as described in *Section 74.6.3: EPU Commands*. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in *Section 74.7.5.3: Control Process Active (CPA) Function* and *Section 74.7.6: Configuration Change Packets (CP)*. Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in *Section 74.6.3.5.1.3: Store Conditional 2-bit (STC2)*.

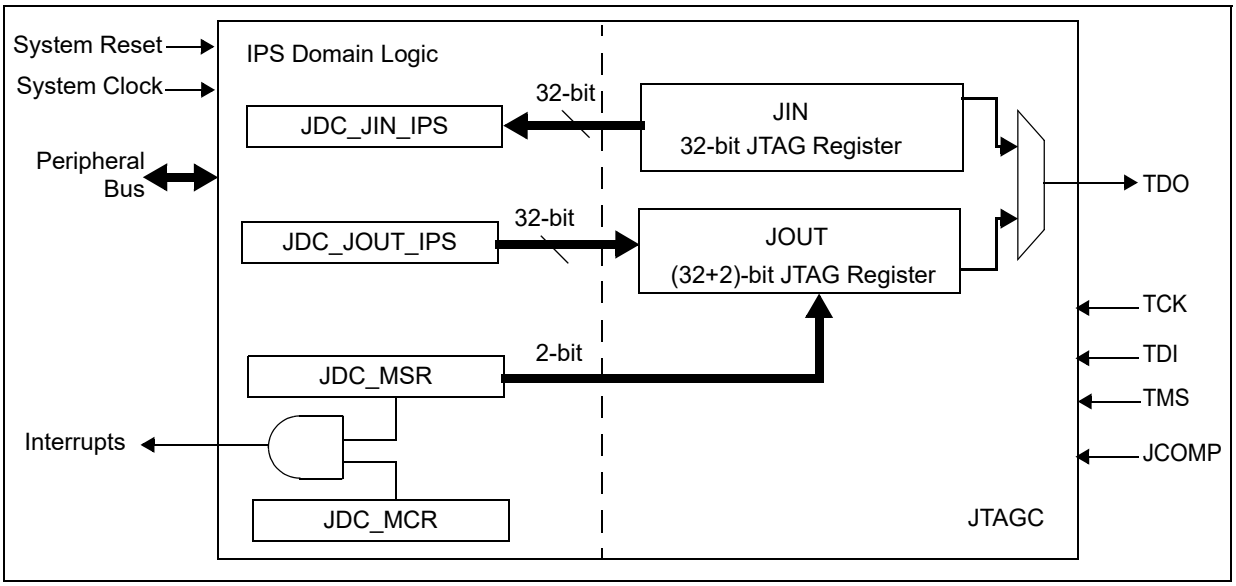
75 JTAG Data Communication (JDC)

75.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

75.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.



The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 1981*.

Figure 1981. JDC block diagram

75.3 Register definition

Table 1919 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1919. JDC memory map

Address offset	Register	Access	Reset value	Location
0x0	Module Configuration Register (JDC_MCR)	R/W	0x0000_0000	*Section 75.3.1.1*

Figure 1984. JDC_JOUT_IPS register

The JDC_JOUT_IPS register is described in *Table 1922*.

Table 1922. JDC_JOUT_IPS register field descriptions

Field	Description
0:31 DATA	Contains JOUT_IPS data.

75.3.1.4 JTAG input IPS data register (JDC_JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JDC_JIN_IPS register, where it can be read via IPS. *Figure 1985* shows the format of the JDC_JIN_IPS register. This register is reset by system destructive reset.

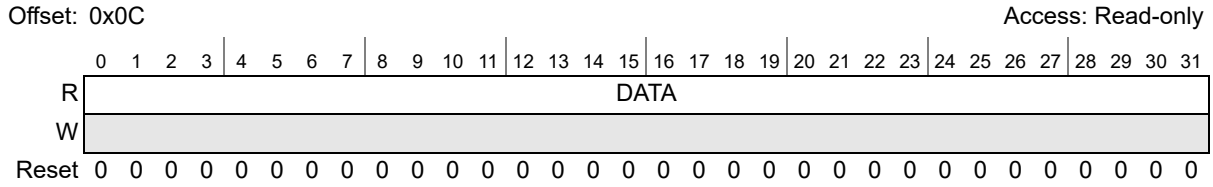

Figure 1985. JDC_JIN_IPS register

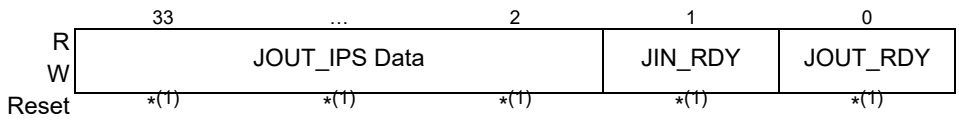
The JDC_JIN_IPS register is described in *Table 1923*.

Table 1923. JDC_JIN_IPS register field descriptions

Field	Description
0:31 DATA	Contains JIN_IPS data.



75.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

75.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JDC_JIN_RDY and JDC_JOUT_RDY status bits. *Figure 1986* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

Figure 1986. JOUT JTAG register

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in *Table 1924*.

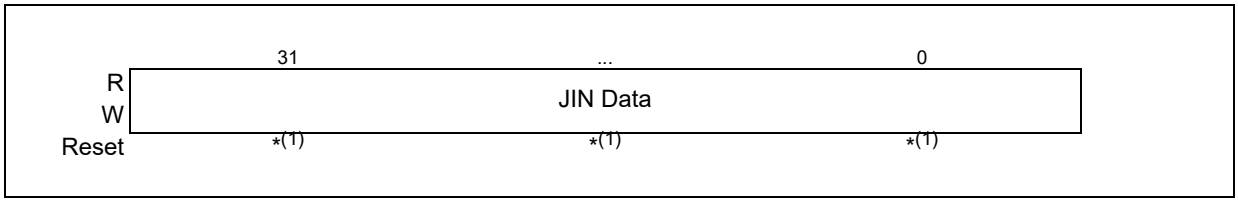


Table 1924. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

75.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 1987* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

Figure 1987. JIN JTAG Register

1. The reset value of the JIN register is 32'b0.

The JIN register is described in *Table 1925*.

Table 1925. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JDC_JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

75.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data

is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

75.4.1 IPS register access

IPS access is available to the registers described in *Section 75.3.1*.

75.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

75.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 1926*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1926. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

75.5 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The JDC_MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate

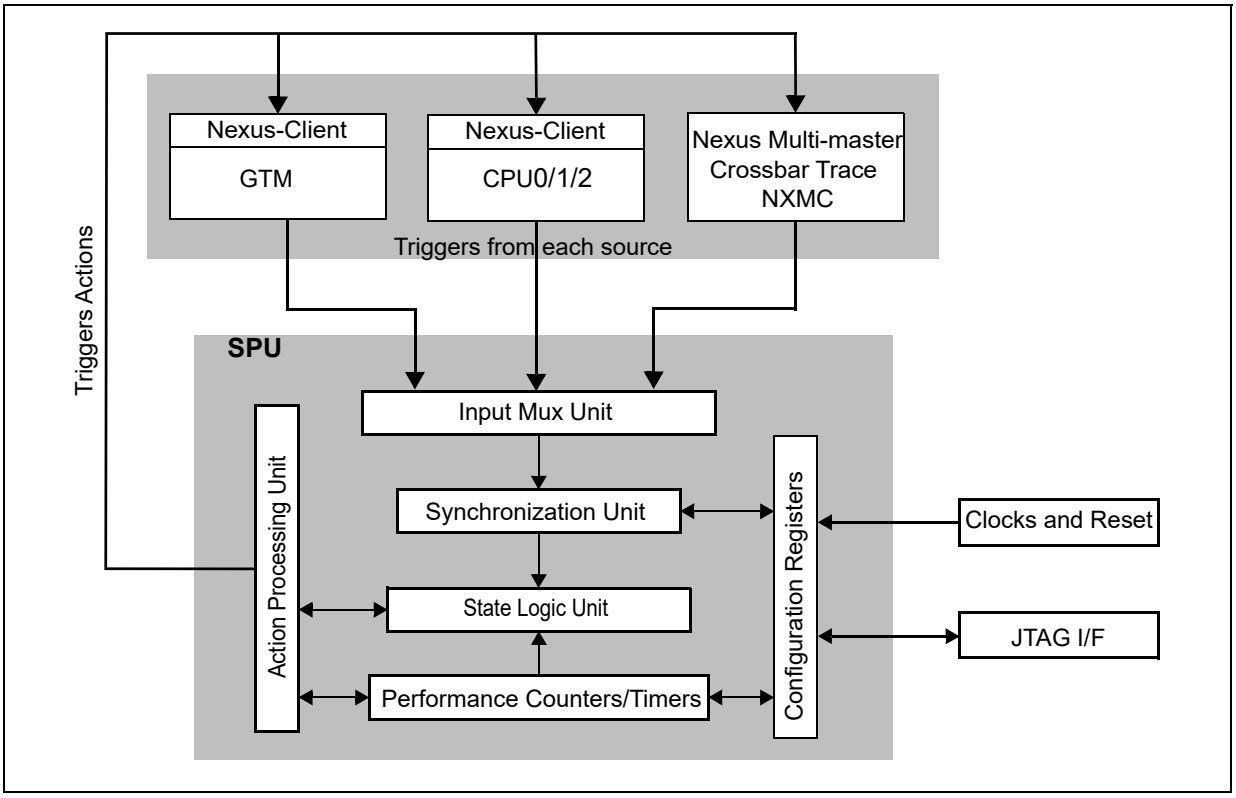
the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the JDC_MCR[JOUT_IEN] is set.

7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

76 Sequence Processing Unit (SPU)

76.1 Introduction



The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores, GTM, or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

76.1.1 SPU block diagram

Figure 1988 shows a top-level block diagram of the SPU.

Figure 1988. SPU block diagram

76.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, GTM, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 2027*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 2028*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 2029* and *Figure 2030*. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU writes to VariableB. If CPU writes a value to VariableB which is 0x100, then enable trace for the GTM and halt CPU.

The SPU consists of the following sub-blocks:

- Input Mux Unit: receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 2027*.
- State Logic Units (SLU): responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan's law, allows for generalized signal combinations. This is shown in *Figure 2028*.
- Action Processing Unit: takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers: the SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

76.1.3 Features

The features of the SPU are as follows:

- clients:
  - 3 CPUs
  - 1 GTM
  - 2 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics

  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
  - Access to timer/counter values via JTAG
- Prescaler for timer mode only
  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from GTM
  - SPU to/from NAR
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces
  - CPU
  - GTM
  - System bus
  - NAR
  - DCI
- Configuration registers: 32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions: SPU block triggers various actions based on the derived events, these actions are defined in *Section 76.2*.

76.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Halt1: single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2: single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Single interrupt for INTC to interrupt a CPU: de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin: output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source: Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals): four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

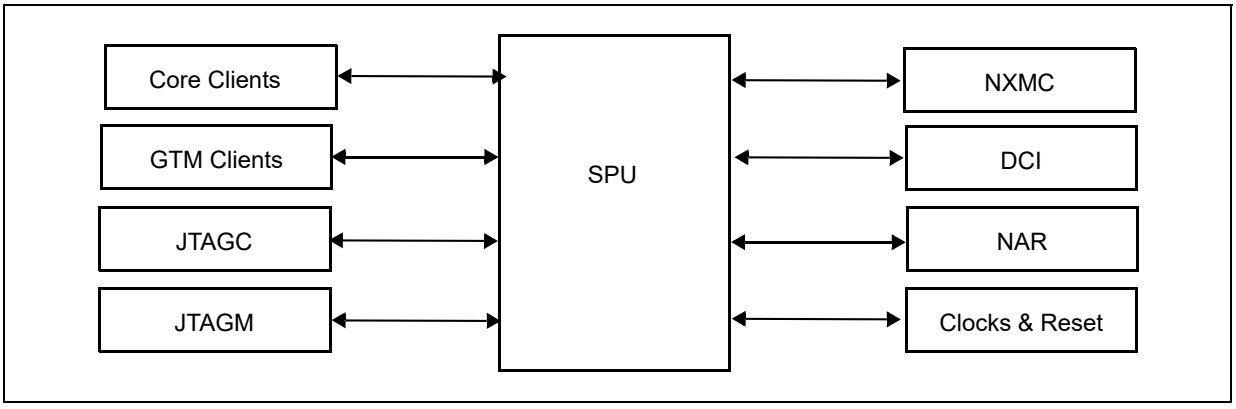
In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

76.3 Operation mode

76.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:



- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

76.4 SPU module interface

The SPU is connected to many clients such as the cores, GTM, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 1989*.

Figure 1989. SPU module interface

76.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 1927 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x01–0x49) registers is 4'h3.
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x01–0x72) is 4'h2.

76.5.1 Registers description

76.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 2027*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

76.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 1990 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see Calibration and Debug (or Debug and Trace) chapter that describes how the modules are configured.

Field	Description
24:31 CPU2	CPU2 Priority Interrupt Selection

76.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 76.5.1.1: Level1 input Mux configurations registers*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 2027* for State0. Similar logic is provided for States 1 to 7.

Figure 2006. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

76.5.1.2.1 Level2 Mux state n selection 0 (L2nSEL0)

Figure 2007 shows the format of the L2nSEL0 register where the state number, n = 0 to 7.

76.5.1.3 Sequence unit registers

76.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 2011* shows the format of the IOICn register where the state number, n = 0 to 7.

Offset: 0x37 n*0x1 (n=0 to 7) Access: Read/Write

76.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 2012* shows the format of the SCTRL register.

Offset: 0x3F Access: Read/Write

Table 1941. SCTRL register field descriptions (continued)

Field	Description
25:27 S1ST2	Sequence 1 End State 000 State 0 is the Stop state for sequence 1 001 State 1 is the Stop state for sequence 1 010 State 2 is the Stop state for sequence 1 011 State 3 is the Stop state for sequence 1 100 State 4 is the Stop state for sequence 1 101 State 5 is the Stop state for sequence 1 110 State 6 is the Stop state for sequence 1 111 State 7 is the Stop state for sequence 1
28:30 S1ST1	Sequence 1 Start State 000 State 0 (Always)
31 S1ST0	Sequence1 Enable/Disable(2) Once enabled, this bit is disabled at the end of the Sequence 1. 0 Sequence 1 is disabled 1 Sequence 1 is enabled

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.
2. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.

76.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 2013 shows the format of the SnGC register where the state number, n = 0 to 7.

Offset: 0x40 +n*0x1 (n= 0 to 7) Access: Read/Write

Figure 2013. State n goto control (SnGC)

The SnGC register fields are described in *Table 1942*.

Table 1942. SnGC register field descriptions

Field	Description
24:26 NF	Next State on False Condition Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
27 FE	GOTO Control of State Under False Condition Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5]. If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition. 0 Disable Goto control 1 Enable Goto control
28:30 NT	Next State on True Condition Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
31 TE	GoTo Control of State Under True Condition Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition. 0 Disable Goto control 1 Enable Goto control

76.5.1.4 SLU status register (SS)

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. *Figure 2014* shows the format of the SS register.

Figure 2015. SPU enable register (SE)

The SE register fields are described in *Table 1944*.

Table 1944. SE register field descriptions

Field	Description
30 DIV	Div Option Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required
31 SED	SPU Enable/Disable This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled

Note: Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

76.5.1.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

76.5.1.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example, if there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

76.5.1.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in *Section 76.2*.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in *Section 76.2*, becomes redundant with Div4 option.

76.5.1.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 76.2*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 1945* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 1945. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

76.5.1.7.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a true condition of every state. All the possible actions and their encoding are listed in *Table 1945*. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

Figure 2016 shows the format of the SnTA0 register where the state number, n = 0 to 7.

76.5.1.7.3 State n false action 0 (SnFA0)

The SPU can be programmed to enable up to four different actions against a false condition of every state. All the possible actions and their encoding are listed in *Table 1945*. A total of 12 bits are needed to code every action. The first two actions for a false condition are defined in SnFA0 and the next two actions are defined in SnFA1. *Figure 2018* shows the format of the SnFA0 register where the state number, n = 0 to 7.

76.5.1.7.5 Trace group configuration registers (DTMTGC, PTMTGC, OTMTGC, WTMTGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace: clients are configured with the DTM trace group configuration (DTMTGC) register
- PTM trace: clients are configured with the PTM trace group configuration (PTMTGC) register
- OTM trace: clients are configured with the OTM trace group configuration (OTMTGC) register
- WTM trace: clients are configured with the WTM trace group configuration (WTMTGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 2020 shows the format of the trace group configuration registers.

Offset: 0x21 (DTMTGC)

76.5.1.7.6 Interrupt status (INTS)

The status of the external interrupt request to the processor core through the JTAGM is registered in the Interrupt status (INTS) register. This status bit is cleared when the acknowledge is received from the JTAGM. *Figure 2021* shows the format of the INTS register.

Offset: 0x25 Access: Read/Write

23	Reserved. This bit is for internal use only and must be set to 0.
24 SW_RESET	Reset Counter can be reset by software. 0 Software reset is disabled 1 Software reset
25:27 PRESCALING	Prescaling Divides the timer clock by a defined value. 000 No scaling, divide by 1 001 Divide by 4 010 Divide by 16 011 Divide by 32 100 Reserved 101 Reserved 110 Reserved 111 Reserved
29 COUNT_INCR	Count Increment 0 Increment the counter based on the actions generated from the sequences 1 Increment the counter based on the PMC input. The mapping of the PMC inputs with the counters is shown in *Figure 2034*.
30 MODE	Mode Select Select counter or timer operation. 0 Counter 1 Timer
31 ENABLE	Enable 0 Counter disabled 1 Counter enabled

76.5.1.9 Counters compare n registers (CCMPn)

A 32-bit comparator value can be programmed for each of the counters. This value is compared with the corresponding counter/timer to generate an event for the SPU. *Figure 2023* shows the format of the CCMPn registers where the counter number, n = 0 to 15.

Offset: 0x36 + n*0x1 (n = 0 to 15) Access: Read/Write

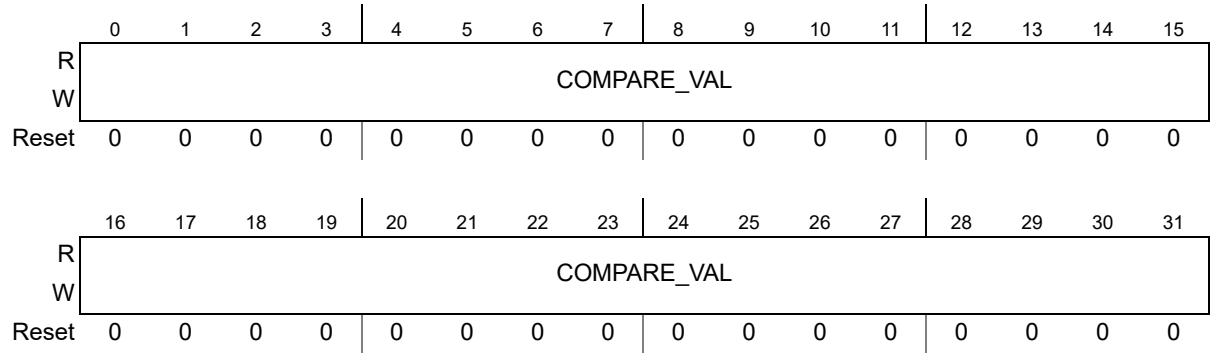

Figure 2023. Counters compare n registers (CCMPn)

The CCMPn register fields are described in *Table 1953*.

Table 1953. CCMPn register field descriptions

Field	Description
0:31 COMPARE_VAL	Compare value This value is compared with the corresponding counter/timer value to generate an event for the SPU.

76.5.1.10 Status registers

76.5.1.10.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. *Figure 2024* shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in *Table 1954*.

Note: Counter compare values and other settings are not recommended to change dynamically, so w1c on CCOMS should be performed in either condition:

- *Counter is in disabled state (ENABLE bit of CCTRLn set to 0)*
- *SW-Reset bit (SW_RESET) is set*

76.5.1.10.3 Counter capture status (CCAPS)

Whenever a counter value is captured, the corresponding capture status register bit for that counter is set. If the counter capture value causes a FIFO overflow, the captured value is lost and the status bit is not set. The bits in this register can be cleared by writing a 1 to them. *Figure 2026* shows the format of the CCAPS register.

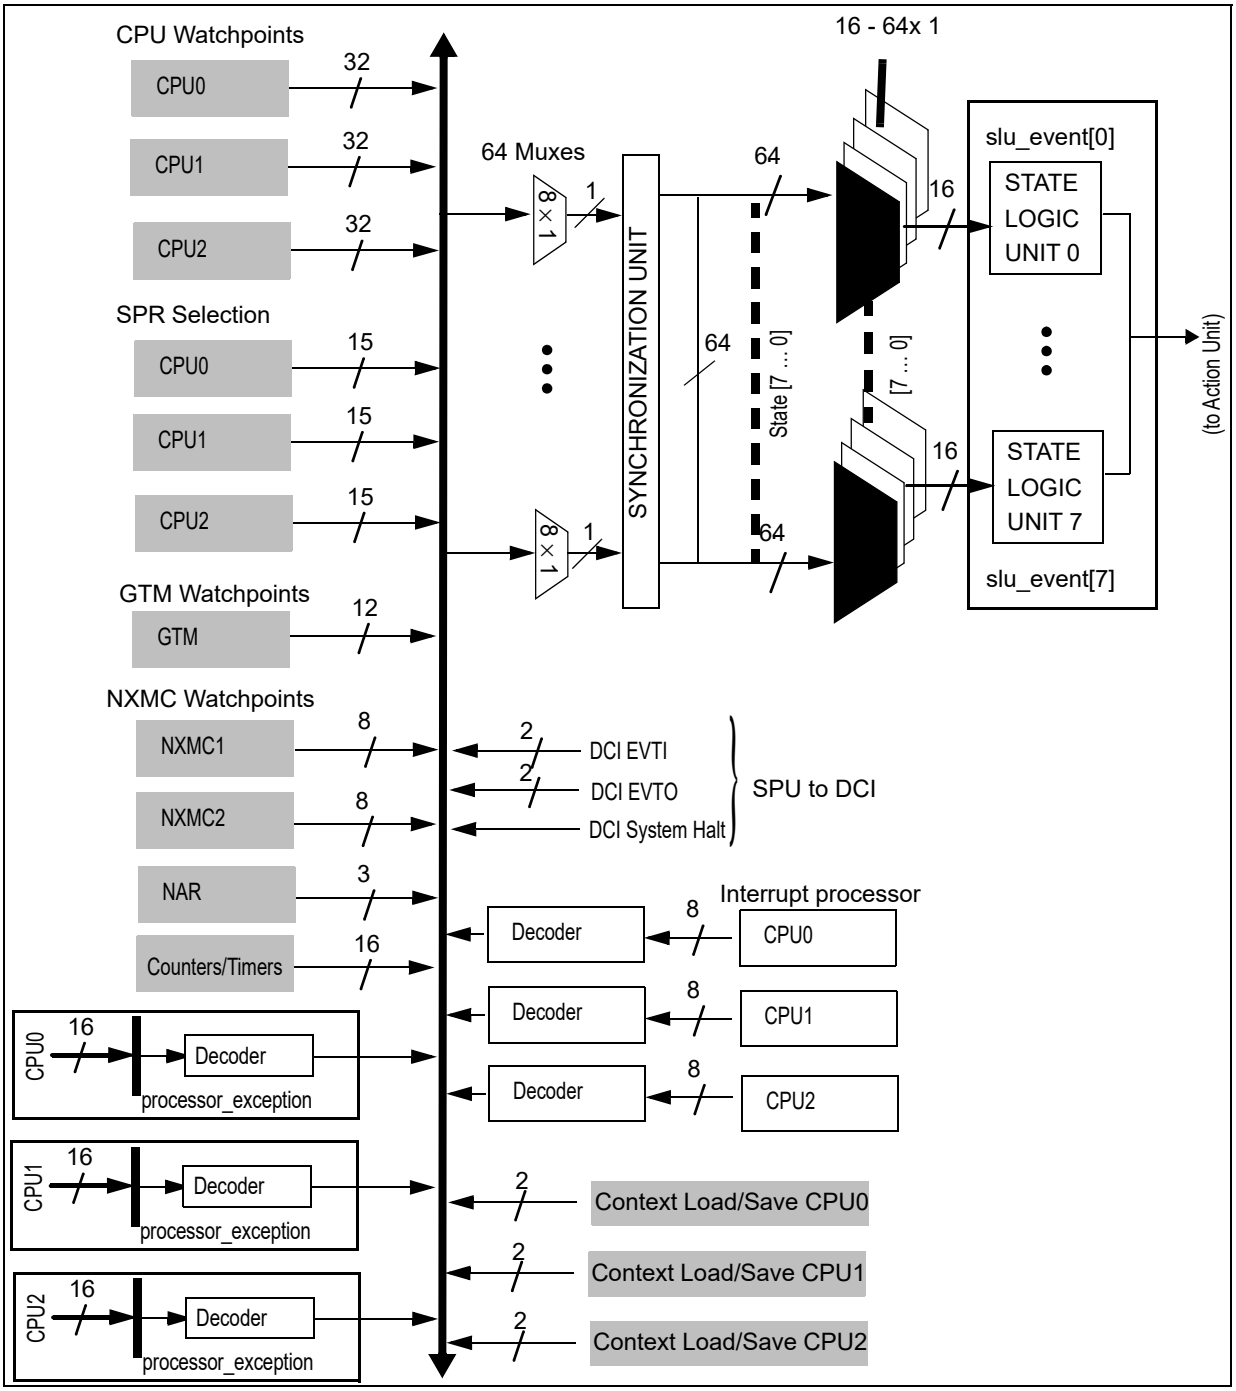
76.6 Functional description

76.6.1 Input Mux unit



The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client

input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in *Figure 2027*.

- Level 1 Muxing: At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 2027*.
- Level 2 Muxing: At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.
  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16×8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 2027*.

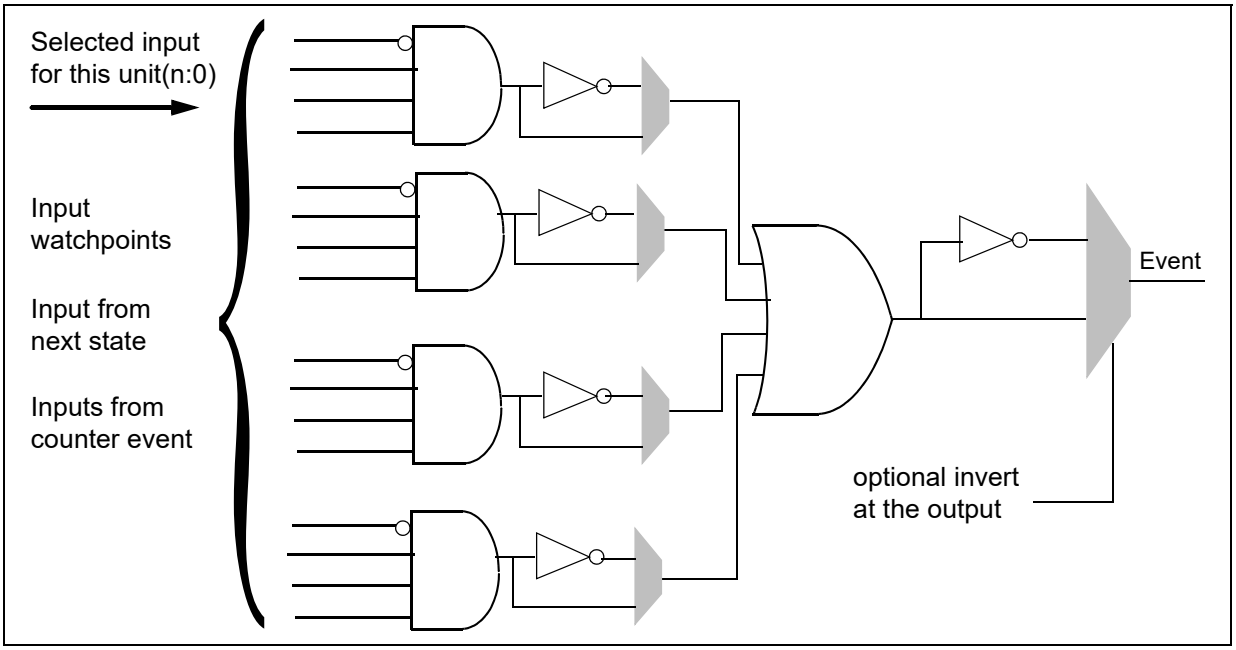
Figure 2027. Input Mux unit block diagram

76.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input

condition as shown in *Table 1957*. The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0 to 2) registers as shown in *Table 1957*.

Table 1957. Processor exception processing conditions



CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input: autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input: autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input: vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input: vectored

76.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 2028*.

Figure 2028. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

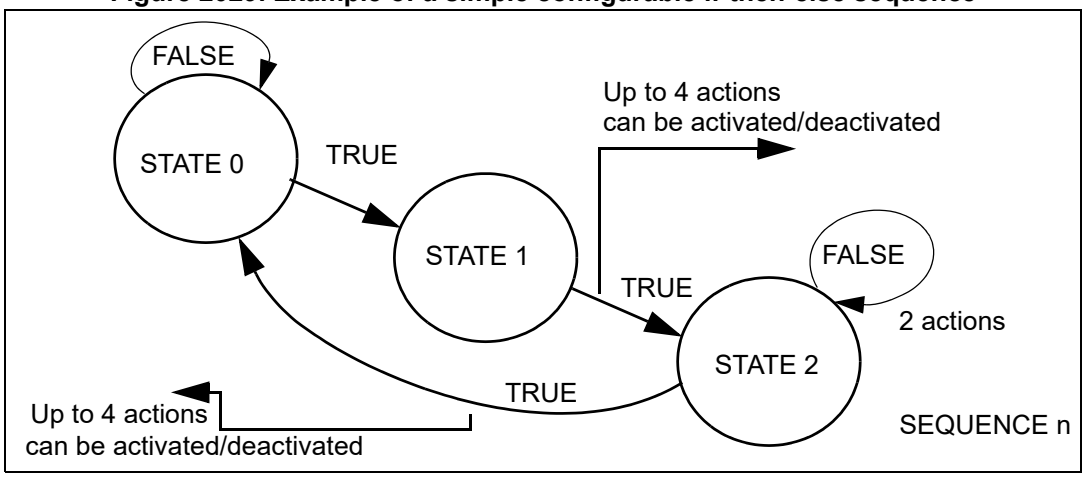
An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

76.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.



For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 2029*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic.

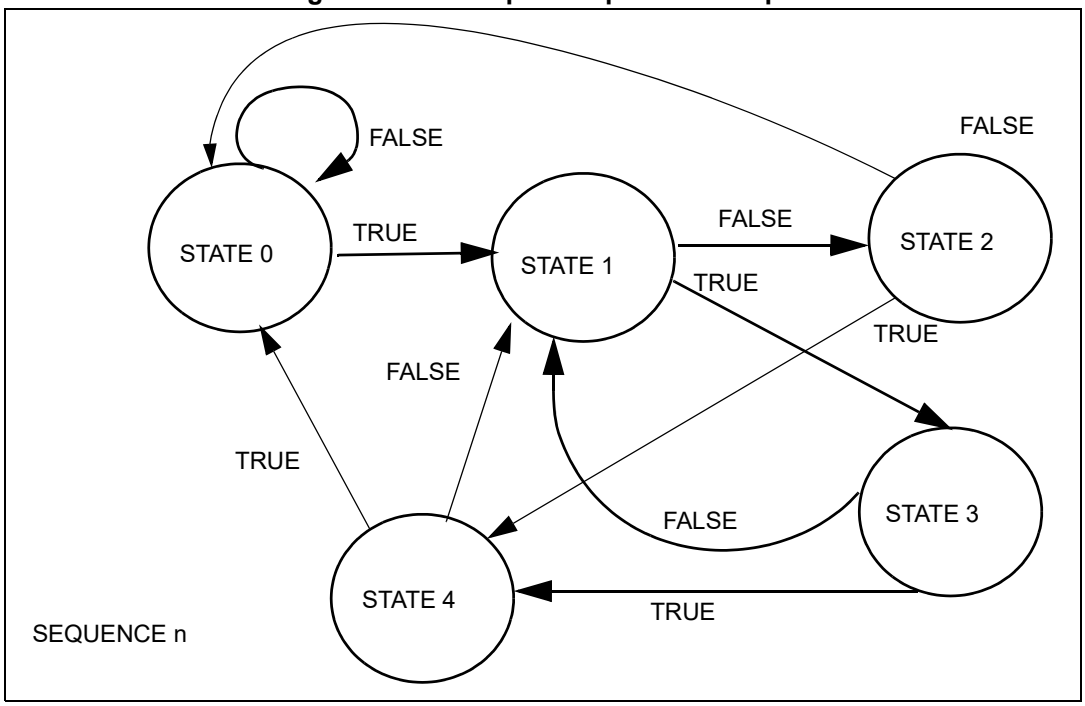


Figure 2029. Example of a simple configurable if-then-else sequence

76.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 2030*.

Figure 2030. Complex sequence example

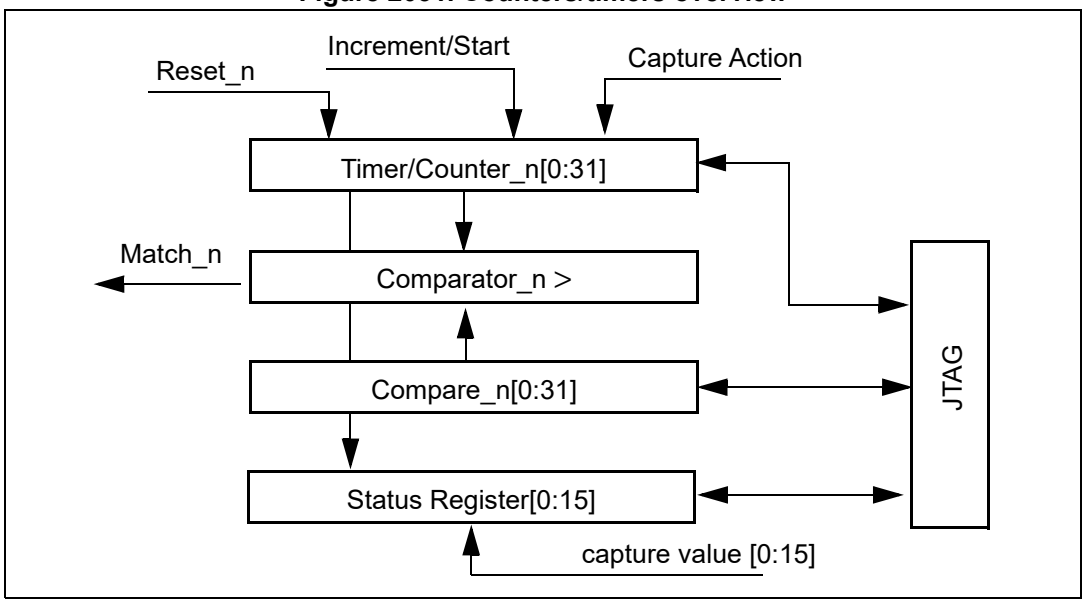
76.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurrence of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

76.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:



- States: each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register
- Sequence status: each sequence has a field indicating the active state of the state machine. This is a read only field

76.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 2031*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

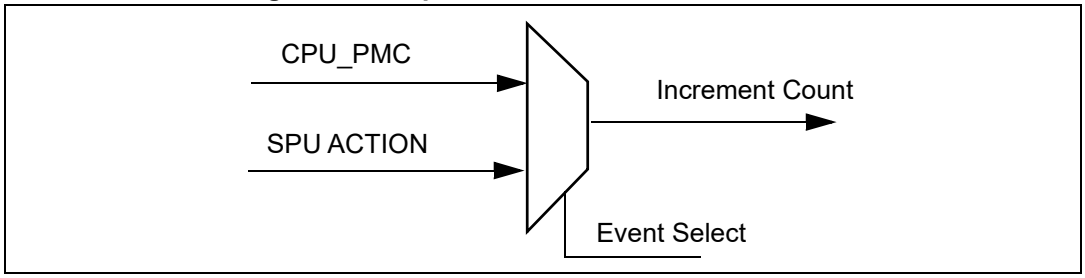
Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 2031. Counters/timers overview

76.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are type write 1 to clear (W1C).

There are two classes of signals, actions and events:



- Actions: each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.
- Event: on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

76.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 2032*. These inputs include signals from the primary SPU muxes or SPU events of counters.

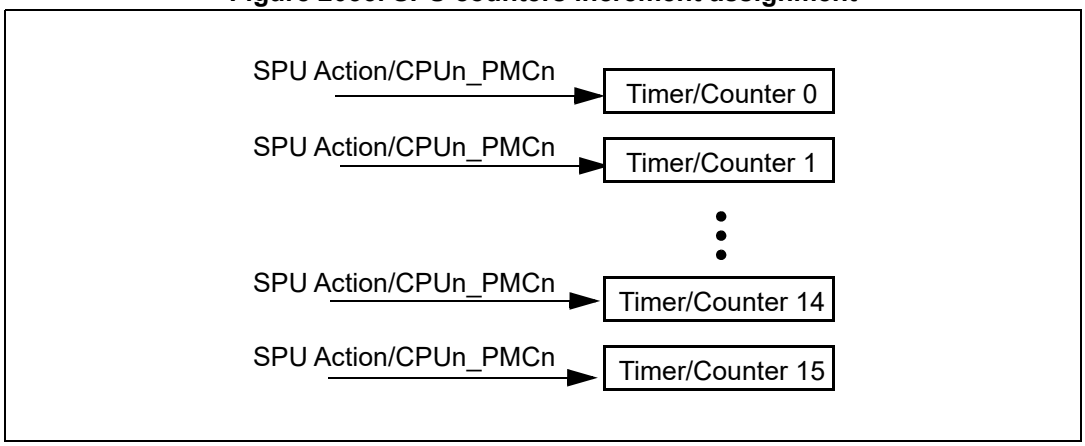


Figure 2032. nput selection for count increment

76.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 2033*.

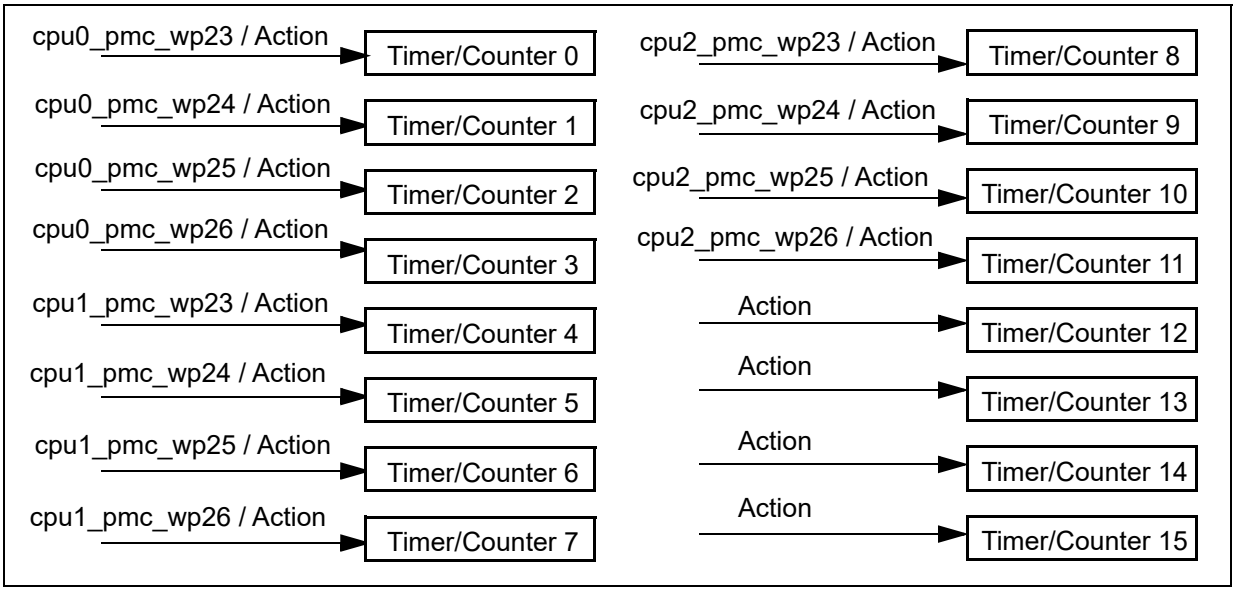

Figure 2033. SPU counters increment assignment

76.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 2034*.

Figure 2034. CPU PMC mapping inside the SPU unit

76.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 76.2*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers**.** Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

76.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers, defined in *Table 1950*, are available where the user can group the different traces from same or different clients.

76.6.8 Format for CKSRC & CKDATA Values

The format of the CKSRC is defined for the SPU Peripheral (as In-Circuit trace client):

Table 1958. CKSRC format

ICT CLIENTS	CKSRC Value
SPU Counter Trace Client	b00_0000
Reserved	b00_0001–b11_1111

The format for the CKDATA field for the SPU Counter trace client is:

Table 1959. CKDATA format

CKDATA	
CKDATA[CTR_Index]	CKDATA[CTR_VALUE]
4 bits	32-bits

77 Buddy Device—JTAG Master (JTAGM)

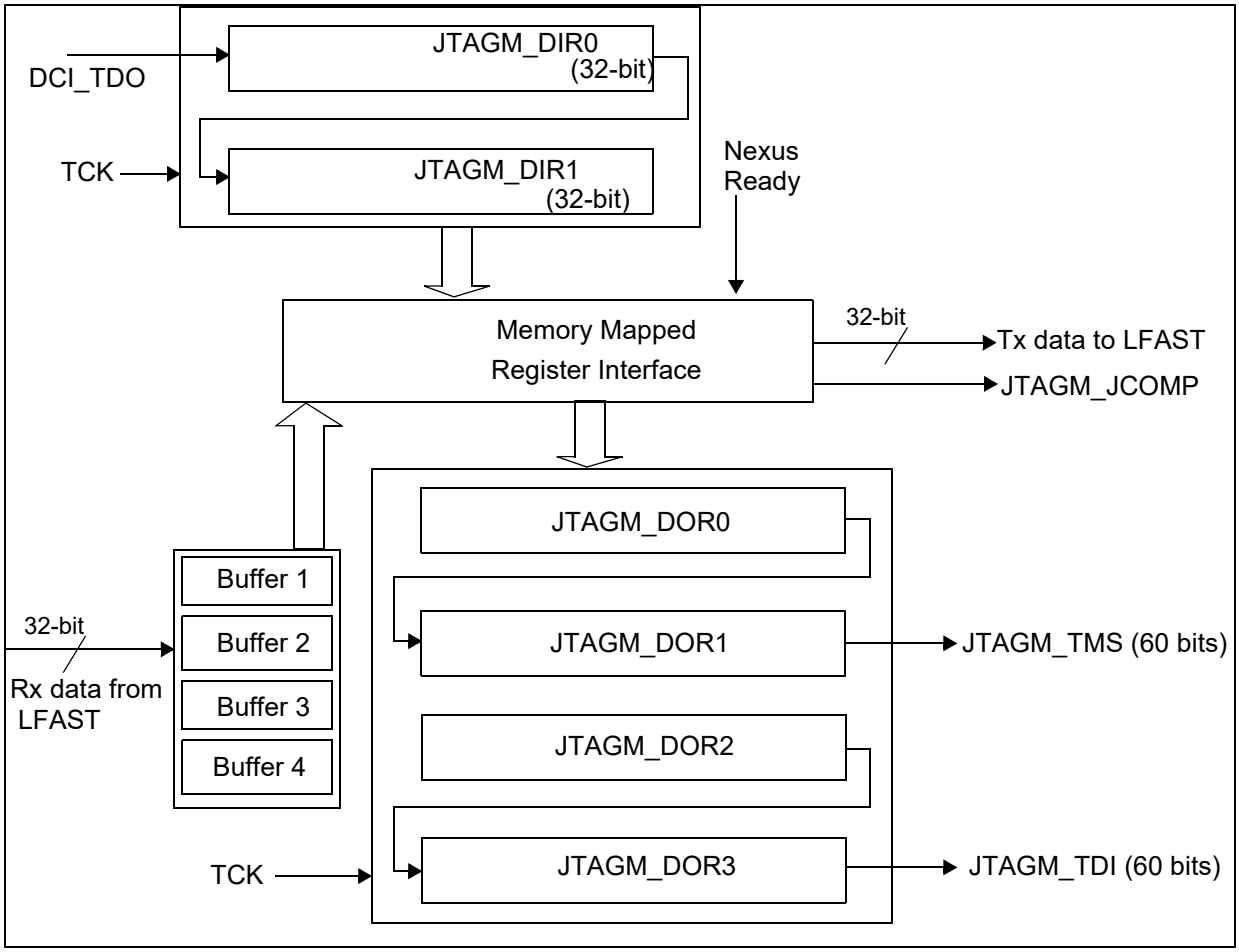
77.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

77.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RXCRC receive register
- Two data input registers

All these registers, described in detail in *Section 77.4: Memory map and register definition*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 2035 shows the block diagram of the JTAGM.

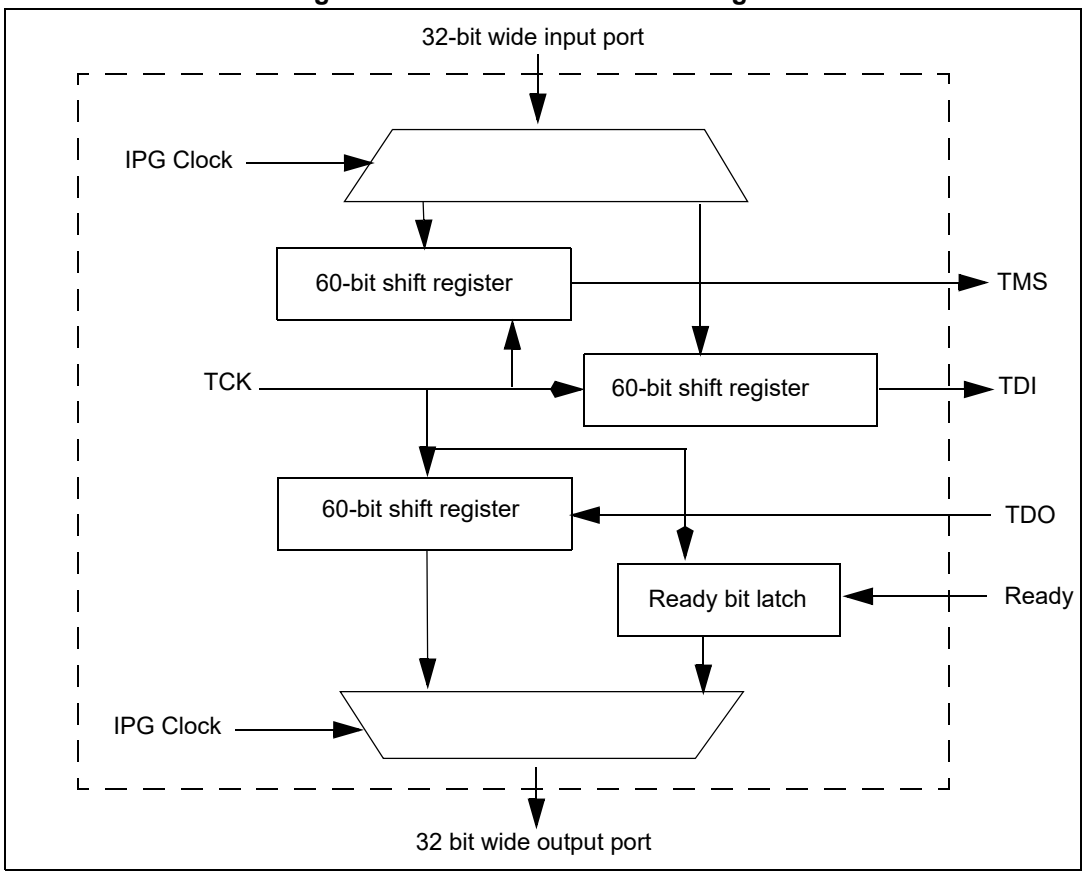
Figure 2035. JTAGM block diagram

77.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

77.2 Functional description



77.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 2036 shows the flow diagram of the LFAST to DCI connection.

Figure 2036. LFAST-to-DCI flow diagram

77.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

77.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

77.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

77.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

77.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has

toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

77.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

77.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

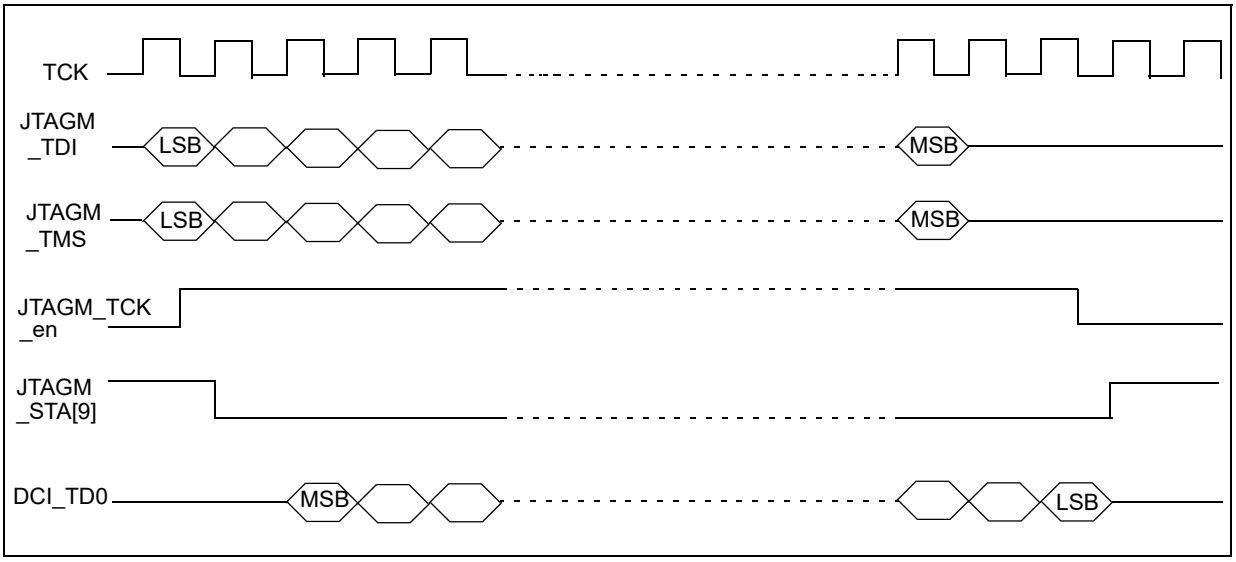
Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.

77.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 77.2.5.1: Status register*

ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written
- 32-bit value to be written to the configuration register
- 24-bit mask of which bits within the status register should be written
- 8 bits of zero-padding
- 24-bits of data to be written to the status register
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data)



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

77.2.8 JTAGM to DCI serial interface

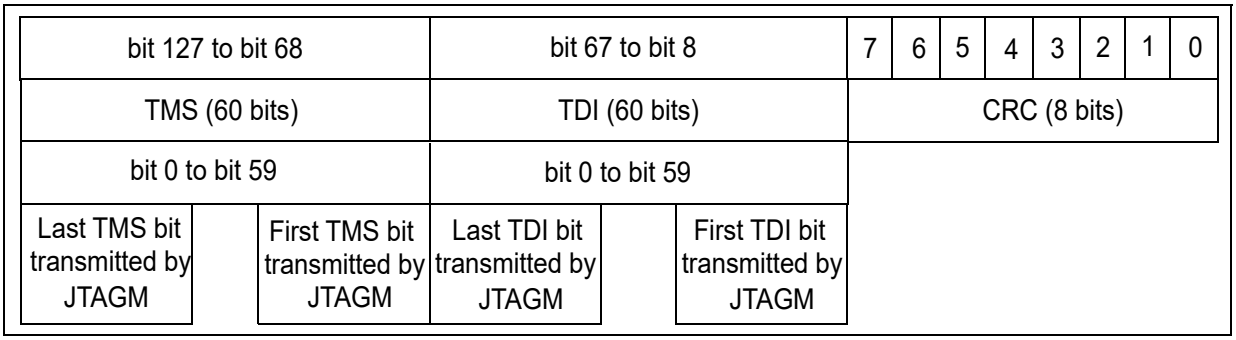
Figure 2037 shows the data transfer timings between JTAGM and DCI.

Figure 2037. JTAGM to DCI serial interface diagram

77.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 2038 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 2038. Bit ordering for LFAST to JTAGM transfer



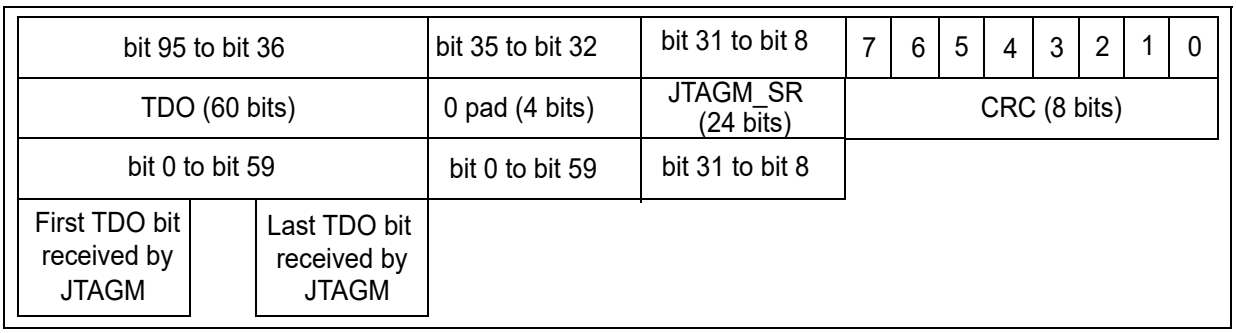


Figure 2039 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 2039. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 2039*).

77.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

77.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

77.4 Memory map and register definition

Table 1960 contains the memory map of the JTAGM registers.

Table 1960. Memory map

Offset	Register	Location

77.4.1 Register descriptions

77.4.1.1 Module configuration register (JTAGM_MCR)

This register contains the status bits for the current transfer. *Figure 2040* shows the format of the JTAGM_MCR. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. The only exception is the SIE bit, which always needs to be programmed in the Production Device instance of the JTAGM, regardless of being ED or not.

Figure 2040. JTAGM_MCR register

The JTAGM_MCR register is described in *Table 1961*.

Table 1961. JTAGM_MCR register field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit. Writing a 0 has no effect. **Note:** After being written to “1” , this bit is auto cleared within 3 TCK cycles.
1:2 evto0_sense	Determines JTAGM response to activity on $\overline{\text{EVTO}}$0 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$0 edges (default setting) 01 evto0_edge status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$0 10 evto0_edge status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$0 11 evto0_edge status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$0
3:4 evto1_sense	Determines JTAGM response to activity on $\overline{\text{EVTO}}$1 line 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$1 edges (default setting) 01 evto1_edge status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$1 10 evto1_edge status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$1 11 evto1_edge status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$1
5 evto_IE	Enables $\overline{\text{EVTO}}$ triggered JTAGM interrupt 0 No JTAGM interrupt is generated In response to any $\overline{\text{EVTO}}$0 or $\overline{\text{EVTO}}$1 activity 1 JTAGM interrupt is generated when evto0_edge or evto1_edge are set
6 evti0_assert	EVTI0 Assert 0 Set jtagm_evti0 low/asserted 1 Set jtagm_evti0 high/de-asserted
7 evti1_assert	EVTI1 Assert 0 Set jtagm_evti1 low/asserted 1 Set jtagm_evti1 high/de-asserted **Note:** In the SW mode (when DTM =1) , regardless of the state of “evti1_assert” bit the internall “evti” signal remains de-asserted. Though this bit can be written, writing to this bit has no effect .
18:23 inter_jtag_frame_timer	TCK delay 000000 0 TCK cycle 000001 1 TCK cycle … 111111 63 TCK cycles
25 SIE	SPU Interrupt Enable(1) 0 JTAGM does not generate an interrupt to the CPU 1 JTAGM generates an interrupt to the CPU if the SPU interrupt request is asserted
26 IIE	Idle Interrupt Enable 0 JTAGM does not generate an interrupt to the CPU upon completion of a 60-bit JTAG transfer 1 JTAGM generates an interrupt to the CPU upon completion of a 60-bit JTAG transfer **Note:** Before enabling a JTAGM idle interrupt by setting JTAGM_MCR[IIE] = 0b1, set the Idle bit (JTAGM_SR[Idle]) to 0b1 to clear any previous interrupts.

Table 1961. JTAGM_MCR register field descriptions (continued)

Field	Description
27:29 TCKSEL	TCK Divider division factor control value. (TCK Divider divides the clock input to JTAGM IP to generate TCK out(input to DCI)). 000 TCK Divider division factor is 1 001 TCK Divider division factor is 2 010 TCK Divider division factor is 3 011 TCK Divider division factor is 4 100 TCK Divider division factor is 5 101 TCK Divider division factor is 6 110 TCK Divider division factor is 7 111 TCK Divider division factor is 8 **Note:** It should be taken care that the maximum frequency of TCK input to DCI, should be equal or less than half of system clock.
30 jtagm_JCOMP	JTAG reset 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data for JTAG transferred by LFAST 1 Data for JTAG transferred by software

1. The BD JTAGM instance does not receive signals from the SPU. If required, this feature needs to be enabled in the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

77.4.1.2 Status register (JTAGM_SR)

77.4.1.2.1 LFAST mode

Figure 2041 shows the format of the JTAGM_SR in LFAST mode. In the ED, all bits of this register need to be accessed in the BD instance of the JTAGM. The exceptions are the bits related to the SPU interrupts (SPU_INT, SPU_INT_CLR), which always need to be accessed from the PD JTAGM, regardless of being ED or not.

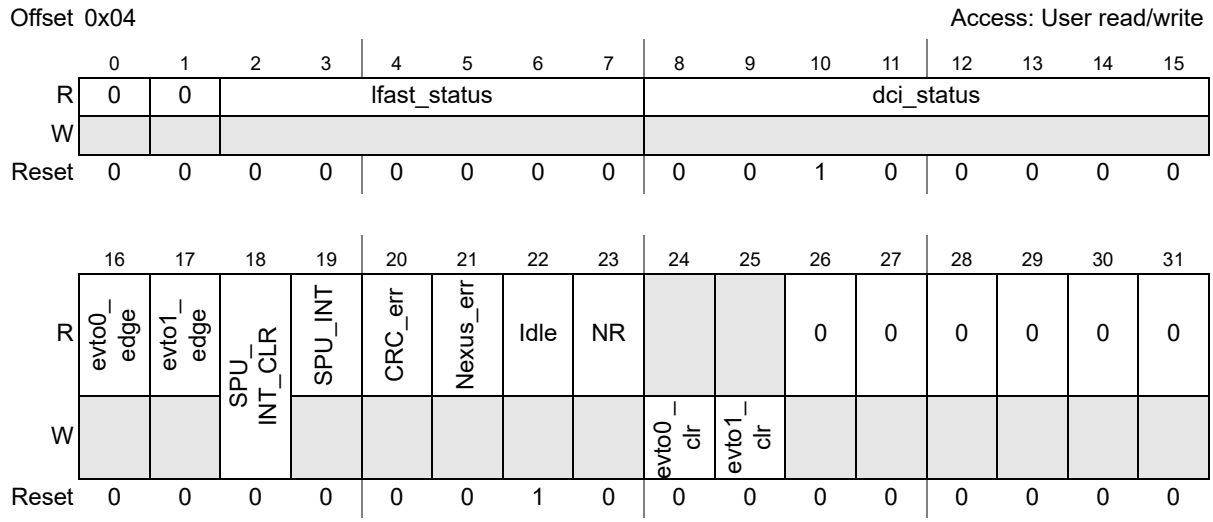

Figure 2042. JTAGM_SR register in SW mode

The JTAGM_SR register is described in *Table 1962*.

Table 1962. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected

Table 1962. JTAGM_SR register field descriptions (continued)

Field	Description
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$0
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1
18 SPU_INT_CLR	Write 1 clears the SPU_INT(1) This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit. (1)
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to ‘1’ when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode(when DTM =0) , this bit has no effect and acts as a “dont care” . This bit should not be used by the application in the LFAST mode
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

1. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

78 Debug Zipwire

78.1 Overview

The Debug SIPI and Debug LFAST modules work together as a single unit called Debug Zipwire. The Debug LFAST portion of the two modules allows for high speed debugging capabilities.

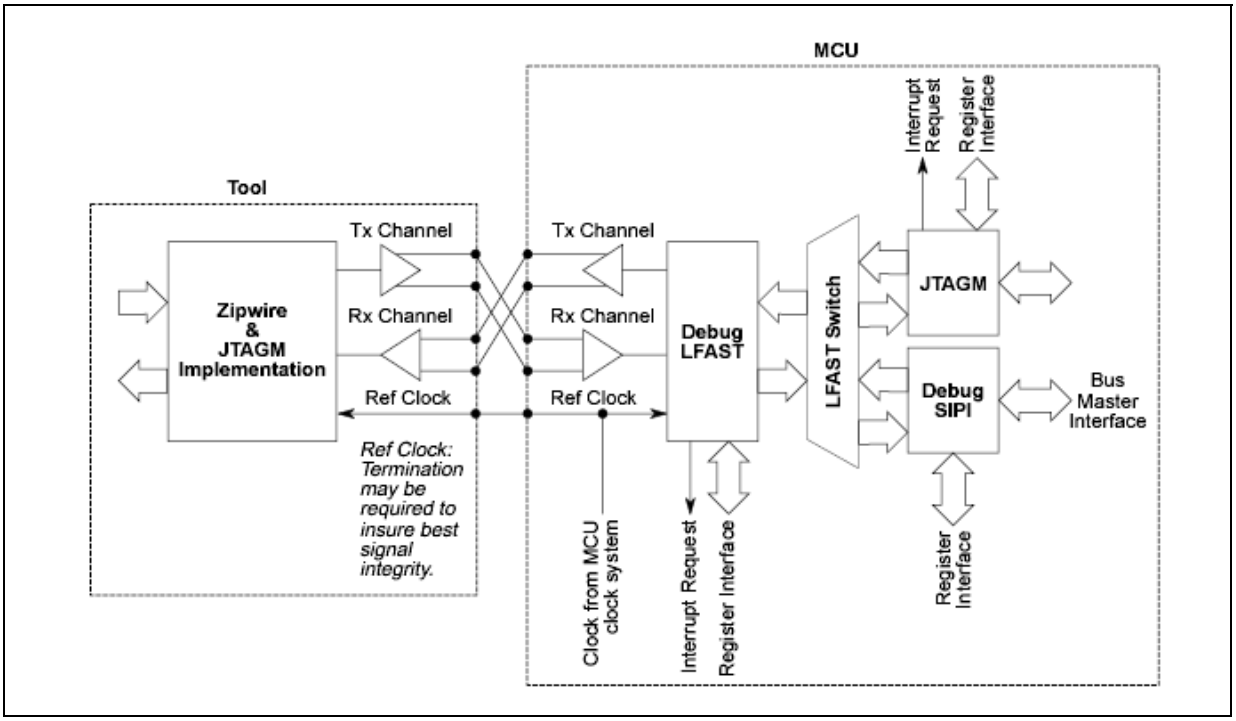
The Debug LFAST operates in slave mode configuration. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

78.2 Debug Zipwire Overview

Dedicated Zipwire functionality is available for debug use allowing support for increased bandwidth read/write operations to the chip memory space performed over the debug interface. This Debug Zipwire function is available on both production and ED devices. The modules used to support Debug Zipwire are the Debug SIPI module, the Debug LFAST module and the LFAST Switch. The Debug Zipwire functionality does not use the LFAST or SIPI modules which support the Zipwire interprocessor bus. The only resource shared between the Debug and interprocessor bus Zipwire interfaces is the use of a single shared LFAST PLL on the Production Device (PD).

The Debug Zipwire interface allows a connected tool to perform 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address in the microcontroller. The Zipwire architecture is fully pipelined and supports multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.The Debug Zipwire interface does not support streaming mode commands.



For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

78.3 Debug Zipwire Block Diagram

Figure 2050 shows a tool connected to the MCU via five wires. These five pins are shared with the standard JTAG pins, but for simplicity this is not shown in the diagram. The MCU Debug Zipwire only supports the Target mode of Zipwire. The Debug SIPI Bus Master Interface is used for all Target Mode transactions. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST Reference clock coming from the MCU clock system.

Figure 2050. Debug Zipwire connection diagram

78.4 Architecture

Debug Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200 mV swing.The pads are shared with JTAG signals.

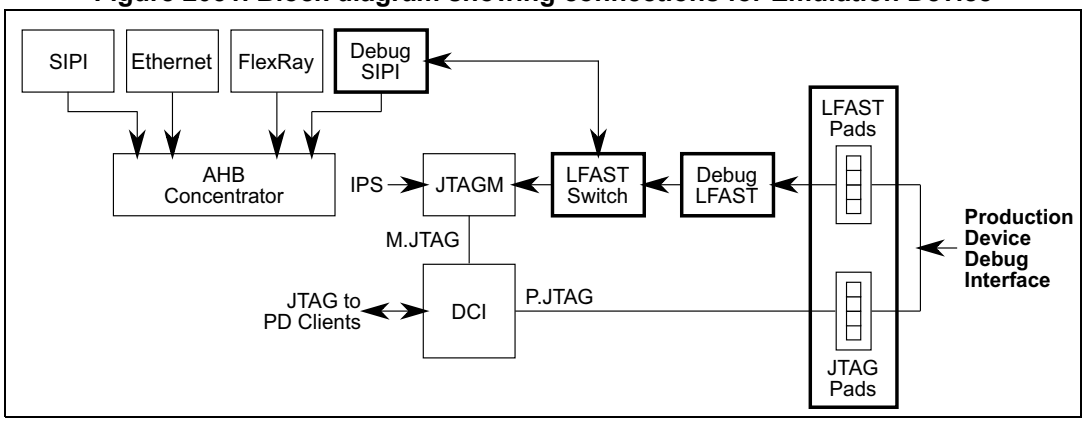
The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). Debug SIPI runs on top of Debug LFAST and is fully encapsulated within the Debug LFAST payload. Debug SIPI uses three fixed sizes of Debug LFAST payload in Debug Zipwire:

- 32-bit
- 64-bit
- 96-bit

The SIPI protocol implements a suite of commands initiated by a tool, for reading and writing any 32-bit address location in a connected MCU. Only the tool can initiate commands. The MCU only responds to commands initiated by the tool and never creates any unsolicited messages.



For Debug Zipwire, a reduced version of the SIPI module called Debug SIPI is used. The Debug SIPI module implements only the recipient part of the SIPI protocol (called Target

mode). The Debug SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating tool, Debug SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

78.5 Debug Zipwire implementation

Figure 2051 shows the modules on the production device which support the Debug Zipwire function, along with their interconnections to the debug interface signals.

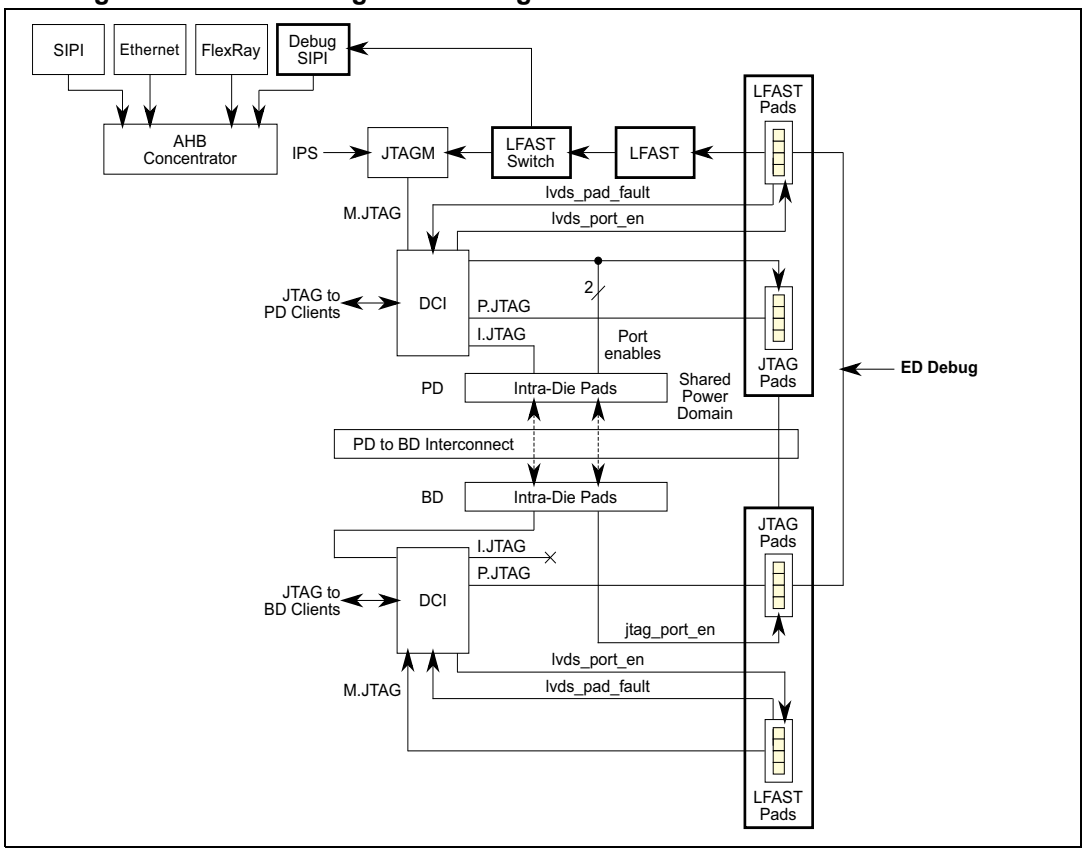


Figure 2051. Block diagram showing connections for Emulation Device

Internal connections to other debug modules which are used to support other debug interface protocols such as JTAG and JTAG over LFAST are also shown. The Debug SIPI module is connected to the Debug LFAST module via an LFAST switch module, which controls routing of debug LFAST traffic to either the Debug SIPI or the JTAGM module.

Figure 2052 shows the equivalent connections for ED devices utilizing the LFAST switch.

Figure 2052. Block diagram showing connections for the Emulation Device

78.6 LFAST clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data. This PLL is used to support both interprocessor bus Zipwire and Debug Zipwire so care must be taken to ensure that any tool configuration of this resource is compatible with application usage of Interprocessor Bus Zipwire. The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to as the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

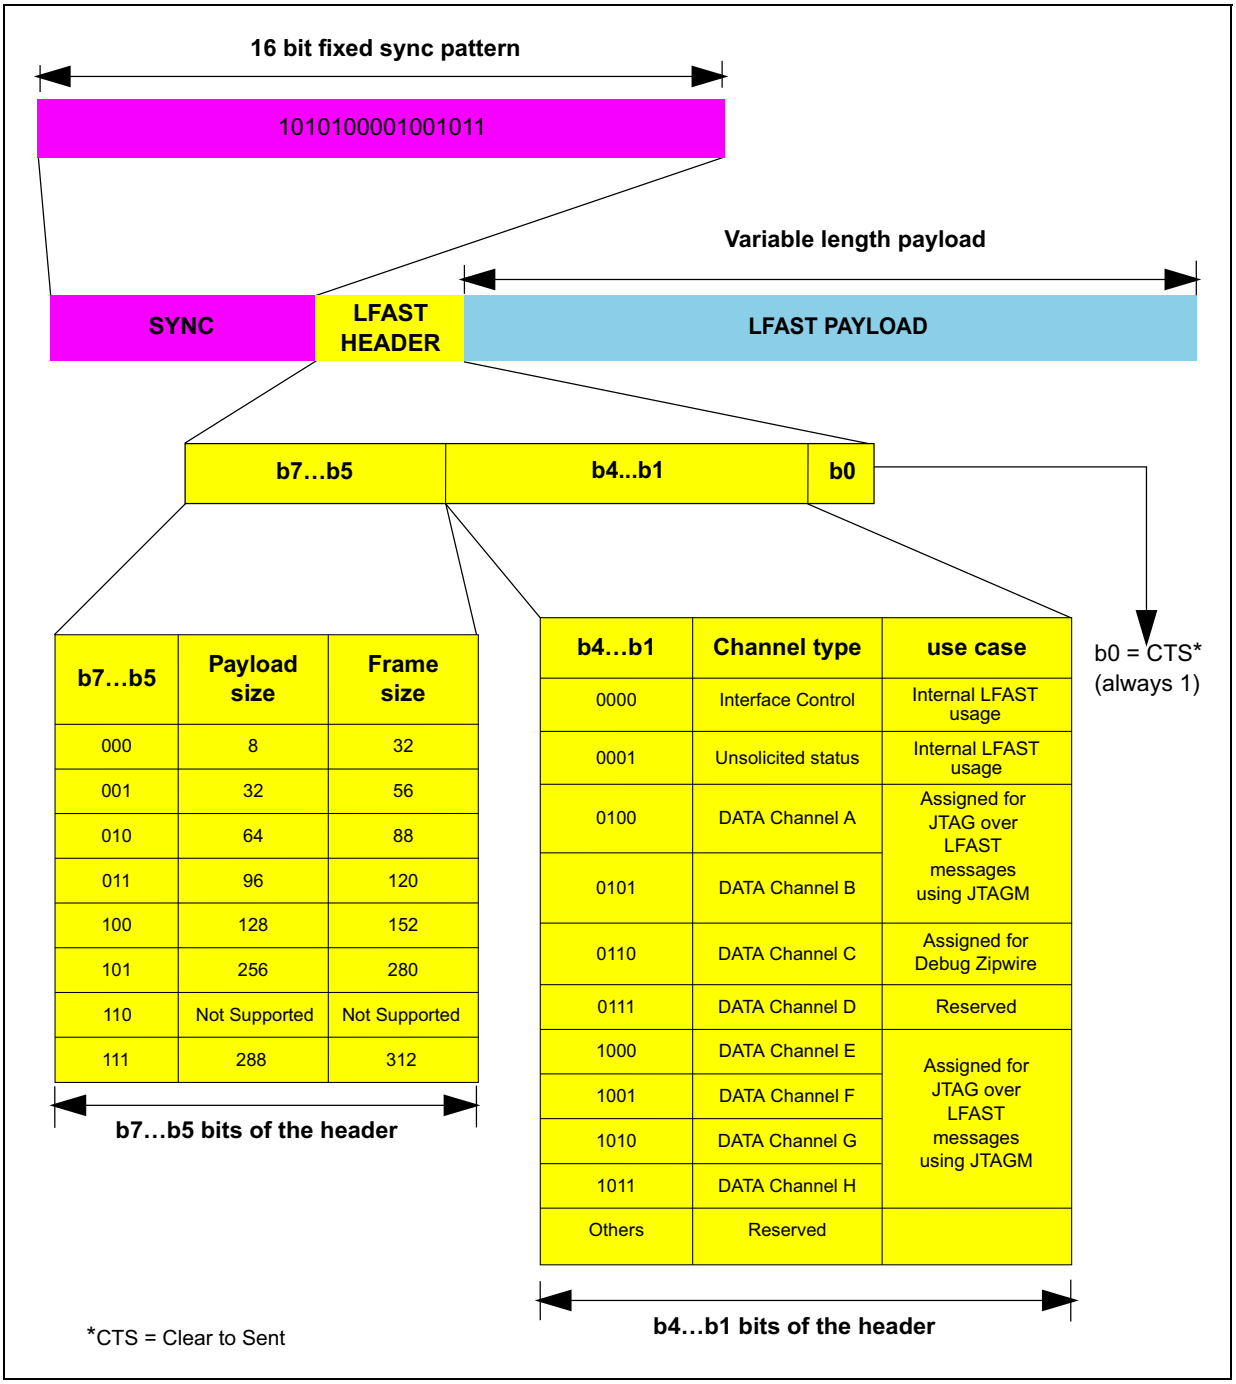
- XOSC
- Output of PLL0 (PLL0:PHI)
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator (XOSC) from one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.



78.7 LFAST switch

Incoming messages on the Debug LFAST interface can be either for JTAG over LFAST use through the JTAGM or debug Zipwire messages. Differentiation of these messages is via use of LFAST channel number. DATA channel C is used to identify high speed Debug SIPI accesses, while JTAG over LFAST messages are supported using LFAST channels A, B, E, F, G, H as shown in *Figure 2053*.

The LFAST SWITCH module is used to direct LFAST messages based on the above scheme, with JTAG over LFAST messages being routed to the JTAGM IP block and debug Zipwire messages being routed to the Debug SIPI block.

The LFAST switch has no accessible registers and requires no user configuration.

Figure 2053. LFAST channel allocation

b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	Not Supported	Not Supported
111	288	312

b4…b1	Channel type	use case
0000	Interface Control	Internal LFAST usage
0001	Unsolicited status	Internal LFAST usage
0100	DATA Channel A	Assigned for JTAG over LFAST messages using JTAGM
0101	DATA Channel B	
0110	DATA Channel C	Assigned for Debug Zipwire
0111	DATA Channel D	Reserved
1000	DATA Channel E	Assigned for JTAG over LFAST messages using JTAGM
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

78.8 Debug SIPI module

The debug SIPI module is used to support high bandwidth read/write accesses over the LFAST debug interface. It is dedicated for debug use and is entirely separate from the SIPI module used to support interprocessor bus zipwire interface.

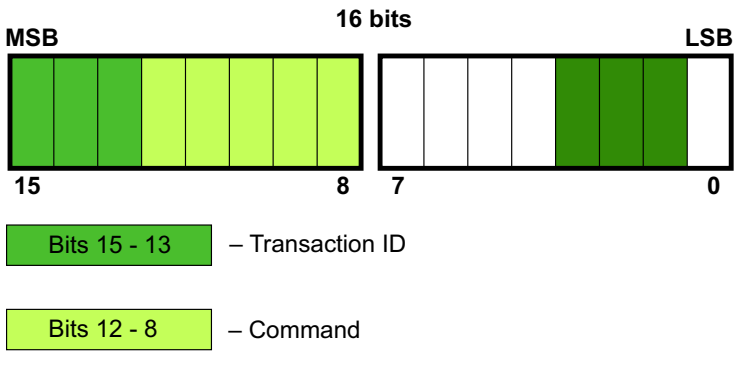
The debug SIPI characteristics are shown in *Table 1970*.

Table 1970. Debug SIPI feature set

Feature	Debug implementation
Number of channels supported	1
Initiator support	No
Target support	Yes
Block transfer support	No
Chip XBAR connection	M1 on XBAR_1

The debug SIPI module issues read and write accesses via the AHB concentrator connected to physical master port 2 on XBAR_1, which is shared with the ethernet, FlexRay and Zipwire SIPI bus masters.

The debug SIPI memory mapped registers are accessible via PBRIDGE_0 (off platform - slot 10) with base address FFFD_4000h.



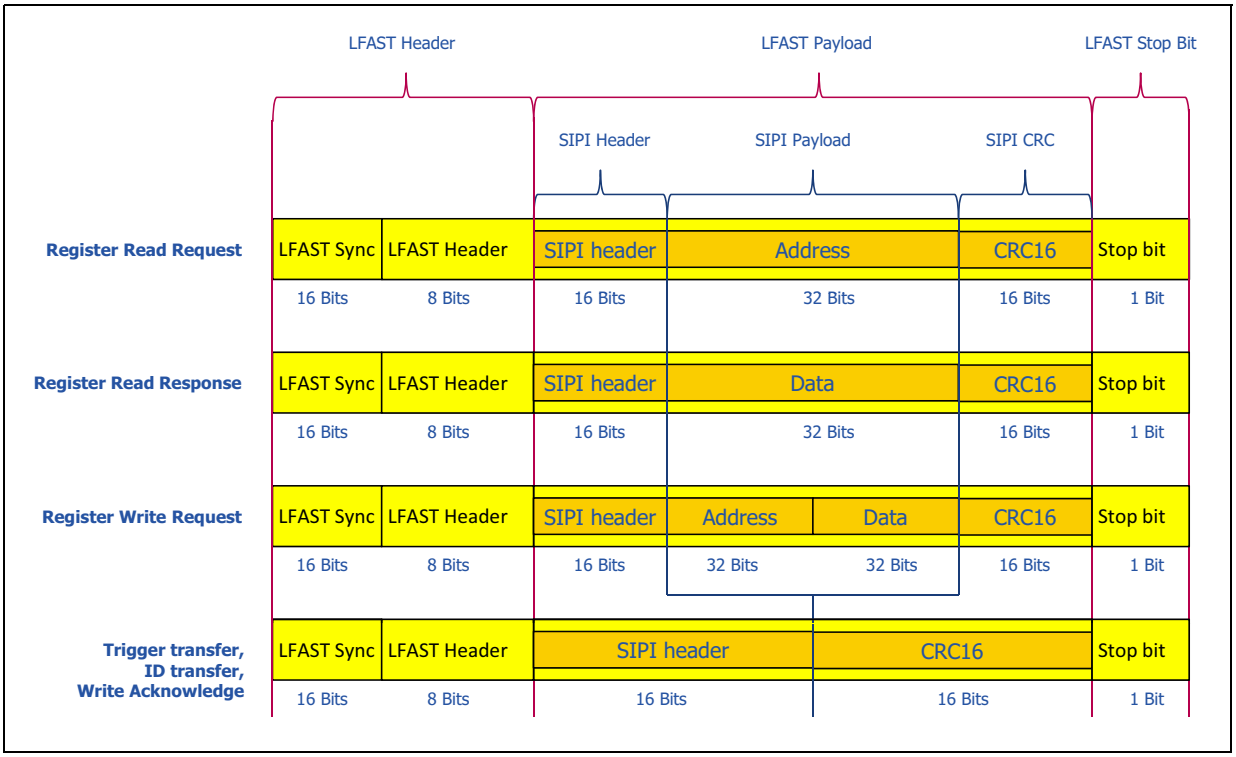
The debug SIPI has Logical Bus Master Assignment of 6 for SMPU0 and SMPU1, an NXMC trace source ID (SRC) of 1101b and a trace master ID (MASTER) = 1011b.

The debug SIPI supports only target mode SIPI operations on a single channel with a reduced command set. Commands supported include read (8/16/32 bits) and write (8/16/32 bits) along with the appropriate responses. Other SIPI commands are unimplemented as noted in *Table 1971*.

The debug SIPI will be capable of:

- receiving a 64-bit command on LFAST channel C and responding with either a 64-bit response or 32-bit error response on LFAST channel C.
- receiving a 96-bit command on LFAST channel C and responding with either a 32-bit acknowledge or 32-bit error response on LFAST channel C.

Figure 2054. Debug SIPI header



Note: See Figure 2053 for the description of bits[7:0]

Table 1971. SIPI header command coding

Bits[12:8] (hex)	Command	Payload Size	Message Direction at chip (SIPI Target)
00	Read 8 bits (Received by SIPI from LFAST)	64	Rx
01	Read 16 bits (Received by SIPI from LFAST)	64	Rx

1F	Reserved	—	—

1. ACK – Fault is also referred to as “NACK” and “ACK Error” in the HSSL/SIPI Interprocessor Bus Protocol Specification.

Figure 2055. Zipwire message format

Note: Identification Register Read is the same as the Register Read response format.

78.8.1 ED power supply constraints

For ED devices the following power domain user constraints must be observed:

- The Vdd_hv_jtag_osc and Vdd_hv_io_bd supplies need to be connected on the application PCB.
- For cold start operation where a tool must be able to communicate via JTAG and read/write ED RAM contents, Vdd_lv_stby, Vdd_hv_jtag_osc and Vdd_hv_io_bd must remain powered.
- For cold start operation where only ED RAM contents have to be maintained, only Vdd_lv_stby must remain powered.

78.9 Debug Zipwire interconnections

Debug LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Connected to the LFAST Switch. This allows LFAST data to be dynamically routed to/from either Debug SIPI for Debug Zipwire operation or JTAGM for JTAG over LFAST operation.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

LFAST Switch has the following connections:

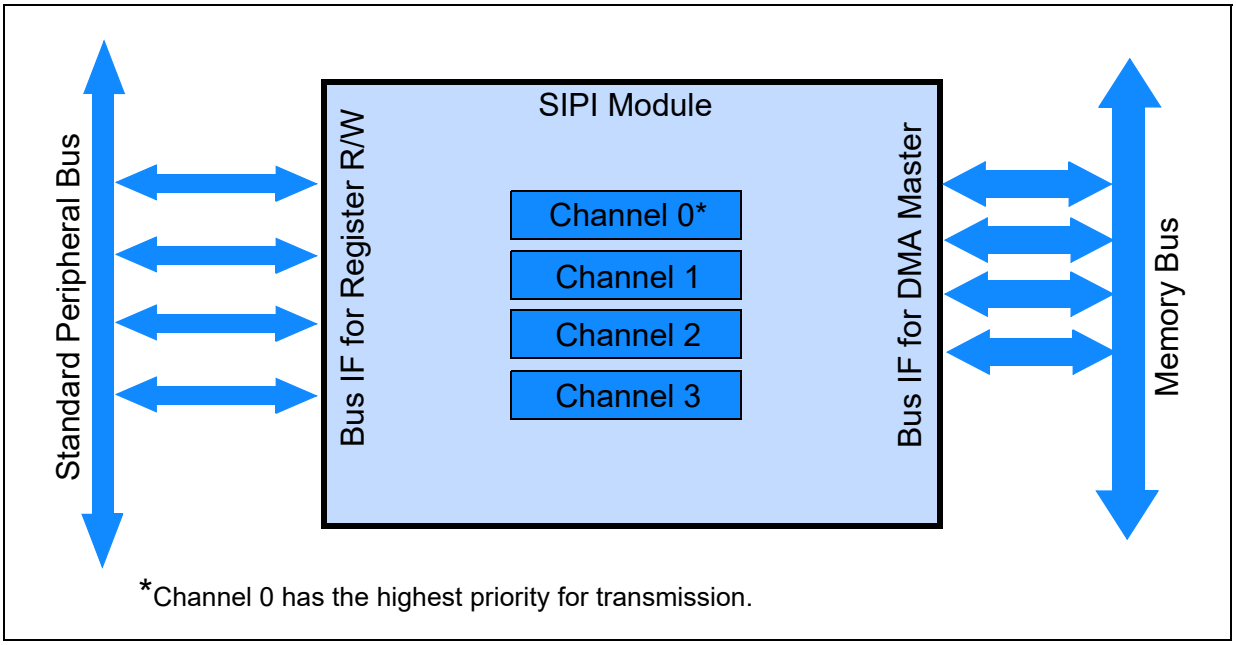
- Tx Data Port/Rx Data port directly connected to Debug SIPI.
- Tx Data Port/Rx Data port directly connected to JTAGM.
- Tx Data Port/Rx Data port directly connected to Debug LFAST.
- LFAST switch has no IPS interface; no registers; no interrupts.

Debug SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers. For the Debug SIPI, a restricted set of registers is implemented. In use, no configuration of these registers is needed from either s/w or a connected tool, as the default settings should be usable for typical operation.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.

79 Debug Serial Interprocessor Interface (SIPI)

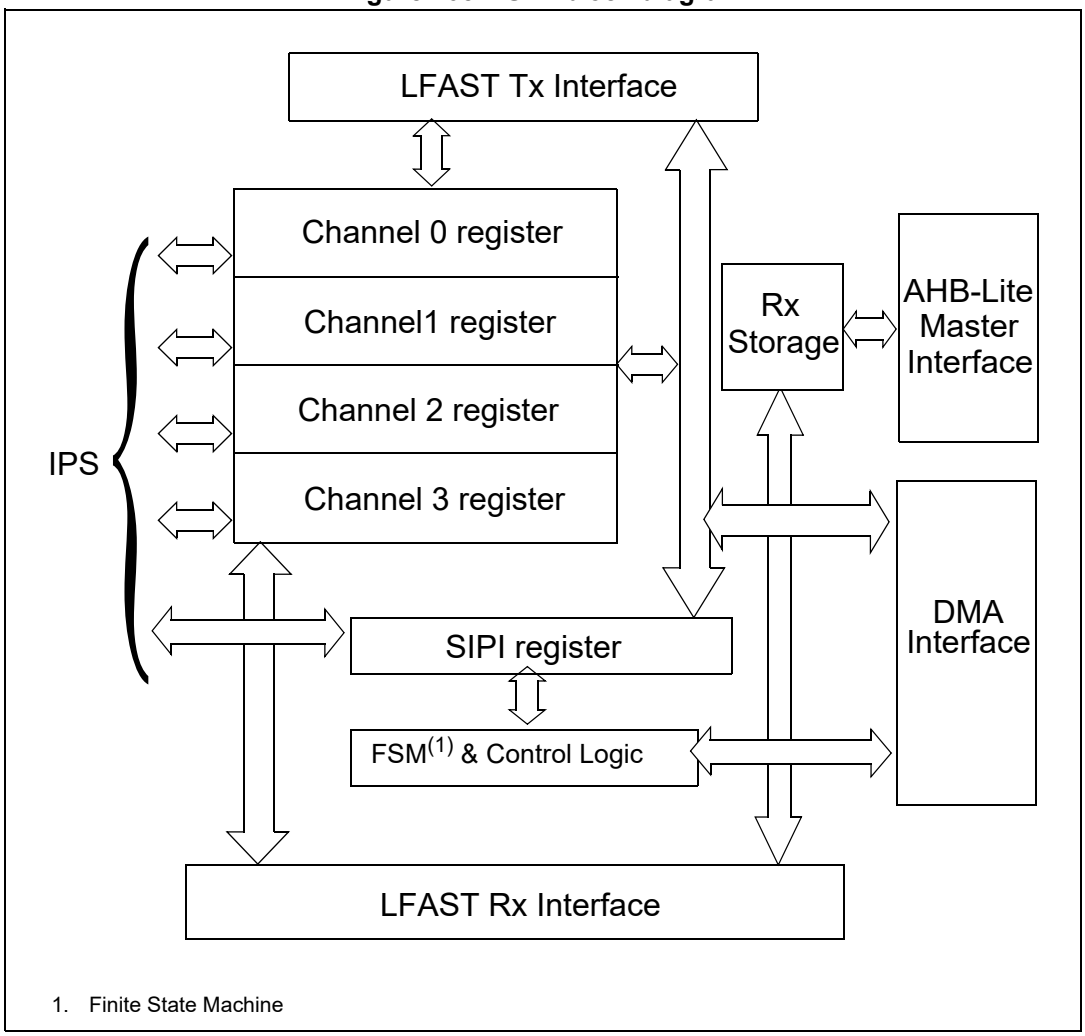
79.1 Introduction



The Debug Serial Interprocessor Interface (SIPI) is an application layer protocol that runs on top of the LFAST module. It is used by the local device to access the shared memory of a remote device. Debug SIPI defines point-to-point full duplex communication between two nodes, where LFAST works as a physical medium of communication between both the devices.

Debug SIPI implements the Target mode of a communication protocol in hardware. Debug SIPI can interpret 'read' and 'write' commands received from an LFAST module and convert them into bus accesses to local memory; then send back to the LFAST module either read data or a write acknowledge response. This provides a mechanism for an external device, such as an external tool, to read and write the address map of the local MCU. The bandwidth of these read/write commands is approximately 10 MBytes/second when accessing random addresses using 32-bit transfers.

79.2 Overview



Debug SIPI can access memory mapped resources directly through its AHB master interface. Debug SIPI has four channels, 0, 1, 2, 3. Payload width for all channels is 32 bits.

Figure 2056. SIPI module

79.3 Debug SIPI block diagram

Figure 2057. SIPI block diagram

1. Finite State Machine

79.4 Feature description

This section describes the features of the Debug SIPI module.

79.4.1 Main features

- Supports 8, 16 and 32-bit read and write commands
- Command/response includes a 16-bit CRC to ensure data integrity
- Command/response include a 2-bit tag to allow tracking of data to commands in a pipelined system
- Command/response include a 3-bit channel identifier to allow multiple Initiators to send commands to a single target node
- Command/response includes a 16-bit header that defines, the function, channel and tag
- Every command generates a response to allow a 'sliding window' flow control protocol to be implemented
- AHB master interface that is used by target node to access memory mapped resources

79.4.2 Standard features

- IPS bus interface
- AHB master interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

79.5 Debug SIPI operation from reset

When the Debug SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

79.6 Functional description

79.6.1 External signals

The Debug SIPI has no chip external signals.

79.6.2 Frame format

All frames have the same general format:

- 16-bit header
- Address, address and data, or nothing
- 16-bit CRC

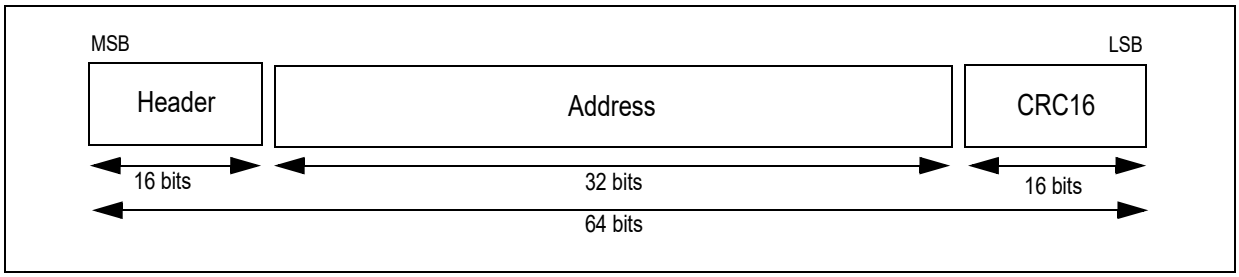
There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

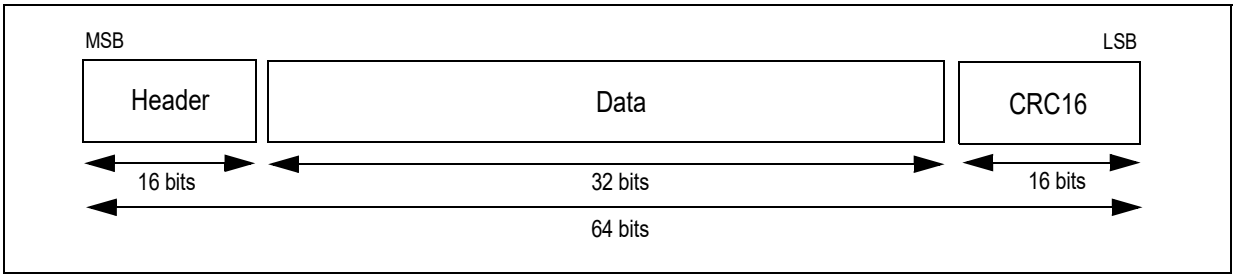
There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID.



The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

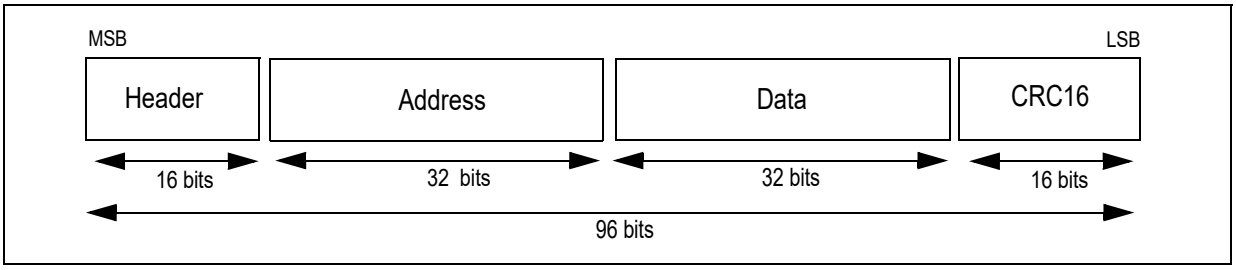
The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

Note: SIPI module architecture is always big endian but the storage in host memory depends on endianness architecture of host memory.



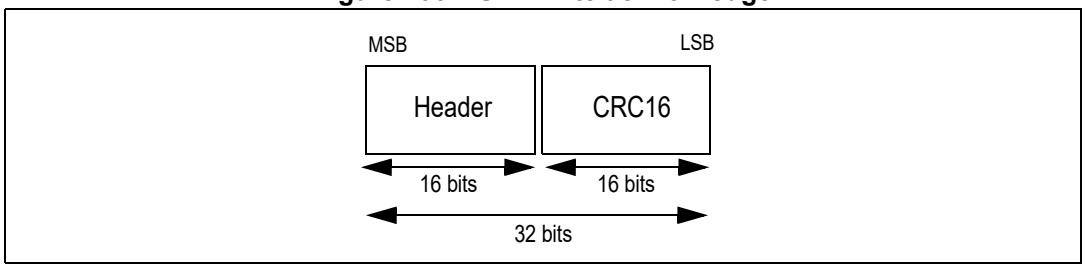
79.6.2.1 Register read request

Figure 2058. SIPI register read request



79.6.2.2 Register read response, ID request response

Figure 2059. SIPI read response



79.6.2.3 Register write request

Figure 2060. SIPI register write request

79.6.2.4 ID transfer, write acknowledge

Figure 2061. SIPI write acknowledge

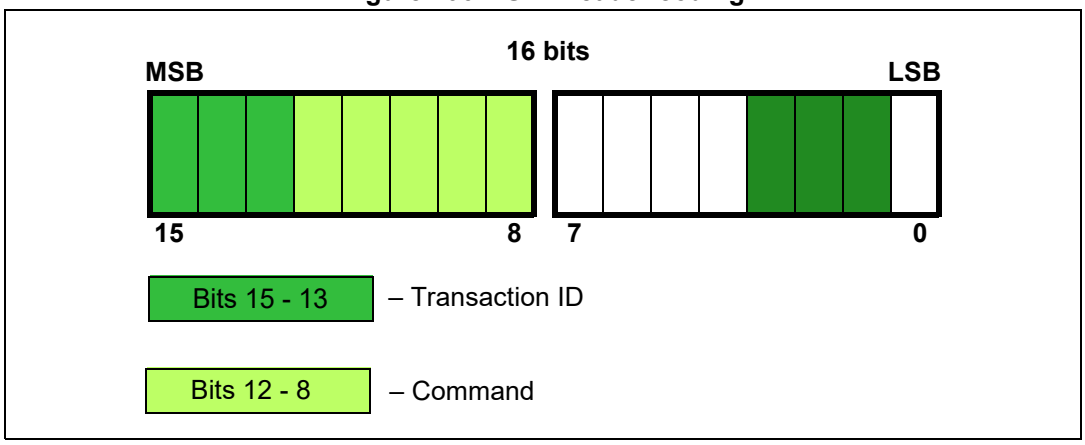
79.6.2.5 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

79.6.2.5.1 Debug SIPI header coding

Figure 2062, *Table 1972*, and *Figure 2063* show how the Debug SIPI header bits are coded.

Figure 2062. SIPI header coding



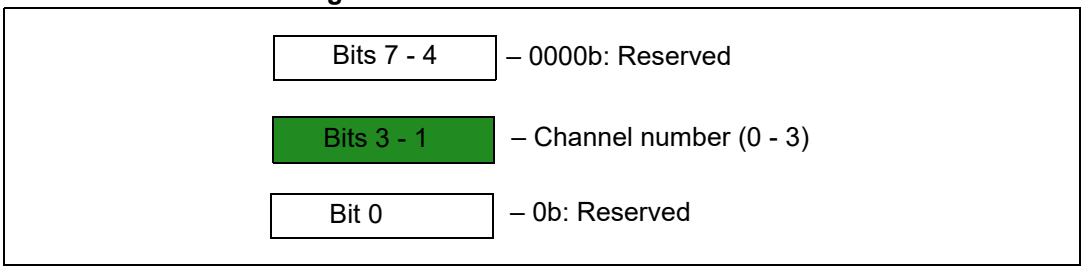


Table 1972 shows the command coding for the bits[12:8] of the header.

Table 1972. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
0x00	Read 8 bits	64
0x01	Read 16 bits	64
0x02	Read 32 Bits	64
0x03	Reserved	—
0x04	Write 8 bits with ACK	96
0x05	Write 16 bits with ACK	96
0x06	Write 32 bits with ACK	96
0x07	Reserved	—
0x08	ACK – OK	32
0x09	ACK – Fault	32
0x0A	Read Answer – OK	64
0x0B	Reserved	—
0x0C	Reserved	—
0x0D	Reserved	—
…	…	…
0x11	Reserved	—
0x12	ID Register Read Request	32
0x13	Reserved	—
…	…	…
0x16	Reserved	—
0x17	Reserved	—
0x18	Reserved	—
…	…	...
0x1F	Reserved	—

Figure 2063 shows the content of bits[7:0] in the SIPI header.

Figure 2063. SIPI header channel field

79.6.2.6 Address field

The address field is 32 bits wide with the MSB transmitted first.

79.6.2.7 Payload field

Table 1973 shows the payload sizes of LFAST frames.

Table 1973. Payload size of LFAST channel frame

LFAST code for payload size	Debug SIPI Code	LFAST payload size (bits)(1)	LFAST payload size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16
101b	101b	256	32
111b	111b	288	36

1. Only 32, 64, 96 and 288 bits sizes are used for SIPI.

Table 1974 shows the coding of LFAST channel for a given Debug SIPI channel code.

Table 1974. Converted coding of LFAST channel code for Debug SIPI headers

LFAST channel code	Debug SIPI channel code	Data channel(1)
0100b	**100b**	**Data channel A**
0101b	**101b**	**Data channel B**
0110b	**110b**	**Data channel C**
0111b	**111b**	**Data channel D**
1000b	**000b**	**Data channel E (not used by Debug SIPI)**
1001b	**001b**	**Data channel F (not used by Debug SIPI)**
1010b	**010b**	**Data channel G (not used by Debug SIPI)**
1011b	**011b**	**Data channel H (not used by Debug SIPI)**

1. Debug SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
Debug SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
Debug SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
Debug SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

79.6.2.8 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). The data stream is transmitted with the MSB sent first.

79.6.2.8.1 CRC examples

Example 1 – 32-bit write

- Header = 0x260A
- Address = 0x1122_3344
- Data = 0xCCDD_EEFF
- CRC = 0xBF7D

Example 2 – 32-bit read

- Header = 0x420C
- Address = 0x89AB_CDEF
- CRC = 0x6B80

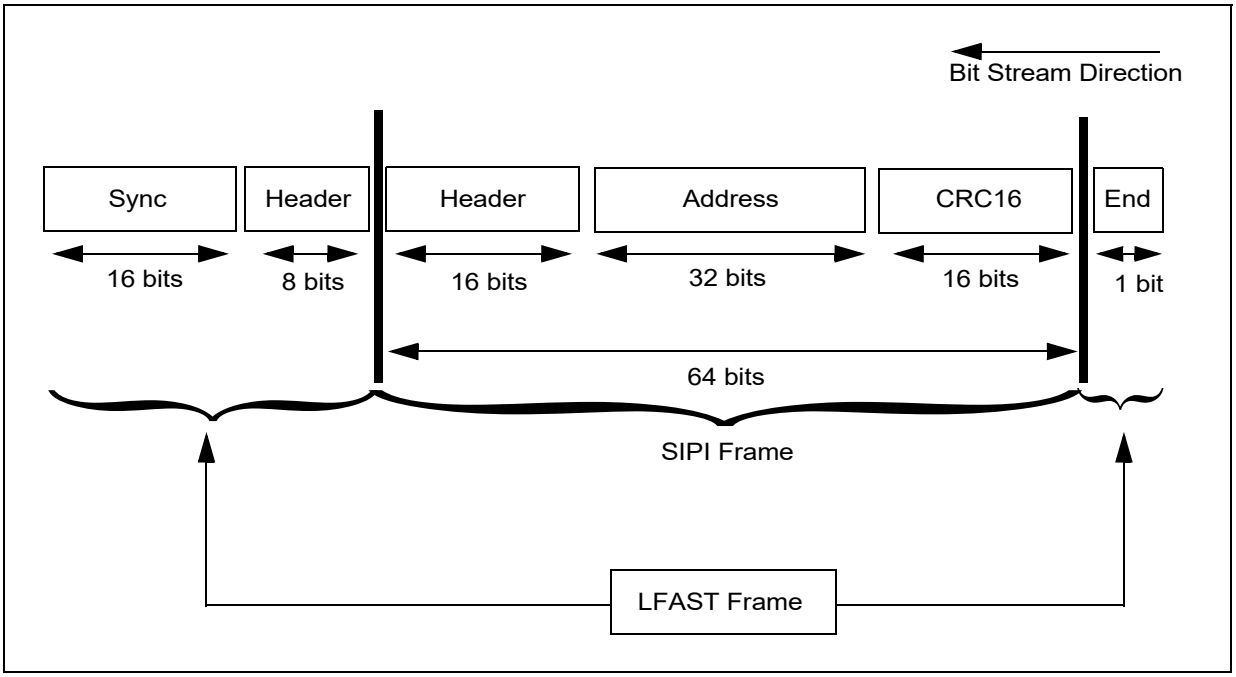
Example 3 – Event command

- Header = 0x6C0E
- CRC = 0xB286

79.7 Transfer types

This section describes the available transfer types of the Debug SIPI module. The Debug SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

79.7.1 Read transfer



A Read transfer can be of two types:

- Read request transfer (at initiator node)
- Read response transfer (at target node)

79.7.1.1 Register read request transfer

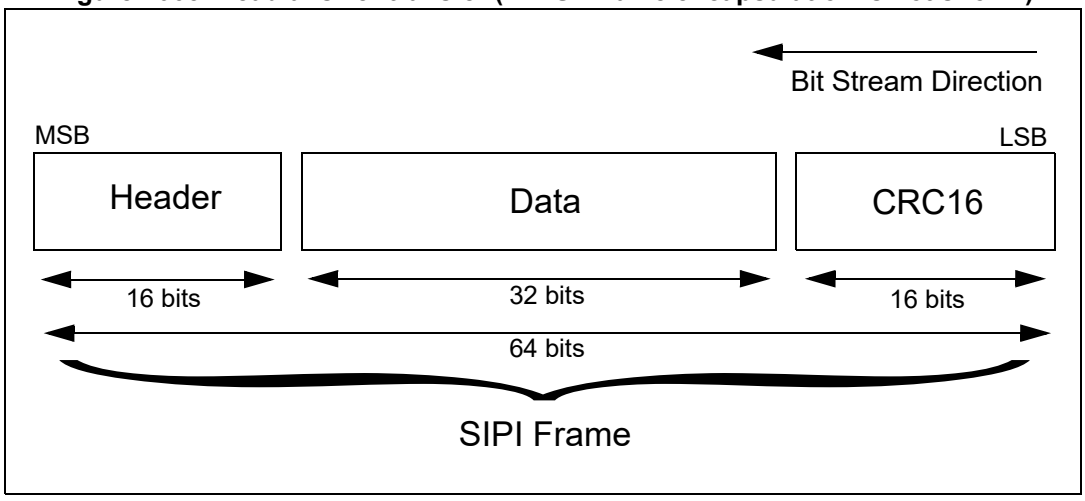
If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in *Figure 2064*.

Figure 2064. Read request transfer (showing LFAST frame encapsulation)

79.7.2 Register read answer transfer

In response to a read request, Debug SIPI sends header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (refer to *Figure 2065*). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (refer to *Figure 2066*).

Figure 2065. Read answer transfer (LFAST frame encapsulation is not shown)



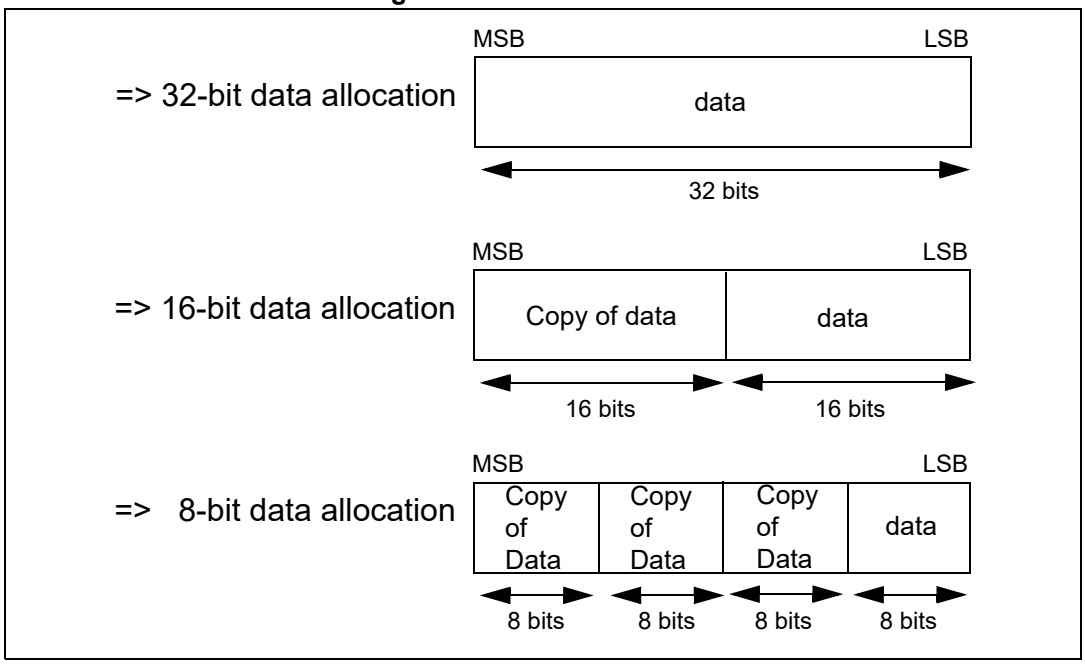


Figure 2066. Data allocation

Note: For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables (big endian):

Bits[1:0]:

- *00: Byte 3 enabled (MSB)*
- *01: Byte 2 enabled*
- *10: Byte 1 enabled*
- *11: Byte 0 enabled (LSB)*

For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable (big endian).

Bit[0]:

- *0: Half-word 1 enabled (MSB)*
- *1: Half-word 0 enabled (LSB)*

Note: Byte Ordering depends from address written in CAR and transfer width:
Example:

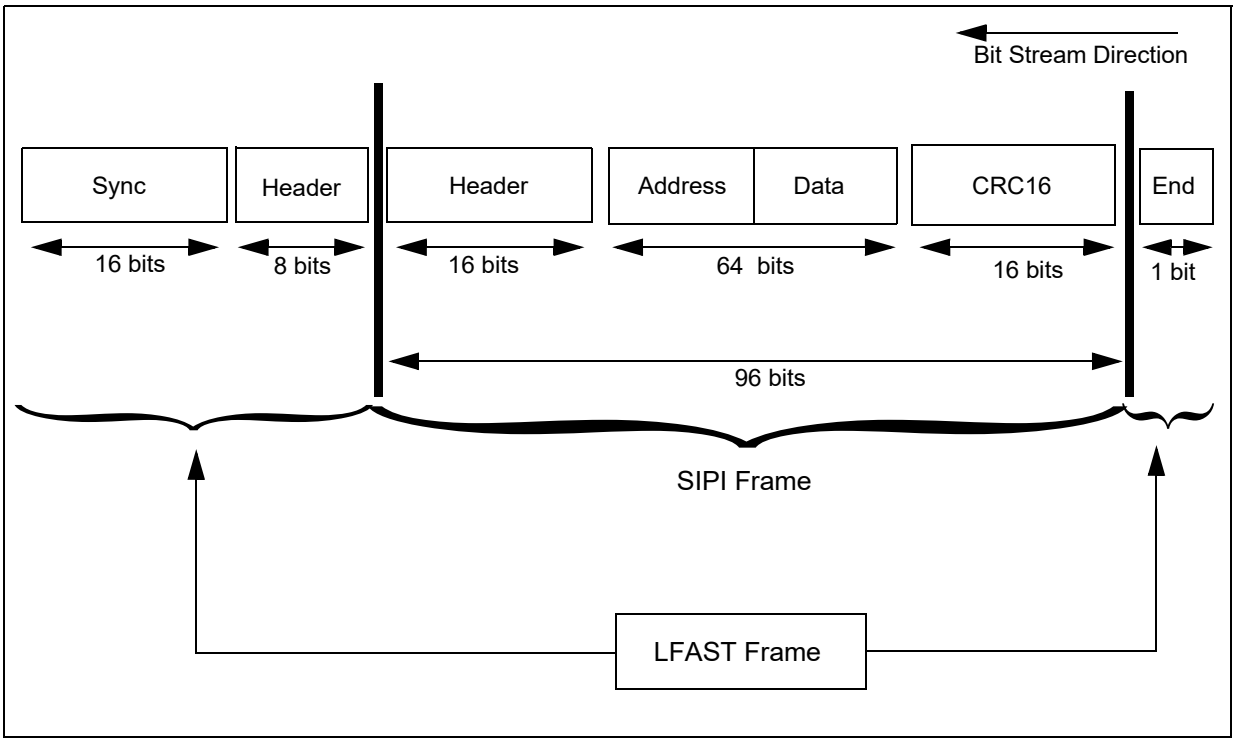
- *CDR content: 0x12345678*
- *CAR content: see table columns*

Table 1975. Target Memory content dependent from CAR content

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
32-bit transfer	0x02040	12	12	12	12
	0x02041	34	34	34	34
	0x02042	56	56	56	56
	0x02043	78	78	78	78

Table 1975. Target Memory content dependent from CAR content (continued)

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
16-bit transfer	0x02040	12	56	xx	xx
	0x02041	34	78	xx	xx
	0x02042	xx	xx	12	56
	0x02043	xx	xx	34	78
8-bit transfer	0x02040	12	xx	xx	xx
	0x02041	xx	34	xx	xx
	0x02042	xx	xx	56	xx
	0x02043	xx	xx	xx	78



79.7.3 Register Write transfer

Register Write transfer can be of type:

- Normal Write transfer – channels 0, 1, 2 and 3

A Register Write transfer can be done through Normal Write transfer - channels 0, 1, 2 and 3 (refer to *Section 79.7.3.1: Normal write transfer*) as shown in *Figure 2067*.

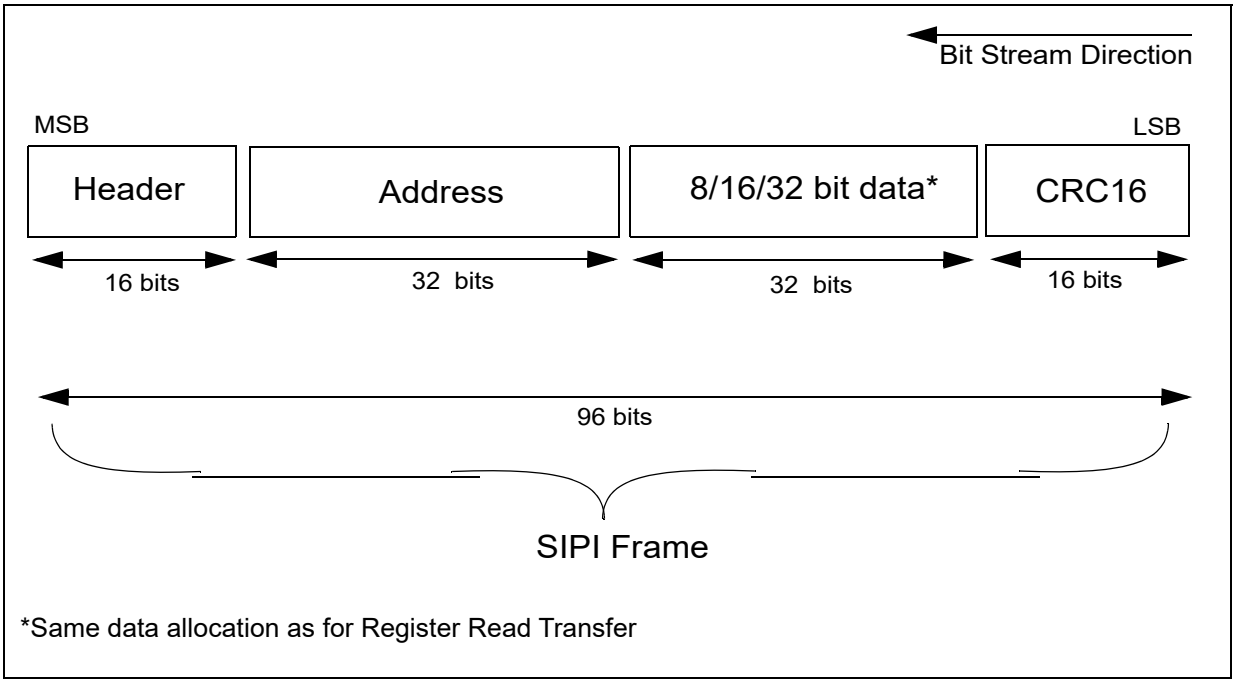


Figure 2067. Register write transfer (showing LFAST frame encapsulation)

79.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and 16-bit CRC as shown in *Figure 2068*.

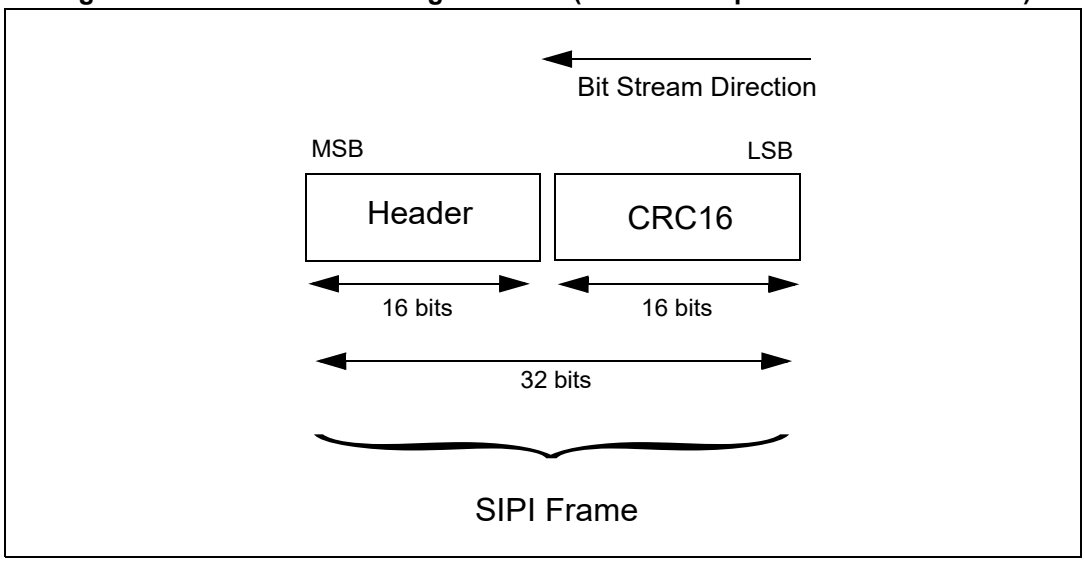
Figure 2068. Write transfer (LFAST frame encapsulation is not shown)

Note: In the case of an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as a byte enable:

Bits[1:0]:

- *00 – byte 3 enabled (MSB)*
- *01 – byte 2 enabled*
- *10 – byte 1 enabled*
- *11 – byte 0 enabled (LSB)*

In the case of a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as a half-word enable:



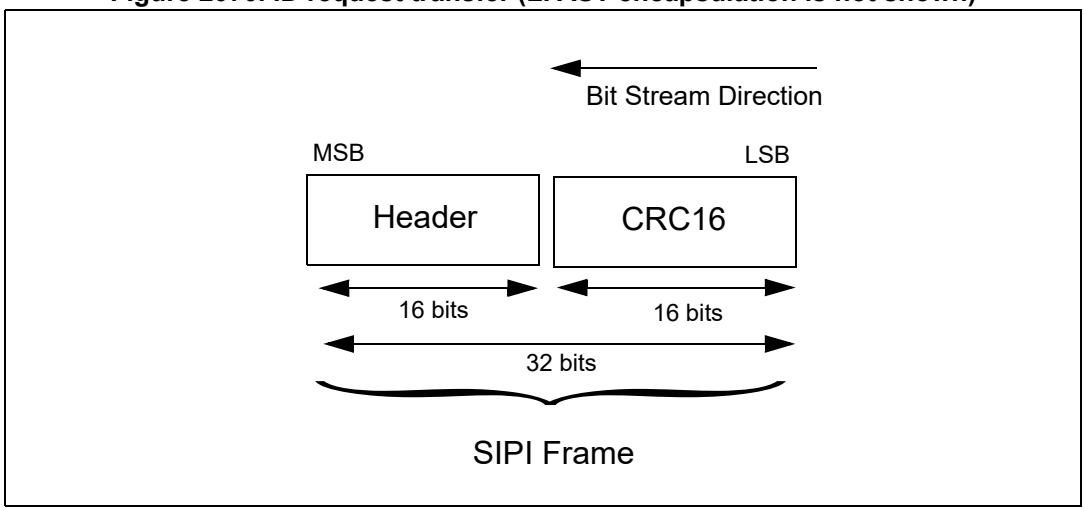
Bit[0]:

- *0 – half-word 1 enabled (MSB)*
- *1 – half-word 0 enabled (LSB)*

79.7.4 Write acknowledge transfer

A write acknowledge transfer contains only header and CRC bits (refer to *Figure 2069*). The CRC bits are calculated on the header field.

Figure 2069. Write acknowledge transfer (LFAST encapsulation is not shown)



79.7.5 ID request response

79.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in *Figure 2070*.

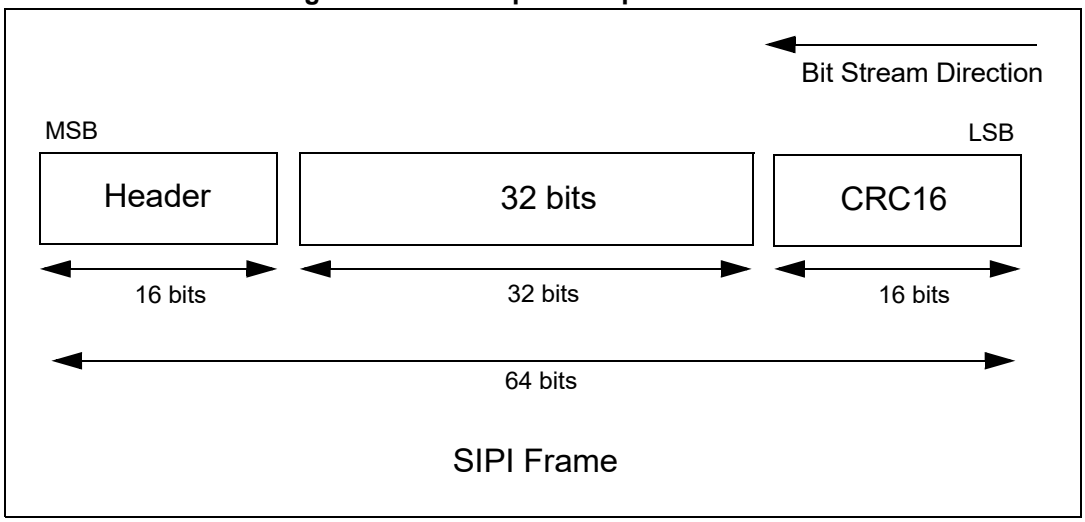


Figure 2070. ID request transfer (LFAST encapsulation is not shown)

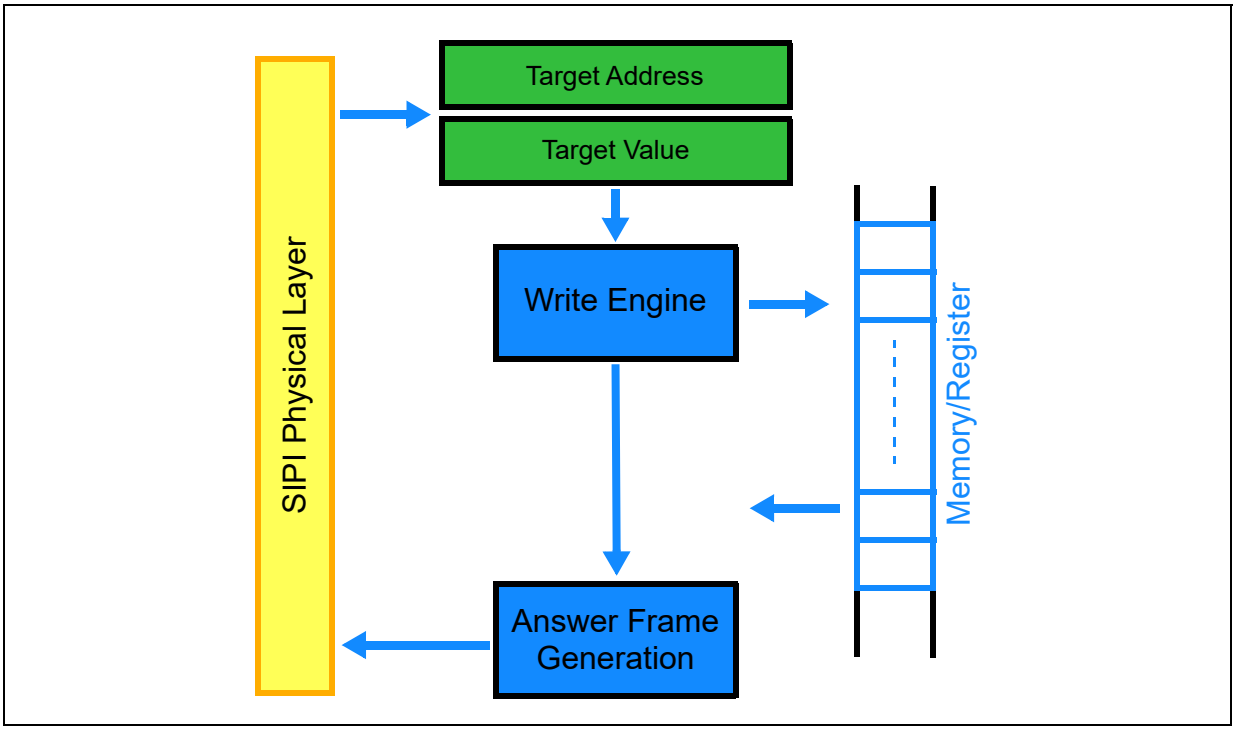
79.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in *Figure 2071*.

Figure 2071. ID request response transfer



Note: The ID request response contains the value of the CHIP ID in place of data.

79.8 Transfer API and flow charts

On a single write transfer request reception (refer to *Figure 2072*):

1. Debug SIPI will place the address, data and control information on its AHB master interface.
2. When the process in completed, the Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

Figure 2072. SIPI single register write API – Flow chart

On multiple write transfer request reception:

1. Debug SIPI will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

On single read transfer request reception:

1. Debug SIPI will place the address and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will send read response back to LFAST.

On multiple read transfer request reception:

1. Debug SIPI then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

79.9 CRC calculation

Example 1

If header is 0xAABB, address is 0x1122_3344 and data is 0xCCDD_EEFF. Then CRC calculation will take place as follows:

1. The CRC seed is initialized by 0xFFFF_FFFF.
2. All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
3. So the header will be sent as 0xDD55_0000, byte_enable = 0xC.
4. Address will be sent as 0x22CC_4488, byte_enable = 0xF.
5. Data will be sent as 0xFF77_BB33, byte enable = 0xF.

79.10 Memory map and register description

Table 1976. SIPI memory map

Offset from SIPI base (hex)	Register	Section/Page
0x0000–0x009B	Reserved

Figure 2073. SIPI Module Configuration Register (SIPI_MCR)

Table 1977. SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. 0 No Freeze mode request. 1 Enters Freeze mode if FRZ bit is asserted.
29 INIT	Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits cannot be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete. Statical configuration, data and address registers remain unchanged.

79.10.1.2 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Offset: 0x00A0 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

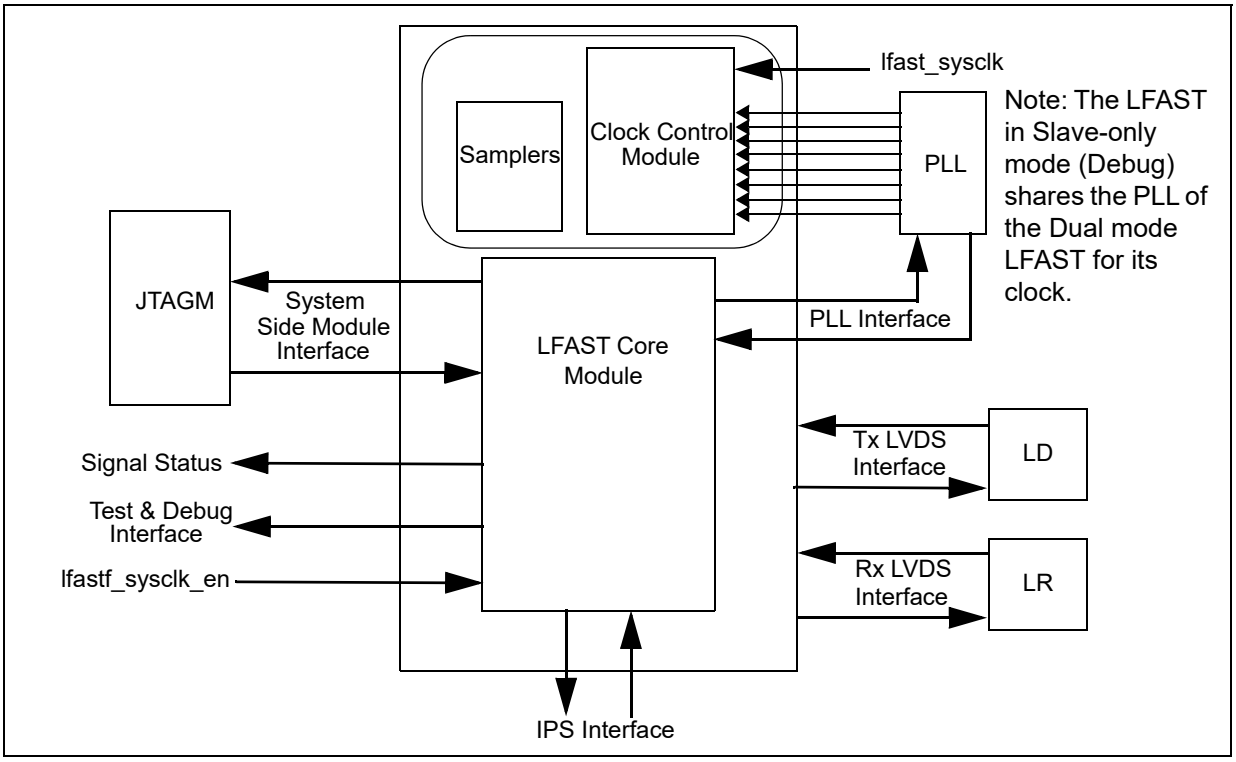
Figure 2074. SIPI Status Register (SIPI_SR)

Table 1978. SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI not in any low power modes 1 SIPI is in Disable mode

80 LVDS Fast Asynchronous Serial Transmission – High Speed Debug



80.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

80.2 Block diagram

Figure 2075 depicts LFAST interaction with other modules on the device.

Figure 2075. LFAST block diagram

80.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
  - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

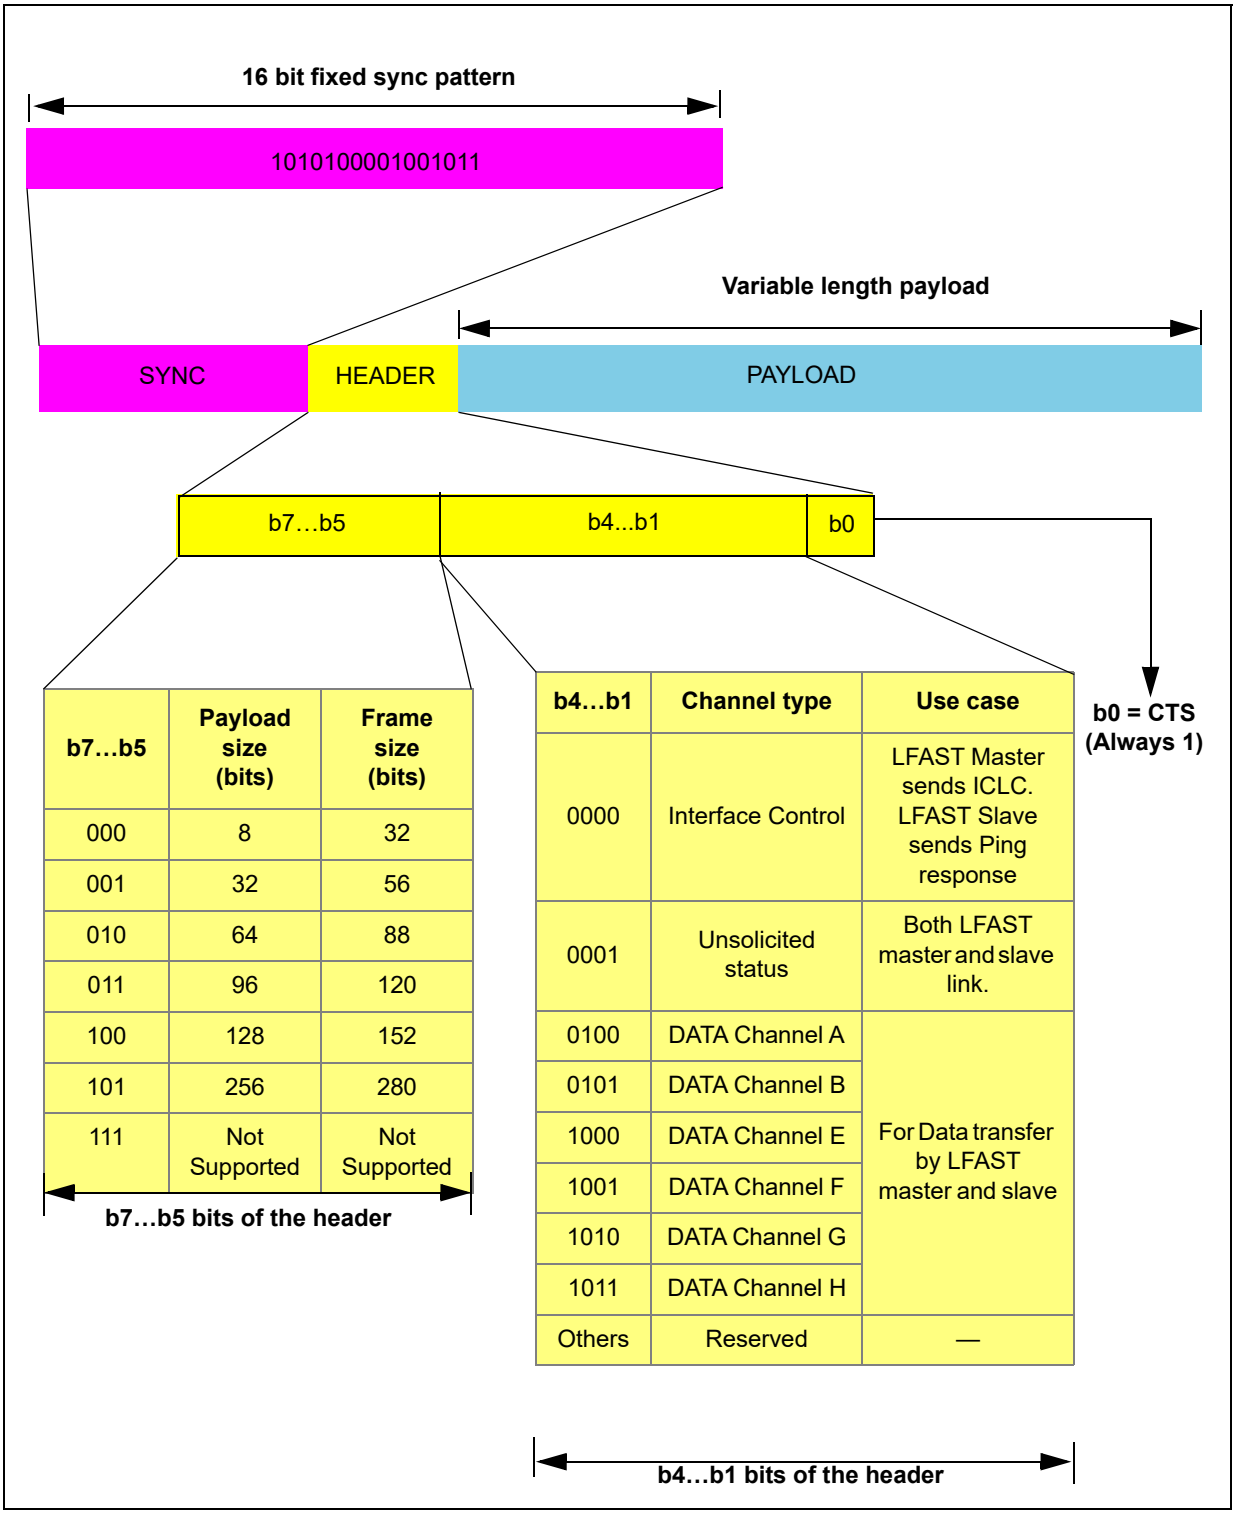
LFAST interface is an asynchronous high speed LVDS interface.

80.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

80.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.



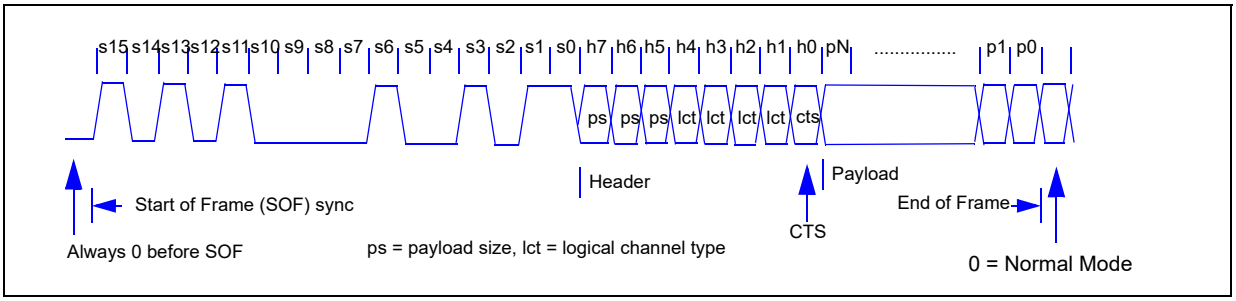
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See *Figure 2076* for details of the LFAST frame.

Figure 2076. LFAST frame structure



b7…b5	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported

b4…b1	Channel type	Use case
0000	Interface Control	LFAST Master sends ICLC. LFAST Slave sends Ping response
0001	Unsolicited status	Both LFAST master and slave link.
0100	DATA Channel A	For Data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	—

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 2077. Serial frame structure

The frame structure is shown in *Figure 2077* and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto-correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to *Table 1979*.

Table 1979. Header payload sizes

b7-b5 (bin)	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

80.5 Features

- Supports slave only mode
- Supports asynchronous data transfer rates up to the maximum data rated shown in the product Datasheet
- Transmits and receives data and unsolicited frames
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes
- Supports flow control using sliding window protocol
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits
- Supports PLL configuration (such as feedback loop divider) through registers
- Supports LVDS configuration through registers
- Supports multiple loopback modes for checking the physical interface
- Supports automatic ping response generation
- Supports for detection of unsupported channel number and unsupported payload size

80.6 Memory map and register definition

All registers are 32-bit wide.

80.6.1 Memory map

Table 1980. LFAST memory map

Offset from LFAST_BASE (hex)	Register	Access	Reset Value (hex)	Location
0000	LFAST Mode Configuration Register (MCR)	R/W	0x0000_0010	*Section 80.6.2.1*

1. Set by user software and cleared by system hardware.

Figure 2078. Mode Configuration Register (MCR)

Table 1981. MCR field descriptions

Field	Description
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode Refer to *Section 80.10.2: Slow speed clock* for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.

Table 1981. MCR field descriptions (continued)

Field	Description
17 RXEN	LFAST Receiver Enable This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave hardware on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
27 TXARBD	Tx Arbiter Disable This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
30 DRFRST	LFAST Soft Reset This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

80.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Offset: 0x0004 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Only writable when MCR[DRFEN] = 0.

Figure 2079. Speed Control Register (SCR)

Table 1982. SCR field descriptions

Field	Description
15 DRMD	Data Rate Controller mode Defines the mode set for LFAST slave device by the software or the LFAST master. This bit should not be modified by the software and left as SCR[DRMD] =1.
23 RDR	Receiver Data Rate This bit defines the receiver data rate. This bit should not be modified by the software.
31 TDR	Transmit Data Rate This bit defines the transmitter data rate. This bit should not be modified by the software.

80.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Only writable only when MCR[RXEN] = 0.

Figure 2080. Correlator Control Register (COCR)

Table 1983. COCR field descriptions

Field	Description
0:7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection) Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 0x00 Sampler Data Path selected by correlator 0x01 Sampler Data Path 0 selected 0x02 Sampler Data Path 1 selected 0x04 Sampler Data Path 2 selected 0x08 Sampler Data Path 3 selected 0x10 Sampler Data Path 4 selected 0x20 Sampler Data Path 5 selected 0x40 Sampler Data Path 6 selected others Sampler Data Path 7 selected
28:30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation …. 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 0 8 phases 1 4 phases

80.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Offset: 0x000C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Writable only when TMCR[LPON] = 0.

Figure 2081. Test Mode Control Register (TMCR)

Table 1984. TMCR field descriptions

Field	Description
6 CLKTST	Clock Test mode The software can define when the clock test mode is enabled. This bit can also be set and cleared by hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable The software can define when the loopback logic is enabled. This bit can also be written by LFAST slave hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled. 0 Loopback mode is disabled.
13:15 LPMOD	Loopback mode Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by the software)
16:31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Check 1 frame have correct sync, header and payload. … 0xFFFE: Check 65534 frames have correct sync, header and payload. 0xFFFF: Check 65535 frames have correct sync, header and payload.

80.6.2.5 Auto Loopback Control Register (ALCR)

1. Writable only when TMCR[LPON] = 0.

Figure 2082. Auto Loopback Control Register (ALCR)

Table 1985. ALCR field descriptions

Field	Description
15 LPCNTEN	Auto Loopback Frame Transmission Count Enable Enables fixed number of auto predefined loopback frame transmission. 0 Infinite predefined loopback frame transmission enabled 1 Fixed count of predefined loopback frame transmission enabled
16:31 LPFMCNT	Auto Loopback Frame Transmission Count Defines the number of predefined auto loopback frames to be sent. The predefined loopback frame has payload CBh, header 13h and valid sync. This mode is valid if TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Send 1 frame with correct sync, header and payload. ... 0xFFFE: Send 65534 frames with correct sync, header and payload. 0xFFFF: Send 65535 frames with correct sync, header and payload.

80.6.2.6 Rate Change Delay Control Register (RCDCR)

Offset: 0x0014 Access: User read/write

1. Only writable when MCR[DRFEN] = 0.

Figure 2084. Wakeup Delay Control Register (SLCR)

Table 1987. SLCR field descriptions

Field	Description
0:7 HSCNT	High Speed Sleep mode Exit Time Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. 0x00: cycle 0x01: 1 cycle … 0x12: 18 cycles (200 ns + 8 cycles of High speed clock) … 0xFE: 254 cycles 0xFF: 255 cycles
12:15 LSCNT	Low Speed Sleep mode Exit Time Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. 0x0: 0 cycle 0x1: 1 cycle (200ns + 1 cycle of Low speed clock) … 0xE: 14 cycles 0xF: 15 cycles
16:23 HWKCNT	Wake Up time for the LD Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. 0x00: 0 cycles 0x01: 1 cycle … 0x5F: 95 cycles (1.18 us) … 0xFF: 255 cycles Maximum
28:31 LWKCNT	Wake Up time for the LD Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. 0x0: 0 cycle 0x1: 1 cycle 0x2: 2 cycles (1.18 us) … 0xE: 14 cycles 0xF: 15 cycles

1. Set by user software and cleared by system hardware.
2. Only writable when MCR[DRFEN] = 0.

Figure 2085. Ping Control Register (PICR)

Table 1988. PICR field descriptions

Field	Description
15 PNGREQ	Ping Response Frame Request This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. This field can only be written when MCR[DRFEN] = 1. 1 Ping response frame transmission request is queued. 0 No pending Ping response frame transmission request.
16 PNGAUTO	Ping Response Enable Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master This bit should not be modified by the software.
24:31 PNGPYLD	Defines the LFAST slaves ping reply frame payload content.

80.6.2.9 LVDS Control Register (LCR)

Figure 2086. LVDS Control Register (LCR)

Table 1989. LCR field description

Field	Description
8 SWWKLD	Software signal to take LVDS LD out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep).
9 SWSLPLD	Software signal to put LVDS LD into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep.
10 SWWKLR	Software signal to take LVDS LR out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep).
11 SWSLPLR	Software signal to put LVDS LR into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up).
12 SWOFFLD	Software signal to turn OFF the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.

Table 1989. LCR field description (continued)

Field	Description
13 SWONLD	Software signal to turn ON the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
14 SWOFFLR	Software signal to turn OFF the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
15 SWONLR	Software signal to turn ON the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode.
17 LVTXOE	LVDS LD output buffer enable 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad.
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only). 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only). 0 Use for LFAST receiver baud rates less than maximum baud rate 1 Required for LFAST receiver maximum baud rate
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection 0 Micro-Second Bus selection 1 LFAST Bus selection

Table 1989. LCR field description (continued)

Field	Description
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 Normal clock used to sample the LVDS data 1 Adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

80.6.2.10 Unsolicited Tx Control Register (UNSTCR)

Offset: 0x0044 Access: User read/write

Figure 2096. Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Table 1999. UNSRDR8–UNSRDR0 field descriptions

Field	Description
0:31 UNRXD	Unsolicited Receive Data This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288-bit payload.

80.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements (Refer to the “Functional safety” chapter for register classification details. All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

80.7 Functional description

80.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

80.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCR are programmed according to the LVDS parameter in the device datasheet.
2. The PLLCR[30] is programmed with the configuration parameters of the PLL.
3. The LCR is programmed with the configuration parameters of the LVDS.
4. MCR[DATAEN] fields is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 0x31 is received the hardware writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 0x00 frame is received and the hardware writes RIISR[ICPRF] = 1.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 0x02 is received and the hardware writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 0x80 is received and the hardware writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 0x10 is received and the hardware writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 0x00 is received and the hardware writes RIISR[ICPRF] = 1.

80.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

LFAST interface enable (lfast_sysclk_en) negation:

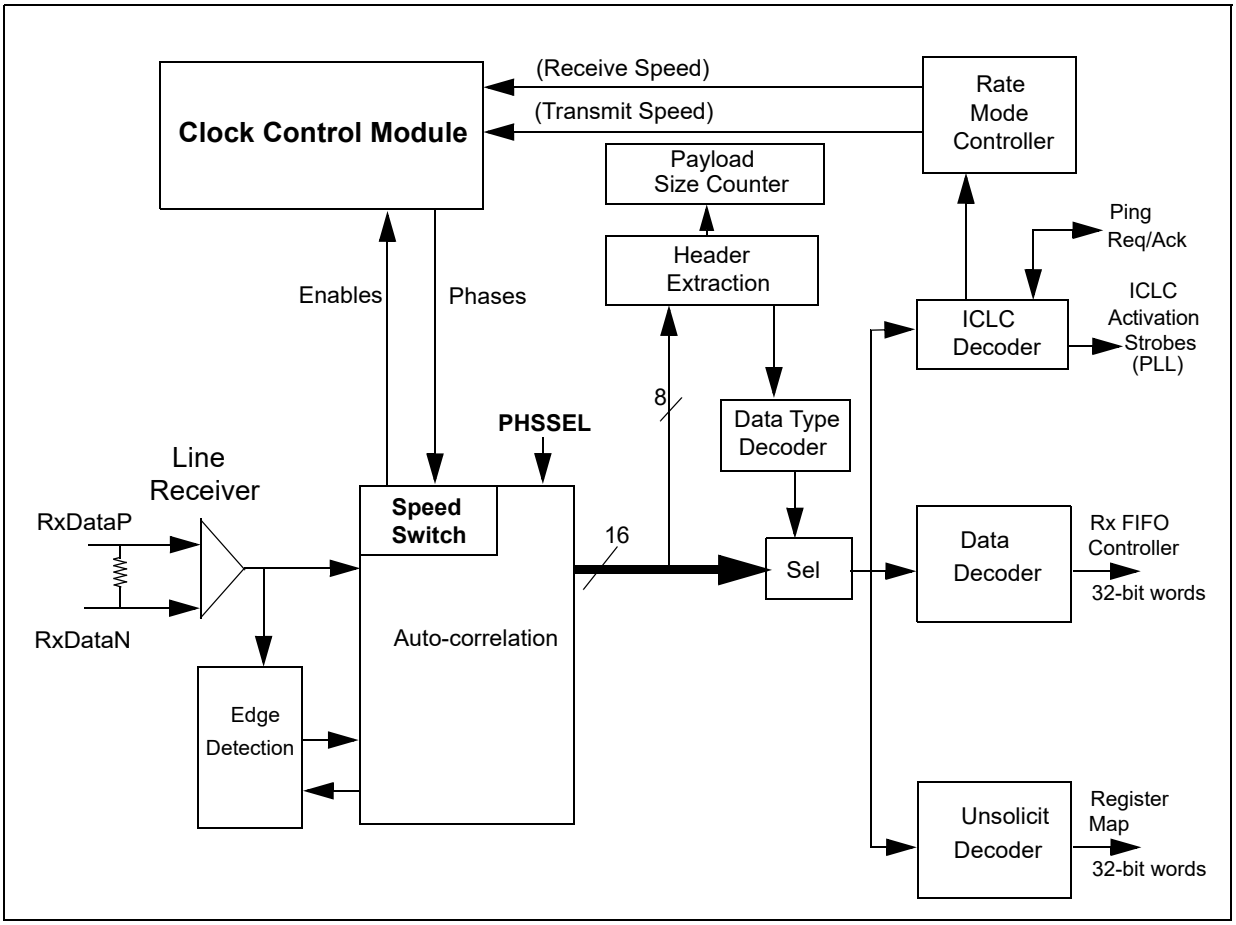
1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then the software writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

30. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

1. The LD LVDS pad is power up, if all conditions are met:
   – LCR[SWOFFLD] = 0.
   – LCR[SWONLD] = 1.
   – MCR[TXEN] = 1.
   – When frame ICR[ICLCPLD] = 0x31 is received.
2. LR LVDS pad is powered up if all conditions are met:
   – LCR[SWOFFLR] = 0.
   – LCR[SWONLR] = 1.
   – MCR[RXEN] = 1.

80.7.3 Line Receiver (LR)



80.7.3.1 Introduction

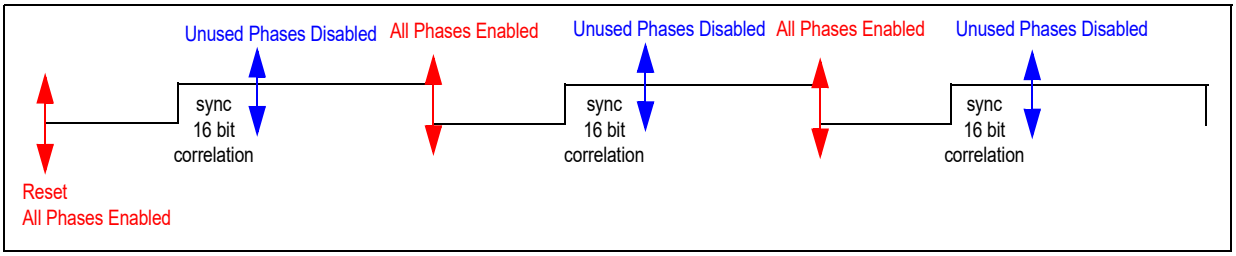
The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto-correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 2097 shows the block diagram of Uplink controller.

Figure 2097. Top level receive controller

80.7.3.2 Edge-detection and auto-correlation



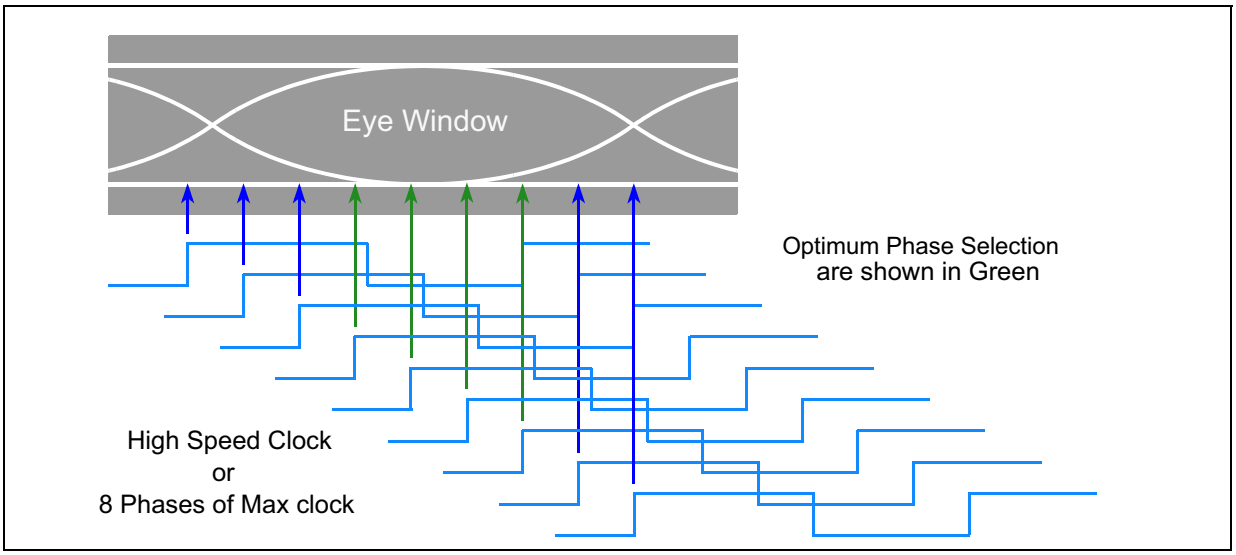
The edge-detection and auto-correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

80.7.3.2.1 Auto-correlation modes

80.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

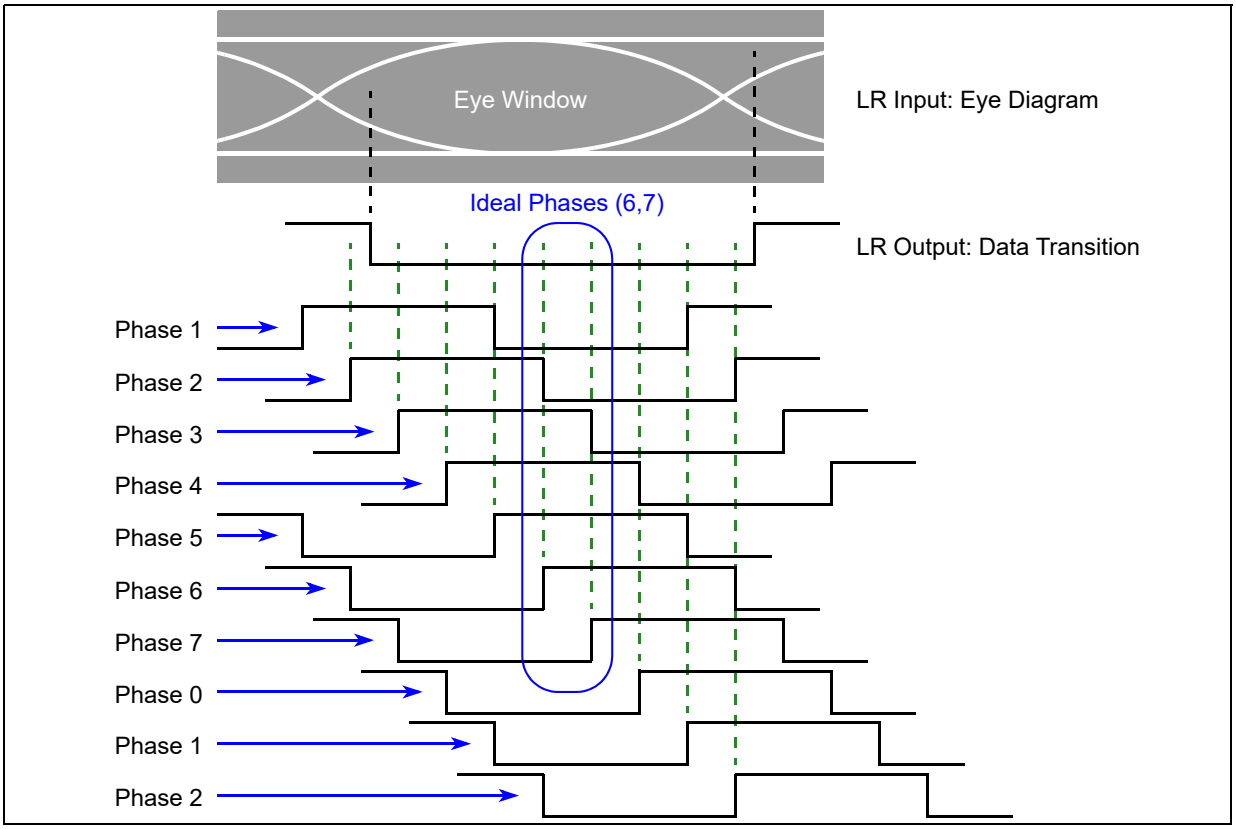
Figure 2098. Hunt correlation mode



80.7.3.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

80.7.3.2.3 Auto-correlation



The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto-correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in *Figure 2099*.

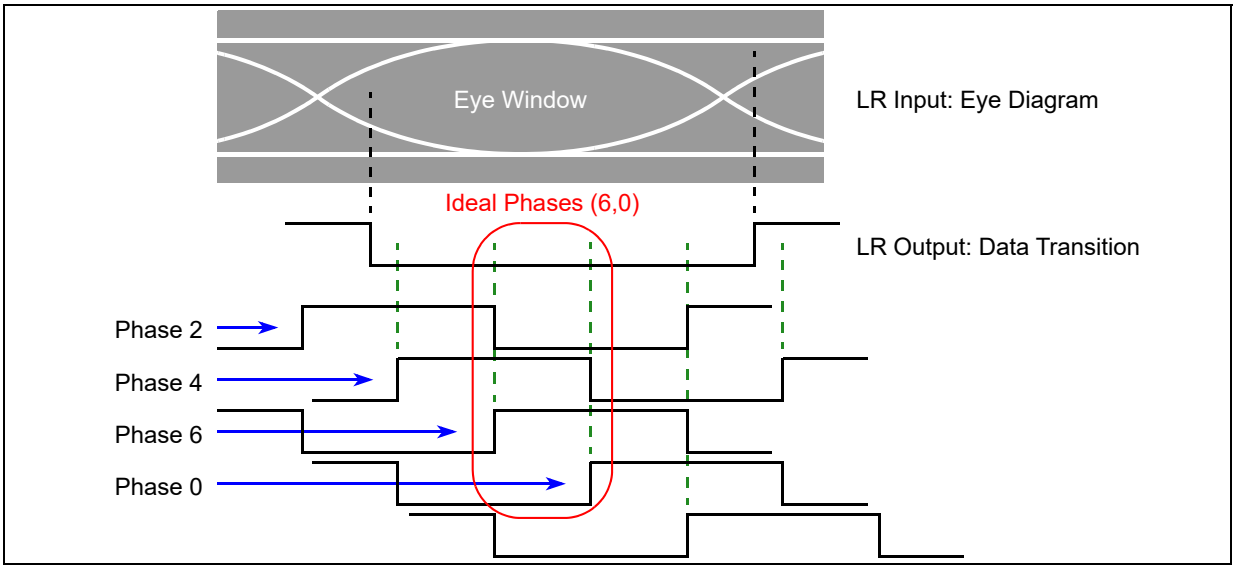
Figure 2099. High speed 8 phase selection

The objective of the auto-correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in *Figure 2100*.

Figure 2100. High speed 8 phase clock alignment example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in *Figure 2101* and *Figure 2102*.

Figure 2101. High speed 4 phase clock alignment example



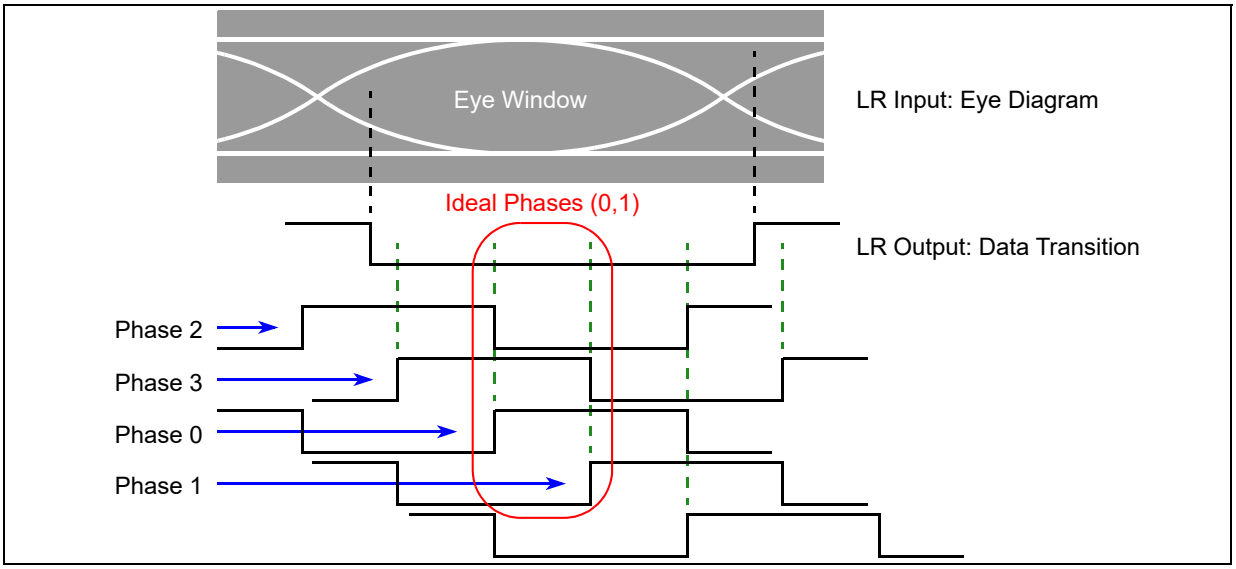


Figure 2102. Low speed 4 phase clock alignment example

The auto-correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to an intermediate phase as shown in *Table 2000*, *Table 2001*, and *Table 2002* before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 2000. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0

6	Phase 6	Phase 4	Phase 0
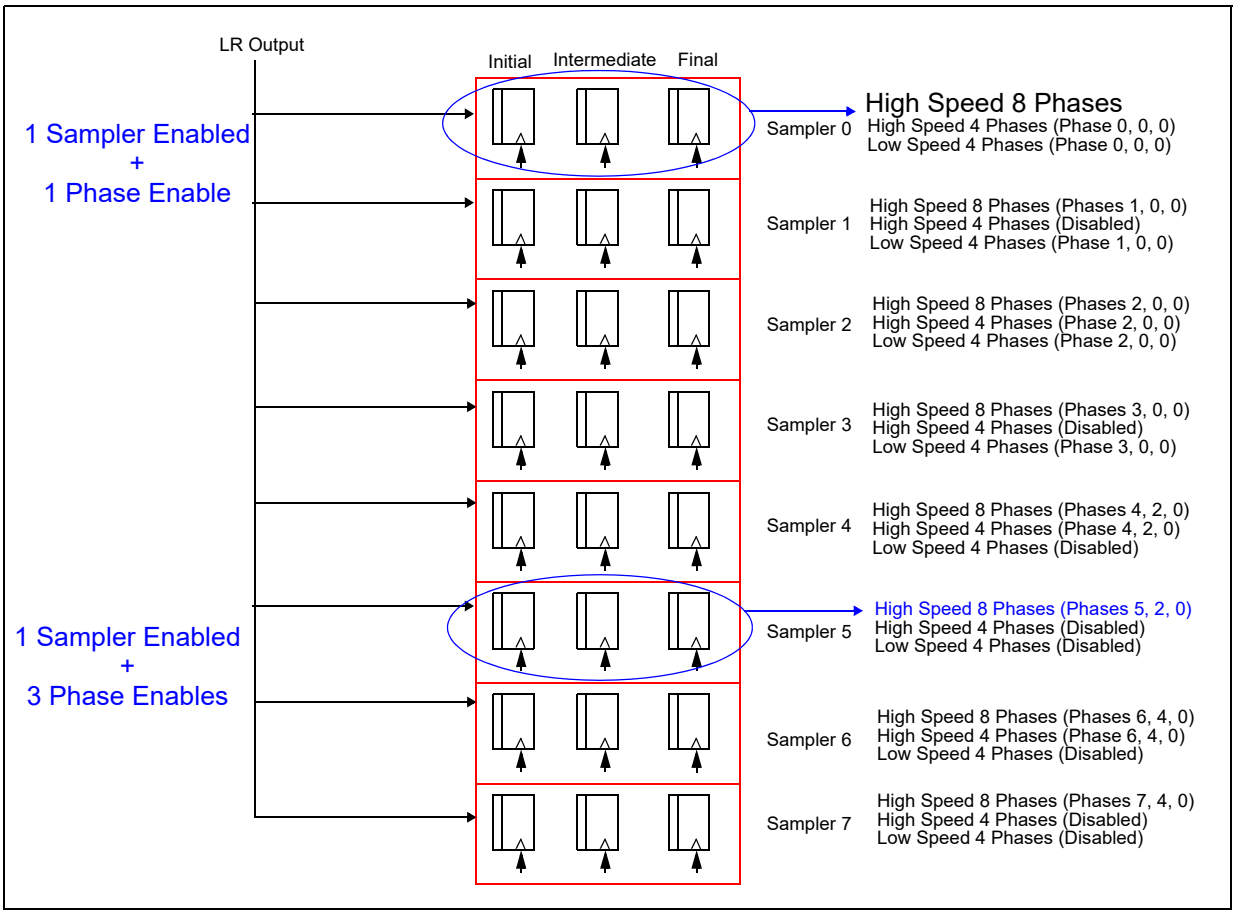
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See *Table 2001*, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 2002. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See *Table 2002*, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.



80.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto-correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in *Figure 2103*.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for instance Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

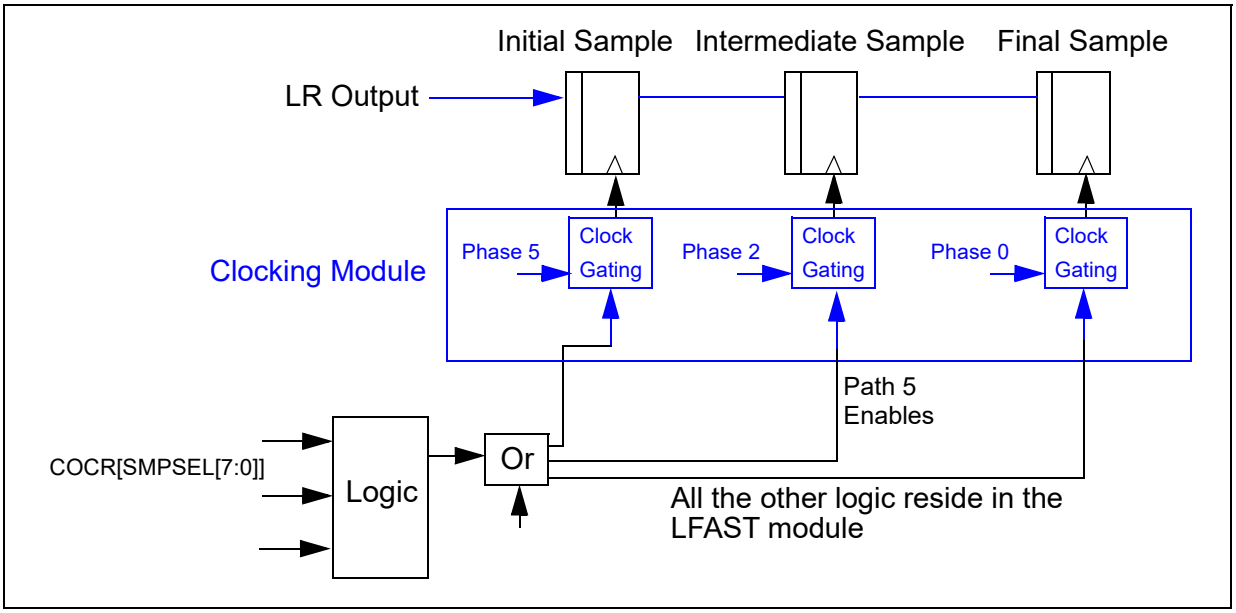


Figure 2103. Samplers, each sampler has 3 registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in *Figure 2104*.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

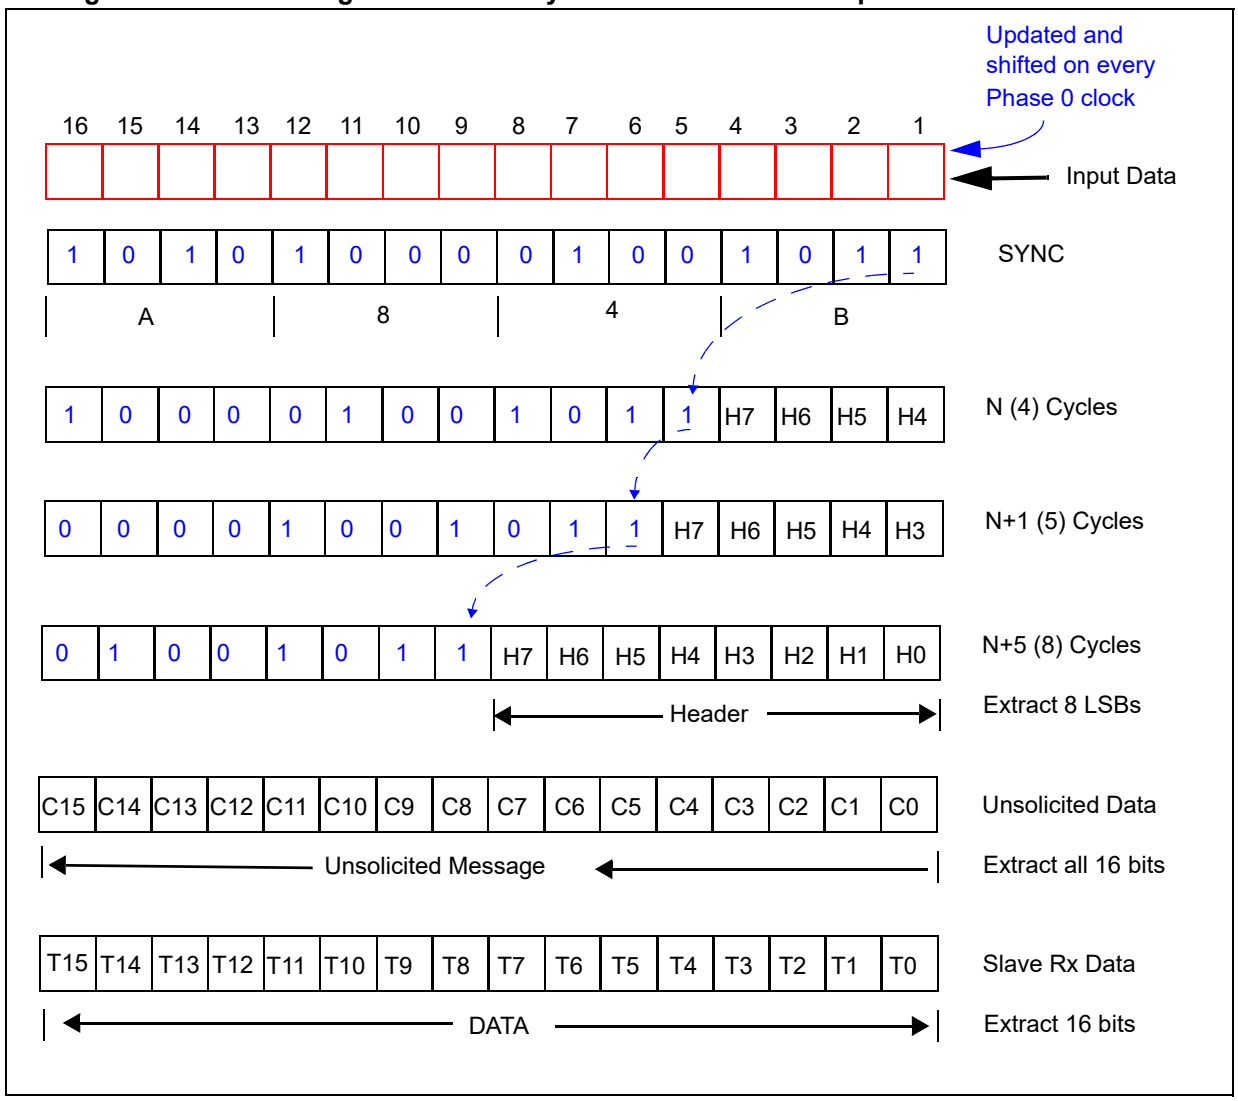

Figure 2104. Sampler 5 Logic

80.7.3.3 Header and Payload extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16-bit word, bit shifted every Phase 0 clock as shown in *Figure 2105*.

Figure 2105. Extracting Header and Payload from the 16-bit output from Auto-correlation

80.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown
  The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep
  The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- Normal
  In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 2003. Line Receiver state

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

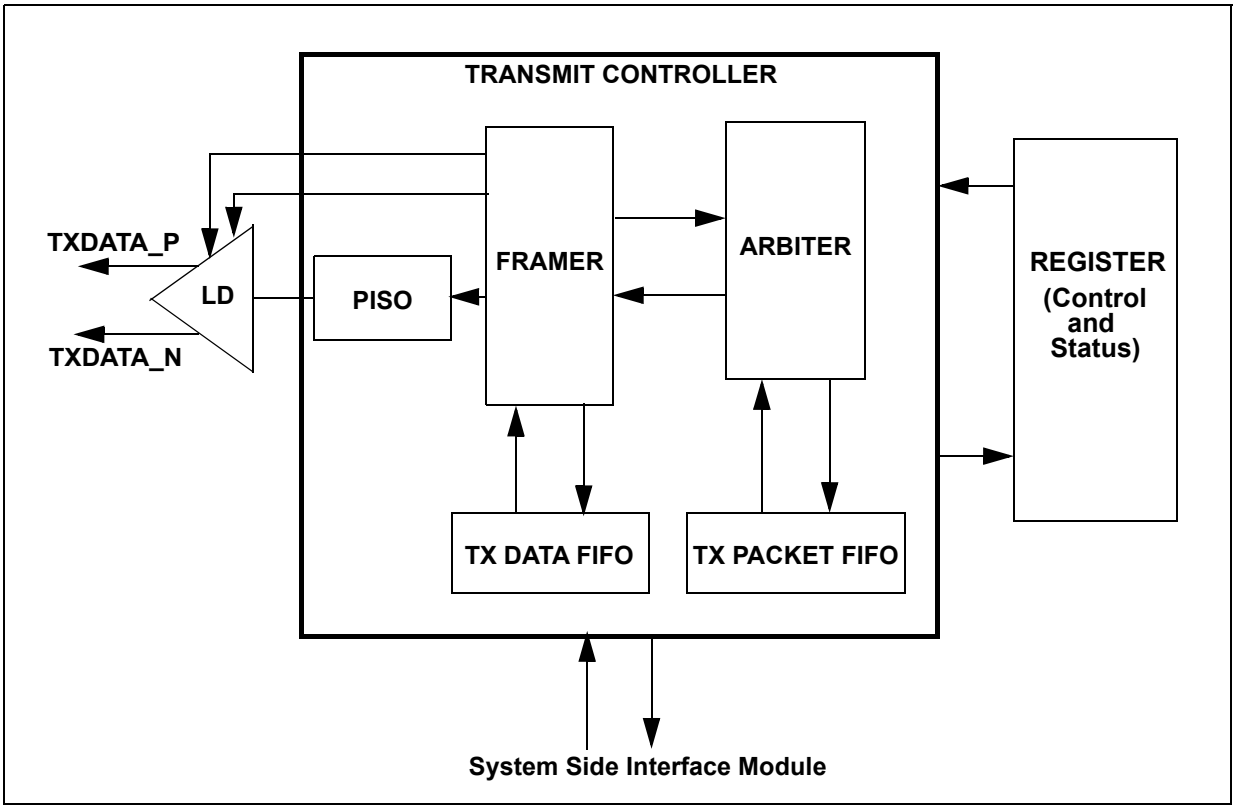
80.7.4 Transmit controller

80.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, such as unsolicited, ICLC, ping. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:



- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in *Figure 2106*.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 2106. Transmit controller connections

80.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- Software programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in *Table 2004*.

Table 2004. Priority levels for the Transmit controller

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 2004. Priority levels for the Transmit controller (continued)

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

Table 2005. Line driver states

LD state	LFAST slave triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

80.7.5 Frames supported

Table 2006 provides the frames supported and their permissible payload sizes

Table 2006. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO(1)	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

80.7.6 Frame flow

The following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

80.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

80.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

80.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.

80.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

80.7.6.2 Unsolicited flow

80.7.6.2.1 Unsolicited frame transmit flow

The software is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

80.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the *Mode Configuration Register (MCR)* to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1.
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

80.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

80.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

80.7.6.3.1 .ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

80.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The software can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame.The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

80.7.6.3.1.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

80.7.6.3.1.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

80.7.6.3.1.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or software programs MCR[TXEN] = 1.

80.7.6.3.1.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

80.7.6.3.1.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

80.7.6.3.1.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

80.7.7 Test and debug support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

80.7.7.1 Loopback test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

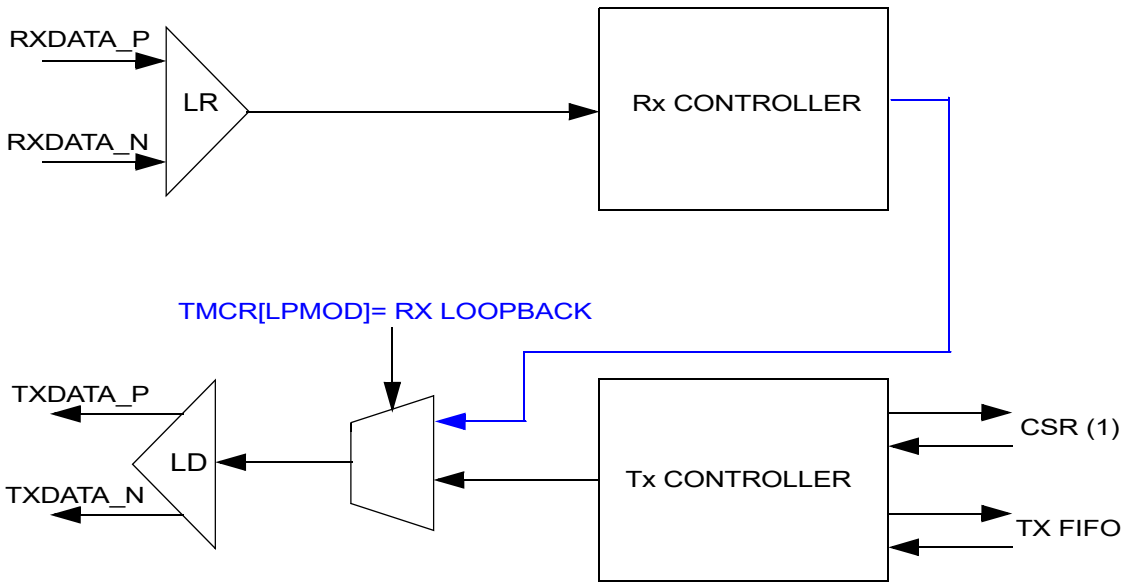
- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for software should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 2007. Loopback modes

LPMOD[2:0]	Mode selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by the software, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.



In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

80.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

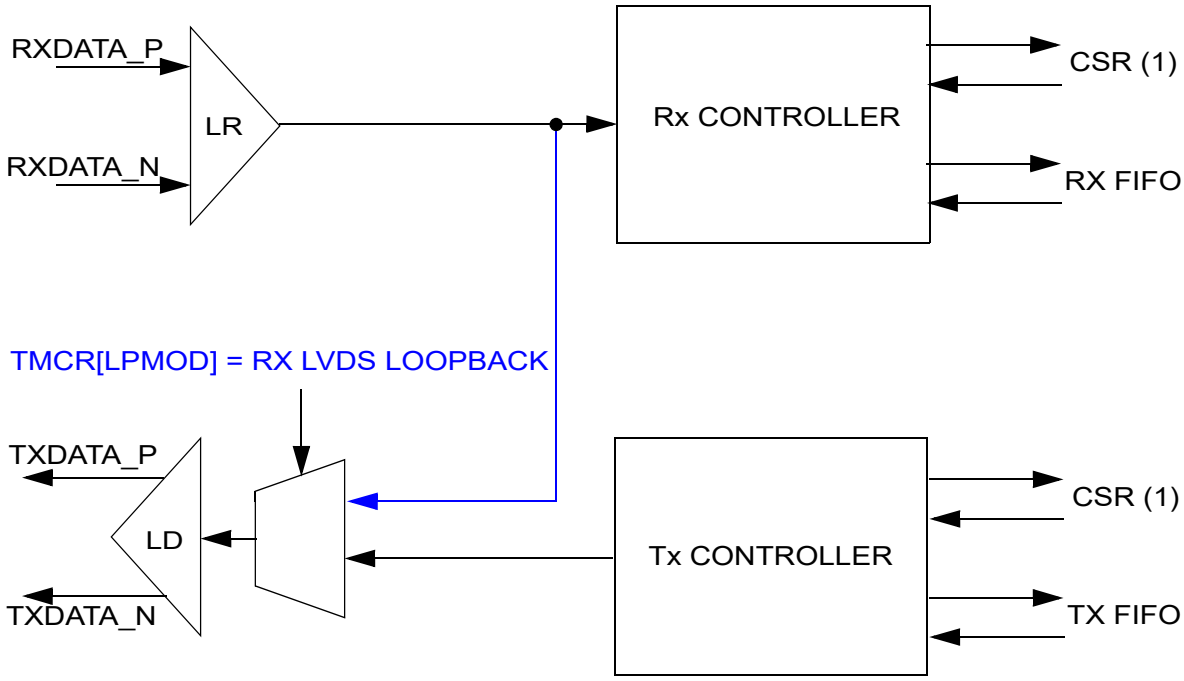
Figure 2107. Rx Loopback mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx Loopback mode:

1. Software programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload 0xFF (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:



- Software programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 0x38 (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

80.7.7.1.2 Rx LVDS Loopback mode

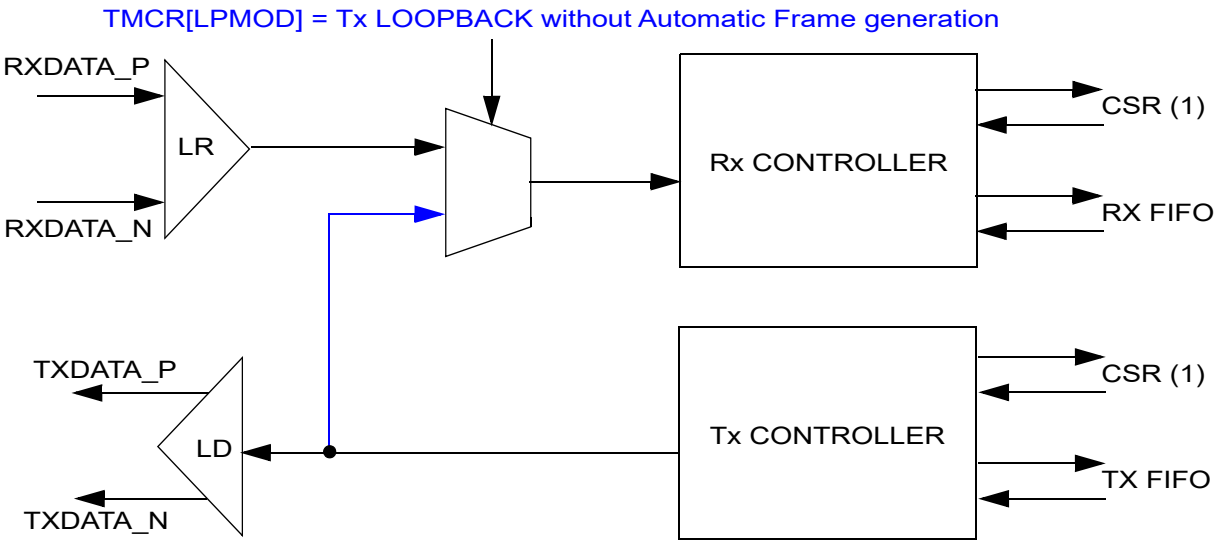
This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 2108. Rx LVDS LoopBack mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx LVDS Loopback mode:

1. Software programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   - The software writes TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload = 0xFF (Loopback mode ON), from LFAST Master.



Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 0x38 (Test mode off), from LFAST Master.
  - Deassertion of the LFAST interface enable (lfast_sysclk_en).

80.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 2109. Tx LoopBack mode without automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback without Automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from LFAST Master

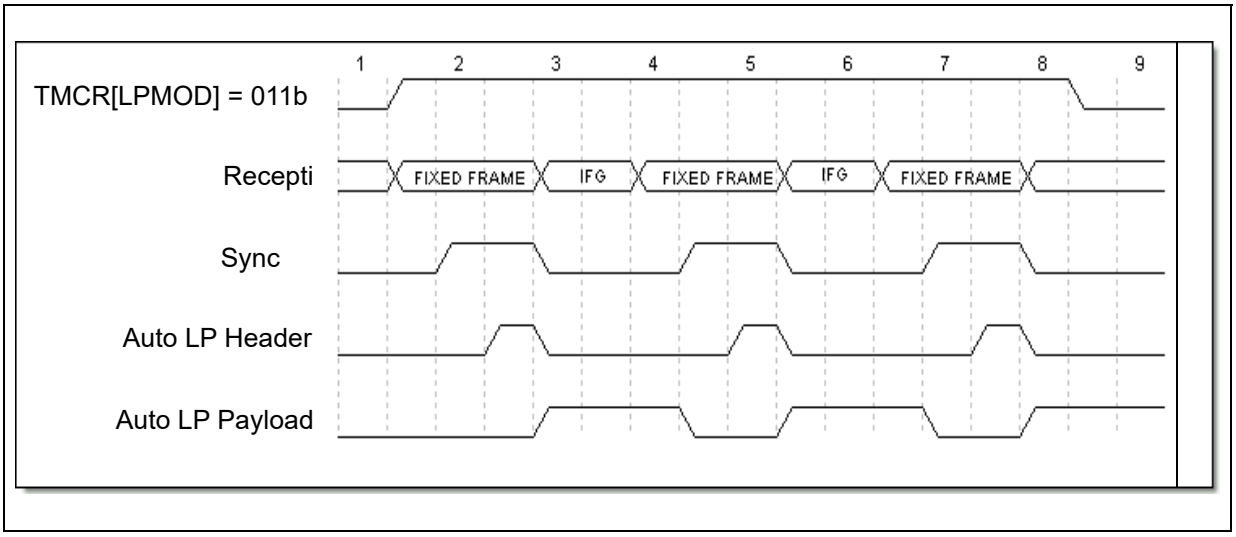
Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

80.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal software intervention.



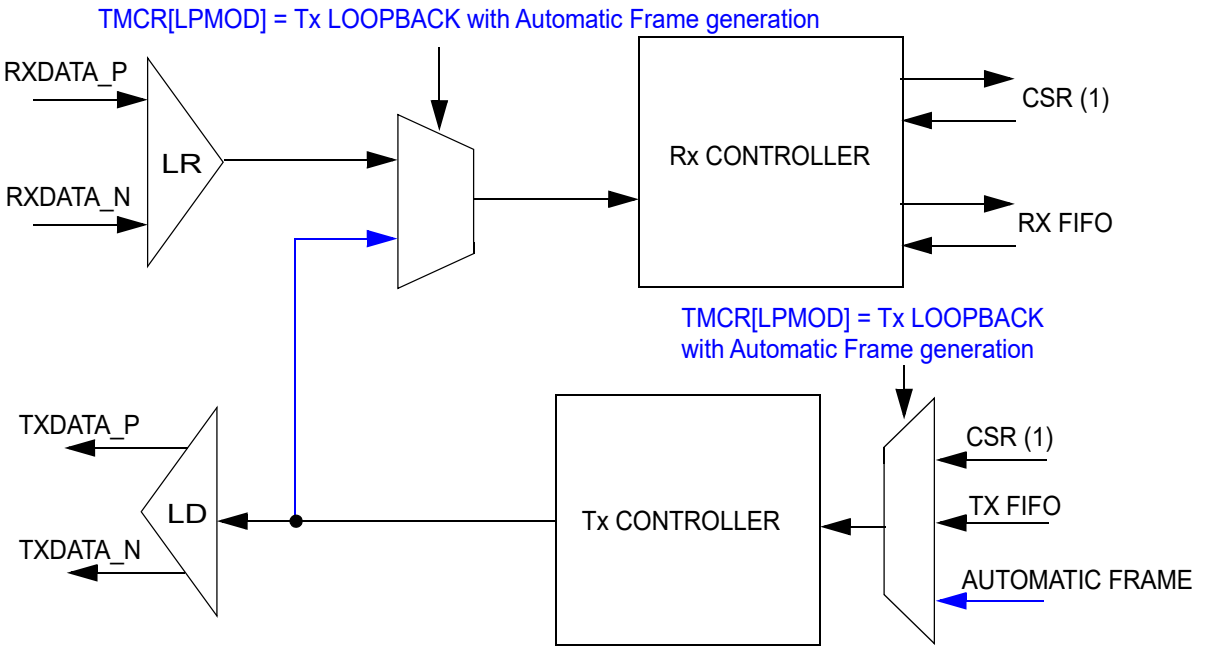
The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 0x13 received.
- GSR[LPCPDV]: Frame with Payload of 0xCB received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 2110. Automatic Loopback test status signal timings



The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

80.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

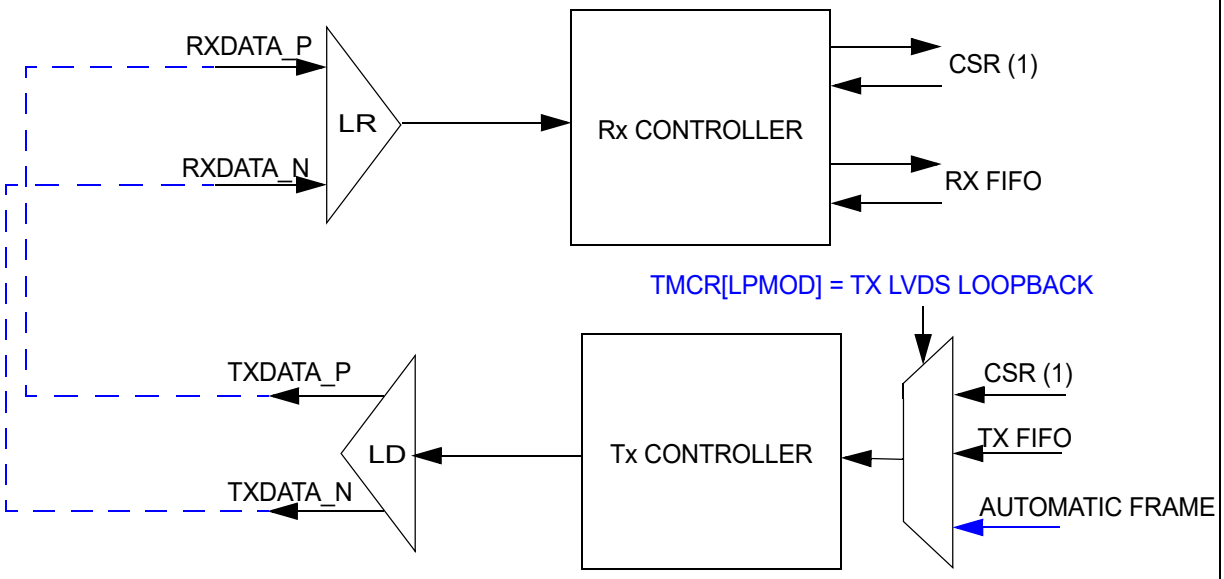
When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the software. The frames generated have fixed header of 0x13 and payload of 0xCB. The successful reception of this frame is indicated by the status signals and registers.

Figure 2111. Tx LoopBack mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from the LFAST Master.



Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

80.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 2112. Tx LVDS Loopback (external) mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx LVDS loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

80.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- Software programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 0x34 (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be canceled by any of the following methods:

- Software programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

80.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 2008. Frames supported by LFAST interfaces

Frame Type	Tx Buffer (in bits)	Rx Buffer (in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet(1)	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

1. Ping response packet

80.9 Resets

The various blocks in LFAST are reset as described in *Table 2009*.

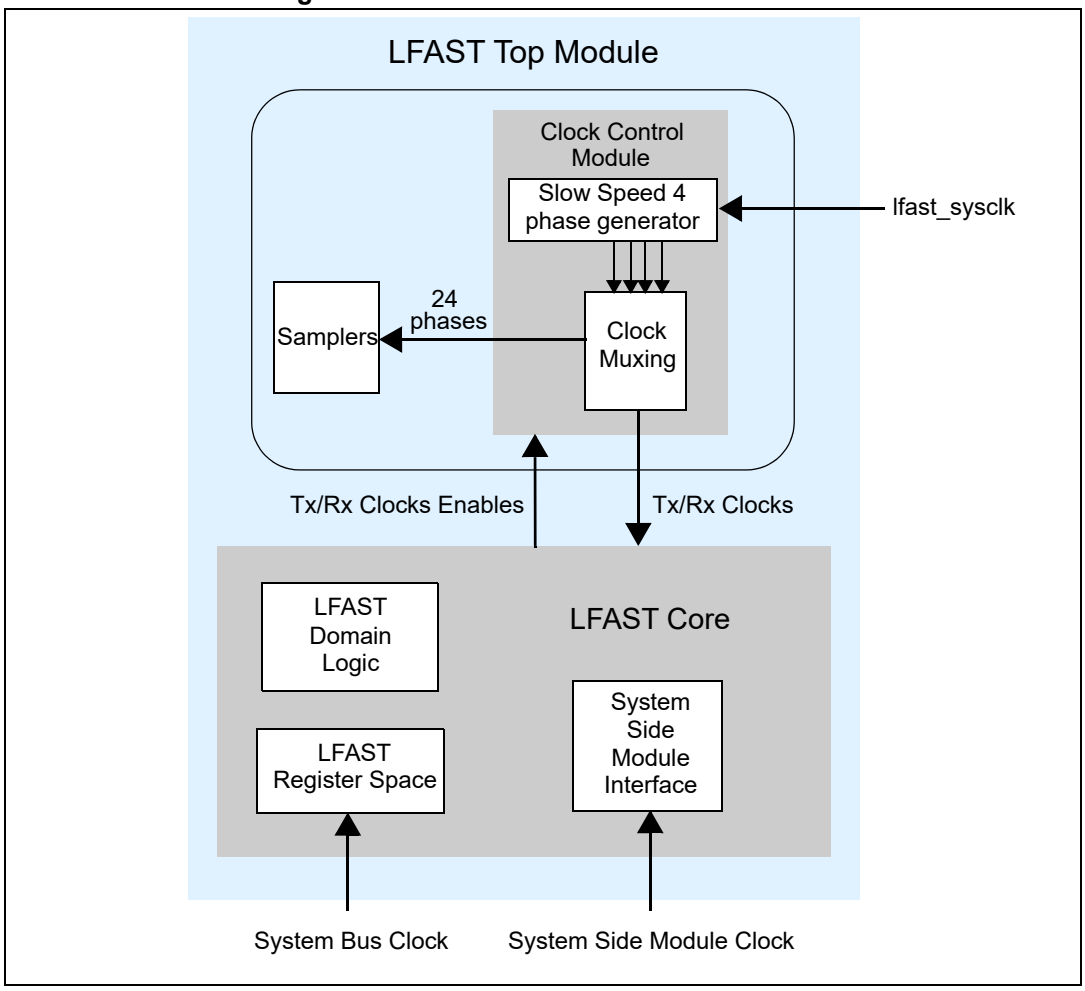
Table 2009. Recommended receive exception handling mechanism

Reset	Blocks reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of *Mode Configuration Register (MCR)*	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space

Table 2009. Recommended receive exception handling mechanism (continued)

Reset	Blocks reset
DRFEN bit of *Mode Configuration Register (MCR)*	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

80.10 Clocks



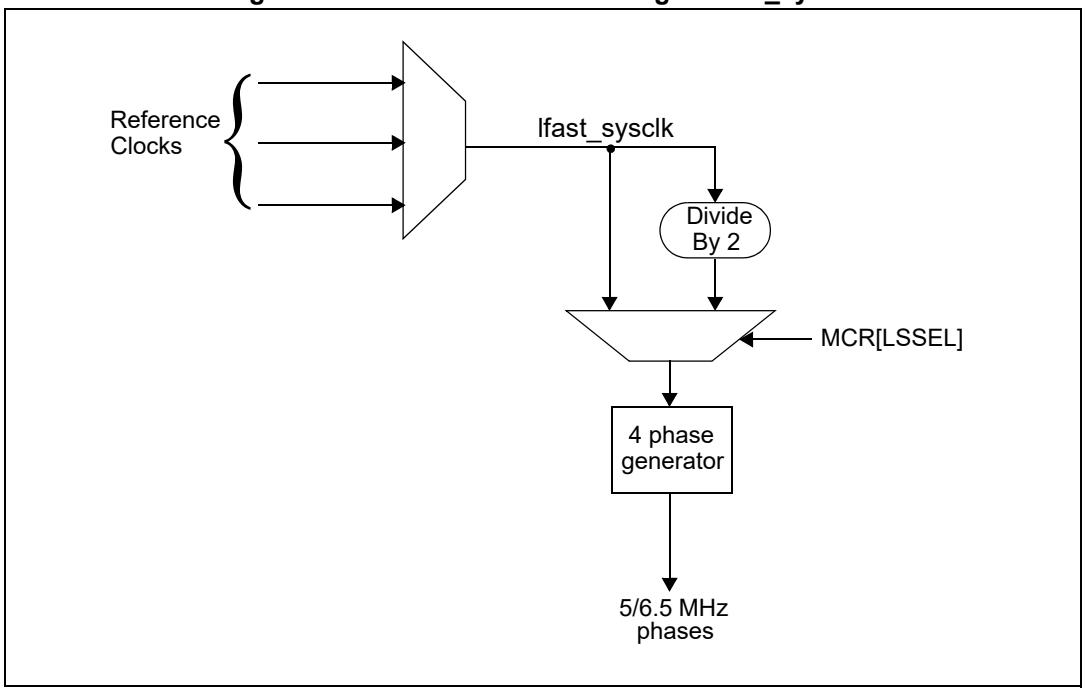
The LFAST mainly works on two clocks:

- System Bus Clock, used to program the registers.
- System Side Module clock, which is synchronous to the System Bus clock.

80.10.1 Clocking strategy

Figure 2113 shows the clock domain in which each module functions. The Clock Module will generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 2113. LFAST module clock domains



80.10.2 Slow speed clock

80.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in *Figure 2114*, *Figure 2115* and *Figure 2116*.

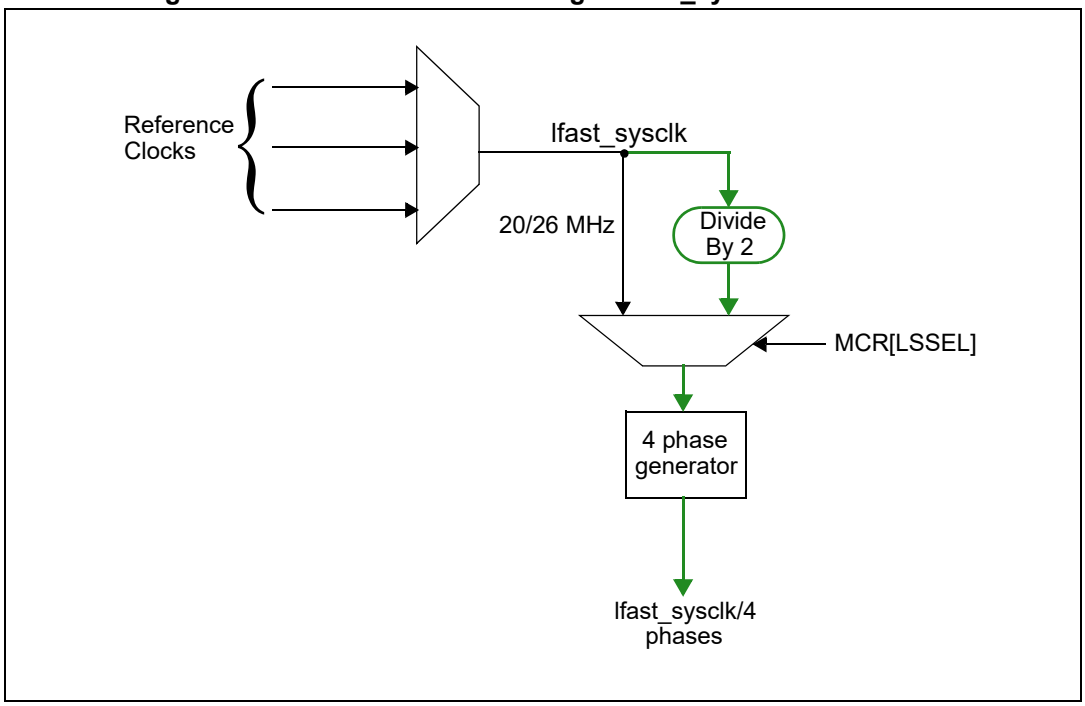


Figure 2114. External clock muxing of lfast_sysclk

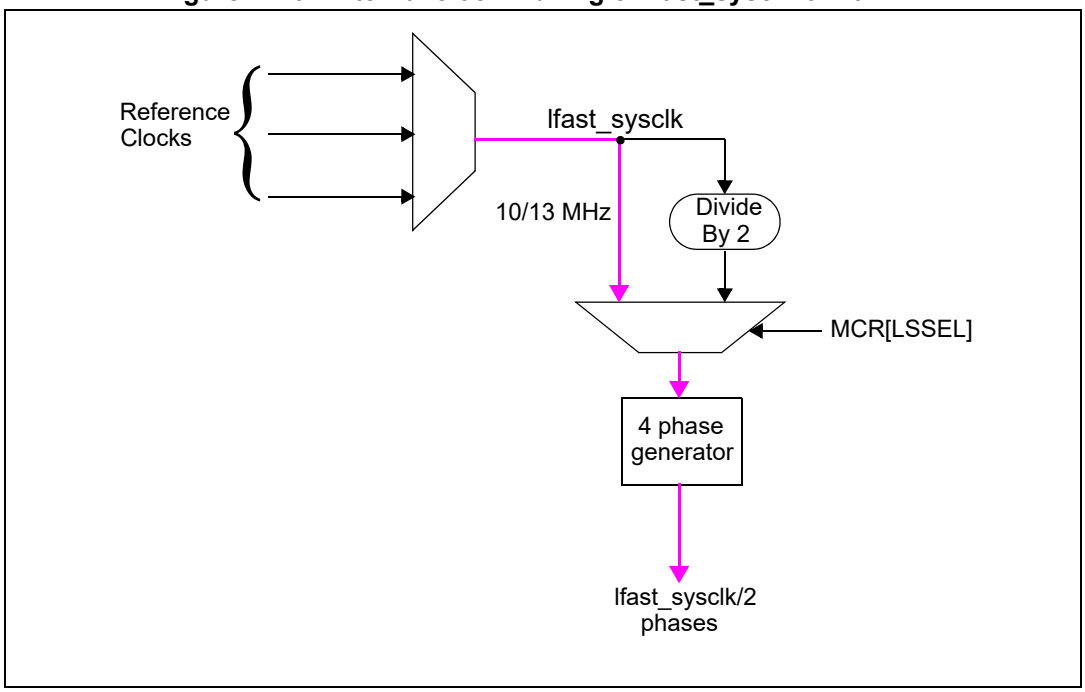
All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in *Figure 2114*.



The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2115* (selected clock path shown in green).

Figure 2115. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2116* (selected clock path selected shown in magenta).

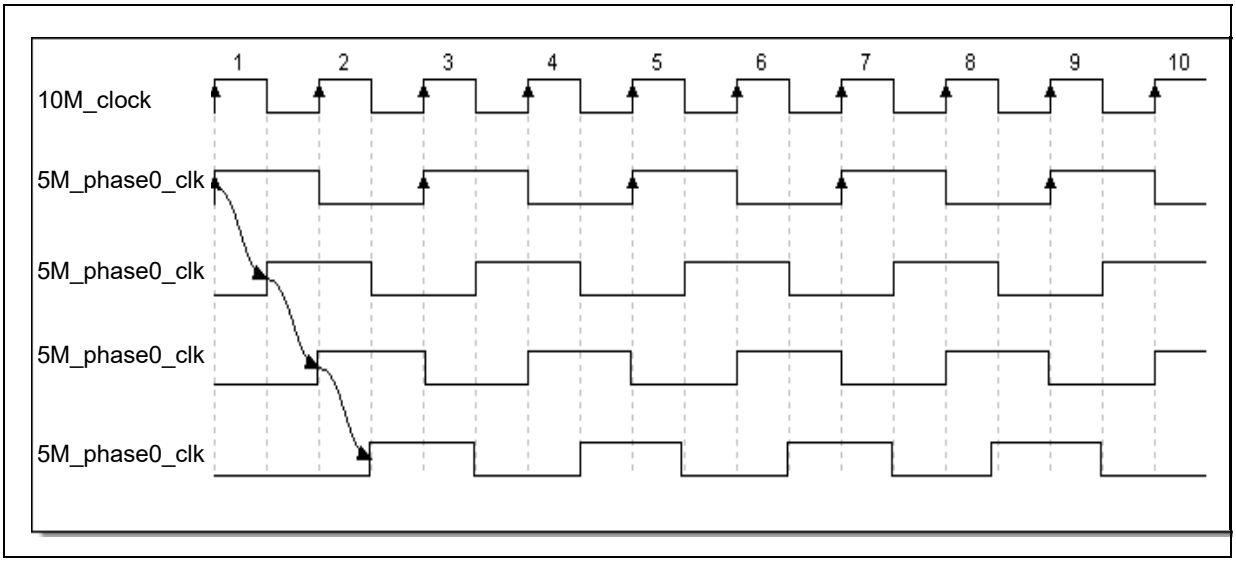


Figure 2116. External clock muxing of lfast_sysclk of 10 MHz

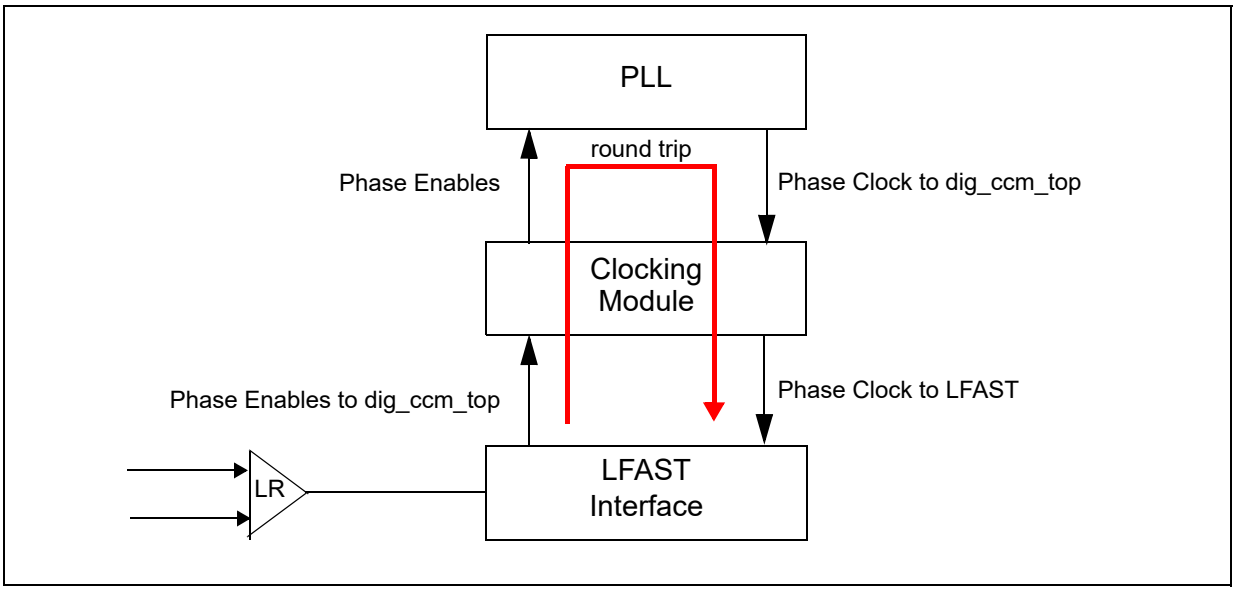
80.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. *Figure 2117* Shows 4 phases getting generated using lfast_sysclk.

Figure 2117. Slow speed 4 phases generation



80.10.3 Rx controller clocks

80.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in *Figure 2118*.

Figure 2118. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

80.10.3.2 Clock module requirements for low speed phases

80.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

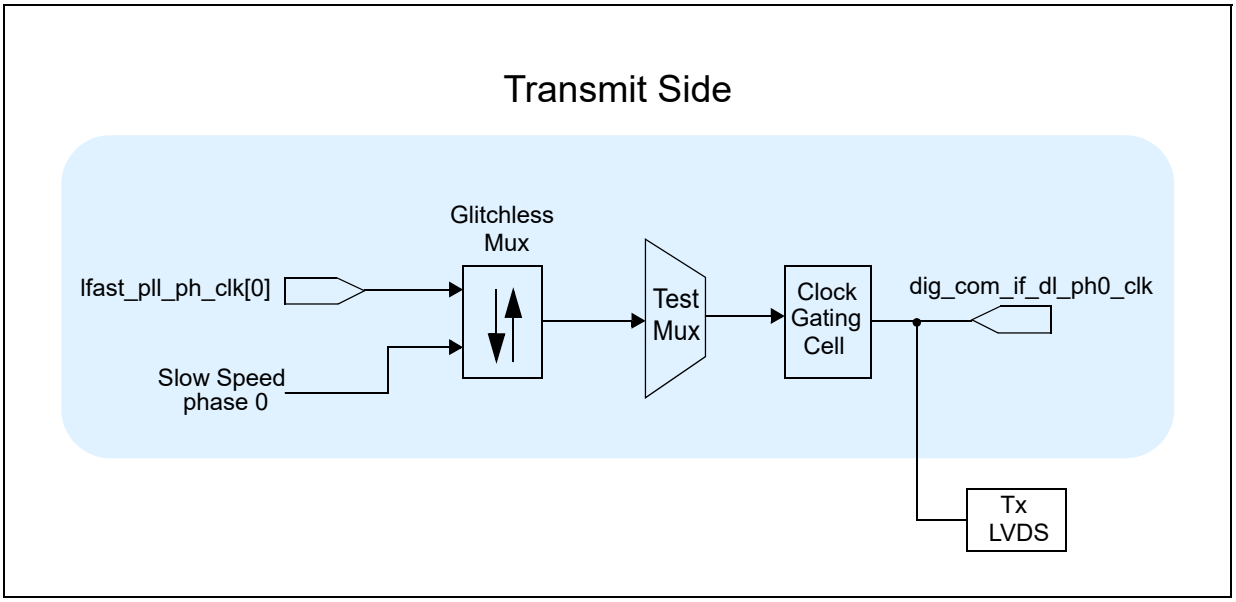
Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 2010. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

80.10.4 Tx controller clocks

80.10.4.1 Clocking module requirements for speed phases



The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See *Table 2011*.

Table 2011. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

80.10.4.2 Transmit clock muxing

Figure 2119. Transmit clocks muxing

80.10.4.3 Tx request clock control

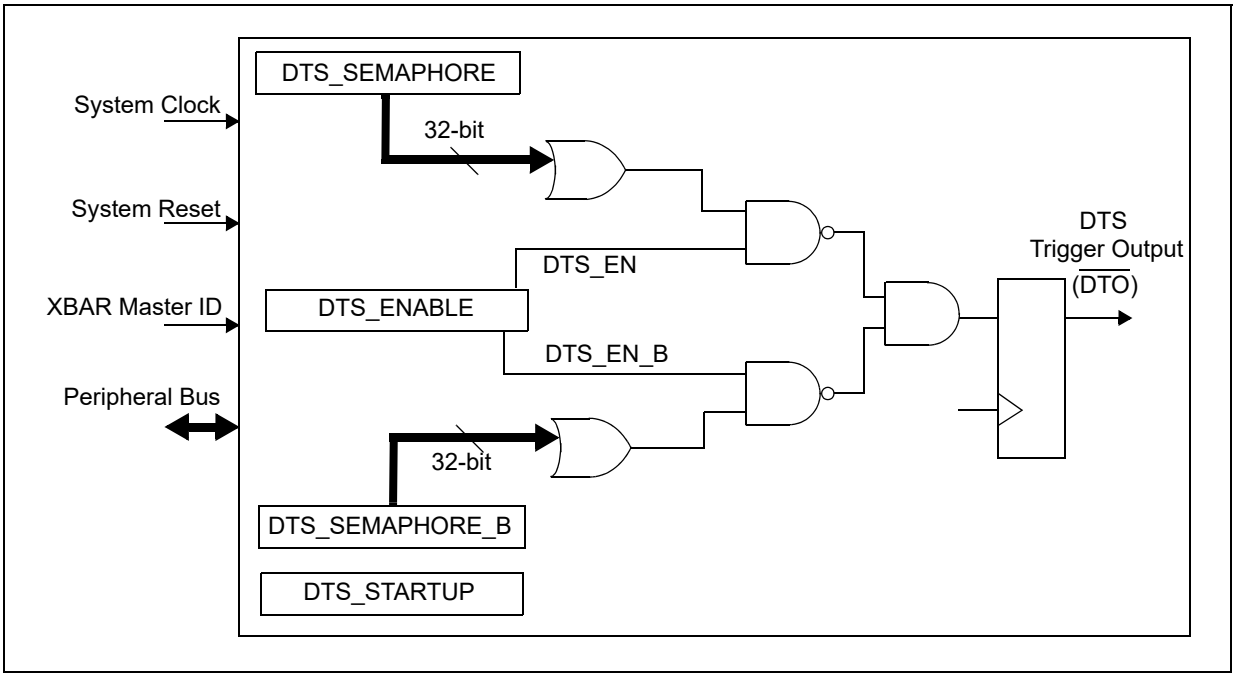
The Tx phase 0 clock is enabled when all the resets are negated.

81 Development Trigger Semaphore (DTS)

81.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.



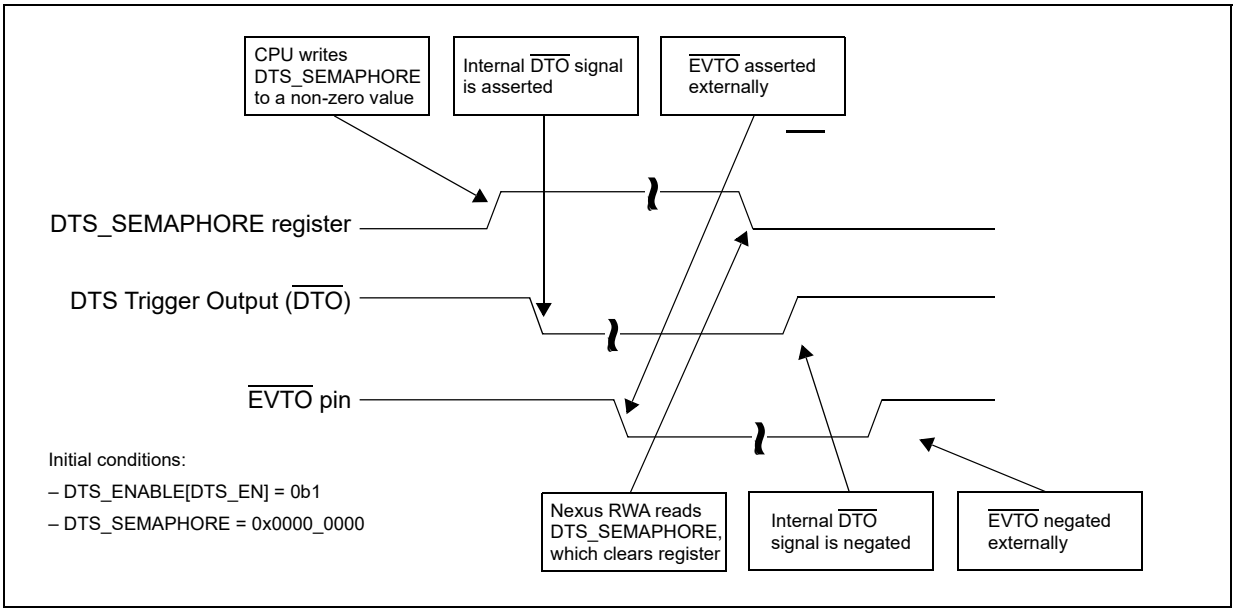
81.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal, DTS Trigger Output (DTO). The registers are as follows:

- DTS_SEMAPHORE register: Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_SEMAPHORE_B register: Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_STARTUP register: This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register: This register provides an enable/disable capability for the DTS feature.

The architecture is shown in *Figure 2120*.

Figure 2120. DTS block diagram



The DTS Trigger Output ($\overline{\text{DTO}}$) signal is connected to one of the $\overline{\text{EVTO}}$ inputs of the Debug and Calibration Interface (DCI). The other $\overline{\text{EVTO}}$ inputs are connected to the other Nexus modules in the device. $\overline{\text{DTO}}$ is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1 or DTS_ENABLE[DTS_EN_B] = 0b1), all other Nexus $\overline{\text{EVTO}}$ functions associated should be disabled by the tool and $\overline{\text{EVTO}}$ becomes the $\overline{\text{DTO}}$. Unlike the $\overline{\text{EVTO}}$ function that only asserts for one clock, the $\overline{\text{DTO}}$ function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 2121 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

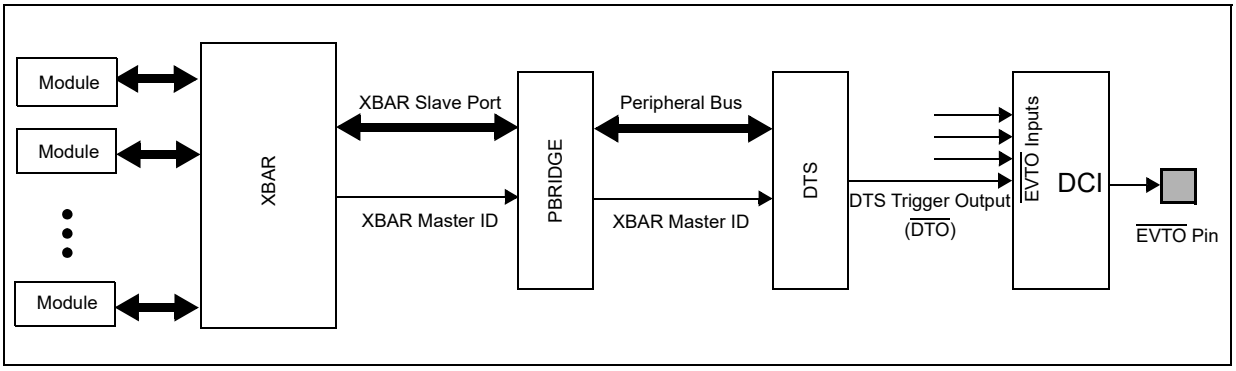


Figure 2121. $\overline{\text{DTO}}$ event sequence example

81.3 DTS device connections

Figure 2122 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 2122. DTS device connections

The registers have limited access as described in *Section 81.3.1: DTS register access*. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool or debug Zipwire can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access or debug Zipwire.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

81.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in *Table 2012*. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 2012. DTS register access effects

Register	32-bit read				32-bit write			
	RWA(1)	Core	eDMA	Other crossbar masters	RWA(1)	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear(2)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear(2)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: The XBAR Master ID should not be confused with the Master Port number of the XBAR. See Chapter 18: Crossbar switch (XBAR), for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core or debug Zipwire. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

81.4 Memory map and register definition

Table 2013 shows the memory map of the DTS module registers.

Table 2013. DTS memory map

Offset addesss	Register name	Access	Reset Value	Location
0x0000	DTS Output Enable register (DTS_ENABLE)	Restricted R/W(1)	0x0000_0000	*Section 81.4.1.1*
0x0004	DTS Startup register (DTS_STARTUP)	Restricted R/W(1)	0x0000_0000	*Section 81.4.1.2*
0x0008	DTS Semaphore Register (DTS_SEMAPHORE)	Restricted R/W(1)	0xFFFF_FFFF	*Section 81.4.1.3*
0x000C	DTS Semaphore Extension (DTS_SEMAPHORE_B)	Restricted R/W(1)	0xFFFF_FFFF	*Section 81.4.1.4*

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

81.4.1 Register descriptions

81.4.1.1 DTS output enable register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. *Figure 2123* shows the format of the DTS_ENABLE register. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA) or debug Zipwire.

Note: Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Offset 0x0000 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DTS_EN_B	DTS_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

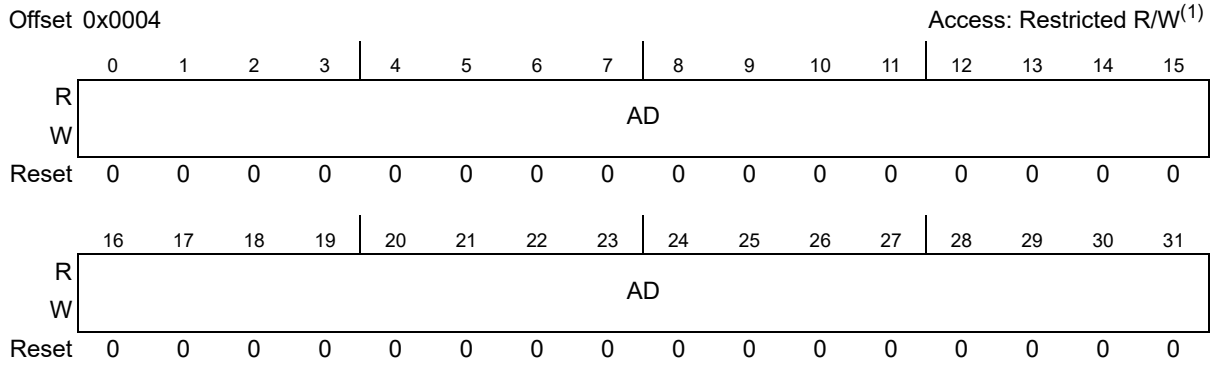

Figure 2123. DTS output enable register (DTS_ENABLE)

Table 2014. DTS_ENABLE field descriptions

Field	Description
30 DTS_EN_B	DTS Enable B Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
31 DTS_EN	DTS Enable Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

81.4.1.2 DTS startup register (DTS_STARTUP)

Figure 2124 shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA modules and other crossbar masters but can only be updated by a Nexus Read Write Access (RWA) or debug Zipwire.

1. The DTS_STARTUP register can be read by the cores, the eDMA module and Nexusbut can only be updated by a Nexus Read Write Access (RWA).

Figure 2124. DTS startup register (DTS_STARTUP)

Table 2015. DTS_STARTUP field descriptions

Field	Description
0:31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access or debug Zipwire to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

81.4.1.3 DTS semaphore register (DTS_SEMAPHORE)

Figure 2125 shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Offset 0x08 Access: Restricted R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 ST	Semaphore Trigger. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

81.4.1.4 DTS semaphore extension (DTS_SEMAPHORE_B)

Figure 2126 shows the format of the DTS_SEMAPHORE_B register. The DTS_SEMAPHORE_B register is used by software to assert the DTO signal on the device EVTO pin. A one in any bit of this register causes the DTO signal on the EVTO pin to be driven low. The intended use of this register is for the DTO signal to notify tools that data is available. Individual bits are used to identify the specific data.

Figure 2126. DTS Semaphore extension register (DTS_SEMAPHORE_B)

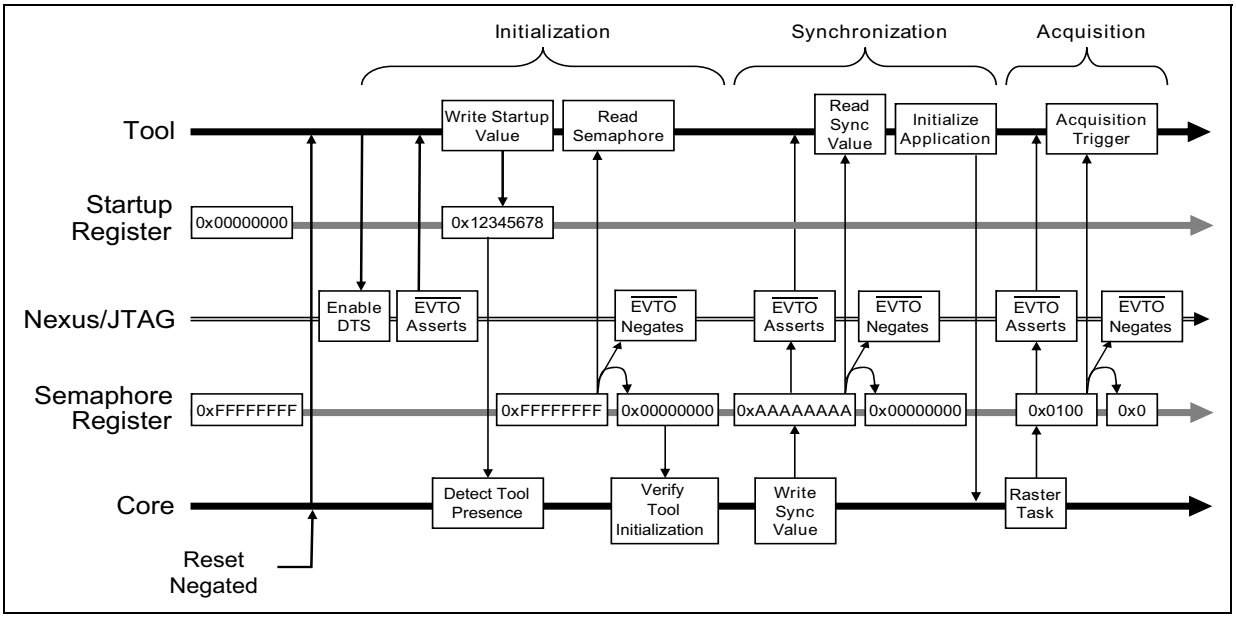
Table 2017. SEMAPHORE_B field descriptions

Field	Description
0:31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

81.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.



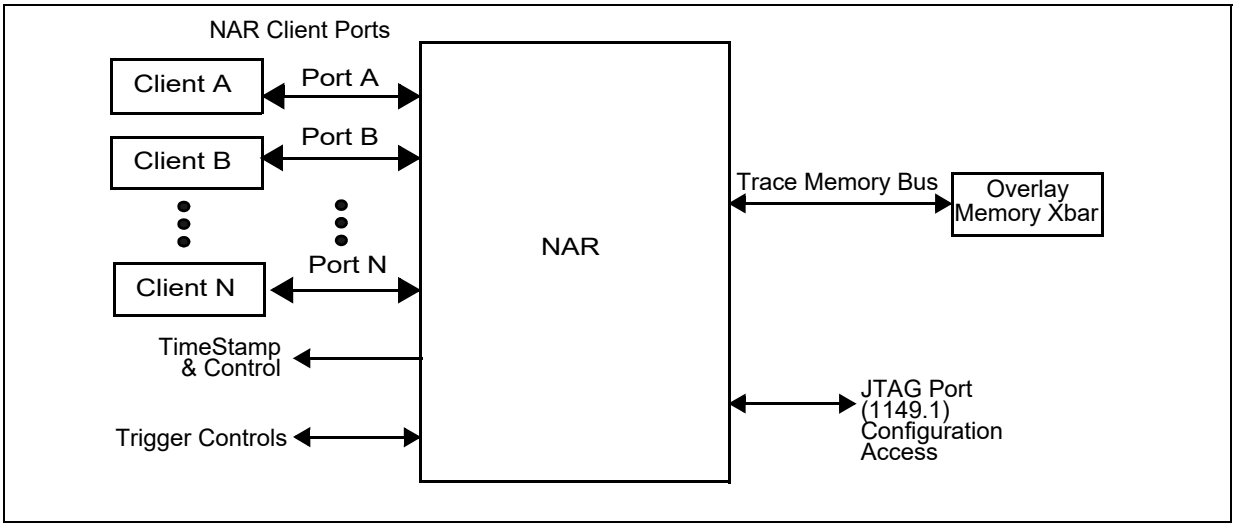
Note: It is the user’s responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

Figure 2127 shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA, all A’s was used

since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 2127. DTS startup sequence example



82 Nexus Aurora Router (NAR)

82.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 2128*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 2128. NAR top level diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

82.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port or the Trace port, or both. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

82.3 Features

The NAR supports the following features:

- Connects 10 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domians.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

82.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 2018. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	*on page 3487*

Figure 2129. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 2019. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 82.5.2.2: Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). *Note: Some clients may only support timestamps on every message.* 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 Reserved 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9	Reserved and must be written with 0s.

Table 2019. NAR_CR field descriptions (continued)

Field	Description
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 Aurora out is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2	Reserved and must be written with 0.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

82.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0

W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 2130. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 2020. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 2034* for coding
23–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)

82.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 82.5.6: Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

82.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

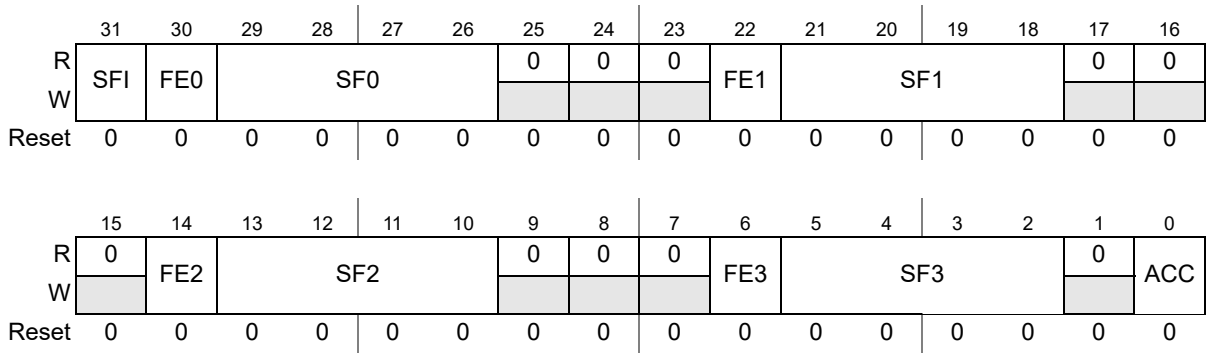

Figure 2131. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2021. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 82.5.6: Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 82.5.6: Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2

Table 2021. NAR_SFR field descriptions (continued)

13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 82.5.6: Output arbitration* for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 82.5.6: Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

82.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 82.5.6: Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 82.5.6: Output arbitration* for an example.

82.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

82.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 2134. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 2023. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 2024. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

82.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is

specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

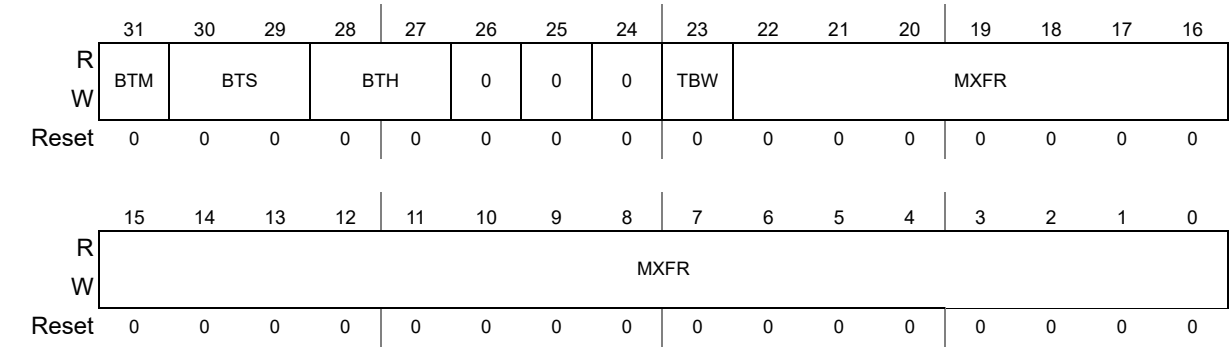

Figure 2135. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 2025. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

82.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 82.5.4: Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to

suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

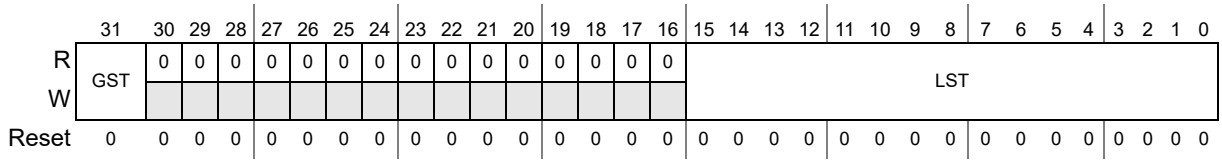

Figure 2136. Suppress trigger control registers (NAR_STCR1–4)

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2026. NAR_STCR field descriptions

Field	Description
31 GST	Global Suppress Trigger. 0 The associated trigger cannot cause NAR to enter global suppress mode 1 The associated trigger is enabled for global suppress mode
29–16	Reserved
15–0 LST	Local Suppress Trigger. 0000000000000000The associated trigger is disabled for local suppress mode for all clients xxxxxxxxxxxxxxx1Trigger is enabled for Client 1 local suppress xxxxxxxxxxxxxx1xTrigger is enabled for Client 2 local suppress xxxxxxxxxxxxx1xxTrigger is enabled for Client 3 local suppress xxxxxxxxxxxx1xxxTrigger is enabled for Client 4 local suppress xxxxxxxxxxx1xxxxTrigger is enabled for Client 5 local suppress xxxxxxxxxx1xxxxxTrigger is enabled for Client 6 local suppress xxxxxxxxx1xxxxxxTrigger is enabled for Client 7 local suppress xxxxxxxx1xxxxxxxTrigger is enabled for Client 8 local suppress xxxxxxx1xxxxxxxxTrigger is enabled for Client 9 local suppress xxxxxx1xxxxxxxxxTrigger is enabled for Client 10 local suppress xxxxx1xxxxxxxxxxTrigger is enabled for Client 11 local suppress xxxx1xxxxxxxxxxxTrigger is enabled for Client 12 local suppress xxx1xxxxxxxxxxxxTrigger is enabled for Client 13 local suppress xx1xxxxxxxxxxxxxTrigger is enabled for Client 14 local suppress x1xxxxxxxxxxxxxxTrigger is enabled for Client 15 local suppress 1xxxxxxxxxxxxxxxTrigger is enabled for Client 16 local suppress All other options Reserved

82.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 2137. Client suppress status register (NAR_CSSR)

The NAR_CSSR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress status, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2027. NAR_CCSR field descriptions

Field	Description
31–16 LSS	Local Suppress Status. 0000000000000000No client is in local suppress mode xxxxxxxxxxxxxxx1Client 1 is suppressed xxxxxxxxxxxxxx1xClient 2 is suppressed xxxxxxxxxxxxx1xxClient 3 is suppressed xxxxxxxxxxxx1xxxClient 4 is suppressed xxxxxxxxxxx1xxxxClient 5 is suppressed xxxxxxxxxx1xxxxxClient 6 is suppressed xxxxxxxxx1xxxxxxClient 7 is suppressed xxxxxxxx1xxxxxxxClient 8 is suppressed xxxxxxx1xxxxxxxxClient 9 is suppressed xxxxxx1xxxxxxxxxClient 10 is suppressed xxxxx1xxxxxxxxxxClient 11 is suppressed xxxx1xxxxxxxxxxxClient 12 is suppressed xxx1xxxxxxxxxxxxClient 13 is suppressed xx1xxxxxxxxxxxxxClient 14 is suppressed x1xxxxxxxxxxxxxxClient 15 is suppressed 1xxxxxxxxxxxxxxxClient 16 is suppressed All other optionsReserved
15–0	Reserved

82.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Register index: C

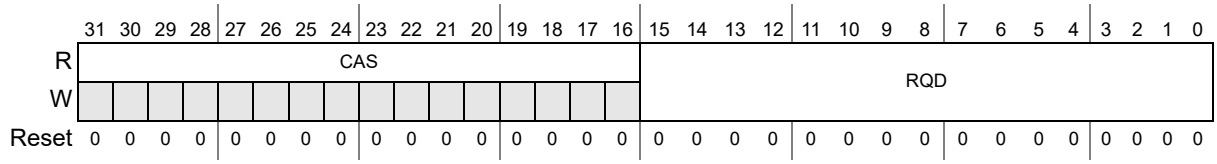

Figure 2138. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2028. NAR_CDR field descriptions

Field	Description

82.4.6 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 2139. Trace memory fill level and partition configuration register (NAR_AHFPAR)

The NAR_AHFPAR is described in the following table.

Table 2029. NAR_AHFPAR field description

Field	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 82.5.12: Overlay and internal trace memory full status generation* **Note:** This is used in PD as it has memory ranges from 1K to 15K

82.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

82.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 82.5.4: Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

82.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 2030. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

82.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

82.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

82.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

82.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

82.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 2031. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8×32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8×32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.

Table 2031. NAR transmit operations (continued)

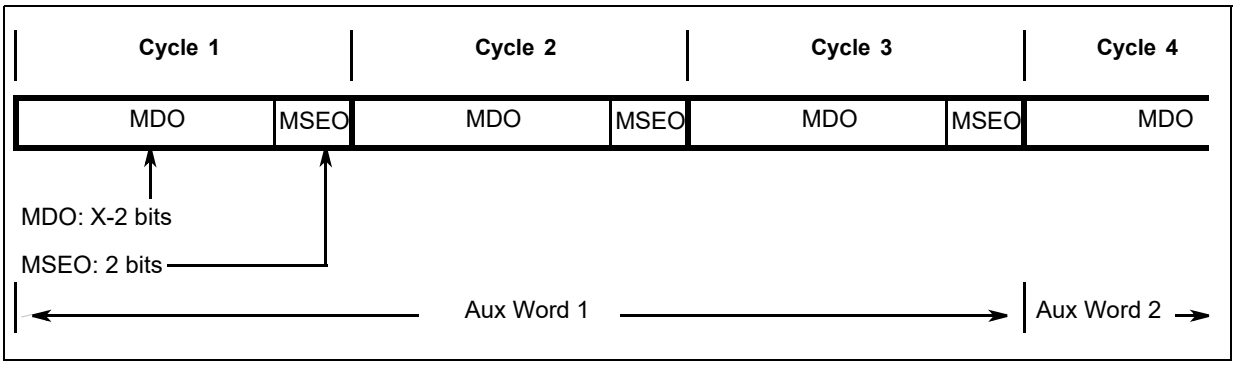
Operation	Description
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

82.5.3 Data reception and arbitration

The NAR supports 10 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn $\times$ 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment.

Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2140. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

82.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only

supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

82.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

82.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type or messages from a particular client, or both, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types or four sources, or both.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0)

or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

82.5.7 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

82.5.7.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 $\times$ 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 $\times$ 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 $\times$ number of lanes).

82.5.7.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data

interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

82.5.8 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

82.5.9 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (that is unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 $\times$ 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

82.5.10 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 2035*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 2032. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 2033*
	12	12	fixed	ECODE	See *Table 2034*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC(2)	NAR source ID
	6	6	fixed	WPHIT	See *Table 2035*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

82.5.10.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 2033. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 2034*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 2034*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 2034*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 2034. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

82.5.10.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

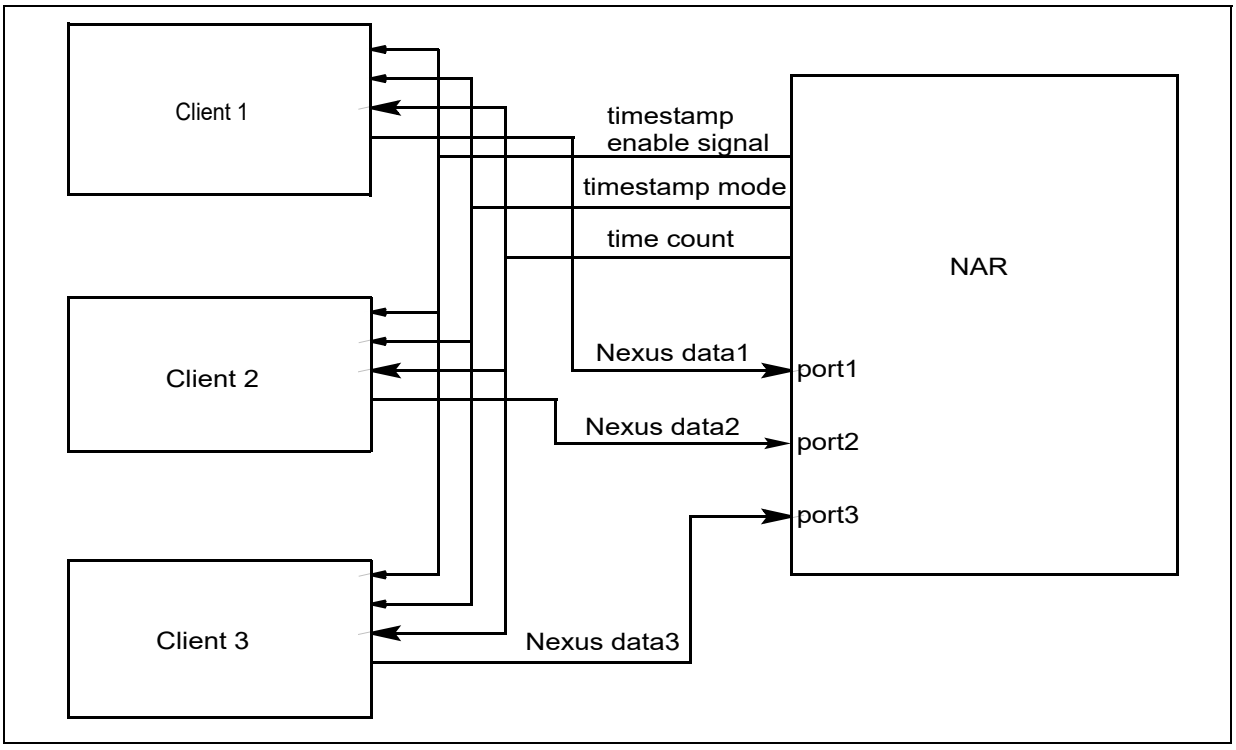


Table 2035. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

82.5.11 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 2141*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2141. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

82.5.12 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

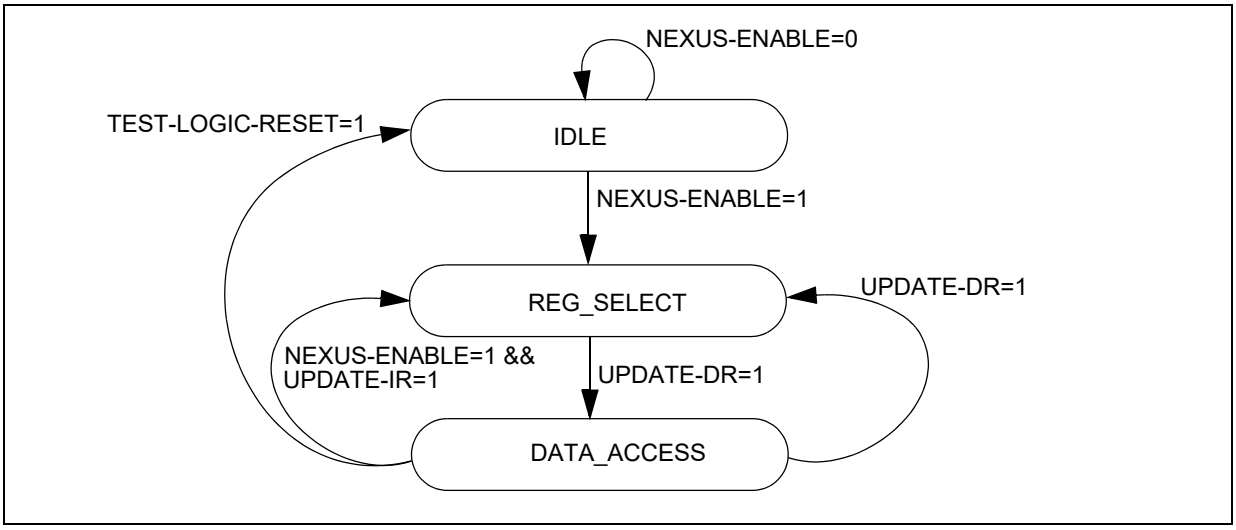
82.5.13 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 2036*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2142. Nexus controller state machine



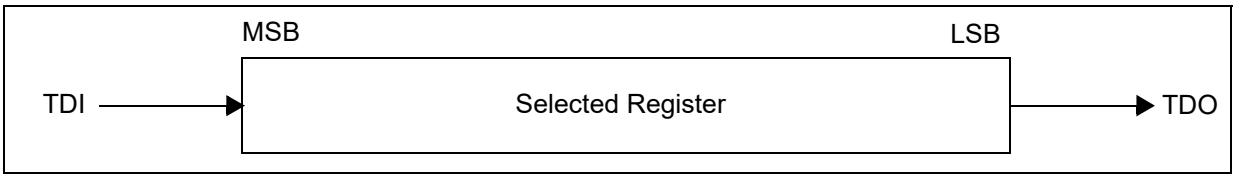


Table 2036. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2143. Shifting data into register

82.5.13.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

82.5.13.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2142*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 2037. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

82.5.13.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2144*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 2018*.

Figure 2144. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 2038. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

82.5.14 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

82.5.14.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

82.5.14.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

82.5.14.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

82.5.15 Legacy client interface controller

This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in *Figure 2145*.

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of paramaterizeable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

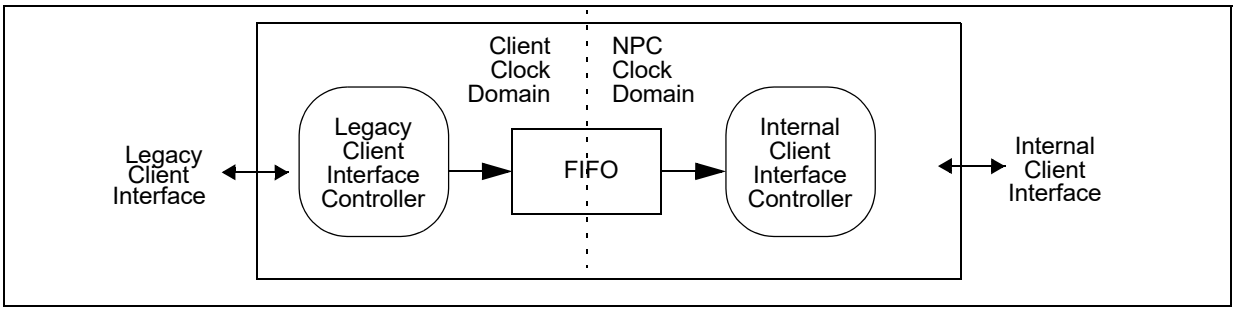

Figure 2145. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how may spaces are freed in receive queue.

82.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 82.5.2.1: Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

82.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 82.5.6: Output arbitration*.

83 e200z420n3 Nexus 3 Module

The e200z420n3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

83.1 Introduction

83.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

83.1.2 Terms and Definitions

Table 2039 contains a set of terms and definitions associated with the Nexus 3 module.

Table 2039. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 2039. Terms and Definitions (continued)

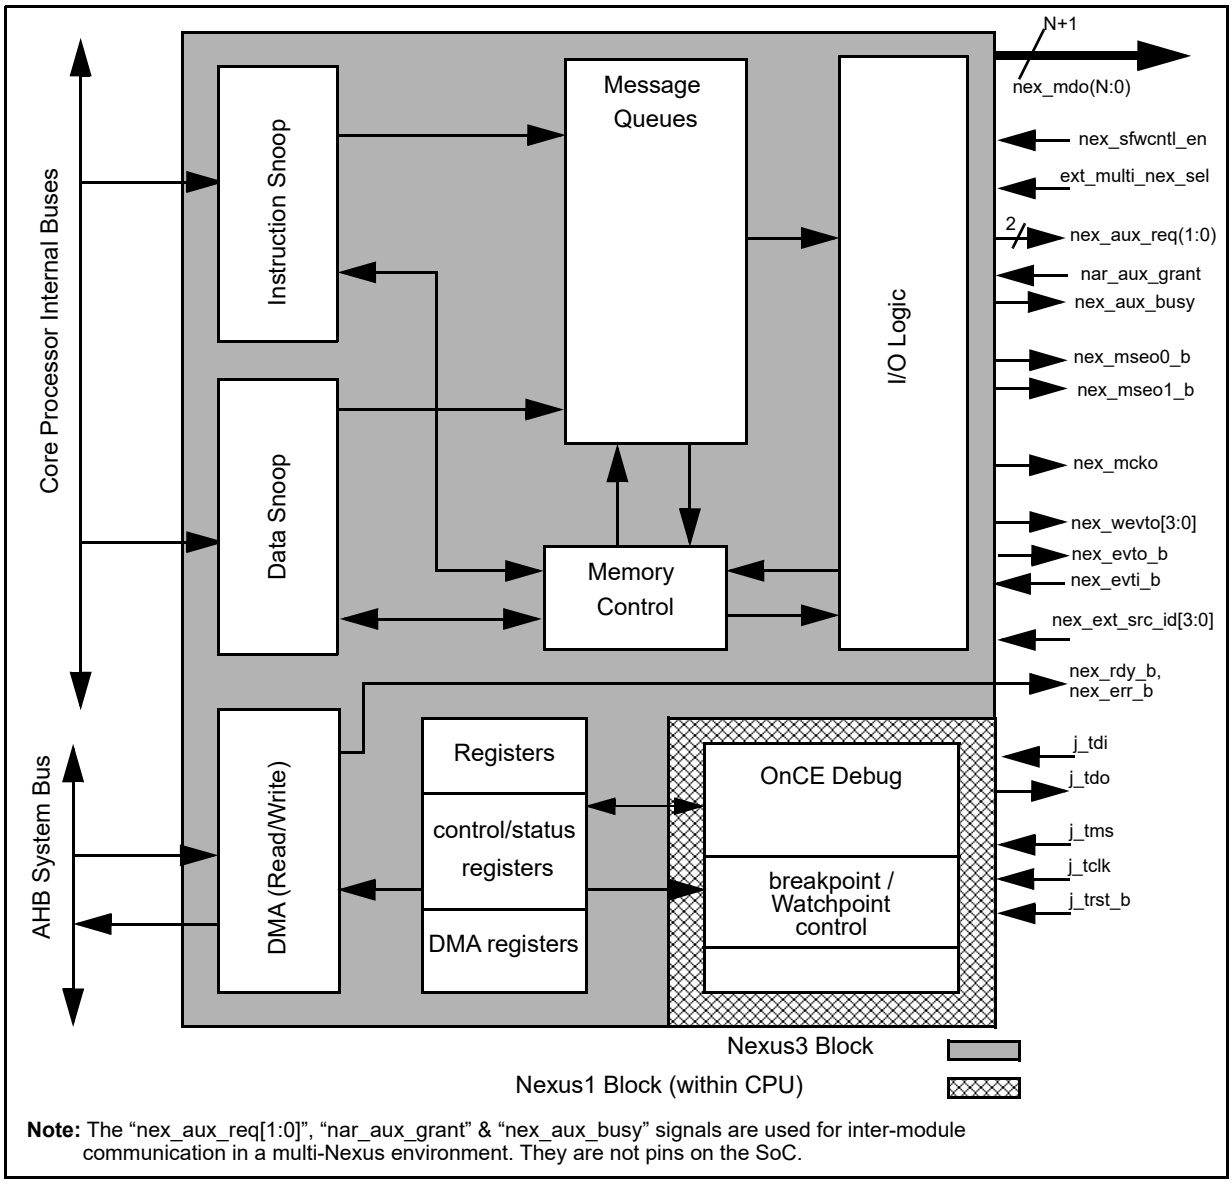
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

83.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (such as direct and indirect branches, exceptions), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

83.1.4 Functional Block Diagram

Figure 2146. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

83.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (NEXUS3-ACCESS) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

83.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

83.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 2040*.

Table 2040. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	6	6	TCODE	fixed	TCODE number = 5
Data Trace — Data Write Message	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2045*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2045*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)

Table 2040. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	6	6	TCODE	fixed	TCODE number = 13
Data Trace — Data Write Message w/ Sync	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2045*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table 2040. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2045*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 2043*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See *Section 83.12.4: Resource Full Messages*.)
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 83.12.1: Branch Trace Messaging types*)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See *Section 83.12.1: Branch Trace Messaging types*.)

Table 2040. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to *Table 2044*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See *Section 83.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See *Section 83.12.5: Program Correlation Messages*.)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 83.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 2041 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 2041. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (such as Debug Status messages)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 2042 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 2042. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 2043 shows the encodings used for resource codes for certain messages.

Table 2043. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 2044 shows the event code encodings used for certain messages.

Table 2044. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 2045 shows the data trace size encodings used for certain messages.

Table 2045. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte

Table 2045. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

83.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 83.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 83.6: Nexus 3 Register Access via Software*for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 2046 details the register map for the Nexus 3 module.

Table 2046. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

83.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Nexus Reg# 0x1; Read-only; Reset: 0x0

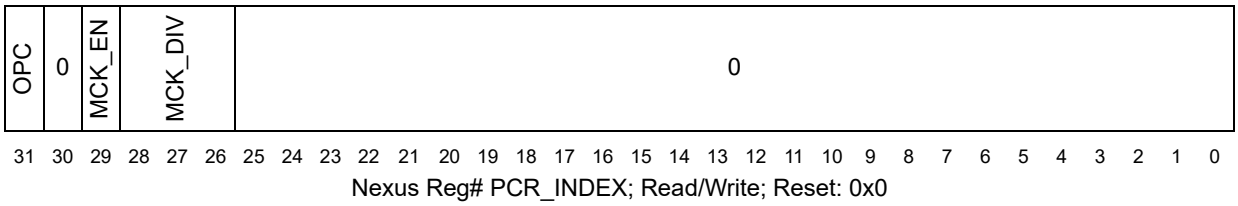

Figure 2147. Client Select Control (CSC) register

Table 2047. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

83.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Nexus Reg# PCR_INDEX; Read/Write; Reset: 0x0

Figure 2148. Port Configuration Register (PCR)

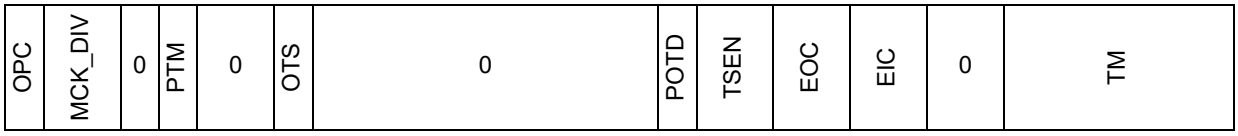

Table 2048. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

83.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 2149* and its fields are described in *Table 2049*.

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

Figure 2149. Development Control 1 (DC1) register

Table 2049. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control 0 — Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined 1 — Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined
30:29	MCK_DIV	MCKO Clock Divide Ratio (see note below) 00 — **nex_mcko** is 1x processor clock freq. 01 — **nex_mcko** is 1/2x processor clock freq. 10 — **nex_mcko** is 1/4x processor clock freq. 11 — **nex_mcko** is 1/8x processor clock freq.
28	—	Reserved for future functionality
27	PTM	Program Trace Method 0 — Program Trace uses traditional Branch Messages 1 — Program Trace uses Branch History Messages
26:25	—	Reserved for future functionality
24	OTS	Ownership Trace PID Select 0 — PID0 data is transmitted within Ownership Trace Messages 1 — Nexus PID Register (NPIDR) data is transmitted within Ownership Trace Messages
26:15	—	Reserved for future functionality
14	POTD	Periodic Ownership Trace Disable 0 — Periodic Ownership Trace message events are enabled 1 — Periodic Ownership Trace message events are disabled
13:12	TSEN	Timestamp Enable — (not implemented, write to 00) 00 — Timestamp is disabled
11:10	EOC	EVTO Control 00 — **nex_evto_b** upon occurrence of Watchpoints (configured in DC2 and DC3) 01 — **nex_evto_b** upon entry into Debug Mode 1*x* — Reserved
9:8	EIC	EVTI Control 00 — **nex_evti_b** is used for synchronization (Program Trace Sync msg is generated) 01 — **nex_evti_b** is used for Debug request 10 — **nex_evti_b** is disabled 1*x* — Reserved

Table 2049. DC1 field descriptions (continued)

Bits	Name	Description
7:6	—	Reserved for future functionality
5:0	TM	Trace Mode(1) 000000 — All Trace Disabled *xxxxx*1 — Ownership Trace enabled *xxxx*1*x* — Data Trace enabled *xxx*1*xx* — Program Trace enabled *xx*1*xxx* — Watchpoint Trace enabled *x*1*xxxx* — Reserved 1*xxxxx* — Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 83.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 83.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

83.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 2150* and its fields are described in *Table 2050*.

83.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in *Figure 2152* and its fields are described in *Table 2052*.

Nexus Reg# 0x5; DCR: 371; Read/Write; Reset: 0x0

1. Refer to *Table 2044* for implemented EVCODEs.

83.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

25:0	—	Reserved for future functionality (read as 0)

83.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between

enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

83.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Figure 2161. Data Trace Control (DTC) register

The following table details the Data Trace Control register fields.

Table 2061. DTC field descriptions

Bits	Name	Description
31:30	RWT1	Read/Write Trace 1 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
29:28	RWT2	Read/Write Trace 2 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
27:26	RWT3	Read/Write Trace 3 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
25:24	RWT4	Read/Write Trace 4 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
23:16	—	Reserved for future functionality (read as 0)
15	STDC1	Stack Trace Disable Control 1 0 Tracing of stack accesses are not disabled for range 1 1 Tracing of stack accesses are disabled for range 1; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
14	STDC2	Stack Trace Disable Control 2 0 Tracing of stack accesses are not disabled for range 2 1 Tracing of stack accesses are disabled for range 2; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
13	STDC3	Stack Trace Disable Control 3 0 Tracing of stack accesses are not disabled for range 3 1 Tracing of stack accesses are disabled for range 3; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
12	STDC4	Stack Trace Disable Control 4 0 Tracing of stack accesses are not disabled for range 4 1 Tracing of stack accesses are disabled for range 4; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs

Table 2061. DTC field descriptions (continued)

Bits	Name	Description
11:8	—	Reserved for future functionality (read as 0)
7	RC1	Range Control 1 0 Condition trace on address within range 1 Condition trace on address outside of range
6	RC2	Range Control 2 0 Condition trace on address within range 1 Condition trace on address outside of range
5	RC3	Range Control 3 0 Condition trace on address within range 1 Condition trace on address outside of range
4	RC4	Range Control 4 0 Condition trace on address within range 1 Condition trace on address outside of range
3	DI	Data Access / Instruction Access Trace 0 Condition trace on data accesses 1 Condition trace on instruction accesses **Note:** The support for monitoring instruction accesses is not guaranteed to be present in all versions of the Nexus 3 module. **Note:** The setting of the DI bit also affects the information provided on the data trace port outputs (See the “Data Trace Port Signals” section in the Core (e200z420n3) Core Debug Support chapter.)
2:0	—	Reserved for future functionality (read as 0)

83.4.11 Data Trace Start Address Registers (DTSA1–4)

The Data Trace Start Address Registers define the start addresses for each trace channel.

Data Trace Start Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 2169. Data Trace End Address 4 register

Table 2062 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2062. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings

indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (that is when the instruction prefetch is discarded).

83.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 2064*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Figure 2170. Read/Write Access Control/Status (RWCS) register

1. ERR and DV are read-only

Table 2063. RWCS field descriptions

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access

RWCS[17:16]	—	Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR(2)	Read/Write Access Error (see *Table 2064*)
RWCS[0]	DV(2)	Read/Write Access Data Valid (see *Table 2064*)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 2064. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

83.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 2171. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 2065* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 2065. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:
"X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 2066 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 2066. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]
Byte @001	0 0 1	—	—	—	AHB[15:8]
Byte @010	0 1 0	—	—	—	AHB[23:16]
Byte @011	0 1 1	—	—	—	AHB[31:24]

Table 2066. RWD byte lane mapping (continued)

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:
"—" indicates byte lanes that will contain unused data.

83.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 2172. Read/Write Access Address (RWA) register

83.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 2046*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 83.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 2046*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 2173. JTAG DR format

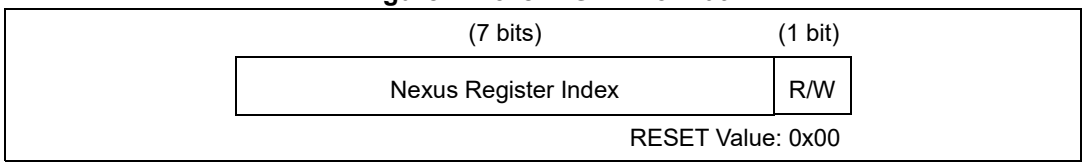

Table 2067. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 2046*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

83.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 2046* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

83.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

83.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

83.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

83.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 2174. Relative address generation and recreation

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

83.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization

messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

83.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

83.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

83.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 83.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

83.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

Section 83.8.1: Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

83.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstance:

- More than three messages are generated in the same cycle

Table 2068 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 2068*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 2068. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)

Table 2068. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

83.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

83.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

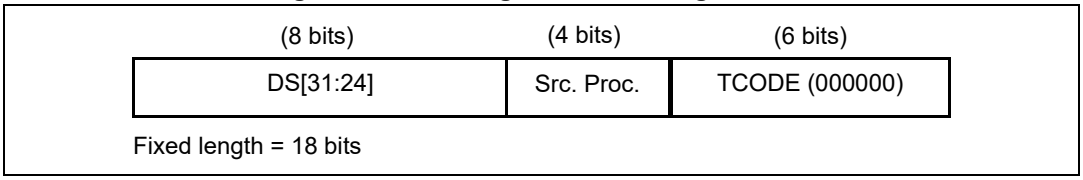
83.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

83.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



83.8.9 Data Trace Message Priority Loss Response

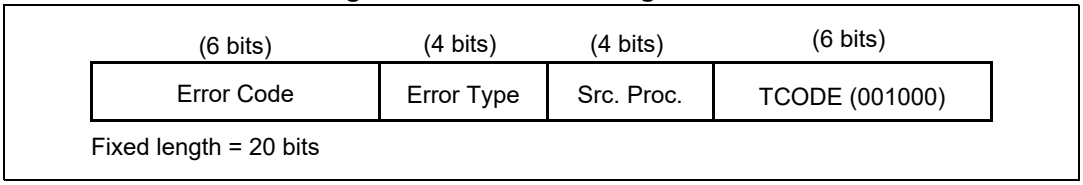
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

83.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 2175. Debug Status message format

83.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see *Table 2041* and *Table 2042*):

Figure 2176. Error message format

83.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

83.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

83.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z420n3) processors contain a *PowerISA 2.06* defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

Nexus 3 Process ID

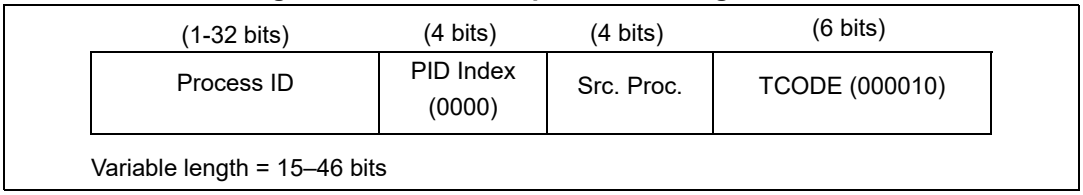
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR — 517; Read/Write; Reset: 0

Figure 2177. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.



There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will

indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 2178. Ownership Trace Message format

83.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z420n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z420n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

83.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. (evsel)Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

83.12.1.1 Indirect Branch Message instructions

Table 2069 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 2069. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfci, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

83.12.1.2 Direct Branch Message Instructions

Table 2070 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 2070. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

83.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. (**evsel**)

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

83.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

83.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

83.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

Figure 2179. Indirect branch message (history) format

(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

83.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Figure 2180. Indirect branch message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

83.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 2181. Direct branch message format

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

83.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

83.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

83.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 2071. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

83.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

83.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 2182. Resource Full Message format

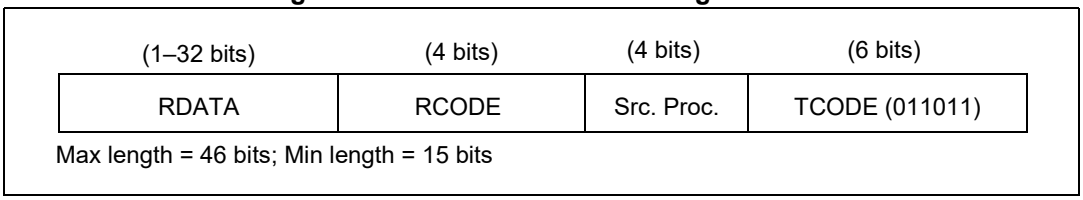


Table 2072 shows the RCODE encodings and RDATA information used for Resource Full Messages.

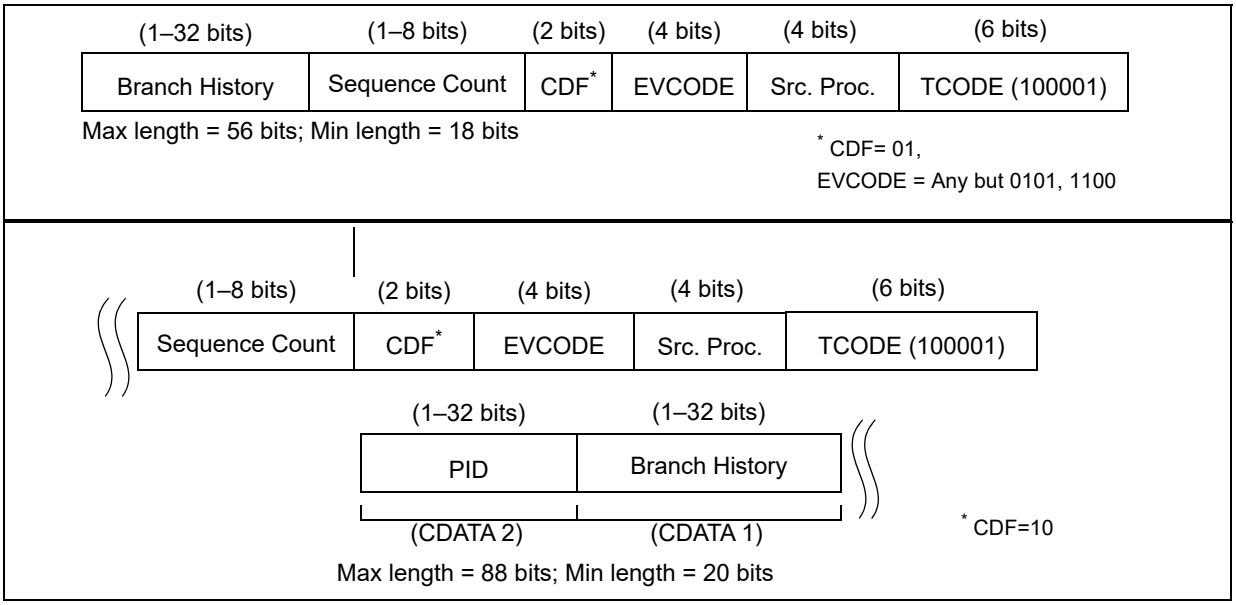
Table 2072. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

83.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 2044* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 2183. Program Correlation message formats

83.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history

and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

83.12.6 Program Trace Overflow Error messages

an Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

83.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 2073*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ ‘1’ with $DC4_{PTMARK}$=‘1’.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 2184. .Program Trace Synchronization message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

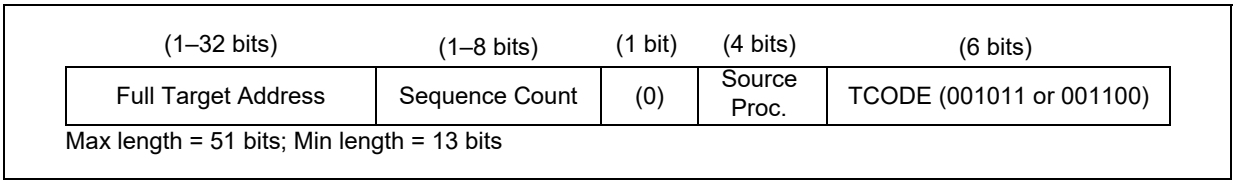
Exception conditions that result in Program Trace Synchronization are summarized in *Table 2073*.

Table 2073. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

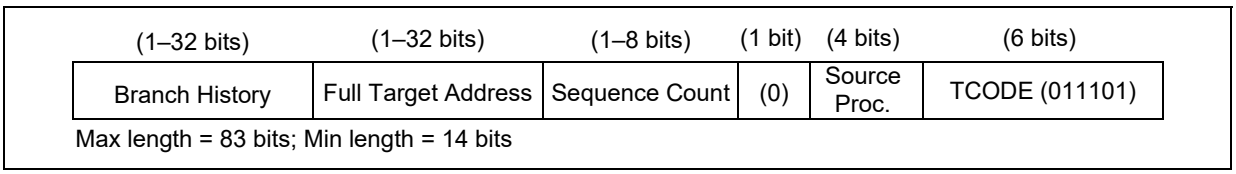
83.12.8 Program Trace Direct/Indirect Branch with Sync messages



Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 2073*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.



The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 2185. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 2186. Indirect Branch History w/ Sync message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 2074*.

Table 2074. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

83.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

83.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)

Figure 2187. Program Trace — Indirect Branch message (Traditional)

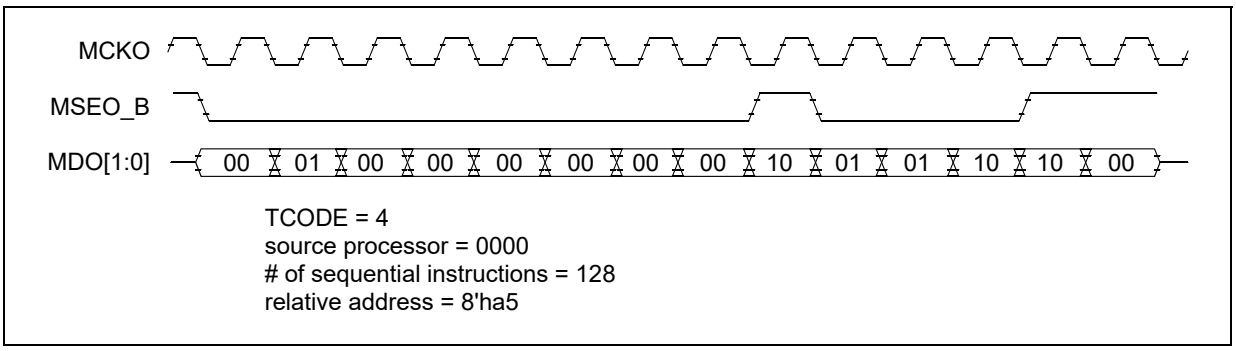


Figure 2188. Program Trace — Indirect Branch message (history)

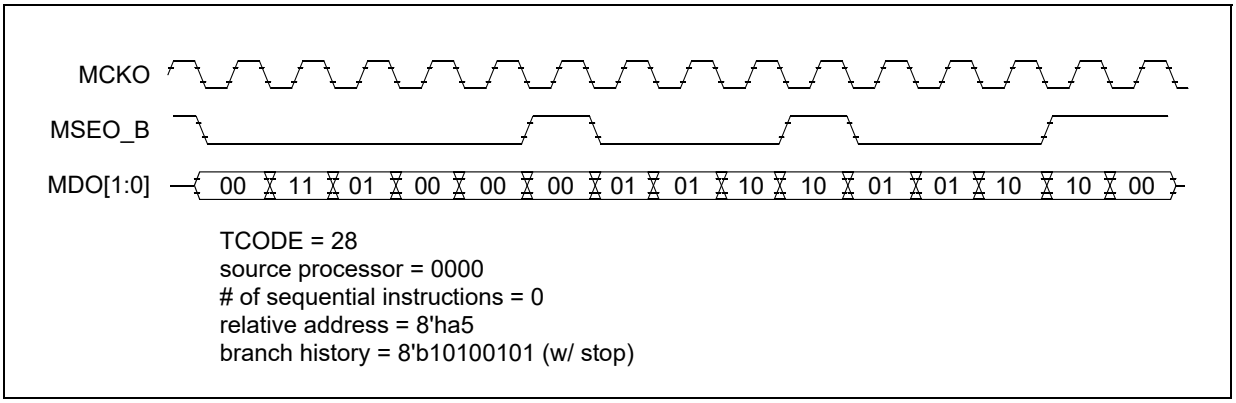

Figure 2189. Program Trace — Direct Branch (traditional) & Error messages

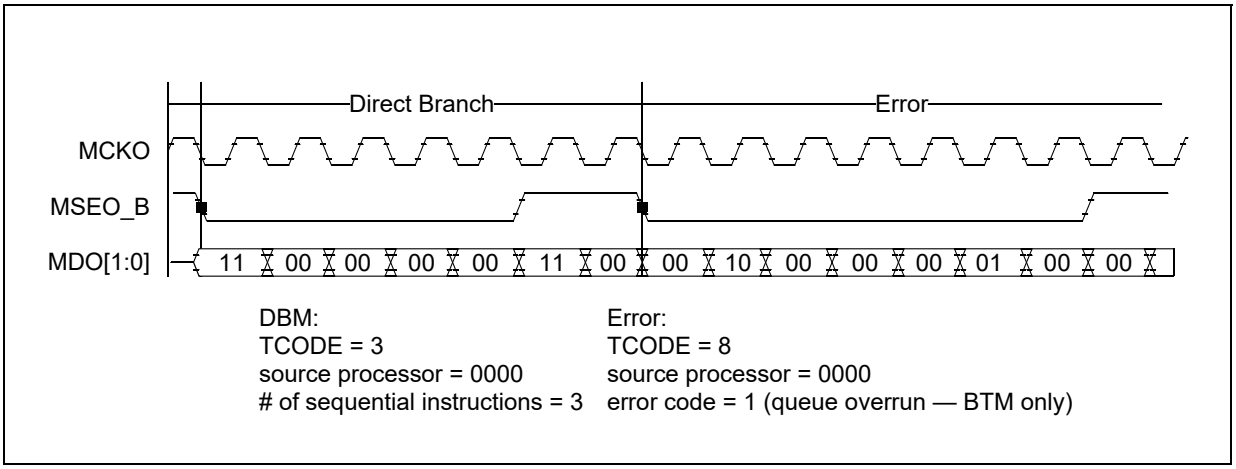

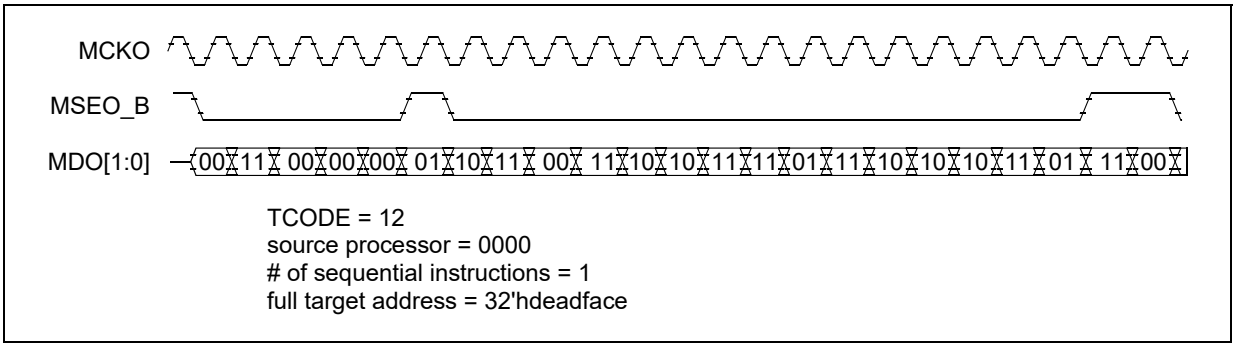

Figure 2190. Program Trace — Indirect Branch w/ Sync message

83.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

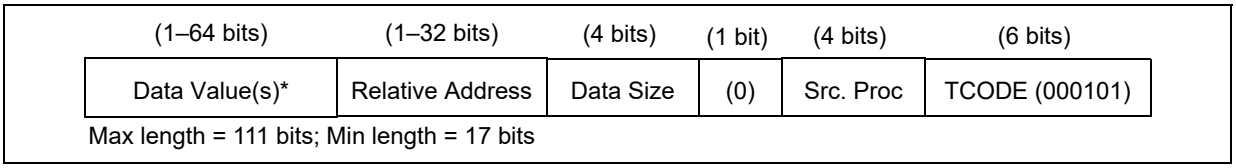
83.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z420n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)



83.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

83.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

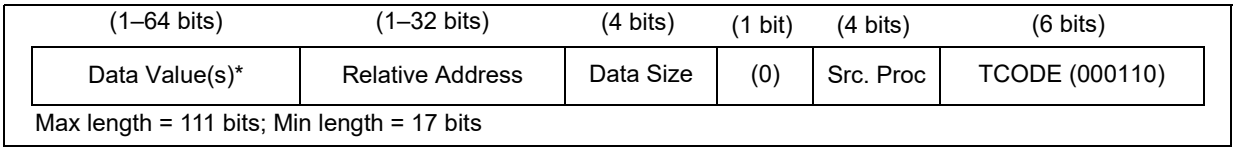


Figure 2191. Data Write message format

83.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 2192. Data Read message format

*Note: Core (e200z420n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.*

*For Core (e200z420n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.

83.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 2075*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 2193. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Exception conditions that result in Data Trace Synchronization are summarized in *Table 2075*.

Table 2075. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.

Table 2075. Data Trace Exception summary (continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

83.13.3 DTM operation

83.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

83.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

83.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

83.13.3.4 Bus cycle special cases

Table 2076. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded

Table 2076. Bus cycle special cases (continued)

Special case	Action
Bus cycle completed without error(1)	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

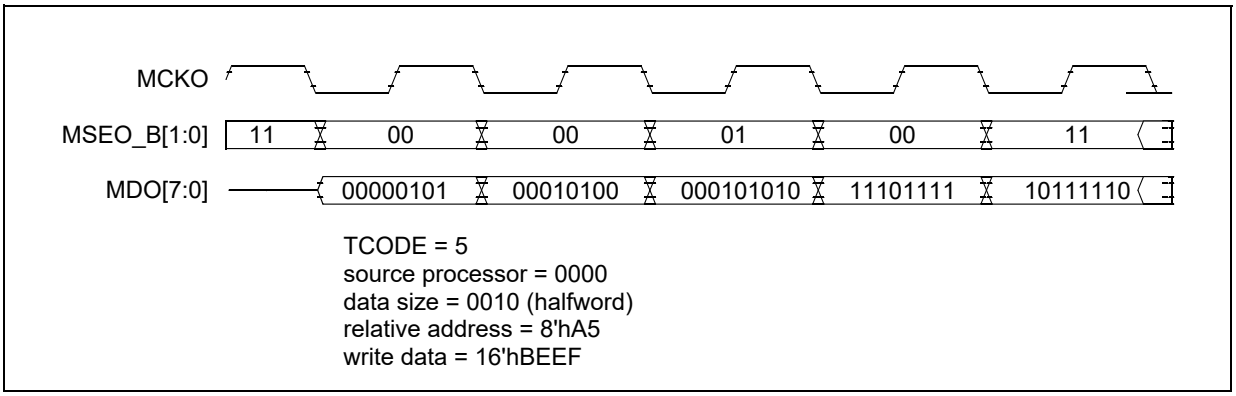
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z420n3) Core Debug Support chapter.)

Note: A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

83.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 2194. Data Trace — Data Write message



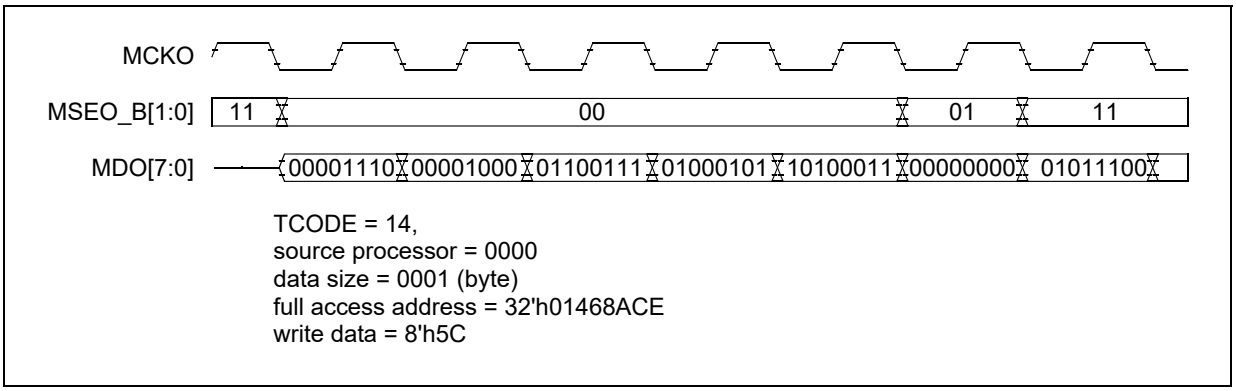


Figure 2195. Data Trace — Data Read w/ Sync message

83.14 Data Acquisition messaging

this section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

83.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

83.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

83.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z420n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Table 2077. .Data Acquisition message format

(1–32 bits)	(8 bits)	(4 bits)	(6 bits)
DQDATA	DQTAG	Src. Proc.	TCODE (011011)

Max length = 50 bits; Min length = 19 bits

83.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z420n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

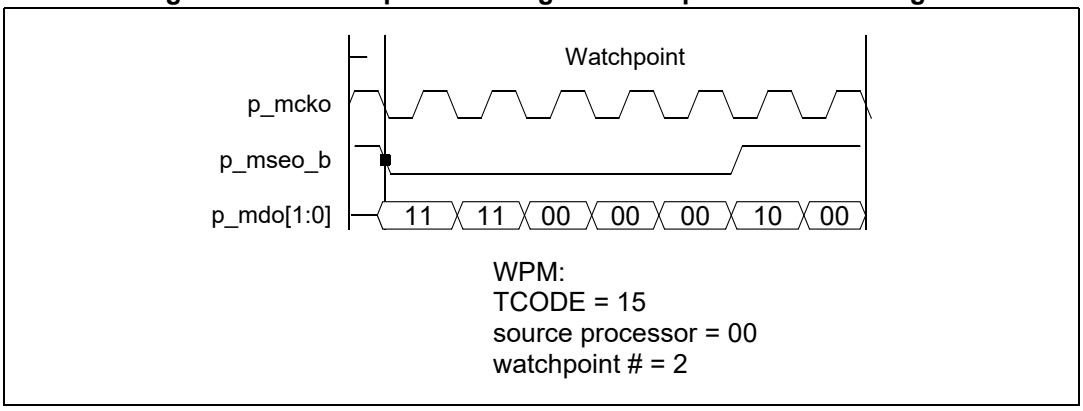
The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 2081* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 2196. Watchpoint message format

(1–30 bits)	(4 bits)	(6 bits)
Watchpoint Source	Src. Proc.	TCODE (001111)

Variable length = 11–40 bits



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 2078. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
00000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1	Watchpoint #0 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*x*	Watchpoint #1 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*xx*	Watchpoint #2 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*xxx*	Watchpoint #3 enabled for WTM

83.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 2197. Watchpoint Message & Watchpoint Error message

83.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 2079* details the external hardware trigger signals.

Table 2079. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 2079. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

83.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

83.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 2081* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note: Only the **nex_ahb_start, nex_rdy_b, and nex_err_b** *pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

83.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 83.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 83.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

83.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 2081* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*.

Note: Only the **nex_ahb_start, nex_rdy_b,** *and* **nex_err_b** *pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

83.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 83.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see *Table 2081* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 2081* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 83.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 83.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (that is doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

83.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

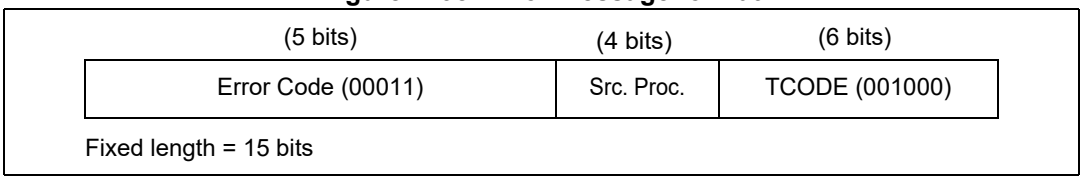
83.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

83.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

83.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 2198. Error message format

83.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

83.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 2081*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 83.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z420n3) Core Debug Support chapter.

Table 2080. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 2081*.

Table 2081. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted

Table 2081. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 83.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

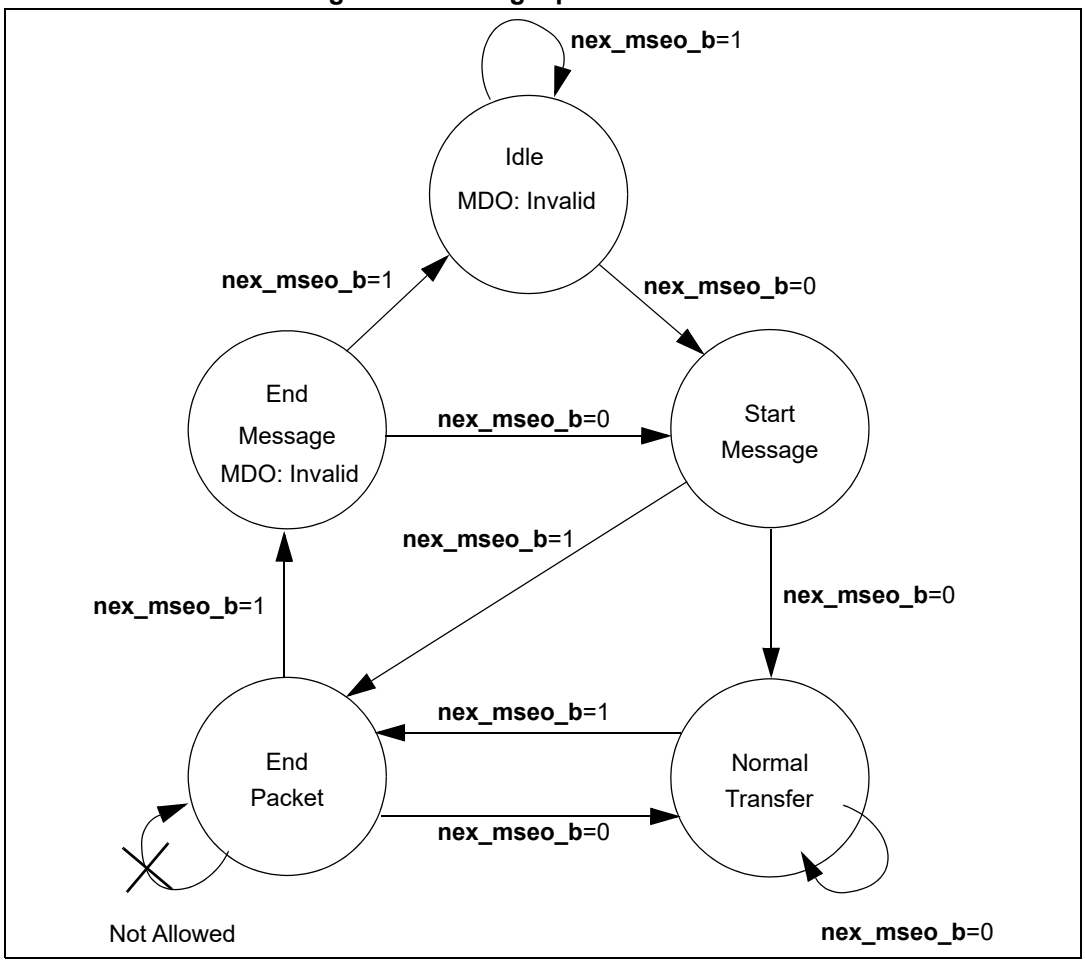
Table 2082. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 2084*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

83.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 2083*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



Single pin MSEO is not supported on the SPC58xEx/SPC58xGx.

Table 2083. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 2199 illustrates the state diagram for single pin MSEO transfers.

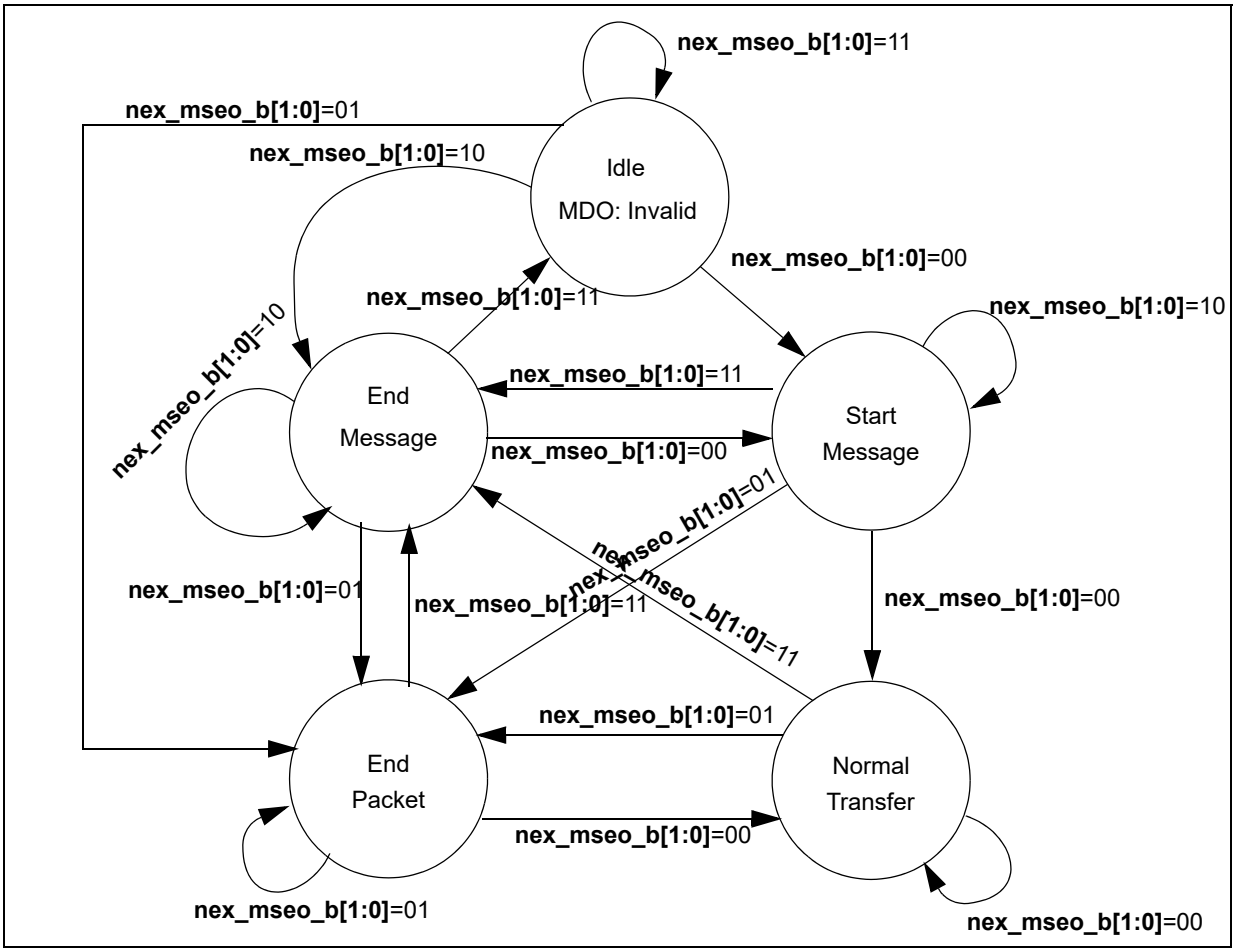


Figure 2199. Single pin MSE transfers

Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 2200 illustrates the state diagram for dual pin MSEO transfers.

Figure 2200. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

83.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is

impossible to know which bit is from the last packet and which bit is from the next packet.)

- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

83.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 2084* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 83.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 2084. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

83.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 2085 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 2086* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 2085. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 2086. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b [1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/ End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2087 and *Table 2088* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 2087. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 2088. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2089 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 2090* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 2089. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)

Table 2089. Data write message example (8 MDO / 1 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b	State
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 2090. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

83.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC58xEx/SPC58xGx Data Sheet.

83.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

83.23.1 JTAG sequence for accessing internal Nexus registers

Table 2091. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR

Table 2091. Accessing internal Nexus 3 registers via JTAG/OnCE (continued)

Step #	TMS Pin	Description
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

83.23.2 JTAG sequence for read access of memory-mapped resources

Table 2092. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

83.23.3 JTAG sequence for write access of memory-mapped resources

Table 2093. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

84 e200z4256 Nexus 3 module

The e200z4256 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

84.1 Introduction

84.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

84.1.2 Terms and definitions

Table 2094 contains a set of terms and definitions associated with the Nexus 3 module.

Table 2094. Terms and definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM or DWM, or both.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 2094. Terms and definitions (continued)

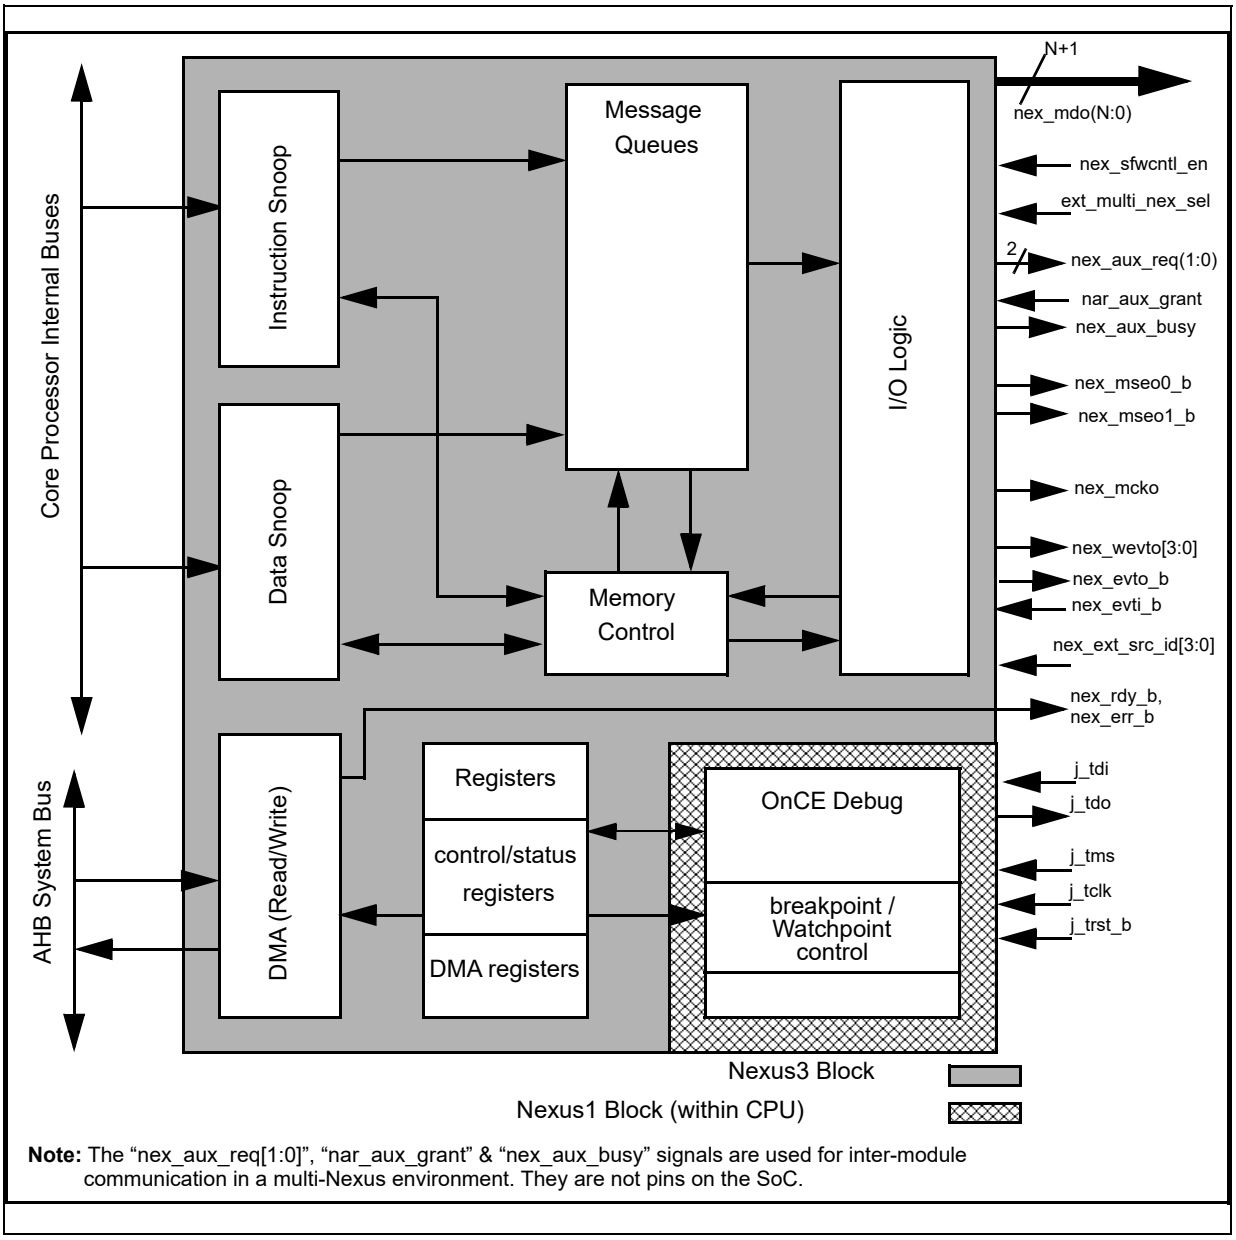
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number or size of packets, or both, to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

84.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (such as direct and indirect branches, exceptions), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins.
- Watchpoint Trigger enable of Program or Data Trace Messaging, or both.
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging.
- Auxiliary interface for higher data input/output.
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**).



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

84.1.4 Functional block diagram

Figure 2201. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

84.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

84.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

84.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 2095*.

Table 2095. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2100*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2095. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2100*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message with Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2095. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch Message with Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2100*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2100*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 2098*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (Refer to *Section 84.12.4: Resource Full Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2095. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (Refer to *Section 84.12.1: Branch Trace Messaging types*)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch History Message with Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (Refer to *Section 84.12.1: Branch Trace Messaging types*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated with program flow (Refer to *Table 2099*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (Refer to *Section 84.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (Refer to *Section 84.12.5: Program Correlation Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 84.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 2096 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 2096. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (such as Debug Status messages)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 2097 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 2097. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 2098 shows the encodings used for resource codes for certain messages.

Table 2098. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 2099 shows the event code encodings used for certain messages.

Table 2099. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 2100 shows the data trace size encodings used for certain messages.

Table 2100. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

84.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. Refer to *Section 84.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 84.6: Nexus 3 Register Access via Software* for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 2101 details the register map for the Nexus 3 module.

Table 2101. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.

2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

84.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Reserved				CS			
7	6	5	4	3	2	1	0

Nexus Reg# 0x1; Read-only; Reset: 0x0

Figure 2202. Client Select Control (CSC) register

Table 2102. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

84.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

OPC	0	MCK_EN	MCK_DIV	0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# PCR_INDEX; Read/Write; Reset: 0x0

Figure 2203. Port Configuration Register (PCR)

Table 2103. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled

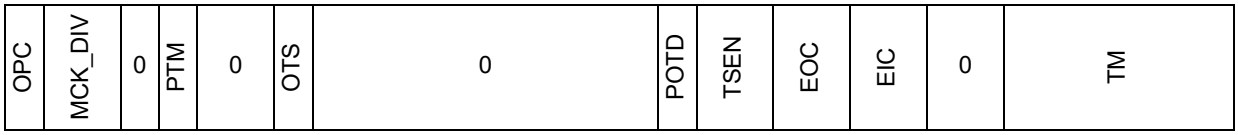

Table 2103. PCR field descriptions (continued)

Bit	Name	Description
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

84.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 2204* and its fields are described in *Table 2104*.

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

Figure 2204. Development Control 1 (DC1) register

Table 2104. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control 0 — Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined 1 — Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined
30:29	MCK_DIV	MCKO Clock Divide Ratio (see note below) 00 — **nex_mcko** is 1x processor clock freq. 01 — **nex_mcko** is 1/2x processor clock freq. 10 — **nex_mcko** is 1/4x processor clock freq. 11 — **nex_mcko** is 1/8x processor clock freq.
28	—	Reserved for future functionality
27	PTM	Program Trace Method 0 — Program Trace uses traditional Branch Messages 1 — Program Trace uses Branch History Messages
26:25	—	Reserved for future functionality

Table 2104. DC1 field descriptions (continued)

Bits	Name	Description
24	OTS	Ownership Trace PID Select 0 — PID0 data is transmitted within Ownership Trace Messages 1 — Nexus PID Register (NPIDR) data is transmitted within Ownership Trace Messages
26:15	—	Reserved for future functionality
14	POTD	Periodic Ownership Trace Disable 0 — Periodic Ownership Trace message events are enabled 1 — Periodic Ownership Trace message events are disabled
13:12	TSEN	Timestamp Enable — (not implemented, write to 00) 00 — Timestamp is disabled

9:8	EIC	EVTI Control 00 — **nex_evti_b** is used for synchronization (Program Trace Sync msg is generated) 01 — **nex_evti_b** is used for Debug request 10 — **nex_evti_b** is disabled 1*x* — Reserved
7:6	—	Reserved for future functionality
5:0	TM	Trace Mode(1) 000000 — All Trace Disabled *xxxxx*1 — Ownership Trace enabled *xxxx*1*x* — Data Trace enabled *xxx*1*xx* — Program Trace enabled *xx*1*xxx* — Watchpoint Trace enabled *x*1*xxxx* — Reserved 1*xxxxx* — Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 84.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 84.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

84.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 2205* and its fields are described in *Table 2105*.

1. EOC bits in DC1 must be programmed to trigger $\overline{\text{EVTO}}$ on Watchpoint occurrence for EWC bits to have any effect.

84.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in *Figure 2207* and its fields are described in *Table 2107*.

1. Refer to *Table 2099* for implemented EVCODEs.

84.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

84.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program or Data Trace, or both, enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace or data trace in DC1, or both, will override these controls, and trace will remain enabled until another direct write to DC1 to disable program or data trace, or both, occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between

enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

84.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0
31 30	29 28	27 26	25 24	23 22 21 20 19 18 17 16	15	14	13	12	11 10 9 8	7	6	5	4	3	2 1 0

Nexus Reg# 0xD; DCR: 376; Read/Write; Reset: 0x0

Figure 2216. Data Trace Control (DTC) register

The following table details the Data Trace Control register fields.

Table 2116. DTC field descriptions

Bits	Name	Description
31:30	RWT1	Read/Write Trace 1 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
29:28	RWT2	Read/Write Trace 2 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
27:26	RWT3	Read/Write Trace 3 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
25:24	RWT4	Read/Write Trace 4 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace
23:16	—	Reserved for future functionality (read as 0)
15	STDC1	Stack Trace Disable Control 1 0 Tracing of stack accesses are not disabled for range 1 1 Tracing of stack accesses are disabled for range 1; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
14	STDC2	Stack Trace Disable Control 2 0 Tracing of stack accesses are not disabled for range 2 1 Tracing of stack accesses are disabled for range 2; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
13	STDC3	Stack Trace Disable Control 3 0 Tracing of stack accesses are not disabled for range 3 1 Tracing of stack accesses are disabled for range 3; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
12	STDC4	Stack Trace Disable Control 4 0 Tracing of stack accesses are not disabled for range 4 1 Tracing of stack accesses are disabled for range 4; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs

Table 2116. DTC field descriptions (continued)

Bits	Name	Description
11:8	—	Reserved for future functionality (read as 0)
7	RC1	Range Control 1 0 Condition trace on address within range 1 Condition trace on address outside of range
6	RC2	Range Control 2 0 Condition trace on address within range 1 Condition trace on address outside of range
5	RC3	Range Control 3 0 Condition trace on address within range 1 Condition trace on address outside of range
4	RC4	Range Control 4 0 Condition trace on address within range 1 Condition trace on address outside of range
3	DI	Data Access / Instruction Access Trace 0 Condition trace on data accesses 1 Condition trace on instruction accesses **Note:** The support for monitoring instruction accesses is not guaranteed to be present in all versions of the Nexus 3 module. **Note:** The setting of the DI bit also affects the information provided on the data trace port outputs (Refer to the “Data Trace Port Signals” section in the Core (e200z425n3) Core Debug Support chapter.)
2:0	—	Reserved for future functionality (read as 0)

84.4.11 Data Trace Start Address Registers (DTSA1–4)

The Data Trace Start Address Registers define the start addresses for each trace channel.

Data Trace Start Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 2224. Data Trace End Address 4 register

Table 2117 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2117. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (that is when the instruction prefetch is discarded).

84.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 2119*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Figure 2225. Read/Write Access Control/Status (RWCS) register

1. ERR and DV are read-only.

Table 2118. RWCS field descriptions

Bits	Name	Description

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 2119. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

84.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 2226. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 2120* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 2120. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:
"X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 2121 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 2121. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]

Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table 2121. RWD byte lane mapping (continued)

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Doubleword @000 first RWD pass second RWD pass	0 0 0	AHB[31:24] AHB[63:56]	AHB[23:16] AHB[55:48]	AHB[15:8] AHB[47:40]	AHB[7:0] AHB[39:32]

Table Notes:
"—" indicates byte lanes that will contain unused data.

84.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 2227. Read/Write Access Address (RWA) register

84.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 2101*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (Refer to *Section 84.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (Refer to *Table 2101*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 2228. JTAG DR format

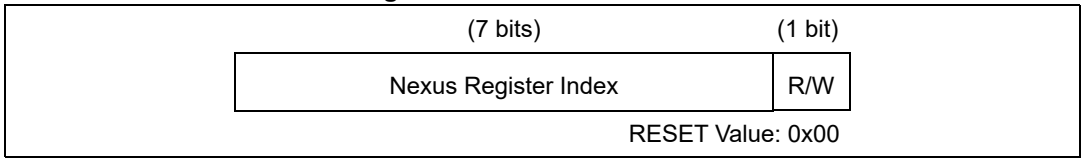

Table 2122. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 2101*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

84.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 2101* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

84.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

84.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

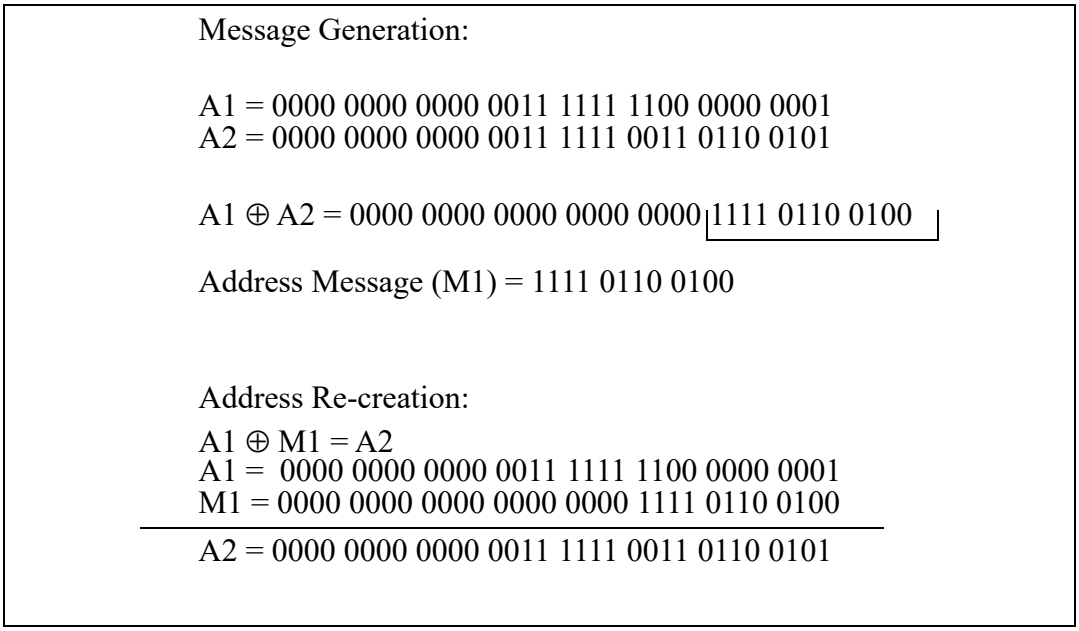
84.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

84.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 2229. Relative address generation and recreation

84.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization

messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

84.7.5 Timestamp Field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the **nex_tsen** input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of **nex_tsmode[0:1]** and the timestamp value is based on the **nex_timebase[0:29]** inputs. These signals are first synchronized to the **nex_clk** clock domain, and for **nex_timebase[0:29]**, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they enter the message queues. Leading zeros in the timestamp value are removed. *Table 2123* shows the **nex_tsmode[0:1]** encodings used for the timestamp mode.

Table 2123. nex_tsmode[0:1] Timestamp mode encoding

nex_tsmode[0:1]	Timestamp mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

84.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

84.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming

messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

84.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 84.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

84.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 84.8.1: Message Queue Overrun*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

84.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstance:

- More than three messages are generated in the same cycle

Table 2124 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 2124*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM $\rightarrow$ DQM $\rightarrow$ PCM_{PIDMSG} $\rightarrow$ OTM $\rightarrow$ BTM $\rightarrow$ DTM) $\rightarrow$ Instruction1 (newer instruction) (WPM $\rightarrow$ DQM $\rightarrow$ OTM $\rightarrow$ BTM $\rightarrow$ DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 2124. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

84.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

84.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

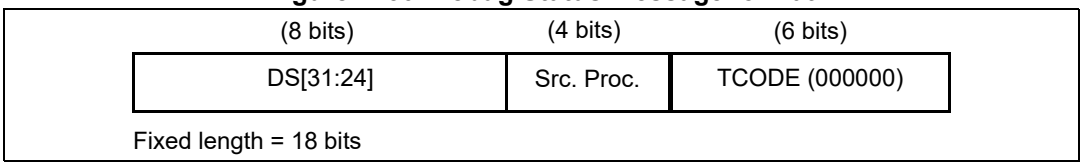
84.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

84.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



84.8.9 Data Trace Message Priority Loss Response

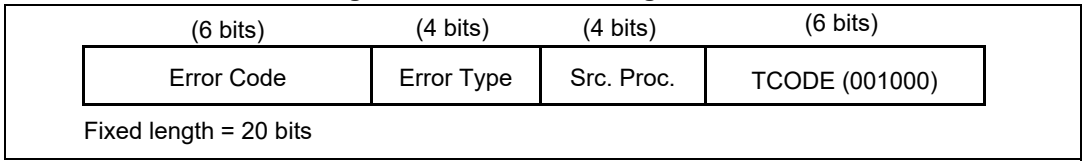
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

84.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 2230. Debug Status message format

84.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also, refer to *Table 2096* and *Table 2097*):

Figure 2231. Error message format

84.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

84.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

84.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z425n3) processors contain a <asisitalic>PowerISA 2.06 defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

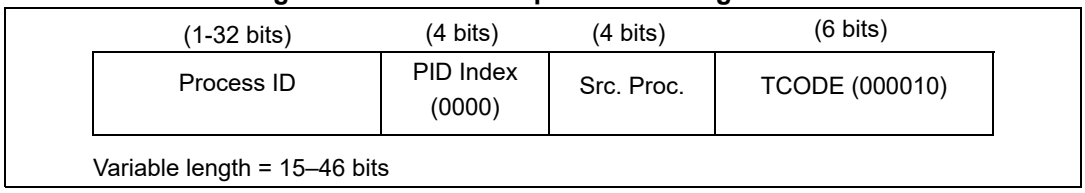
Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

SPR — 517; Read/Write; Reset: 0

Figure 2232. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.



The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 2233. Ownership Trace Message format

84.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z4256 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z425n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

84.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction,

taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. (**evsel**)Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

84.12.1.1 Indirect Branch Message instructions

Table 2125 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 2125. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfci, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

84.12.1.2 Direct Branch Message Instructions

Table 2126 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 2126. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

84.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. (**evsel**)

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

84.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

84.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

84.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to ‘1’, indirect branch information is messaged out in the following format:

Figure 2234. Indirect branch message (history) format

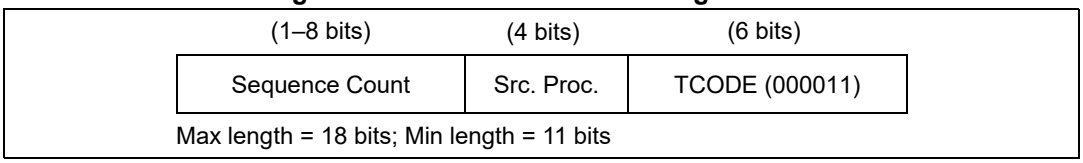
(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

84.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to ‘0’, indirect branch information is messaged out in the following format:

Figure 2235. Indirect branch message format



(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

84.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 2236. Direct branch message format

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

84.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

84.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a with sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

84.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 2127. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

84.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

84.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 2237. Resource Full Message format

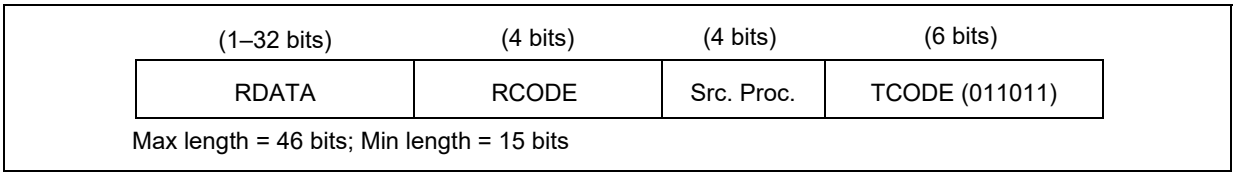


Table 2128 shows the RCODE encodings and RDATA information used for Resource Full Messages.

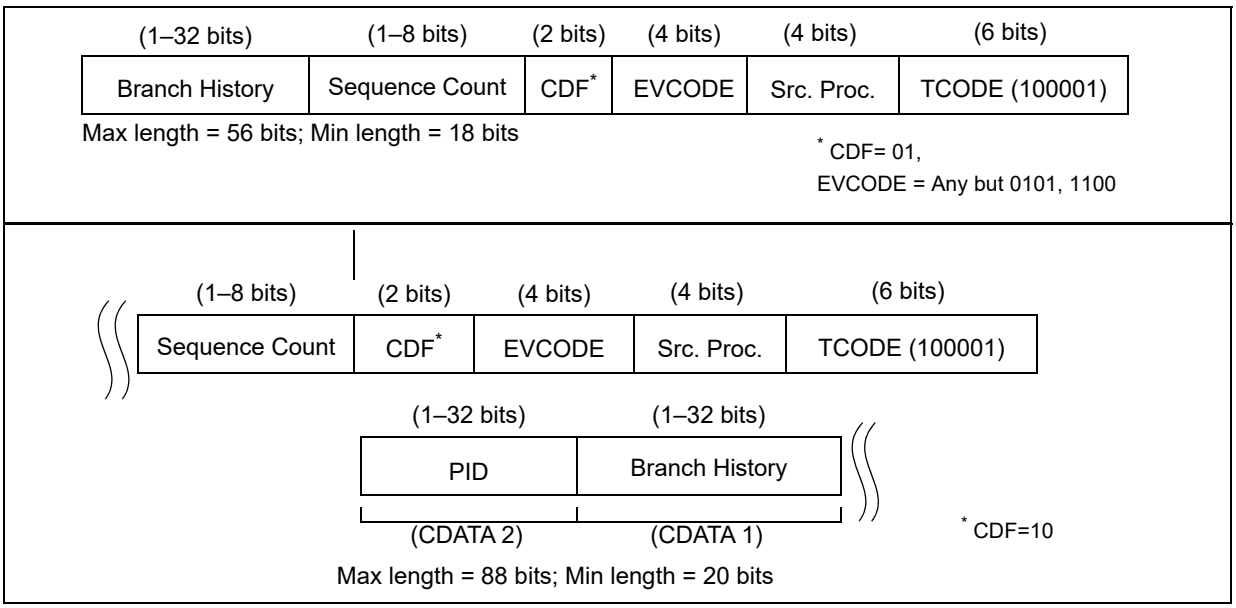
Table 2128. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

84.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions).
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 2099* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 2238. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

84.12.5.1 Program Correlation message generation for PID updates

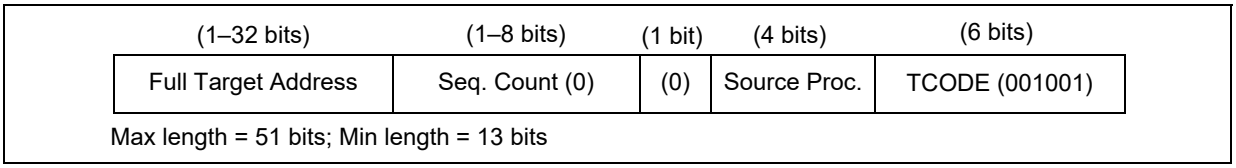
When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

84.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

84.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.



Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (refer to *Table 2129*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 2239. .Program Trace Synchronization message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in *Table 2129*.

Table 2129. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address

of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

84.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (refer to *Table 2129*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent with Sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 2240. Direct/Indirect Branch with Sync message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync Messages is as follows:

Figure 2241. Indirect Branch History with Sync message format

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a with Sync message type are summarized in *Table 2130*.

Table 2130. Program Trace Exception Summary for with Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch with Sync Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch with Sync Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the with Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch with Sync Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

84.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of below ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

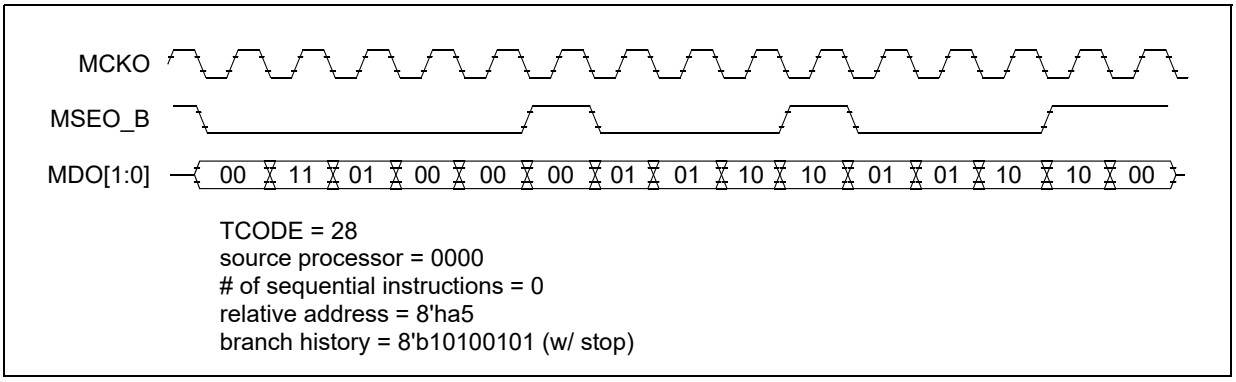

Figure 2244. Program Trace — Direct Branch (traditional) & Error messages

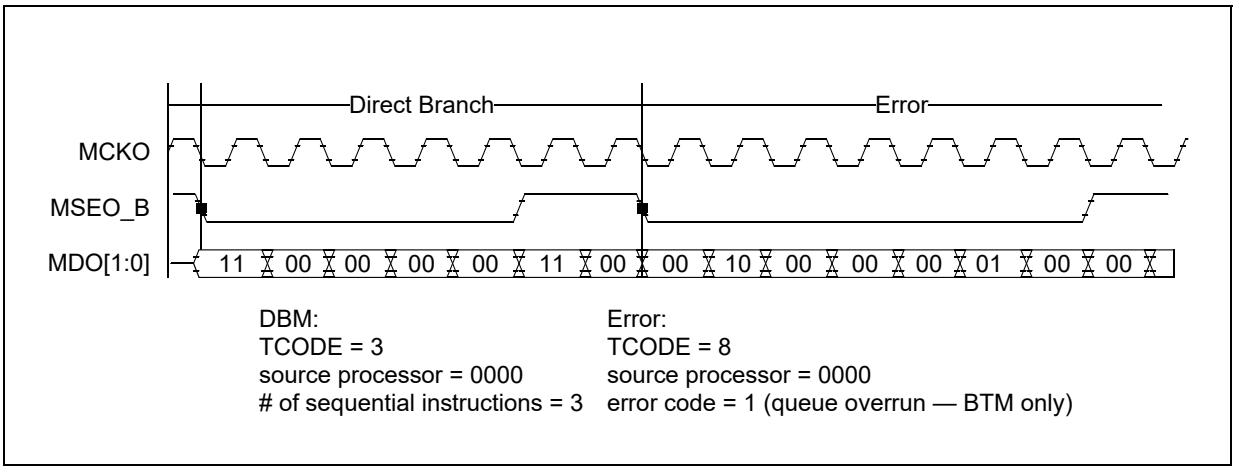

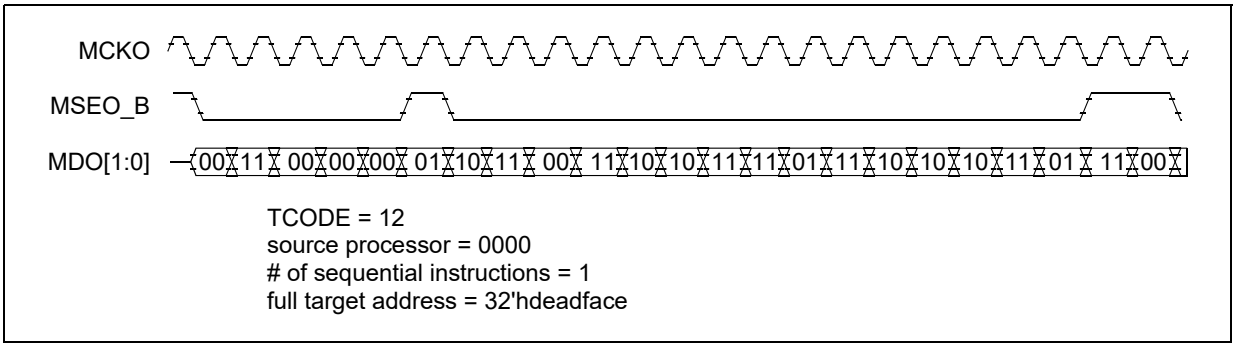

Figure 2245. Program Trace — Indirect Branch with Sync message

84.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

84.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z425n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**).

84.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

84.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 2246. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

84.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 2247. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

*Note: Core (e200z425n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the*

Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

*For Core (e200z425n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.

84.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (refer to *Table 2131*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's with security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync Messages is as follows:

Figure 2248. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in *Table 2131*.

Table 2131. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read with Sync Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read with Sync Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read with Sync Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read with Sync Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write with Sync Message.

84.13.3 DTM operation

84.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

84.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

84.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

84.13.3.4 Bus cycle special cases

Table 2132. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error(1)	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

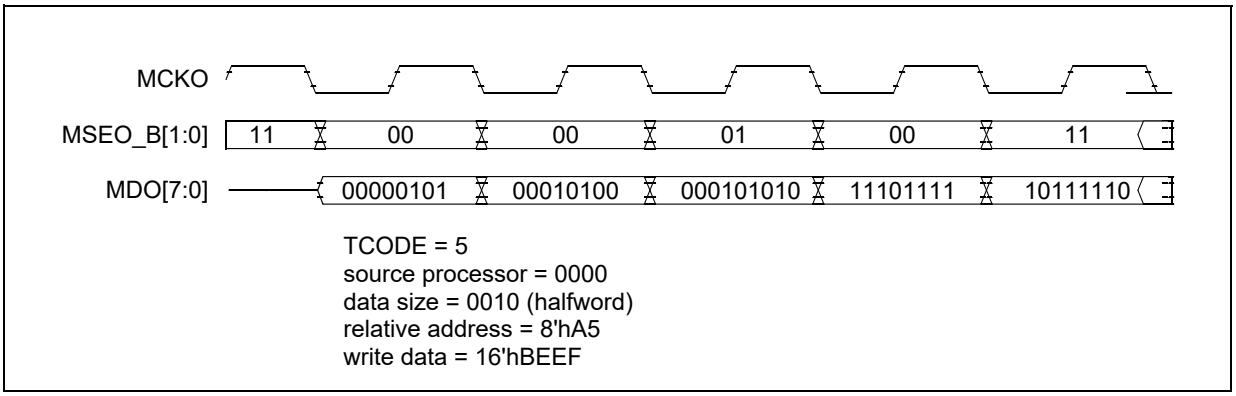
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (Refer to the Data Trace Port section in the Core (e200z425n3) Core Debug Support chapter.)

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

84.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 2249. Data Trace — Data Write message



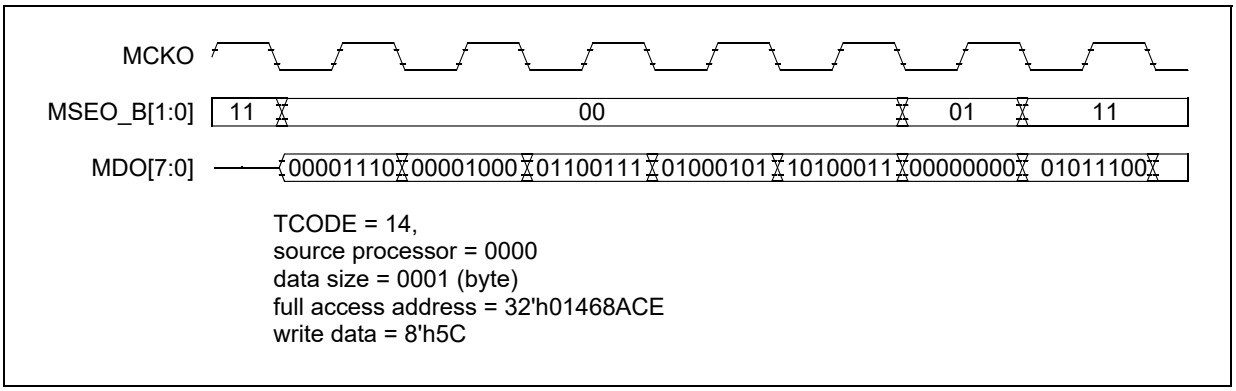


Figure 2250. Data Trace — Data Read with Sync message

84.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

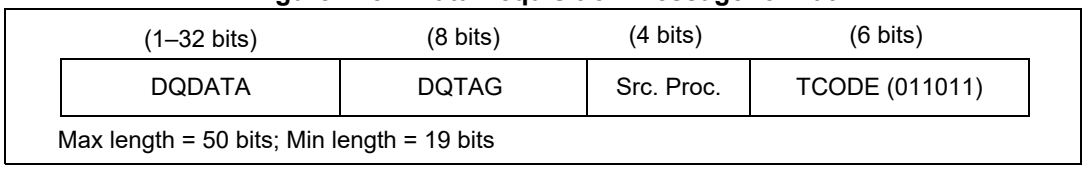
Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

84.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

84.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.



84.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

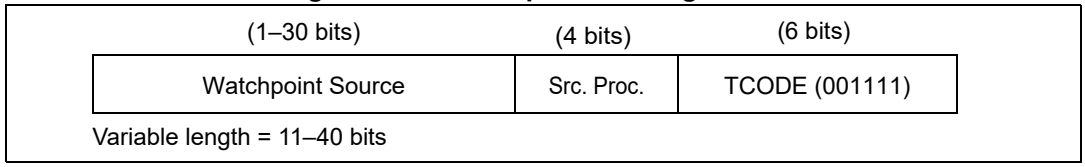
There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z425n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 2251. Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

84.15 Watchpoint Trace messaging



Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Refer to the Core (e200z425n3) Core Debug Support chapter for details on watchpoint initialization.

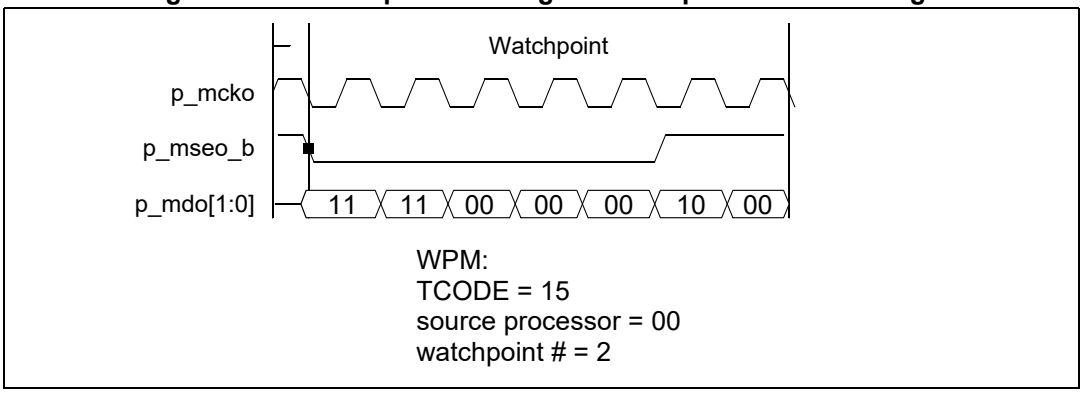
When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. Refer to *Table 2136* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 2252. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 2133. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
00000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1	Watchpoint #0 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*x*	Watchpoint #1 enabled for WTM

84.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 2253. Watchpoint Message & Watchpoint Error message

84.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 2134* details the external hardware trigger signals.

Table 2134. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 2134. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

84.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

84.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (refer to *Table 2136* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

*Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

84.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 84.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 84.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

84.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (refer to *Table 2136* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*.

*Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

84.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 84.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (refer to *Table 2136* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (refer to *Table 2136* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 84.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 84.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (that is doubleword read = two word reads from the RWD).

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

84.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

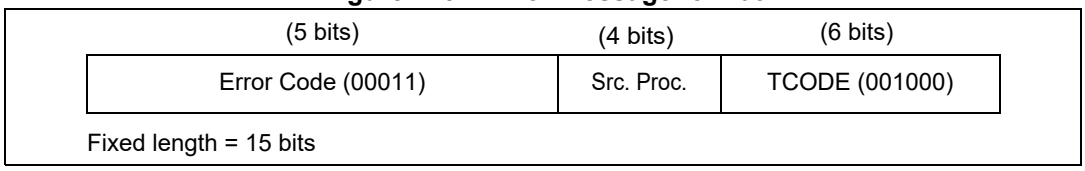
84.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

84.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD or RWA, or both, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

84.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 2254. Error message format

84.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

84.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 2136*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (refer to *Section 84.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z425n3) Core Debug Support chapter.

Table 2135. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 2136*.

Table 2136. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2’b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2’b01

Table 2136. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 84.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

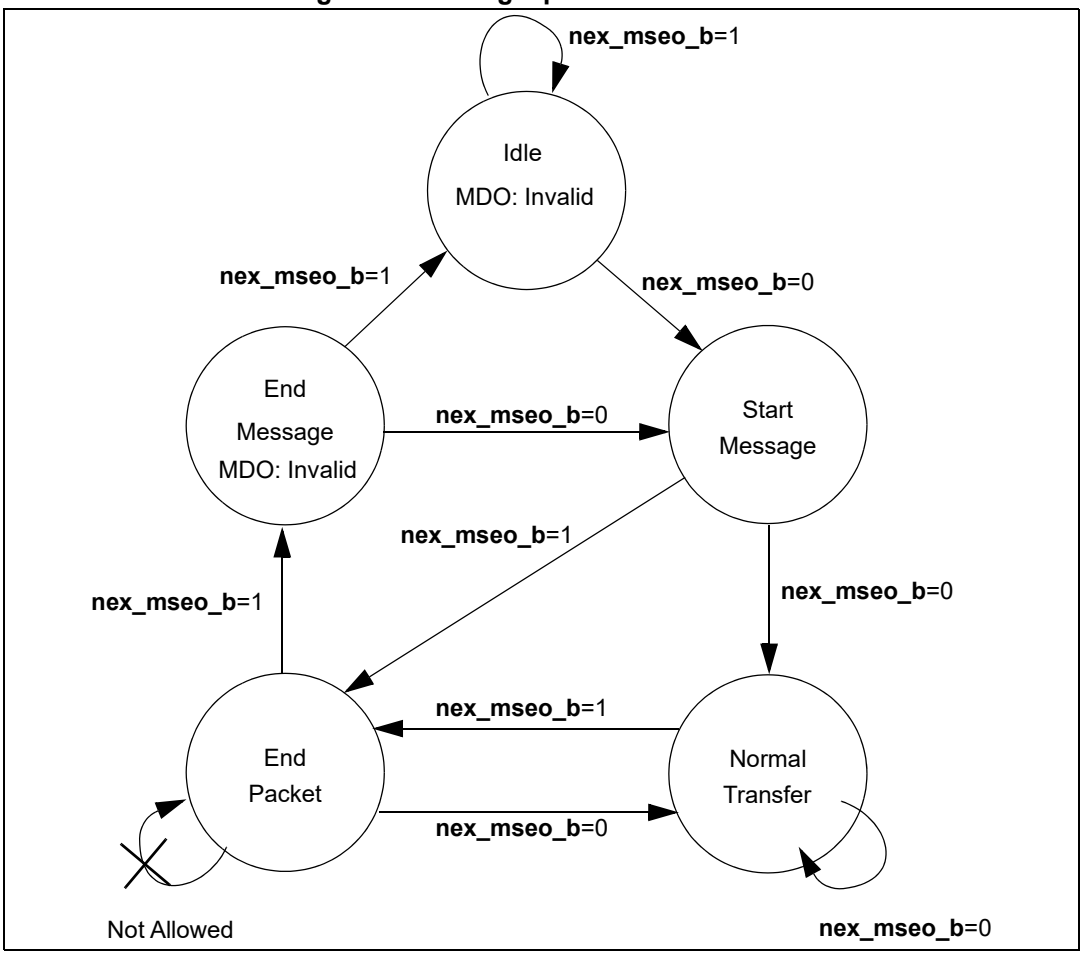
Table 2137. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 2139*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

84.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 2138*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



Single pin MSEO is not supported on the SPC58xEx/SPC58xGx.

Table 2138. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 2255 illustrates the state diagram for single pin MSEO transfers.

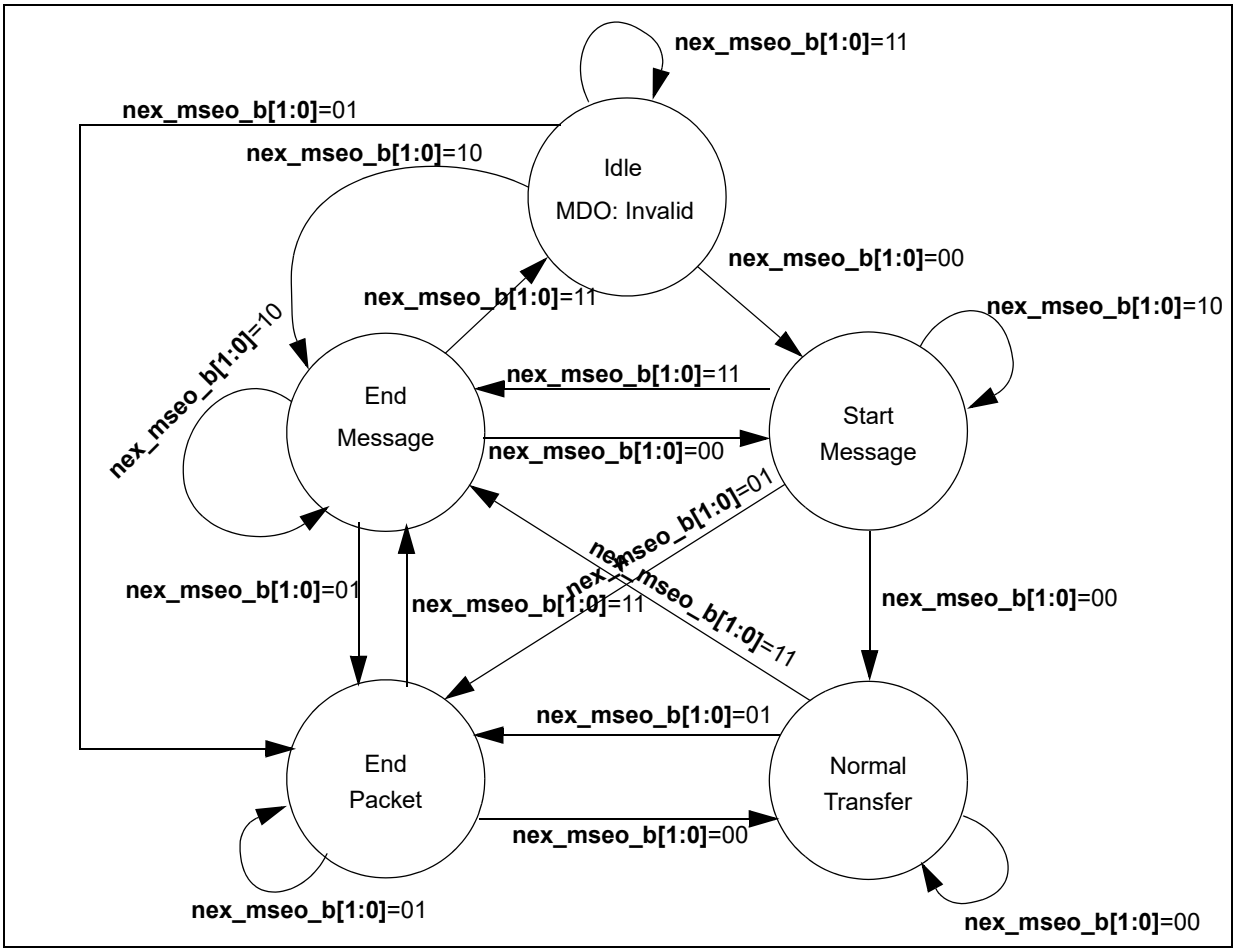


Figure 2255. Single pin MSEO transfers

Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 2256 illustrates the state diagram for dual pin MSEO transfers.

Figure 2256. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

84.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is

impossible to know which bit is from the last packet and which bit is from the next packet.)

- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

84.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 2139* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 84.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 2139. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

84.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 2140 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 2141* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 2140. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 2141. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2142 and *Table 2143* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 2142. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 2143. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2144 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 2145* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 2144. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 2145. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

84.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, refer to the SPC58xEx/SPC58xGx Data Sheet.

84.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

84.23.1 JTAG sequence for accessing internal Nexus registers

Table 2146. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

84.23.2 JTAG sequence for read access of memory-mapped resources

Table 2147. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

84.23.3 JTAG sequence for write access of memory-mapped resources

Table 2148. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

85 Nexus Crossbar Multi-Master Client (NXMC)

85.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA AHB, and CPU Data Bus AHB start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.This also provides the capability of sending user defined messages for the peripherals attached to it.

85.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to (selected) internal memory resources
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

85.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 2150*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (refer to *Section 85.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 2149* describes the JTAG pins.

Table 2149. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 2150. NXMC **auxiliary pins**

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (refer to *Section 85.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

85.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 2151*. The SRC

and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 2151. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2152*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2152*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (refer to *Table 2153*)
	14	14	ECODE	fixed	Error code (refer to *Table 2154*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2152*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2151. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2152*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (refer to *Table 2166*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2152. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 2153. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved

Table 2153. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 2154. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved
Source (SRC) n = peripheral index		
CKSRCn	XXXXXXX1	Reserved
CKSRCn	XXXXXX1X	Reserved
CKSRCn	XXXXX1XX	Reserved
CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

85.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. Refer to *Section 85.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 2155*.

Table 2155. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	0x2	R/W	0x04	0x05
Development Control 2 (DC2)	0x3	R/W	0x06	0x07
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B
Data Trace Start Address1 (DTSA1)	0xE	R/W	0x1C	0x1D
Data Trace Start Address2 (DTSA2)	0xF	R/W	0x1E	0x1F
Data Trace End Address1 (DTEA1)	0x12	R/W	0x24	0x25
Data Trace End Address2 (DTEA2)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register1 (BWC1)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register2 (BWC2)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register1 (BWA1)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register2 (BWA2)	0x1F	R/W	0x3E	0x3F

85.4.1 Register definitions

Detailed register definitions for the current NXMC implementation are described in the following sections.

85.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. *Figure 2257* shows the format of the DC1.

Address: refer to *Table 2155* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. Writing bits 2,3,6,7 has no impact and read value will be 0 for these bits.
3. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

85.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 2259* shows the format of the WT register.

Figure 2262. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 2160 illustrates the ranges that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2160. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range – no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

85.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. *Figure 2263* shows the format of the BWC1 register.

Figure 2265. Breakpoint /watchpoint address registers 1 and 2 (BWA1 and BWA2)

85.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 2155*. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

85.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of TRST and system reset de-assertion, after the JTAG ID register has been read by the tool after negation of TRST and should be programmed before deassertion of system reset.

85.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 85.5.4: NXMC register access via JTAG*.

85.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the TRST pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

85.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the TRST pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set.

85.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 2155*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to *Table 2155*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 2266* and *Table 2163*.

Figure 2266. JTAG DR for Nexus register access

Table 2163. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 2155*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

85.6 Functional description

85.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

85.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

85.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

85.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in *Figure 2267*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

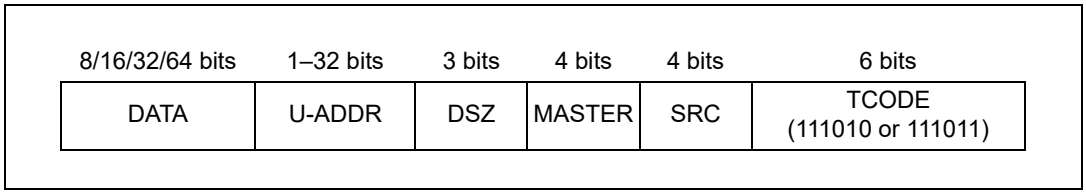

Figure 2267. DTM message format for DATA width = 64 bits

TSTAMP is another optional field which is inserted based on the controls received from the NAR, refer to *Section 85.6.4: Timestamping feature*.

85.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

85.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 2268*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

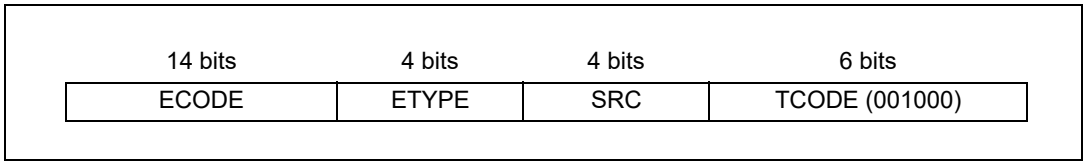

Figure 2268. DTM error message format (fixed length = 48 bits)

85.6.1.2.3.1 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to *Table 2164*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message
- Upon returning from a low power state, the first data trace message is a synchronization message
- Upon returning from debug mode, the first data trace message is a synchronization message
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 2269*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Figure 2269. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 2164*.

Table 2164. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table 2164. Data trace exception summary (continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

85.6.1.3 DTM operation

85.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

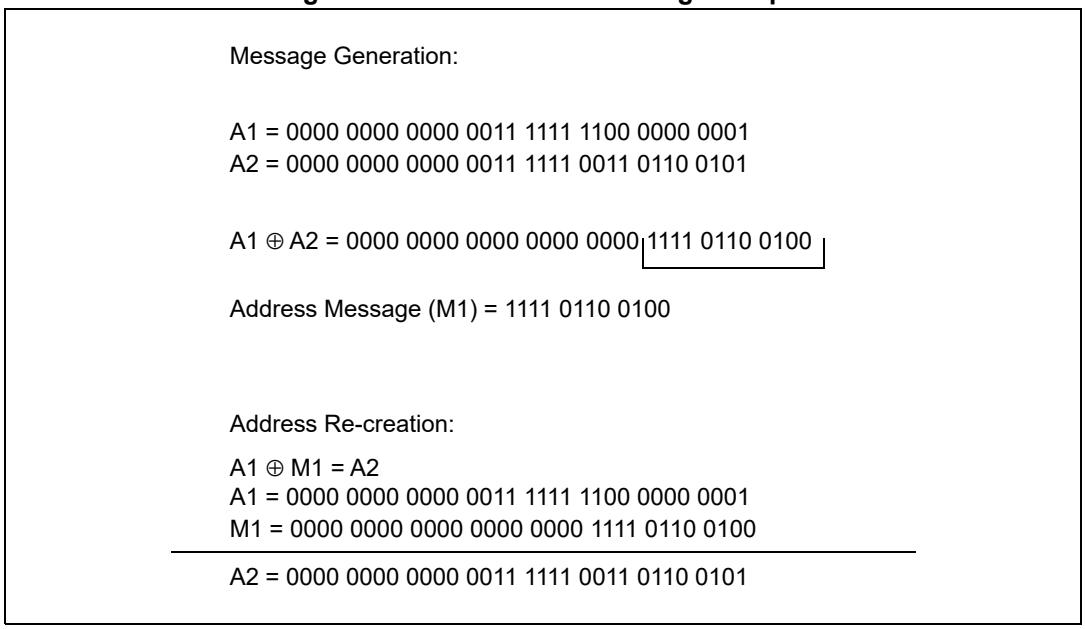
- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (that is DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure the correct DTM functionality.

85.6.1.3.2 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).



85.6.1.3.3 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address

transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 2270*.

Figure 2270. Relative addressing example

85.6.1.3.4 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

85.6.1.3.5 System bus cycle special cases

The system bus cycle special cases are shown in *Table 2165*.

Table 2165. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

85.6.1.3.6 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (refer to figure in *Section 85.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

85.6.1.3.7 HSM master filtering

For security reasons certain HSM masters need to be disabled or filtered from data tracing operations.

85.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

85.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (that are BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints: Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 85.6.1.3.6: System bus multi-master tracing*).
- External watchpoints: The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level.The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (that is on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 2271* and *Table 2166*.

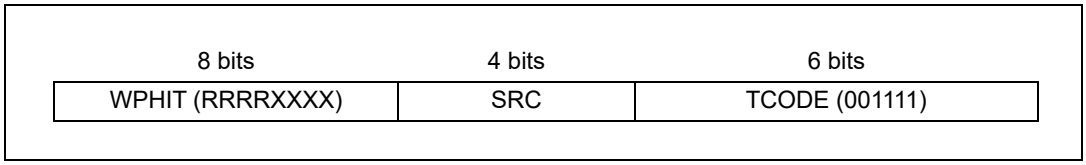


Figure 2271. Watchpoint message format (fixed length = 18 bits)

Table 2166. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1(1)	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

85.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 2272*.

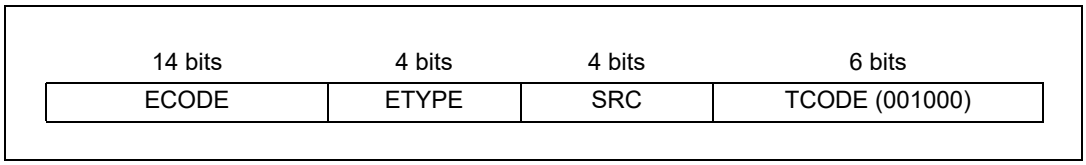

Figure 2272. Error message format (fixed length = 28 bits)

85.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

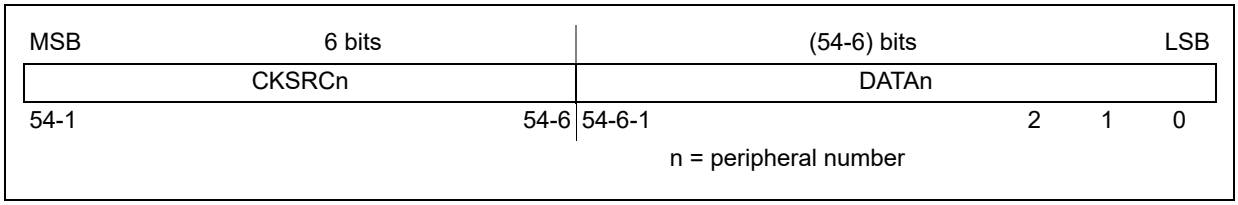

Figure 2273. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

85.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in *Figure 2274*. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

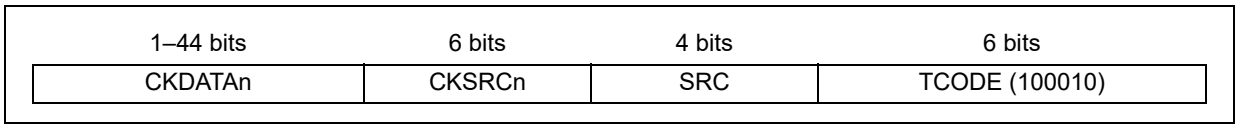

Figure 2274. Peripheral message format (max length = 60 bits, min length = 17 bits)

85.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in *Figure 2275*.

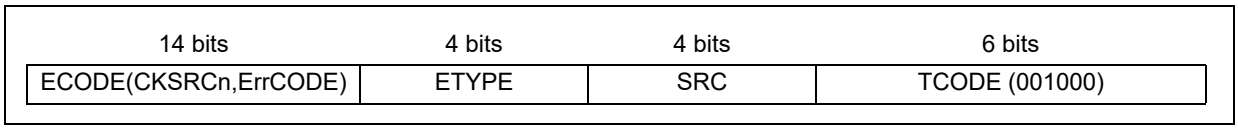

Figure 2275. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in *Table 2153* and *Table 2154*.

85.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. *Figure 2276* shows an example of ICTM message with a TSTAMP field.

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 2276. Message with TSTAMP field example

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via such as TM, PME0 control bits)

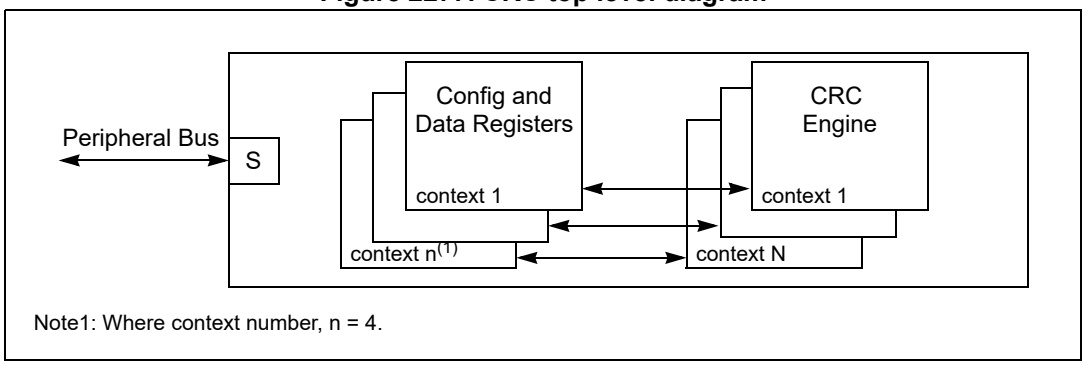
86 Cyclic Redundancy Check (CRC) Unit

86.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

86.2 Main features

- 4 contexts for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 4 hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
  - Support for byte, halfword, or word width of the input data stream



86.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

86.3 Block diagram

The top level diagram of the CRC module is given in *Figure 2277*.

Figure 2277. CRC top level diagram

Note1: Where context number, n = 4.

86.4 Signal description

The CRC module does not generate any external signals.

86.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

86.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

86.5.1 Register description

Table 2167 shows the memory map for the CRC registers.

Table 2167. CRC unit memory map

Offset	Register	Register classification(1)	Location
CRC registers per context (n=0 to CRC_CNTX_NUM - 1 with CRC_CNTX_NUM = 4)			
0x000 + *n**0x10	CRC Configuration Register *n* (CRC_CFG*n*)	Saf-Lat	*Section 86.5.1.1*

Figure 2281. CRC Output Register *n* (CRC_OUTP*n*)

Table 2171. CRC_OUTP*n* field descriptions

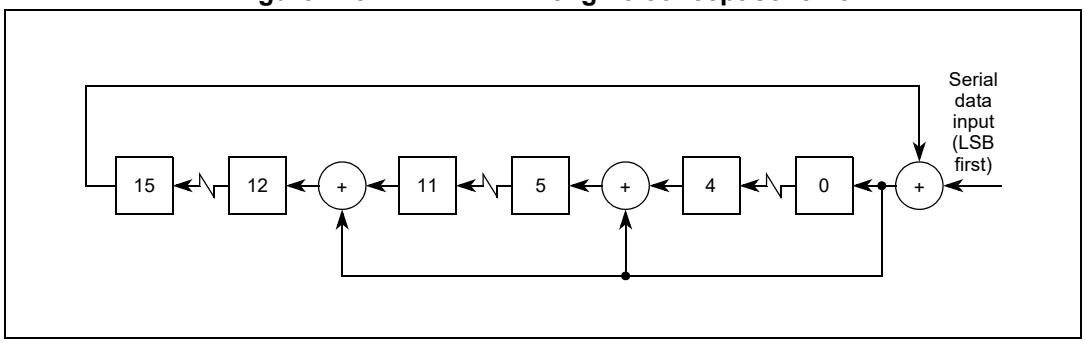
Field	Description
0:31 OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

86.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 92*, *Equation 93* and *Equation 94* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.



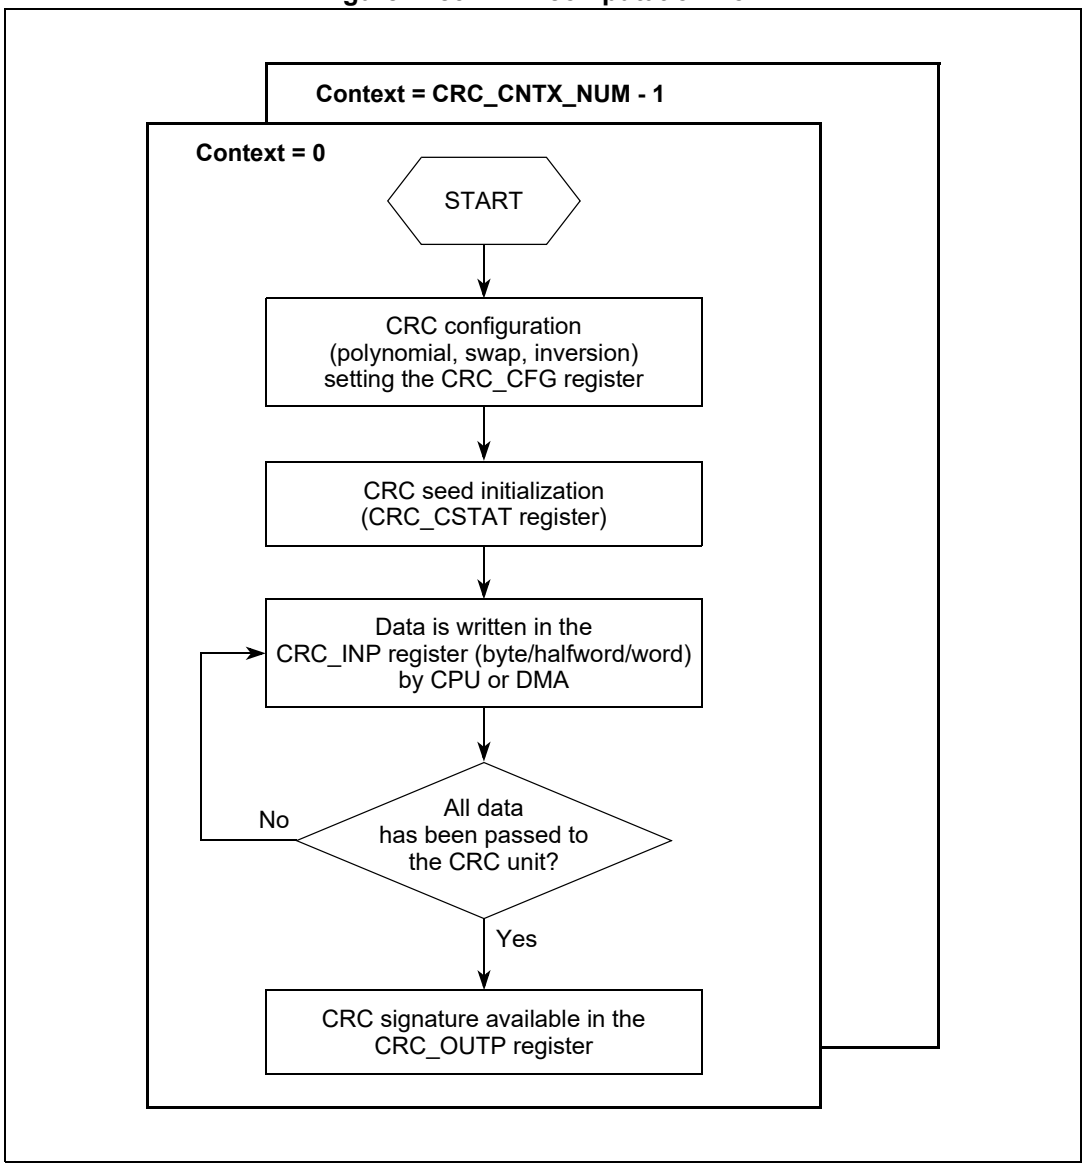
Equation 92 CRC8 VDA CAN:
$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 93 CRC-CCITT (x.25 protocol):
$$x^{16} + x^{12} + x^5 + 1$$

Equation 94 CRC-32 (Ethernet protocol):
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 95 CRC-8-H2F (Autosar 4.0 protocol):
$$x^8 + x^5 + x^3 + x^2 + x + 1$$

Figure 2282. CRC-CCITT engine concept scheme



The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 2282* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (such as SPI), a bit swap (MSB → LSB, LSB → MSB) or bit inversion of the final CRC signature, or both can be applied (CRC_OUTP register) before transmitting the CRC.

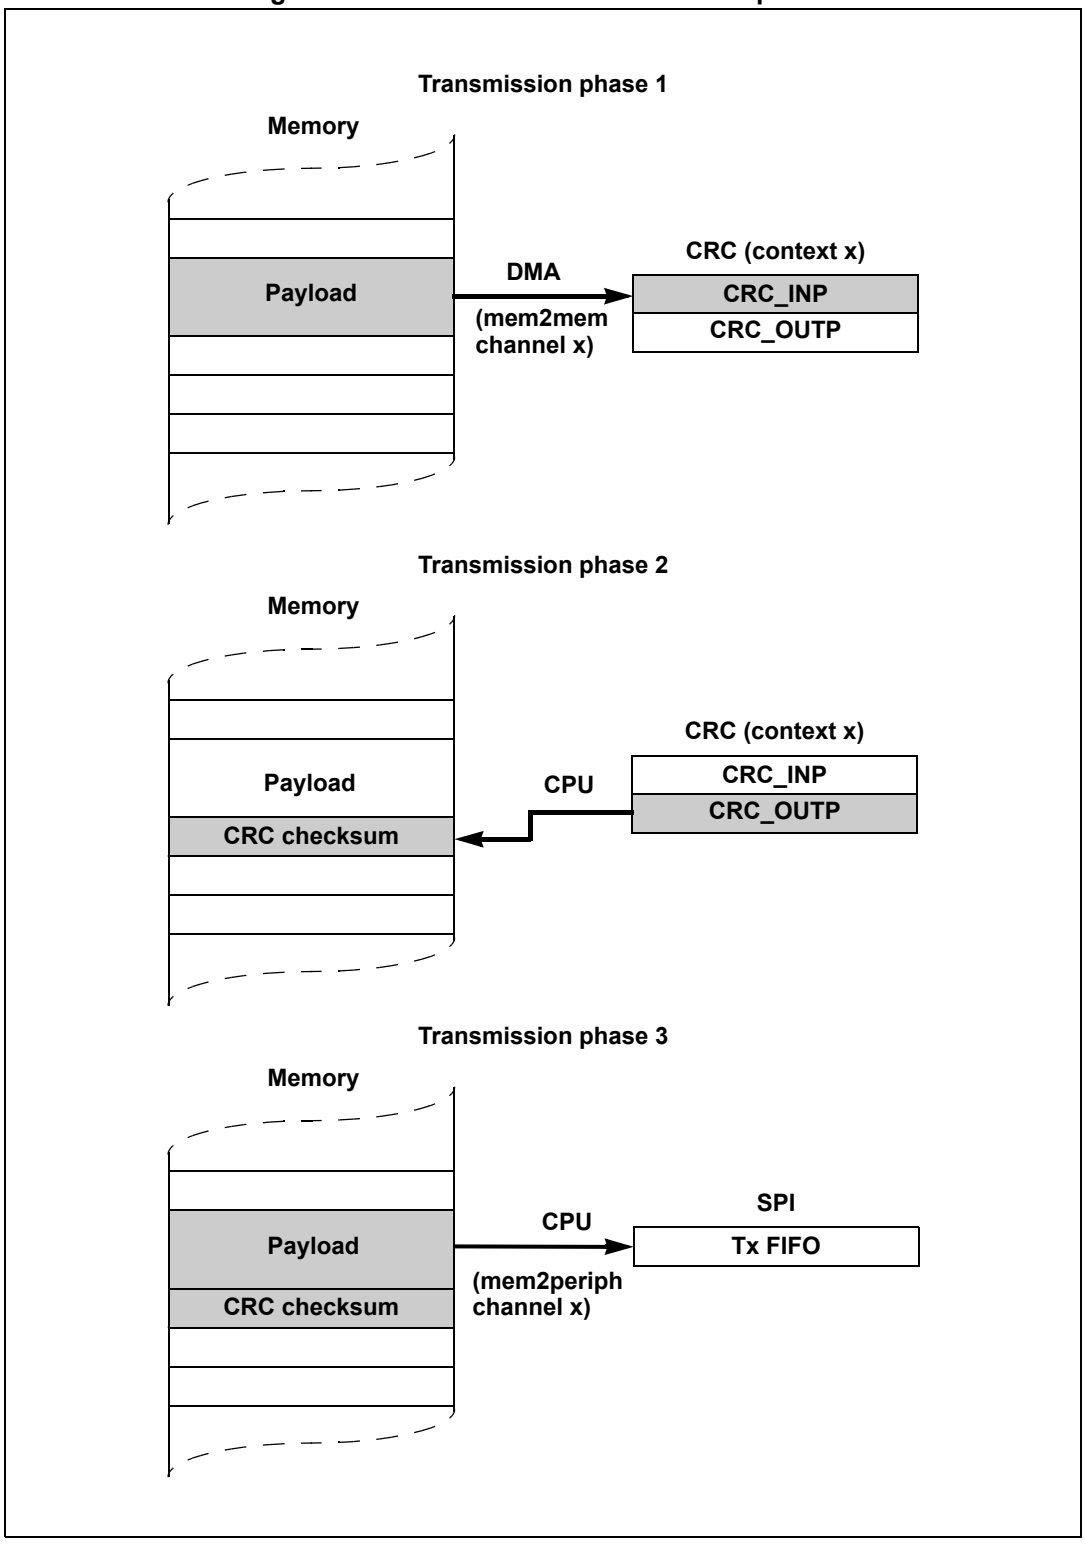
Use of the CRC module is summarized in the flow chart given in *Figure 2283*.

Figure 2283. CRC computation flow

86.7 Use cases

86.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:



- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer: mem2mem, periph2mem, mem2periph; then this sequence, as shown in *Figure 2284*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 2284. DMA-CRC transmission sequence

86.7.2 Register programming

- INV or SWAP, or both (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

87 Memory Error Management Unit (MEMU)

87.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- SRAM
- Peripheral RAM
- Flash memory.

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single/Double bit error in the data part that is detected via ECC for flash memory. Reporting of single/double bit error as correctable error depends on CTRL.FLASH_ERR_SELECT configuration.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Double/Multiple(more than two) bit error that is detected via ECC for Flash Memory. Reporting of double bit error as uncorrectable error depends on CTRL.FLASH_ERR_SELECTION configuration.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

When multiple errors are indicated from various sources at the same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

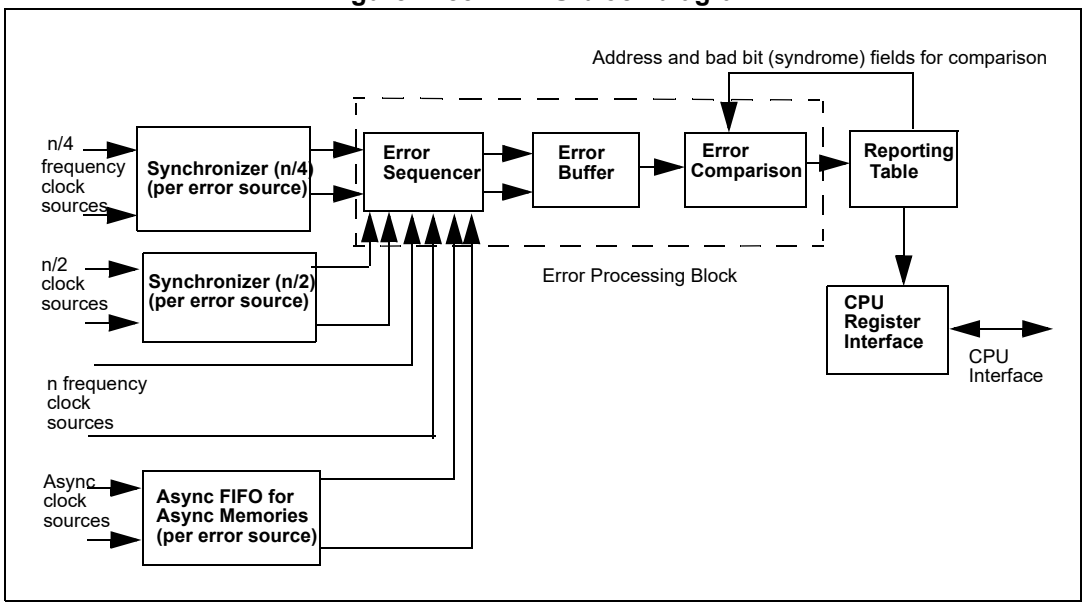
MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral SRAM ECC
- Flash memory ECC.

Each instance has two reporting tables–Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 87.4: Design overview* for the reporting block details.



87.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral SRAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

87.3 Block diagram

Figure 2285. MEMU block diagram

87.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 87.7.3: Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set, else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error (Correctable Error: CE or Uncorrectable Error: UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with

the error buffer, if the type of errors (CE and UCE) differ they are treated as unique.

– Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable).
– Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (*Section 87.6.2.4: System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *Section 87.6.2.6: System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

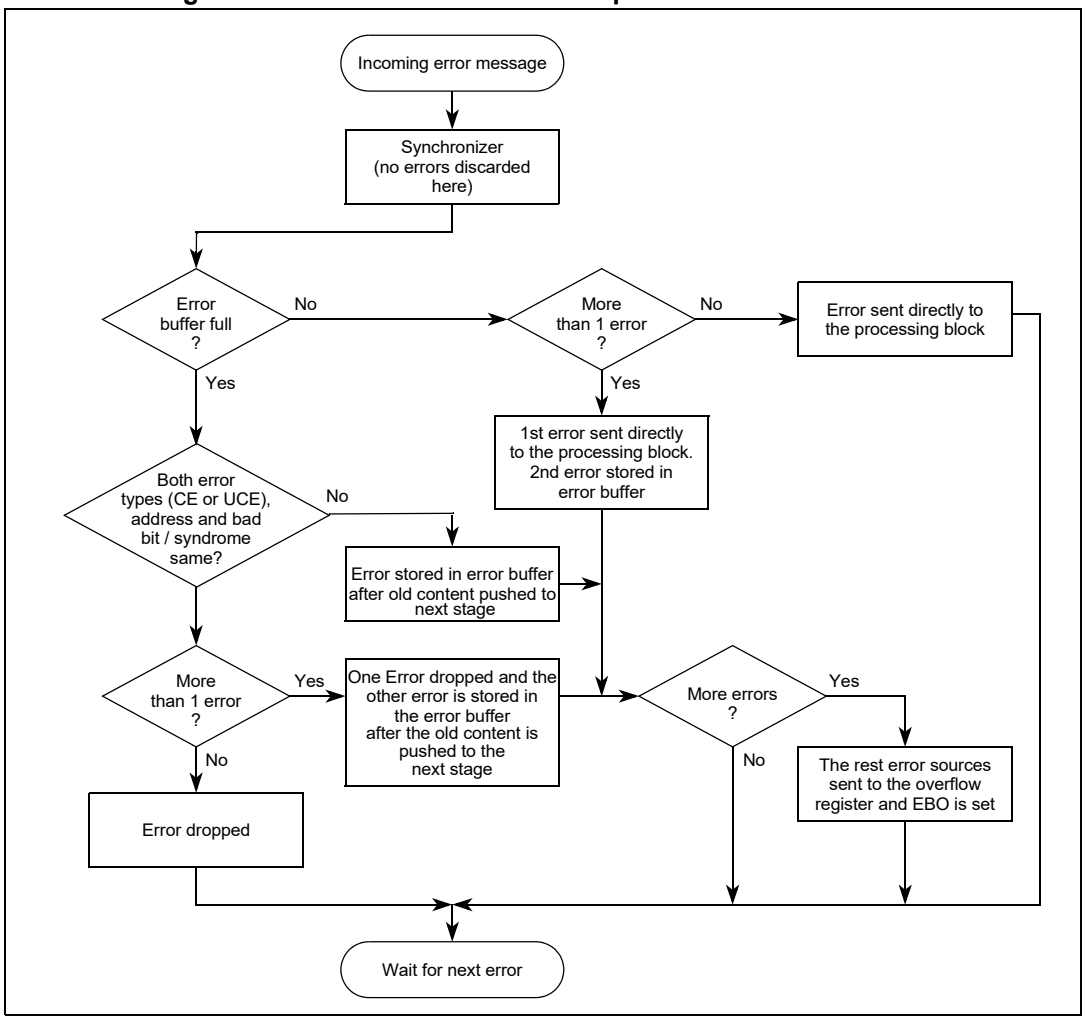
4. Register block

The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 2286. MEMU error buffer uniqueness check flow chart



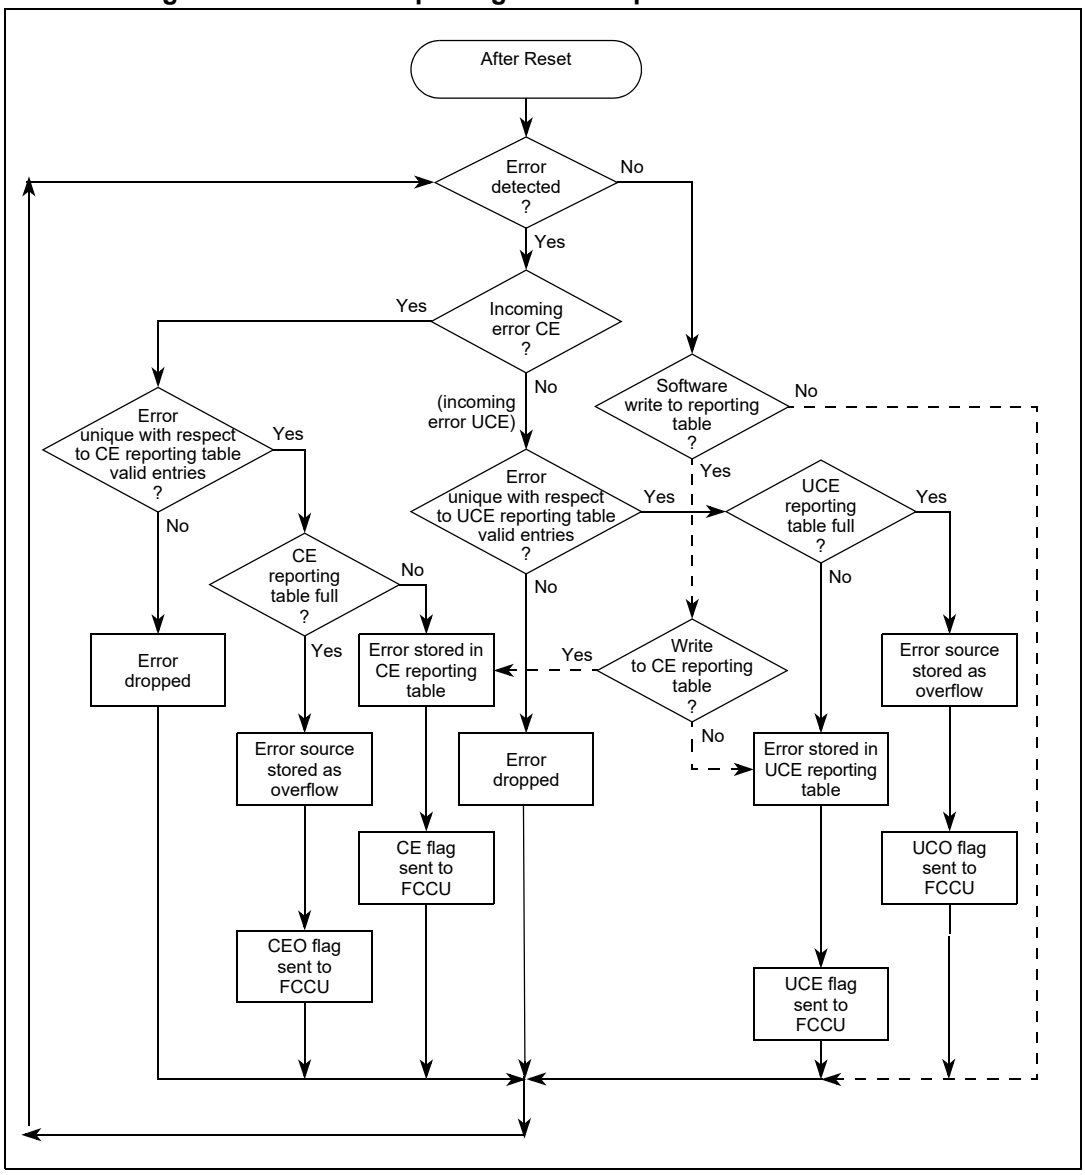


Figure 2287. MEMU reporting table uniqueness check flow chart

87.5 External signal description

MEMU has no external signals.

87.6 Memory map and register definition

87.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see Chapter 7: Device configuration that describes how modules are configured and connected.

1. In this calculation, round any fractional result of the division to the next highest integer. For example, if the division is 94 ÷ 32 = 2.9375 or 66 ÷ 32 = 2.0625, round the result to 3.
2. The corresponding error sources for the Concurrent Overflow Register (OFLW) are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

87.6.2 Register descriptions

87.6.2.1 Control register (CTRL)

Offset: 0x0000 Access: R/W

Figure 2288. Control register (CTRL)

Table 2173. CTRL field descriptions

Field	Description
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
30:31 FLASH_ERR_SELECT	FLASH_ERR_SELECT[1:0] 00 Store 20xDEC (Default). Flash Double-bit error corrections only are stored as correctable errors. 01 Store 20xDEC or SEC. Flash Single-bit or Double-bit error corrections, both are stored as correctable errors. 10 Store 20xSEC. Flash Single-bit error corrections only are stored as correctable errors 11 Reserved

87.6.2.2 Error Flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a ‘1’. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 2289. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 2174. ERR_FLAG field descriptions

Field	Description
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table 2174. ERR_FLAG field descriptions (continued)

Field	Description
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.

Table 2174. ERR_FLAG field descriptions (continued)

Field	Description
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to '1' if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

87.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Field	Description
0:31 OFLW	Overflow Bit Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 87.7.3: Handling overflows (Multiple error reporting)* occurs.

87.7 Functional description

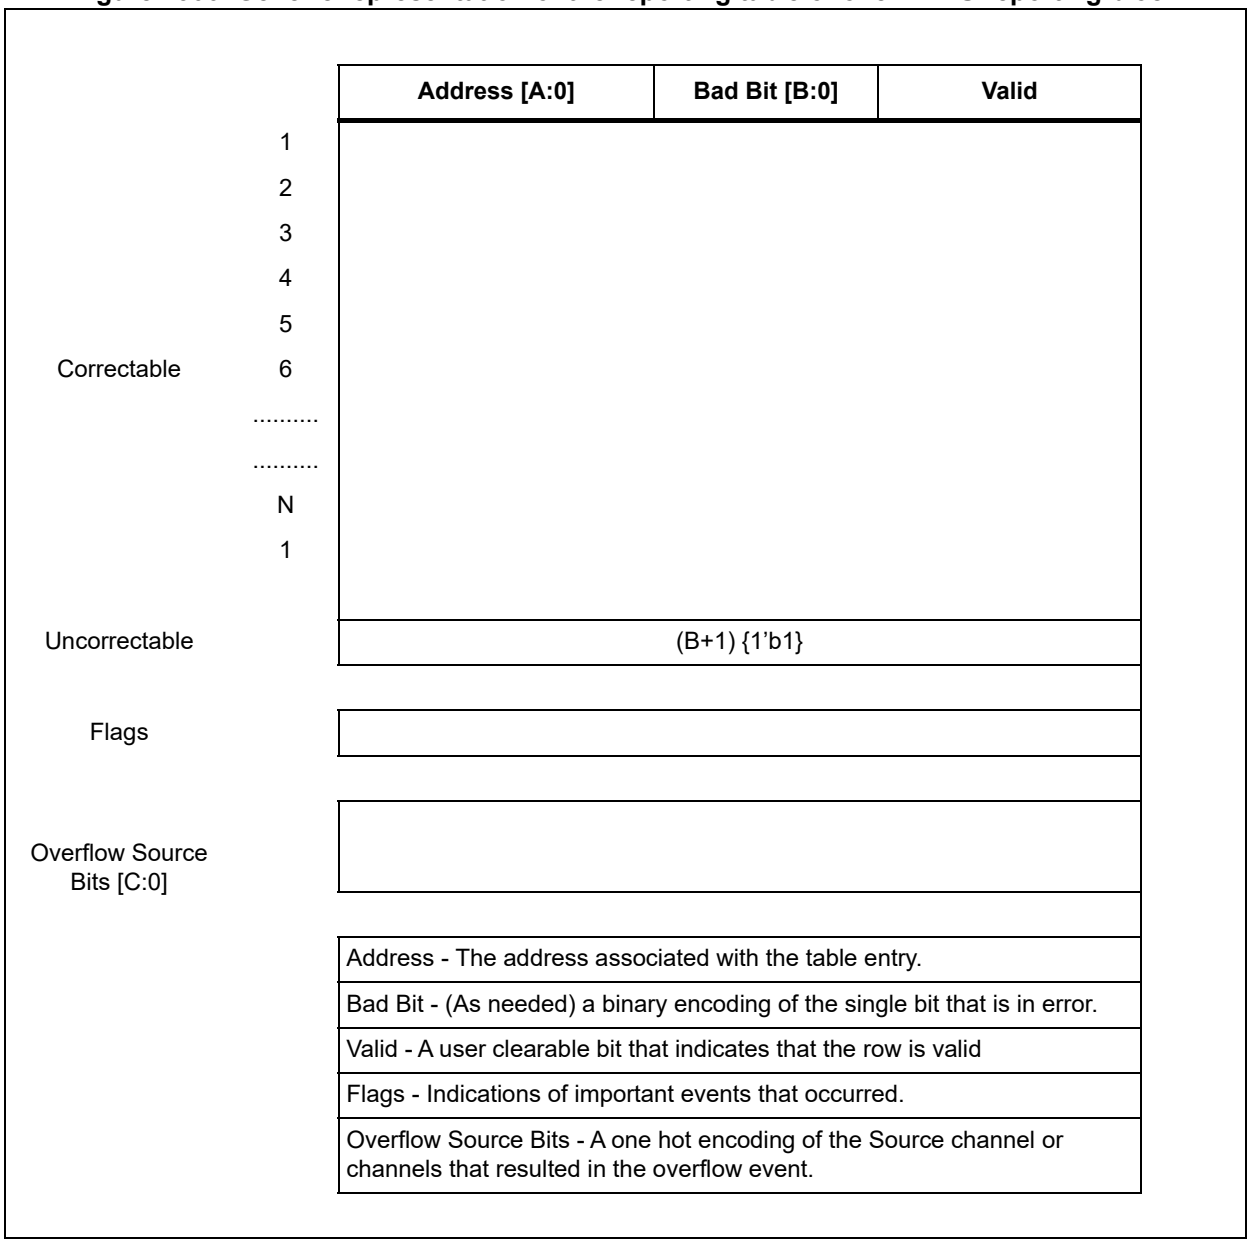
In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

87.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address.The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:



1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (duplicate entries).

87.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 2306. Generic representation of the reporting table of one MEMU reporting block

87.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
   – More than 2 errors detected at the same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
   – An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order which means that if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

88 Indirect Memory Access (IMA)

88.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading or modifying data, or both, including ECC check bits. This capability is useful for test activities, for example, verifying ECC functionality.

The SPC58xEx/SPC58xGx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays.
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. Refer to the Device Configuration chapter for details.

88.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no backdoors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed: I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

88.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control register (CDACNTL)
- Cache Debug Access Data register (CDADATA)

These registers are summarized in the following sections.

88.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

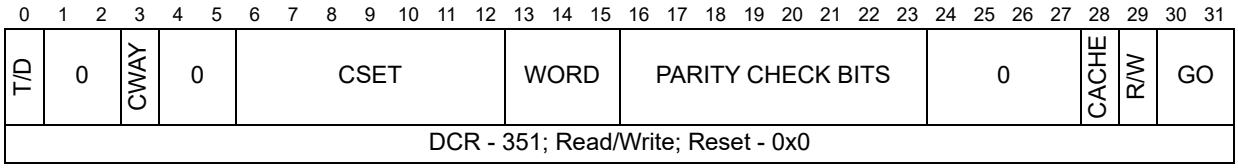


Figure 2307. Cache Debug Access Control register (CDACNTL)

The CDACNTL bits are described in *Table 2191*.

Table 2191. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1:2	—	Reserved - read as zeros.
3	CWAY	Cache Way: Specifies the cache way to be selected.
4:5	—	Reserved - read as zeros.
6:12	CSET	Cache Set: Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13:15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set.
16:23	PARITY CHECK BITS	Parity check bits (I or D-cache): D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24:27	—	Reserved - read as zeros.
28	CACHE	Cache Select: Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30:31	GO	GO command bits: 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

88.2.1.2 Cache Debug Access Data register (CDADATA)

The Cache Debug Access Data register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

DCR - 350; Read/Write; Reset - Undefined/Unaffected																															

Figure 2308. Cache Debug Access Data register (CDADATA)

The CDADATA bits are described in *Table 2192*.

Table 2192. CDADATA field descriptions

Bits	Name	Description
0:31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1- Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23 byte 2 24–31 byte 3

88.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

88.2.2.1 e2eECC Error Control/Status register 0 (E2EECSR0)

The e2eECC Error Control/Status register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31
0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
DCR - 511; Read/Write; Reset - 0x0; Privileged						

Figure 2309. e2eECC Error Control/Status register 0 (E2EECSR0)

The E2EECSR0 bits are described in *Table 2193*.

Table 2193. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros.
4:11	RCHKBIT	Read Checkbits: This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12:15	—	Reserved - read as zeros.
16:17	WRC	Write Control: 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control: 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection

Table 2193. E2EECSR0 field descriptions (continued)

Bits	Name	Description
20:23	—	Reserved - read as zeros.
24:31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask: This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

88.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Note the following restrictions on memory access via IMA:

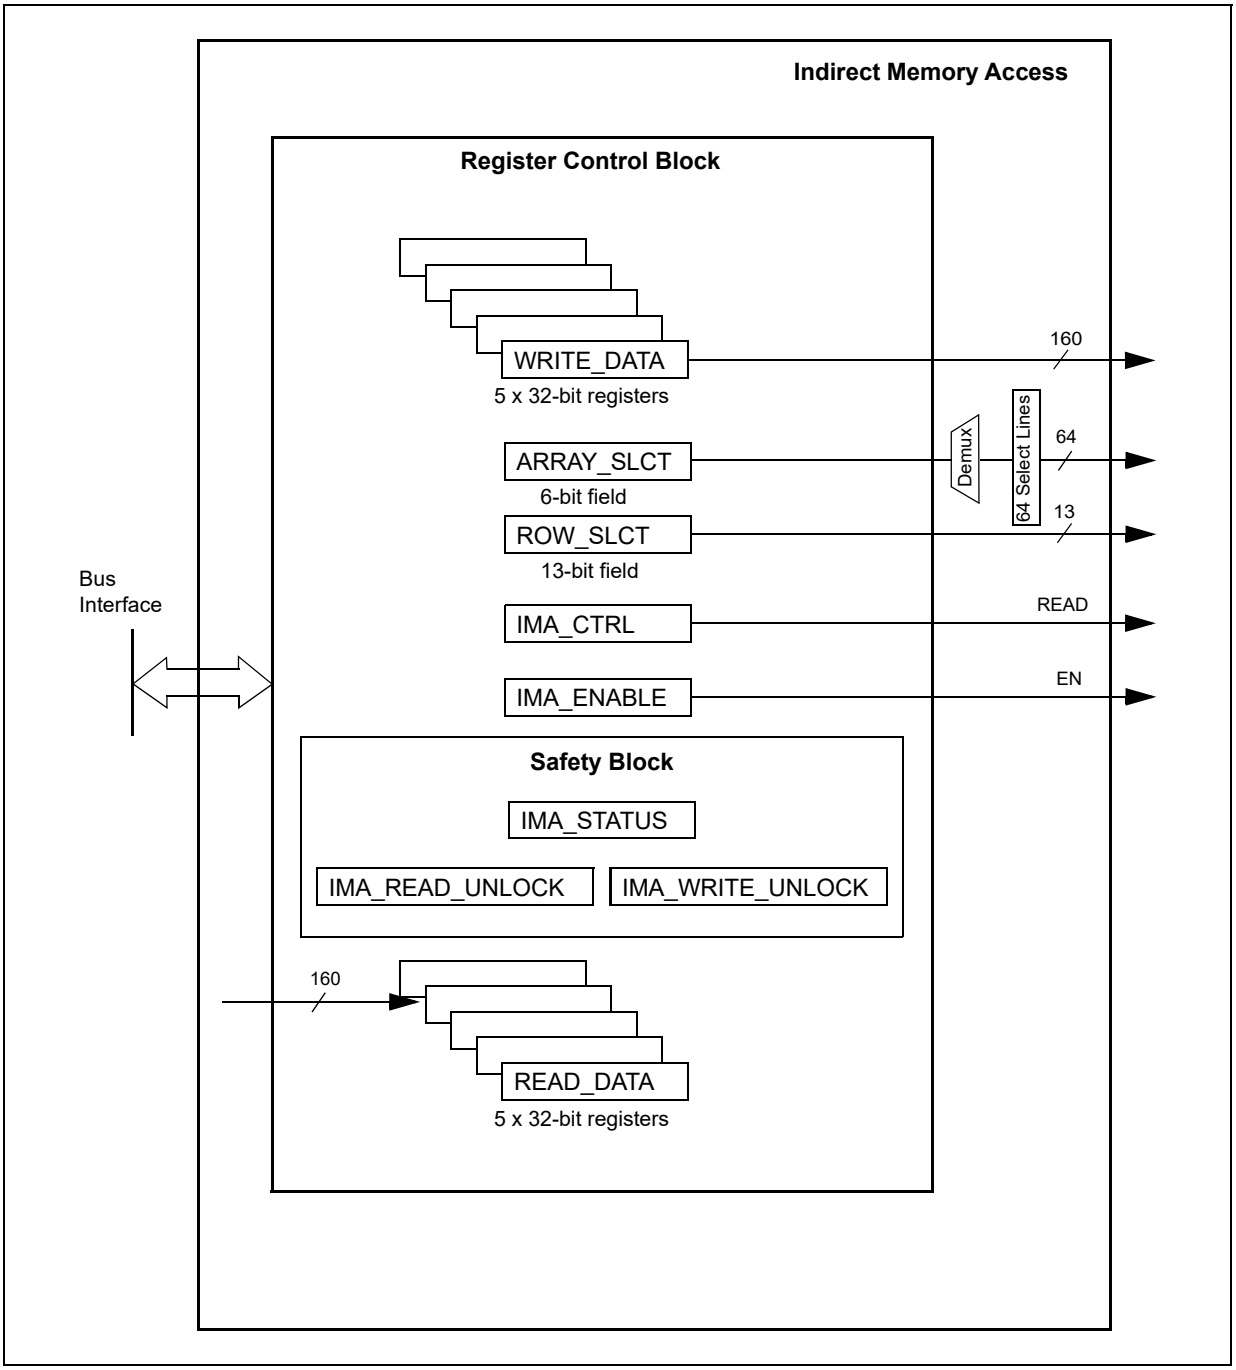
- When a bus master performs an IMA access, no other bus master shall perform an access to the same memory.
- Before any IMA access, the user shall disable the FCCU fault related to the IMA. If not, the FCCU triggers a fault.
- The IMA must be unlocked for reads.

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

88.3.1 Features



The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads.
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data
  - Writes have no effect
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

88.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it too.

Figure 2310. IMA block diagram

88.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 2194. IMA memory map

Offset Address	Register	Section

31 READ	IMA Read This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

88.3.3.2 IMA Enable Access register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: Back to back writes to the enable bit is not valid. It will still generate a two-clock enable pulse and will be considered as a single access initiation.

Offset: 0x04 Access: User read/write

Field	Description
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed. 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

88.3.3.4 IMA RAM Select register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, such as accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. Refer to the Device Configuration chapter for details.

Offset: 0x0C Access: User read/write

Field	Description
3:15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is 32 KB RAM.
26:31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

88.3.3.5 IMA Write Unlock register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

88.3.3.7 IMA RAM Write Data register n (IMA_WRITE_DATA_*n*)

The IMA_WRITE_DATA_*n* registers hold the data values to be written to the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

Field	Description
0:31 WRITE	Contains data to be written to RAM. – WRITE_DATA_4[WRITE] contains write data bits[159:128] – WRITE_DATA_3[WRITE] contains write data bits[127:96] – WRITE_DATA_2[WRITE] contains write data bits[95:64] – WRITE_DATA_1[WRITE] contains write data bits[63:32] – WRITE_DATA_0[WRITE] contains write data bits[31:0]

88.3.3.8 IMA RAM Read Data register n (IMA_READ_DATA_*n*)

The IMA_READ_DATA_*n* registers hold the data values read from the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_*n* registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Offset: 0x4C (READ_DATA_4), 0x50 (READ_DATA_3), 0x54 (READ_DATA_2), 0x58 (READ_DATA_1), 0x5C (READ_DATA_0) — Access: User read

88.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

88.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

88.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

88.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Refer to the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

88.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

88.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY.
2. Write 0x14081B56 to READ_KEY.

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY.

88.3.4.3.3 Unlocking writes

The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY.
2. Write 0xE4A9EBF7 to WRITE_KEY.

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY.
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

88.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

88.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections show the different accesses that are available depending on the options.

88.3.4.5.1 Read access

Read Accesses are expected to follow the sequence below:

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register.
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

88.3.4.5.2 Write access

Write Accesses are expected to follow the sequence below:

1. Unlock Write Access by performing appropriate consecutive writes to WRITE_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

88.3.5 Application information

Caution: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

89 Fault Collection and Control Unit (FCCU)

89.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a systematic approach to fault detection and control. The FCCU provides a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

89.2 Features

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

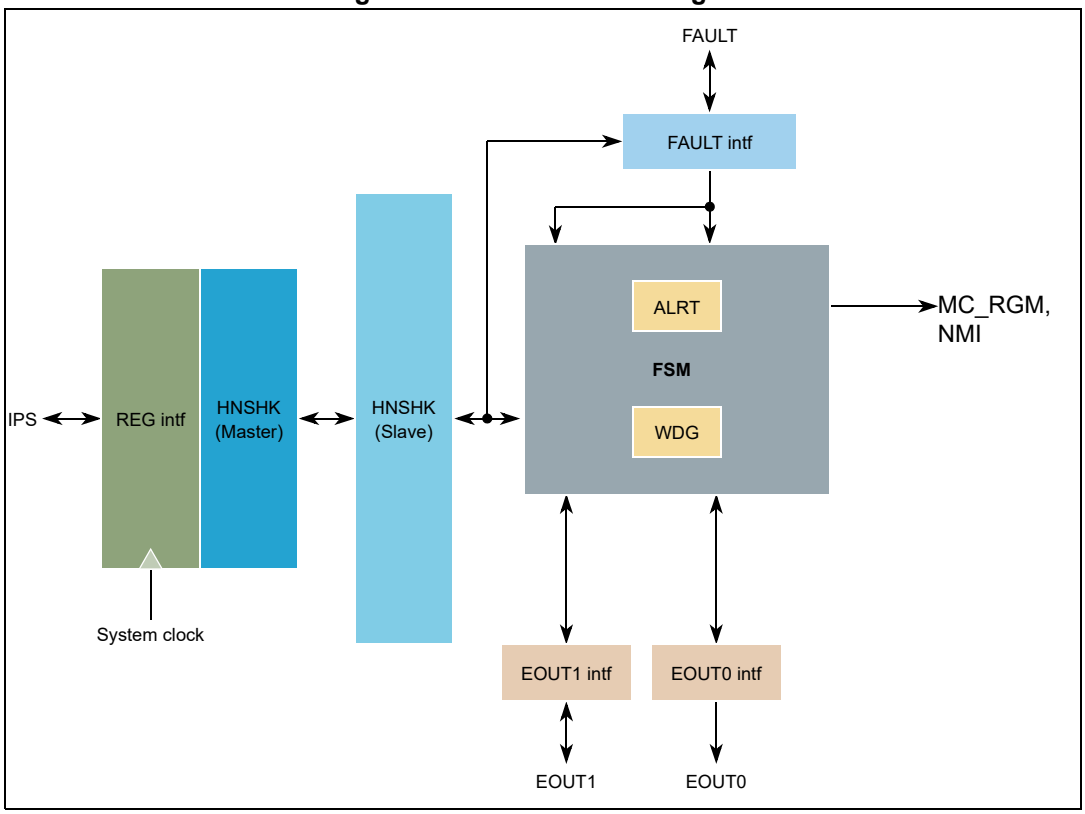
- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; refer to the implementation-specific details)
- Bi-stable, Dual Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Redundant collection of hardware checker (for example RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal (SoC) reactions
  - ALARM state: interrupt request
  - FAULT state: long functional reset request pulse, short functional reset request pulse, NMI
- Internal reactions (independently configurable for each RF)
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU
- Configuration lock: The FCCU’s configuration is lockable in two ways
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into

FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register

- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol that is dual rail and time switching
- After power-on the error out pins have high impedance(31). FCCU goes to operational state only on software request
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms
- The overall error detection, processing and indication time is less than 10 ms
- The actual maximum time is five safe (IRCOSC) clock cycles

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster than the IRC clock.

89.2.1 Standard features



- IPS (slave bus signals) bus interface

89.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 2319*.

31. Actual value depends on the SoC settings at pad level.

Figure 2319. FCCU block diagram

The FCCU module includes the submodules listed in *Table 2203*.

Table 2203. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of two asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: Watchdog timer (WDG) Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

89.4 Signal description

89.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 89.5.9: EOUT interface*.

For the availability of these signals on a chip, refer to the device configuration chapter.

89.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers.
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0] data write/read operations to any registers.
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (for example FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2212: FCCU memory map*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode.

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

89.5 Functional description

89.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization.
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization.
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

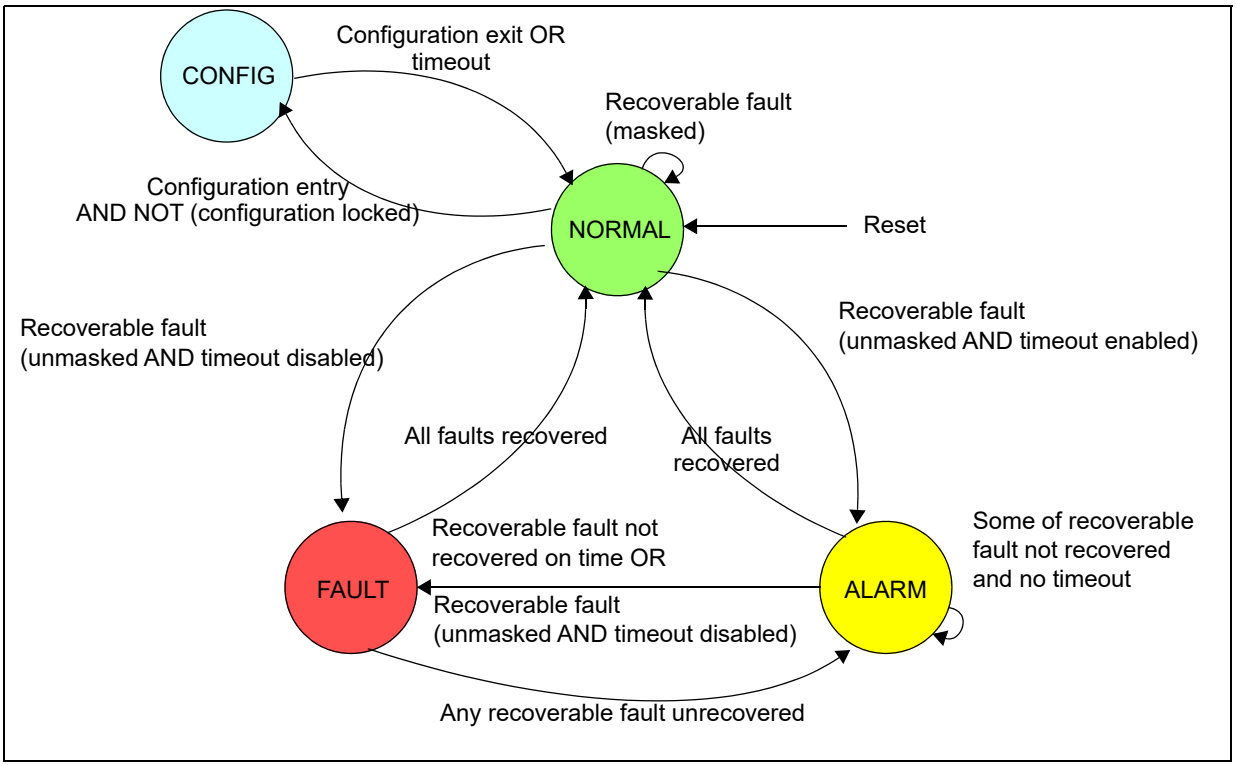
89.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 2320*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Succeeding one of the following events:
  - unmasked recoverable faults with the timeout disabled → the FCCU moves to the FAULT state.
  - unmasked recoverable faults with the timeout enabled → the FCCU moves to the ALARM state.
  - masked recoverable faults → the FCCU stays in NORMAL state.
- ALARM: the FCCU moves into the ALARM state when an unmasked recoverable fault occurs and the timeout is enabled. The transition to the ALARM state goes along with an interrupt request (ALARM state), if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the

FAULT state. The timeout is re-initialized if the FCCU state moves to the NORMAL state. The timeout restarts following the recovery from the FAULT state.



- FAULT: the FCCU moves into the FAULT state when one of the following conditions occurs:
  - timeout related to a recoverable fault when the FCCU is in the ALARM state.
  - unmasked recoverable faults with the timeout disabled.

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional).
- EOUT signaling (optional).
- SW option: Soft reaction (Short functional reset request pulse if configured).
- SW option: Hard reaction (Long functional reset request pulse if configured).

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 2320. FCCU state diagram

89.5.3 Reset interface

The FCCU has two input resets, as described in *Table 2204* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 2205* for each type of fault reaction (hard, soft or self-checking), the respective output reset (Long functional reset, Short functional reset) is activated. In *Table 2206* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit generates the corresponding input reset as described in *Table 2204*.

Table 2204. Input reset

Input reset	Description
System reset	Global reset of the FCCU synchronous to the system clock.
System reset (RC oscillator)	Global reset of the FCCU synchronous to the IRCOSC.

Table 2205 and *Table 2206* describe a typical reset strategy at system level.

Table 2205. Reset reactions

FAULT reaction	Active reset	System reset signal
Hard	Long functional reset	disabled
Soft	Short functional reset	disabled

Table 2206 shows the Reset sources.

Table 2206. Reset sources

Reset source	System reset signal
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 2207 summarizes the MC actions corresponding to each reset generated by FCCU.

Table 2207. MC actions

Active reset	MC action
Long functional reset	Reset Flash and digital modules excluded FCCU, STCU
Short functional reset	Reset digital modules excluded FCCU, STCU

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for two IRCOSC clock periods.

89.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (possible for RFs only) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a RF (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any RF is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the RF that causes an ALARM to FAULT state transition. In this case the alarm timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

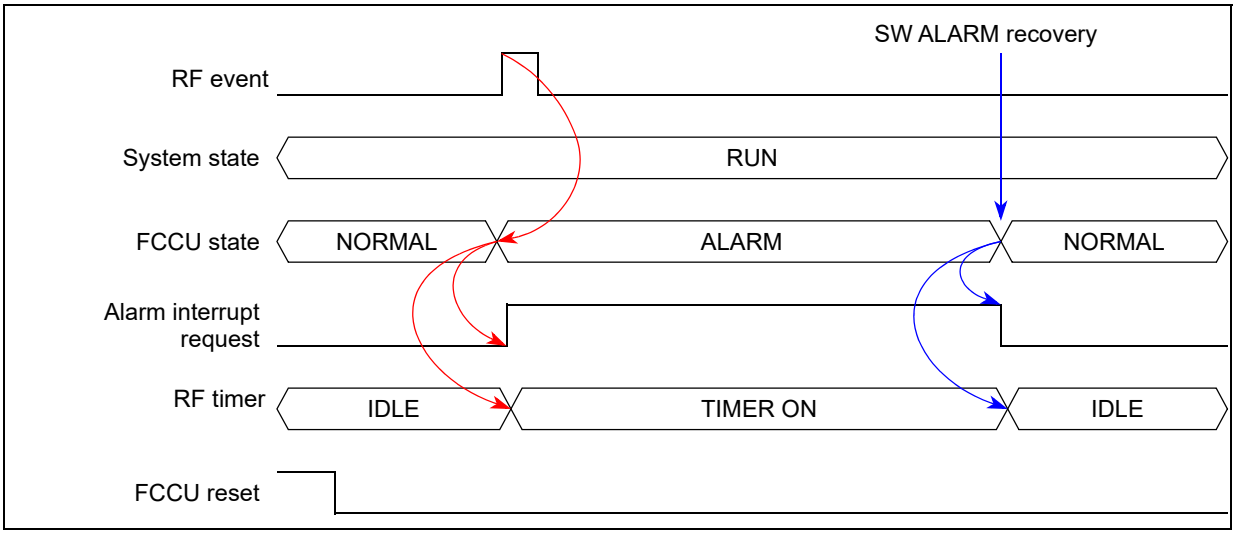
89.5.5 Fault recovery

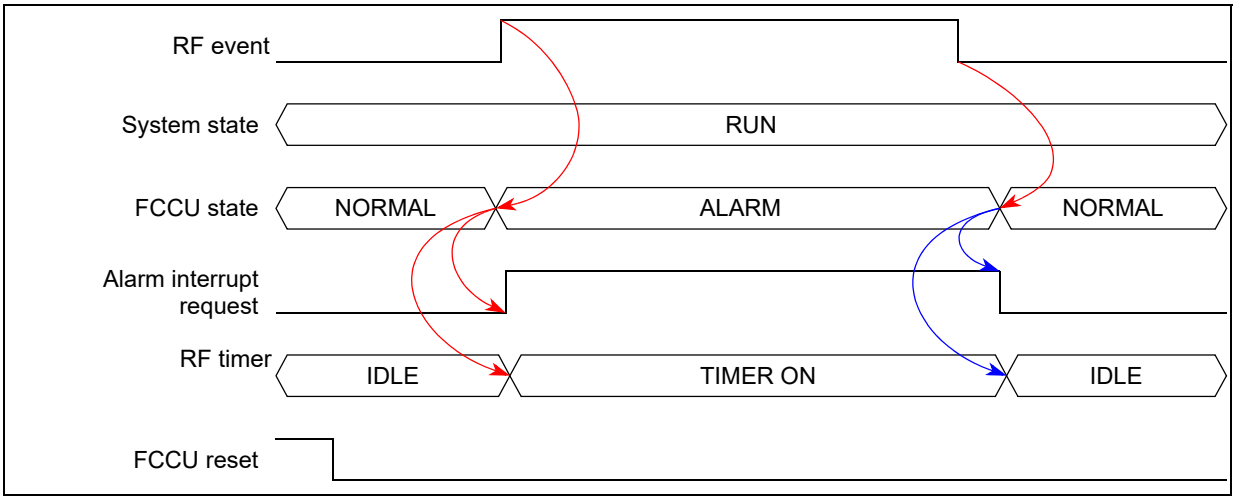
The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a RF management (ALARM state), refer to *Figure 2321* and *Figure 2322*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if configured)
  - Timeout running
- System state: RUN
- Alarm interrupt management: FAULT recovery (by SW): FCCU state transition ALARM → NORMAL

Figure 2321. RF (ALARM state) recovery (a)





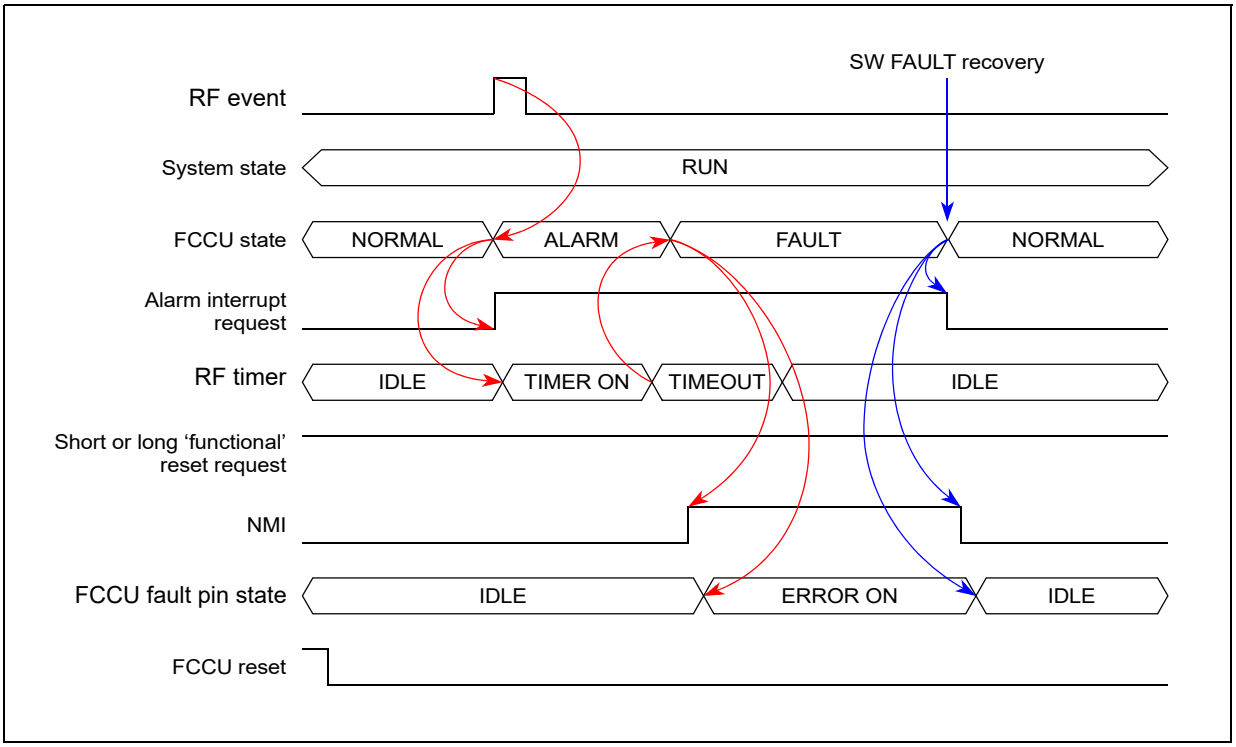


Figure 2322. RF (ALARM state) recovery (b)

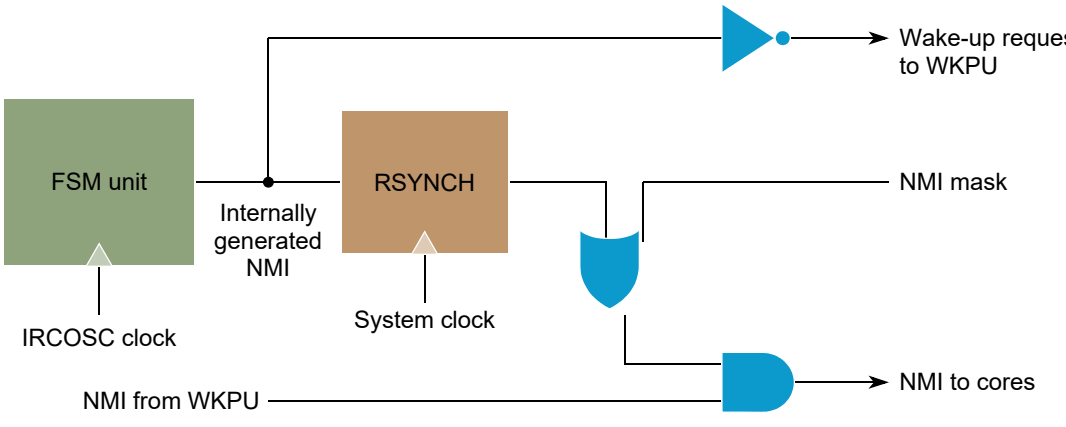
A typical sequence related to a RF management (ALARM → FAULT state), refer to *Figure 2323*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if enabled)
  - Timeout running
- FCCU state transition (following the timeout trigger): ALARM → FAULT: NMI assertion (if enabled)
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL

Figure 2323. RF(ALARM -> FAULT state) recovery

89.5.6 NMI/WKPU interface



The wake-up interface includes Non-maskable interrupt: NMI interrupt source generated by the WKPU. It is synchronous with the system clock and active low. A logical AND interconnects the NMI sources (internally generated by FCCU and by WKPU) in order to provide a single NMI output.

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (MC state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (MC mode SW change request = 1).

Figure 2324. NMI/WKUP scheme

Note: All NMI signals are shown active-low.

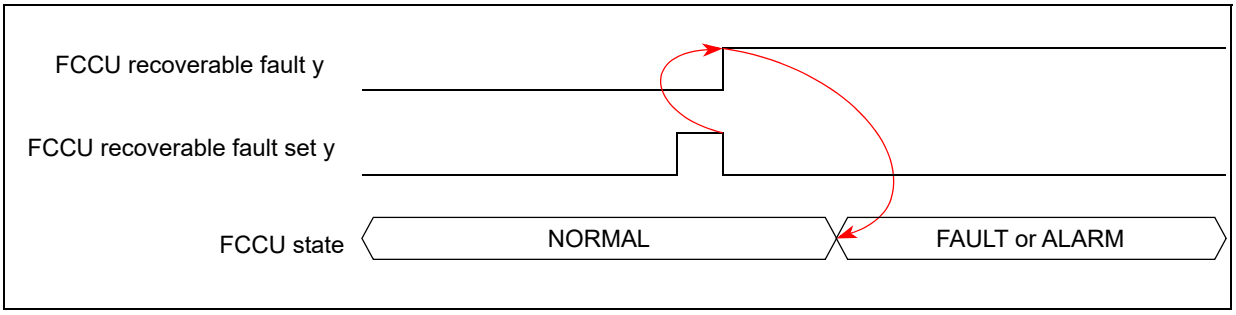
89.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple, programmable edge-sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2325*. The fault injection is executed by a write operation in the FCCU_RFF register.The reaction following a fake RF cannot be masked. The fault injection mechanism is optional; refer to the implementation-specific details. Refer to “FCCU failure inputs” table in Functional Safety chapter, for more details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (FCCU recoverable faults clear) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2326*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_S*n*. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 2325. FAULT injection



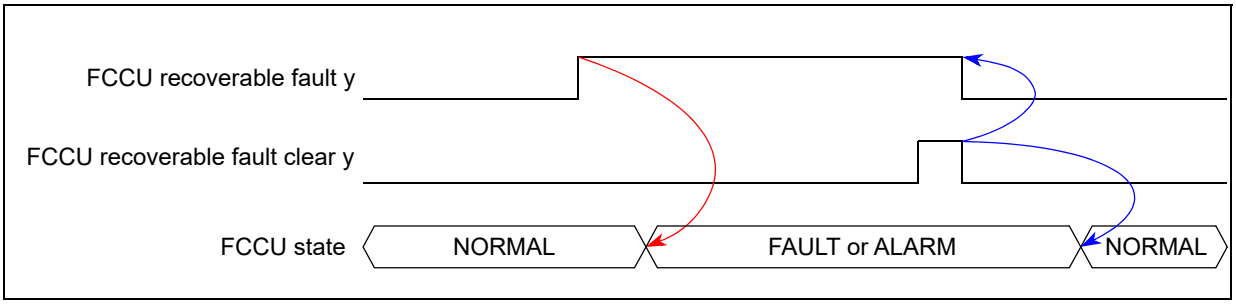


Figure 2326. FAULT clearing

89.5.8 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the following FCCU fault:
  - Recoverable
- The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- A mask (EOUT mask[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible for providing a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible for providing the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 2327. STCU-FCCU (case a)

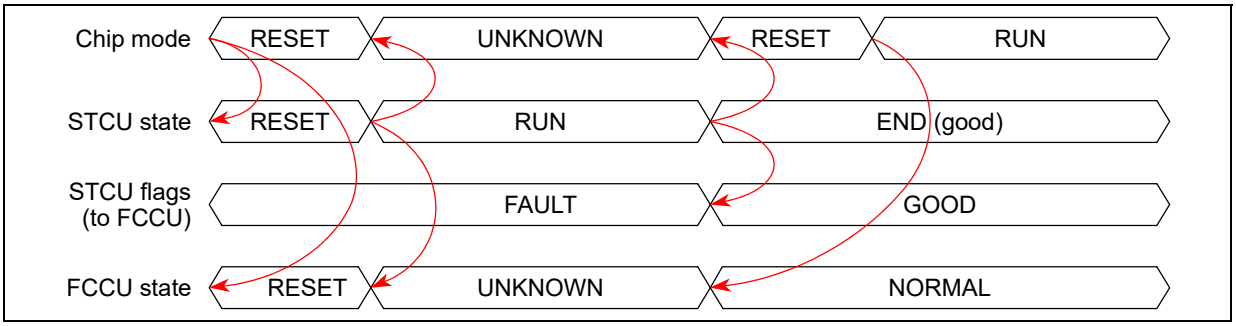

Figure 2328. STCU-FCCU (case b)

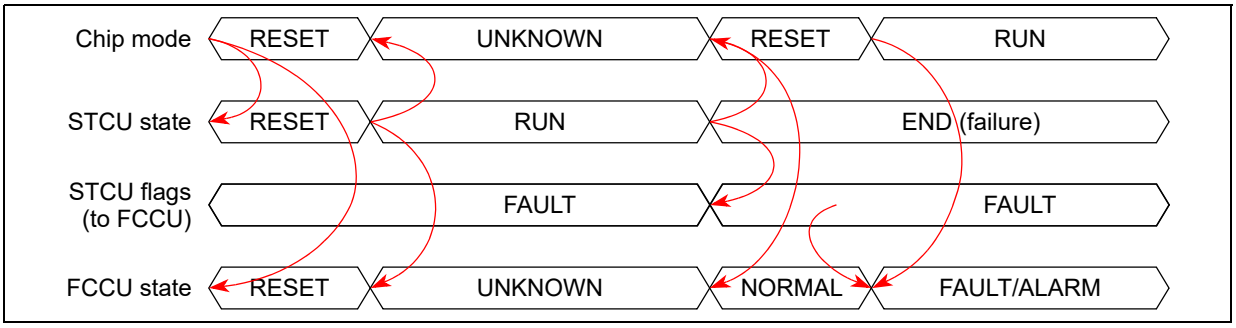

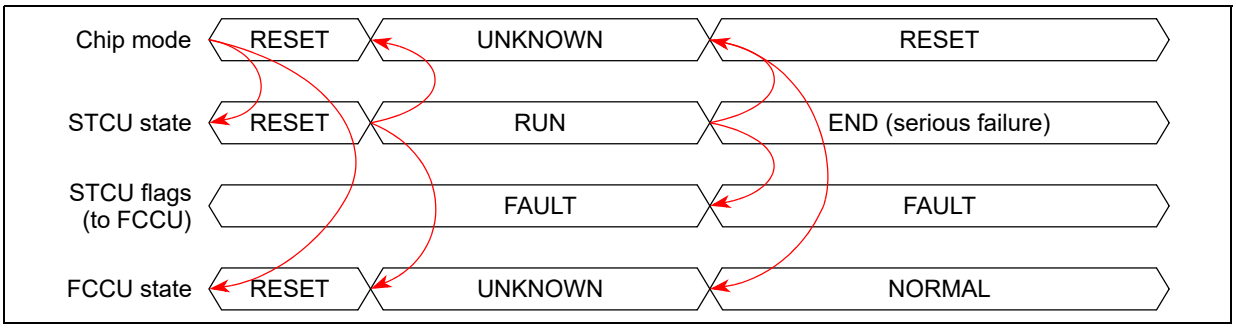

Figure 2329. STCU-FCCU (case c)

89.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (refer to table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS field in the FCCU_CFG register. For example, for PS = 0, FCCU Error output[0] = 0 and FCCU Error output[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual rail or time switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL). The EOUT protocol

transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.

- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occur in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18}. With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual rail or time switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, that is an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset, and software bit FCCU_RST in RGM_PRST5) should not influence the state of the failure indication, pins.

Note: The transition from FAULT to CONFIG state is not possible but is shown to display the behavior in all four states: RESET, NORMAL, FAULT and CONFIG.

Table 2208. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written FCCU_SET_AFTER_RESET bit to 1.

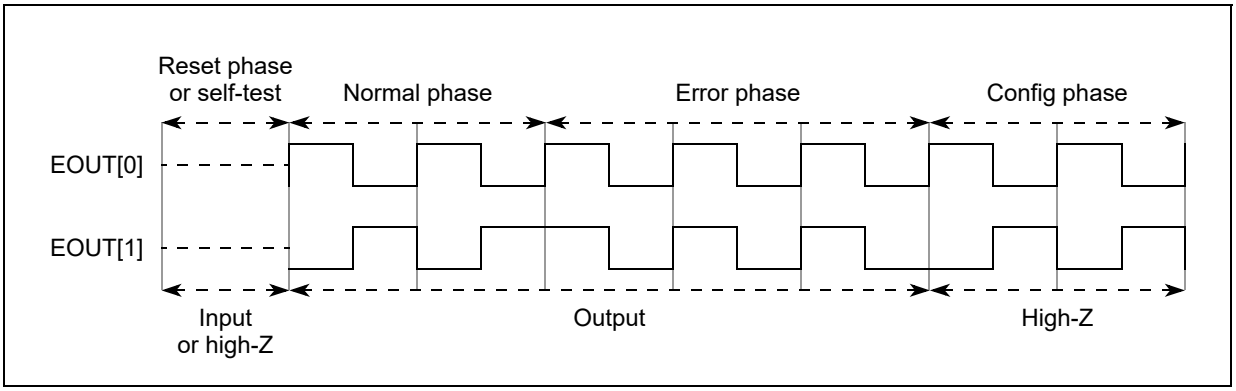
Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

89.5.9.1 Dual rail protocol

Dual rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual rail encoded circuits use two wires to carry each bit. The encoding scheme is given in *Table 2209* and the related timing diagram is given in *Figure 2330* and *Figure 2331*.

Table 2209. Dual rail encoding

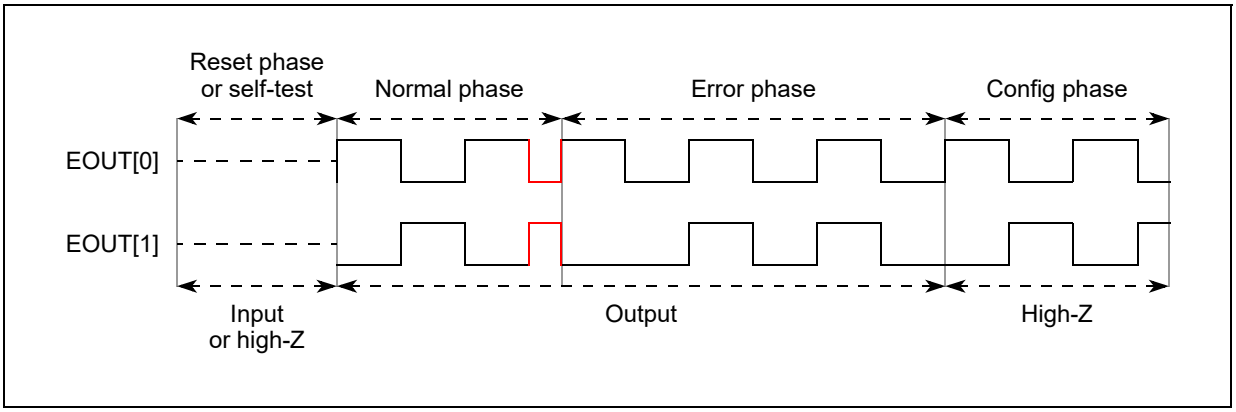
Logical state	Dual rail encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	00	toggling
faulty	11	
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling



1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the RESET phase the output pins are set as “high impedance”(32).



Note: Figure 2330 and Figure 2331 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 2330. Dual rail protocol (slow switching mode)

32. Actual value depends on the SOC settings at pad level.

Figure 2331. Dual rail protocol (fast switching mode)

89.5.9.2 Time switching protocol

The encoding scheme is given in *Table 2210* and the related timing diagram is given in *Figure 2332*.

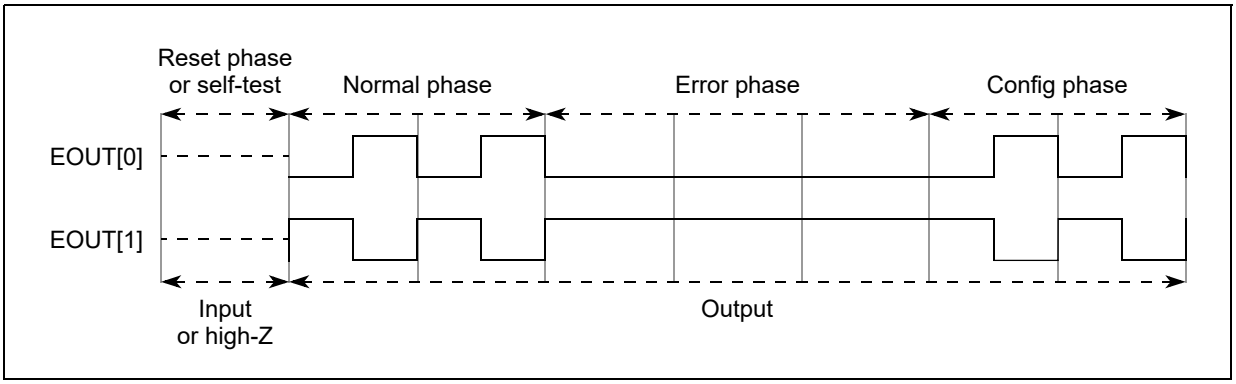
Table 2210. Time switching encoding

Logical state	Time switching encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the FAULT state, the output pin FCCU Error output pin[0] is set as low.



In Time Switching mode the second output (FCCU Error output pin[1]) is the inverted signal of first output (FCCU Error output pin[0]).

In the RESET phase the output pins are set as “high impedance”(33).

Note: Figure 2332 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

33. Actual value depends on the SOC settings at pad level.

Figure 2332. Time switching protocol

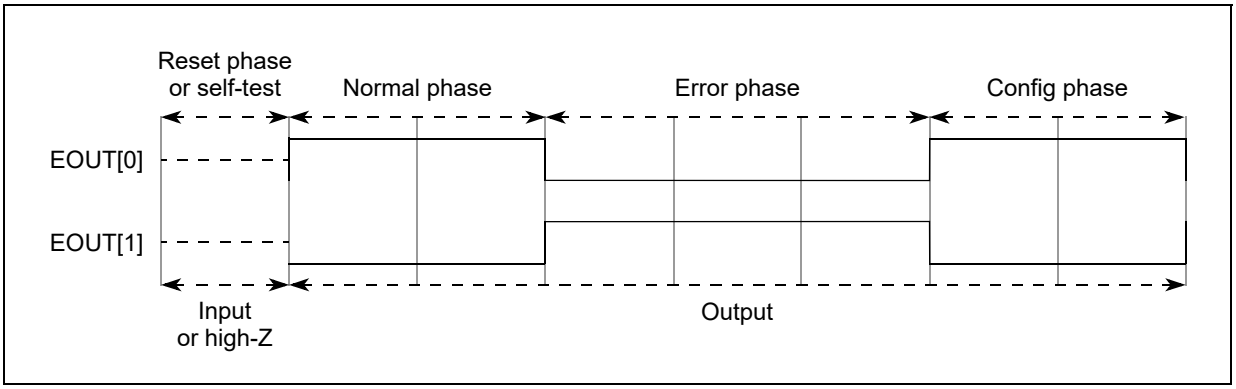
89.5.9.3 Bi-stable protocol

The encoding scheme is given in *Table 2211* and the related timing diagram is given in *Figure 2333*.

Table 2211. Bi-stable encoding

Logical state	Bi-stable encoding (FCCU Error output pins [1:0])	Note
nonfaulty	01	no toggling
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	no toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.



In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (FCCU Error output[1]) is the inverted signal of first output (FCCU Error output[0]).

In the RESET phase the output pins are set as “high impedance”(34).

Note: Figure 2333 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

34. Actual value depends on the SOC settings at pad level.

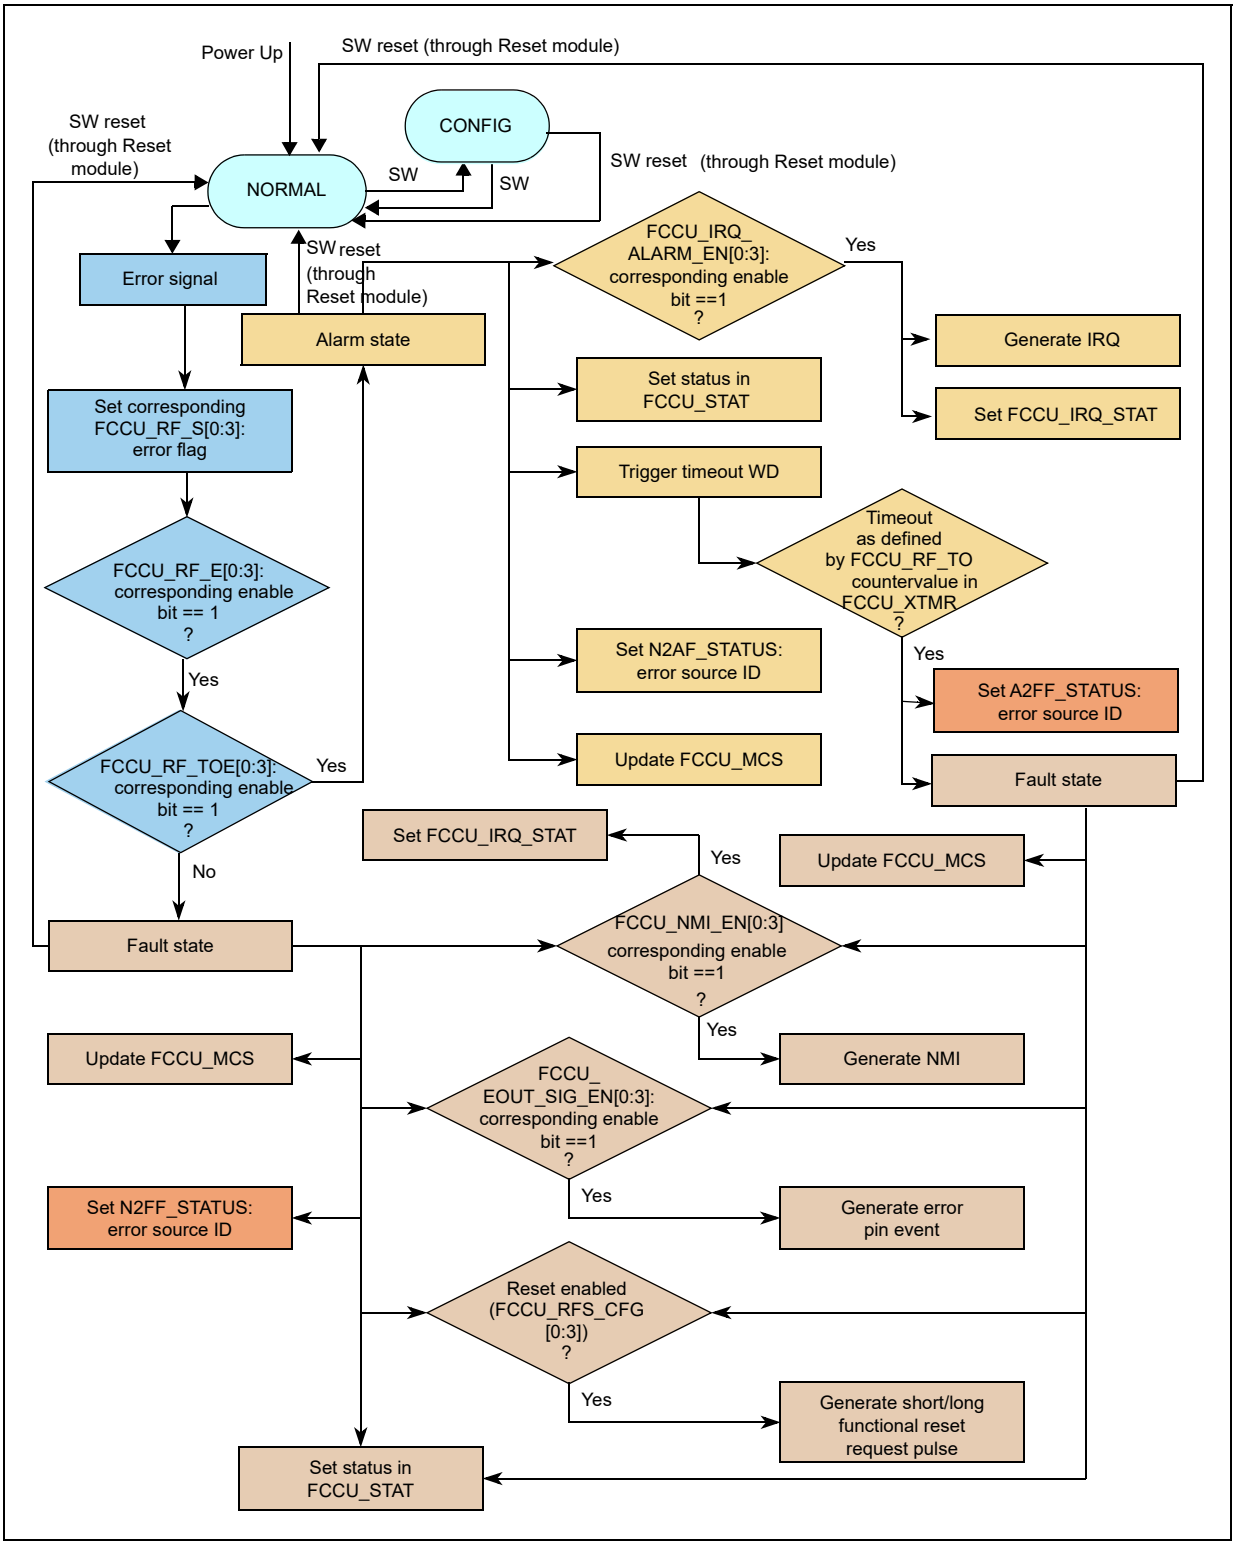


Figure 2333. Bi-stable protocol

89.5.10 Error signal flow for RF case

On Power up, FCCU moves to NORMAL state. SW can configure it by moving it to CONFIG and back again. SW reset leads to movement back to NORMAL. On reaching ALARM state, depending on ALARM being enabled, FCCU generates IRQ (alarm) and the FCCU_IRQ_STAT's alarm status is also set. FSM status is set in FCCU_STAT along with N2AF_STATUS. If Error is enabled (FCCU_RF_E) and timeout disabled (FCCU_RF_TOE), FCCU moves straight to FAULT state and depending on FCCU_NMI_EN or FCCU_SIG_EN, or both, being set, it generates a NMI or signals error, or both, out to the external world. FCCU FSM status is also captured in FCCU_STAT.

Figure 2334. Error signal flow

89.6 Register description

The FCCU registers are listed in *Table 2212*. Any address offset not explicitly mentioned in *Table 2212* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 2212*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

89.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state.
- moving the FCCU state from the CONFIG state into the NORMAL state.
- reading or to clear the RF status register.
- reading the FCCU FSM status register.
- reading or to clear the FCCU freeze registers.
- reading the ALARM timer.
- reading the Watchdog timer.
- configure the glitch filter present on EIN0 input (FCCU failure input #96).

Some critical operations require a key as defined in the FCCU_CTRLK register.

The Glitch filter, filters out pulses of widths up to 50/75/100 µs, as governed by FCCU_CTRL[FILTER_WIDTH]. It becomes active as soon as FCCU_CTRL[FILTER_BYPASS] is de-asserted (default value).

The implementation is as follows:

1. Fault line assertion - If a Fault is asserted, then the output of the filter is asserted after the delay, equal to the programmed glitch width time. If the fault is de-asserted before

the programmed glitch width time, then the output of the filter is not asserted and stays at the deactivated level (after having rejected the spurious glitch).

2. Fault line de-assertion - If a Fault, which was kept asserted for a time greater than the programmed pulse width is de-asserted (and glitch filter output is at asserted level now), then the output of the filter is de-asserted only after the delay equal to the programmed glitch width time. If the fault is again asserted before the programmed glitch width time, then the output of the filter is not de-asserted and stays at the active level (after having rejected the spurious glitch).

The output of the filter becomes the effective fault input fed to the FCCU error management engine. Since there is an inherent latency involved, SW must either wait for the programmed delay value before trying to clear the fault status flag, FCCU failure input #96 or first set FCCU_CTRL[FILTER_BYPASS] to one and then try to clear the fault status flag. This bit should not be made '1' again, till the filter width time elapses, else fault status will be latched again.

Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution The max timing needed for ABORT/SUCCESS response is 15 IRC cycles

89.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There shall not be any other operation in between the above steps and the 32 bits need to be written in one cycle. So, store FCCU_CTRLK, merge with OP1 or OP2 then send it.

The FCCU_CTRLK register is not readable, a 0x0000_0000 value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Offset: 0x004 Access: User write-only

89.6.3 FCCU Configuration Register (FCCU_CFG)

The FCCU_CFG register defines the global configuration for the FCCU module.

This register is writable only in the CONFIG state.

Offset: 0x008 Access: User read/write(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							FCCU_SET_AFTER_RESET	FCCU_SET_CLEAR		0	0	Reserved			
W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved	Reserved		OD	0	SM	PS	FOM			Reserved					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0(2)	0	0	0

1. Writable only in the CONFIG state.
2. After powerup, reset value will be 0. If configuration timeout occurs then default value will be changed to 1.

Figure 2337. FCCU Configuration Register (FCCU_CFG)

Table 2215. FCCU_CFG field descriptions

Field	Description
7 FCCU_SET_AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0 FCCU's Error indication stops functioning and error pins are in HI-Z state(1). 1 write to start FCCU functioning. After power-on the error out pins shall be in high impedance(1). They will go to normal state only on software request, this bit is set to 1. It is Software responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
8:9 FCCU_SET_CLEAR	Error pin state can be controlled by these bits 01 Error Pin driven to logic 0. 11 Error Pin driven to logic 1 (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault). 00 FCCU acts independent of above SW control. 10 FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z(1). Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state. This bit feature may not work with toggling protocols for example say EOUT pins are set high by SW using this bit followed by switching to a toggling protocol after returning control to FCCU FSM via setting this bit to 00 or 10, the user may find that EOUT pins do not toggle as was being expected.

Table 2215. FCCU_CFG field descriptions (continued)

Field	Description
19 OD	Open Drain Mechanism to select between Push-pull and Open drain (OD) mode for the error indicating pin(s). 0 push-pull 1 OD
21 SM	Switching mode 0 EOUT protocol (dual rail, time switching) slow switching mode. 1 EOUT protocol (dual rail, time switching) fast switching mode. SM has no effect on the bi-stable protocol.
22 PS	Polarity selection 0 FCCU Error output[1] active high, FCCU Error output[0] active low. 1 FCCU Error output[1] active low, FCCU Error output[0] active high. This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non toggling in Error phase.
23:25 FOM	Fault Output Mode selection 000 Dual Rail (default state) [FCCU Error output[1:0]= outputs] 001 Time Switching [FCCU Error output[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [FCCU Error output[0]= input, FCCU Error output[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= input] **Note:** In Test mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.

1. Actual value depends on the SOC settings at pad level.

89.6.4 FCCU RF Configuration Register *n* (FCCU_RF_CFG*n*)

The FCCU_RF_CFG*n* registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

89.6.6 FCCU RF Status register *n* (FCCU_RF_S*n*)

The FCCU_RF_S*n* register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_S*n* register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field
3. Wait for the completion of the operation (FCCU_CTRL.OPS field)
4. Read the FCCU_RF_S*n* register in order to verify the effective deletion and in case of failure to repeat the sequence

As a result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (refer to *Section 89.5.7: FAULT interface*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_S*n* read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_RF_S*n* register

In case of reconfiguration of the FCCU (CONFIG state), before returning in NORMAL state the pending status bits into the FCCU_RF_S*n* must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

0x08C	FCCU_RF_S3	RFS[127:96]

89.6.7 FCCU RF Key register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_S*n* register.

The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx

The key must be written for each FCCU_RF_S*n* clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0x0000_0000 value is always returned in case of read operation.

89.6.8 FCCU RF Enable Register *n* (FCCU_RF_E*n*)

The FCCU_RF_E*n* registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_S*n* register is anyway set, only the reaction is masked.

These registers are writable only in the CONFIG state.

89.6.9 FCCU RF Timeout Enable Register *n* (FCCU_RF_TOE*n*)

The FCCU_RF_TOE*n* registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective timeout is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

89.6.10 FCCU RF Timeout Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state. The alarm timeouts value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU timeout.

This register is writable only in the CONFIG state.

Offset: 0x0B4 Access: User read/write(1)

Field	Description
0:31 TO	Recoverable fault timeout Timeout = (TO) x $T_{RC16MHz}$

89.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2212: FCCU memory map*. The watchdog timeout is clocked with the RC oscillator clock (16 MHz). The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

89.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the FCCU Error output pin[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the FCCU Error output pin[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the FCCU Error inputs level

Table 2229 shows Bi-stable encoding.

Table 2229. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

1. FCCU Error input x depends on the PAD configuration, that is, internal pull-up enabled as default or pull-down and therefore EINx bit is 1 or 0 upon reset.
2. Refer to the Device Configuration chapter for chip-specific reset value.

Figure 2346. FCCU IO Control Register (FCCU_EINOUT)

Table 2230. FCCU_EINOUT field descriptions

Field	Description
26 EIN1	Error input 1 0 when FCCU Error input[1] = 0 1 when FCCU Error input[1] = 1 The EIN1 captures the respective FCCU Error input[1] signal.
27 EIN0	Error input 0 0 when FCCU Error input[0] = 0 1 when FCCU Error input[0] = 1 The EIN0 captures the FCCU Error input[0] signal.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => FCCU Error output[1] configured in output mode). 0 force FCCU Error output[1] = 0 1 force FCCU Error output[1] = 1 The EOUT1 set/clear the respective FCCU Error output[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a “do not care” value.
31 EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => FCCU Error output[0] configured in output mode) 0 force FCCU Error output[0] = 0 1 force FCCU Error output[0] = 1 The EOUT0 set/clear the respective FCCU Error output[0] signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a “do not care” value.

89.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status. The FCCU finite state machine (FSM) operates by the RC oscillator clock asynchronous with the System clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization

sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Figure 2347. FCCU Status Register (FCCU_STAT)

Table 2231. FCCU_STAT field descriptions

Field	Description
26:27 PhysicErrorPin	Physical Error Pin state PhysicErrorPin[26] corresponds to error pin 0, PhysicErrorPin[27] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0 Error Pin is at logical 0 1 Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. **Note:** This field indicates the real time status of the Error pin as driven by FCCU (at FCCU boundary) to the pad and not what is seen at/from the pad, which is based on different IPs (such as SIUL2) configurations of the SoC.
28 ESTAT	Current Error Pin Status SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in nonfaulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state.This state is taken from the FCCU Eout logic (That is, as late as possible).
29:31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state Other: UNKNOWN state

89.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the recoverable source (FCCU recoverable fault x) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

89.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

89.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recoverable fault in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 89.5.7: FAULT interface*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

89.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The external interrupt line (Interrupt request) is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Field	Description
31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled. 1 Configuration timeout interrupt enabled.

89.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

EOUTMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it loads (a value corresponding to T_min = 250 µs + value programmed in FCCU_DELTA_T register) and then starts down-counting and becomes 0 on the expiry of T_min window. It reloads on occurrence of another fault event which has EOUT signaling enabled. T_min feature is available only in Bi-Stable

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   a) OP17
   b) OP19
   c) OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

Table 2240 shows Timer state/value.

CFG	Running	0x0001_FFFF	0x0001_FFFF	0x0001_FFFF
EOUTMR	0x0000_0000	0x0000_0000	0x0000_0000	Running

89.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

0x128	FCCU_EOUT_SIG_EN3	EOUTEN[127:96]

89.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (that is FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

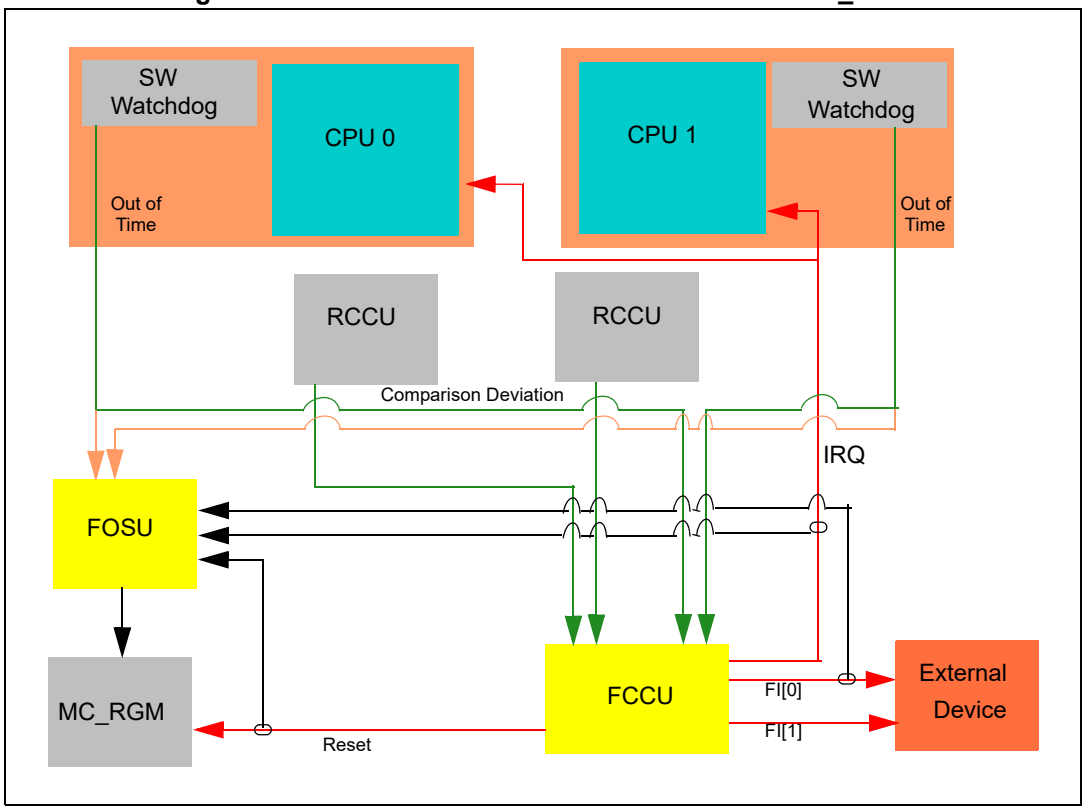
There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a “static” input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state.The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC.The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset.
- IRQ: NMI or Alarm.
- Error out triggered (by FCCU or by SW).

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is de-asserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.
The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as it is used by the FCCU (System reset), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is de-asserted.

The following conditions show a use case of the FOSU:



1. The user configures the channel x of the FCCU to react with a functional reset, either long or short.
2. The user sets the EOUTEN[x] flag of EOUT_SIG_EN register to 0.
3. The software does not clear the FCCU status flag related to the fault x after its first occurrence.
4. The fault x triggers again after the functional reset. Under these circumstances, the FOSU triggers a destructive reset after the FOSU timeout.

The rationale behind is that the functional reset is not able to clear the source of the fault. If the software can't react to the second occurrence of the fault before the FOSU timeout expires, the FOSU triggers a destructive reset.

If the users want to increase the availability of the system by avoiding the destructive reset, they can set the EOUTEN[x] flag of EOUT_SIG_EN register to 1. In such a case, the FOSU does not trigger the destructive reset.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 2363. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

89.8 Use cases and limitations

89.8.1 Mis-configurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.

Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.

4. Software reset is optional.
5. The user must program the FCCU for a higher timeout value than the value hard-coded for FOSU. In this way FCCU reacts later than FOSU expects and as a result, FOSU generates a destructive reset request on its timeout, if a fault occurred when the FCCU was in CONFIG state.

89.8.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, the following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status.
   b) Verify FCCU is in NORMAL state, else repeat step (a) above.
   c) Configure FCCU.
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire.
   b) Check and clear fault status.
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires.
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state.
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU.
   f) Check and clear any new pending fault status until FCCU is in NORMAL state.
   g) Reconfigure FCCU.

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

90 Self-Test Control Unit (STCU2)

90.1 Introduction

The self-test control unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the offline or online, or both, conditions. The hardware can manage the logic built-in self-test (LBIST) and the Memory (SRAM or ROM) built-in self-test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the self-test parameters (LBIST or MBIST scheduling activity, LBIST setup, unrecoverable faults (UF) or recoverable faults (RF) management, CRC and MISR expected values, PLL management, and so on) from Flash memory during the offline self-test phase. This interface is only able to write the configuration parameters and start the self-test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the offline self-test and to load or check the execution of the online self-test.

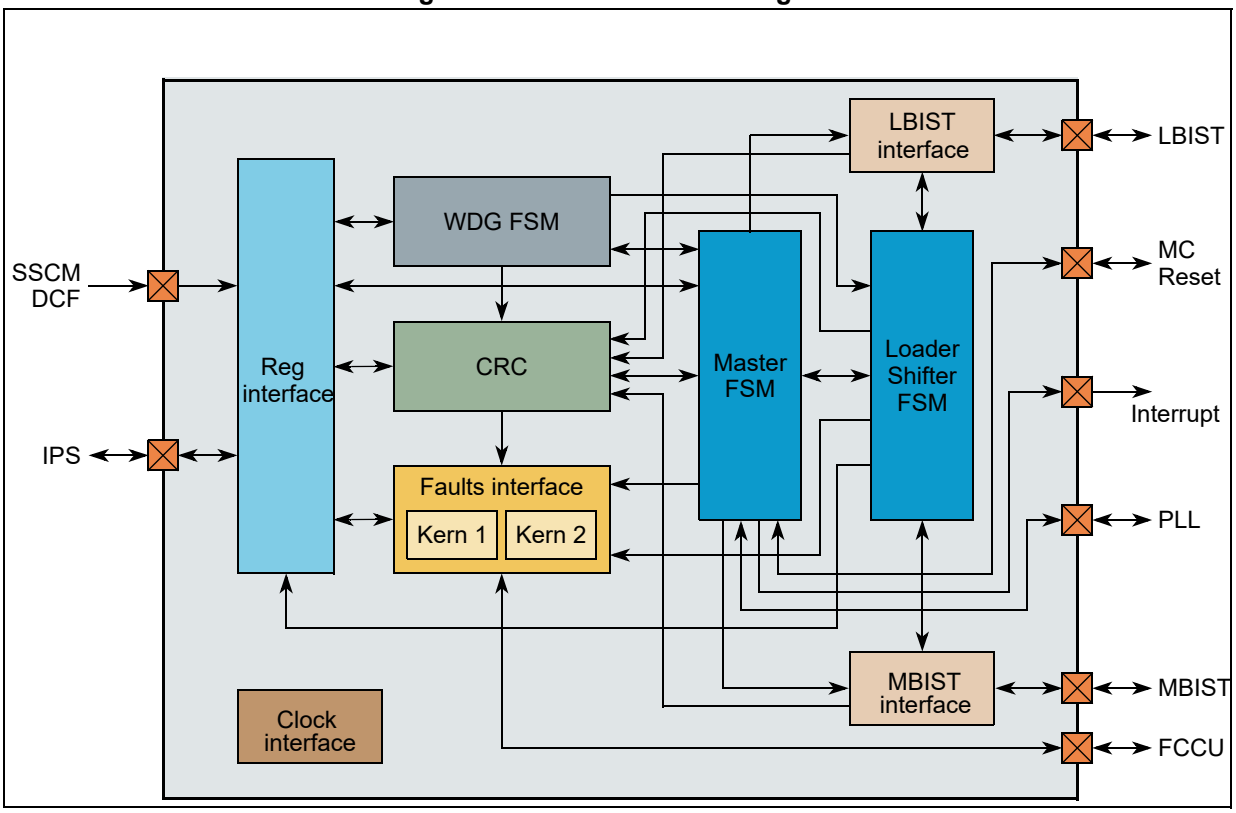
The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the self-test run to increase the STCU2's self-checking capability.
- A programmable watchdog timer (WDG) to check the LBIST and MBIST self-test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before watchdog timeout.
- Direct PLL control during the offline self-test sequence.
- Two interrupt lines enabled only during the online self-test to simplify the software handling of self-test execution end.
- Two sets of registers to separately collect the LBIST or MBIST results during offline and online self-test.

To increase the security of this module, a different security key sequence is also required during offline and online self-test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after self-test sequence is completed.
- The register ITF clock when the WDG timeout is detected after a double security key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

90.2 Main features



- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG[WRP] bit) register interface.
- Programmable scheduler for LBIST or MBIST execution.
- LBIST concurrent/sequential execution.
- MBIST concurrent/sequential execution.
- Programmable LBIST delayed concurrent start.

- 32-bit CRC for STCU2 self-checking capability (enabled by STCU_CFG[CRCEN] bit).
- Online hardware self-test sequence abort capability.
- Programmable internal clock prescaler to reduce internal and MBIST or LBIST TCK clocks.
- Programmable PLL direct control during offline self-test sequence.
- PLL lock signal monitoring during offline and online self-test.
- MBIST dedicated online interrupt source generation.
- Programmable WDG timer for self-check MBIST or LBIST time execution.
- Hard-coded WDG timeout to flag offline initialization errors.
- Hard-coded WDG timeout to auto-lock STCU2 write access after double key sequence.
- LBIST and SRAM or ROM MBIST offline status flags.
- STCU2 internal errors offline status flag.
- LBIST and SRAM or ROM MBIST online status flags.
- STCU2 internal errors online status flag.
- Online hardware abort status flag.
- LBIST and SRAM or ROM MBIST offline or online programmable failure severity (UF/RF).
- STCU2 internal errors offline or online programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software.
- LBIST MISRE registers access to perform redundant software checks.
- Self-test bypass capability.
- Protection mechanism of the global write register based on double security key.
- STCU2 global auto power-saving when:
  - Self-test is completed.
  - bypass mode is selected.
  - WDG timeout is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).
- STCU2 ITF/WDG auto power-saving when hard-coded WDG timeout is detected after software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).

90.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 2364*.

Figure 2364. STCU2 block diagram

The STCU2 module includes the following submodules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface.
- **CRC**: This module is the core of the self-checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface:** This module collects the error conditions respective to LBIST or MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the set or clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- **Clock Block:** This module manages the internal and the LBIST or MBIST TCK clock prescaler, the internal clock gating power saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different watchdogs:
  - A hard-coded Watchdog used to auto-lock the STCU2 access, forcing a reset condition on the double security key registers.
  - A dual function watchdog:

    - After a reset event initializes the STCU2, it is used as a hard-coded watchdog timeout.

    - During LBIST or MBIST runs, it is used as a programmable watchdog timer to check the LBIST or MBIST have completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the self-test sequence.

- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the LBIST or MBIST registers and read back the data to be checked at the end of each self-test operation.
- **LBIST interface**: This module includes the interface between the LBIST engines and the STCU2 controllers of the device.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

90.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The self-test sequence parameters are loaded before offline self-test is executed.
- The IPS access on some specific registers (see *Section 90.5: Register description*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following R/W bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register.
- Any write operation on double security key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the double security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed offline on registers where writes are only allowed during the online self-test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on read only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 90.5: Register description*.

90.4 Functional description

90.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the self-test operations and the other state machines.
- Loader/Shifter State Machine: used to program the MBIST and the LBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the master state machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and LBIST and the timeouts in case of incorrect STCU2 programming.

90.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the offline self-test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the self-test execution phase depends on the self-test conditions and on the content of the STCU_LBRMSW register reported in the following subsections.

In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the associated MC_RGM module.

90.4.2.1 Offline reset generation

At the end of the offline self-test execution, the STCU2 raises the global functional reset. In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module.

90.4.2.2 Online reset generation (only MBIST)

The online execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences respective to the write operations performed by the MBIST execution other than prevent any read/write operation during the self-test execution. If necessary, the software must also restore the memory content (only for RAM) at the end of the self-test execution.

90.4.2.3 Online Reset generation (LBIST enabled)

At the end of the execution, the online execution of the LBIST generates two possible types of reset depending on the status of the STCU_LBRMSW register. See *Section 90.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*.

If all the selected LBISTs do not require the global functional reset, only the partitions subjected to LBIST are cleaned up applying a pulse on the dedicated reset line. If at least one of the selected LBISTs requires the global functional reset, the global functional reset is raised at the end of the online self-test execution.

Note: If an ABORT condition is detected by STCU2 during the online self-test execution, regardless of the value of the STCU_LBRMSW register, only the respective reset line is pulsed to prevent any potential dangerous system level operations

90.4.3 LBIST and MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST or LBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 90.6.4: Design implementation information*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first LBIST is mapped on 0x00, the second on 0x01, and so on. The first MBIST is mapped at the address 0x10, the second on 0x11 and so on. The additional pointers are in the bitfield STCU_LB_CTRL*x*[PTR] for LBIST*x* (where *x* is the selected LBIST) and STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_LB_CTRL[CSM] and STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the LBIST or MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 90.5.38: STCU2 LBIST Control n Register (STCU_LB_CTRLn)* and *Section 90.5.50: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*.

90.4.4 ABORT management

The STCU2 module provides online self-test execution abort. When the abort is detected, the online self-test operation stops running and the status of the currently running MBIST or LBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run. For an LBIST run, see *Section 90.4.2: Reset management*, regarding reset specific management when abort is detected.

90.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a functional reset that requires the self-test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the online self-test execution run.

90.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the offline self-test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 90.5.2: STCU2 Run Software Register (STCU_RUNSW)*.

When STCU_RUN[RUN] is set to start the offline self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configuration parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end of the MBIST run, the clock source reverts to the original one.

The same behavior applies when STCU_RUN[LBPLLEN] is active and LBIST is currently selected.

90.4.6 Interrupt interface

There are two interrupt sources:

- One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1).
- One triggered by LBIST (enabled by programming STCU_RUNSW[LBIE] = 1).

As described in *Section 90.5.2: STCU2 Run Software Register (STCU_RUNSW)*, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential runs in the same session, the number of interrupts generated is equivalent to the number of sequential sessions, thus providing fine granularity with respect to the completed run.

The MBIFLG bit in the *Section 90.5.7: STCU2 Interrupt Flag Register (STCU_INT_FLG)* registers flag interrupt condition and allows the clearing of interrupt requests. Interrupt bit to be cleared by writing the respective bit to 1 to enable the next interrupt request.

90.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an unrecoverable failure (UF) or a recoverable failure (RF) during the self-test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

90.4.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished on time.

90.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the self-test sequence (safety mode).
- Bypass the self-test sequence by setting the STCU_RUN[BYP] bit. If Bypass bit is configured/set by DCF it cannot be anymore changed on the device even though STCU_RUN register itself is not Write once.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded watchdog timeout flags the incorrect behavior. See *Section 90.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* for more details.

90.4.8.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time is configured as described in *Section 90.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* to account for the overall execution time of the self-test sequence. If the selected LBISTs or MBISTs are not yet completed:

- During an offline self-test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBE1/2/3/4 or STCU_LBE registers.
- During an online self-test, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBE1SW/2SW/3SW/4SW or STCU_LBESW.

In case of multiple sequential runs in the same online or offline session and the timeout occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 90.4.2: Reset management*.

90.4.8.3 Write access timeout

The access on the STCU2 registers during the self-test configuration phase (both online or offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software self-test configuration as the software application may enable write access to the STCU2 registers.

90.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomy to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the self-test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

90.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

90.5 Register description

The STCU2 registers are listed in *Table 2251*.

Note: n and k are variables representing the repeated register blocks of the multiple LBISTs and MBISTs: n ranges from 0 up to 6, k ranges from 0 up to 101.

90.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the offline self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Table 2252. STCU_RUN field descriptions

Field	Description
21 BYP	Bypass mode 0 Offline self-test is active. If the STCU_RUN[RUN] bit is not set before the hard-coded WDG timeout, the WDTO error is generated in the STCU_ERR_STAT register. 1 Offline self-test is bypassed and access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
22 MBPLLEN	Offline MBIST with PLL0 Enabled 0 Offline MBIST is executed without using the on-chip PLL0. 1 Offline MBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
23 LBPLLEN	Offline LBIST with PLL0 Enabled 0 Offline LBIST is executed without using the on-chip PLL0. 1 Offline LBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
31 RUN	RUN The RUN bit is automatically cleared by the STCU2 when the offline self-test procedure has been completed. 0 Idle 1 Offline self-test procedure is running

90.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the online self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- Online self-test phase is active. The online condition starts when the offline condition finishes. In this condition, the system is alive and the SW can program the STCU.

Table 2253. STCU_RUNSW field descriptions

Field	Description
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories, the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are concluded. If there is a sequence of concurrent runs in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[MBIFG] bit in between.
21 LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST, the STCU2 forces an interrupt request to notify LBIST of the concurrent selected partitions are concluded. If there is a sequence of concurrent run in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[LBIFG] bit in between.
22 MBSWPLLEN	Online MBIST with PLL1 Enabled 0 Online MBIST is executed without waiting for PLL1 lock. 1 Online MBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.

Table 2253. STCU_RUNSW field descriptions (continued)

Field	Description
23 LBSWPLLEN	Online LBIST with PLL1 Enabled 0 Online LBIST is executed without waiting for PLL1 lock. 1 Online LBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take the PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the online self-test procedure has been completed. 0 Idle. 1 Online self-test procedure is running.

90.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2 asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the offline or online test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: Note that after the self-test sequence has been completed or the bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.

In case of invalid access or sequence (Keys1 and 2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG timeout, STCU2 write access is locked and the WDG and register ITF clocks are switched off. Also in this case the correct sequence must be applied in order to re-enable write access to the STCU2 and the WDG and register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG timeout expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 0x00000000.

90.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the offline and online test steps.

Access to this register is described in *Figure 2368*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the online self-test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

1. You can always read this field. In the offline self-test phase, you can always write to this field. In the online self-test phase, you can write to this field only when WRP = 0.

Figure 2368. STCU2 Configuration Register (STCU_CFG)

Table 2255. STCU_CFG field descriptions

Field	Description
0:7 PTR	LBIST or MBIST pointer. PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0, then the LBIST0 is initially scheduled. (0x00 to LBIST - 1) – pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution.
8:15 LB_DELAY	Delay LBIST run. LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. 0x00 No delay 0x01 1 × 16 STCU2 Core clock cycles 0x02 2 × 16 STCU2 Core clock cycles 0x03 3 × 16 STCU2 Core clock cycles … 0xFD 253 × 16 STCU2 Core clock cycles 0xFE 254 × 16 STCU2 Core clock cycles 0xFF 255 × 16 STCU2 Core clock cycles **Note:** STCU2 is being clocked from PBRIDGE Clock. Refer to Clocking chapter for PBRIDGE clock frequency value.
23 WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after offline self-test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after offline self-test sequence has completed, thus preventing any user application write operation.

Table 2255. STCU_CFG field descriptions (continued)

Field	Description
26 CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values. 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS test is not enabled 1 MBIST PMOS test is enabled
28 MBU	MBIST MBU Test Enabled. 0 MBIST full algorithm or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified multi-bit upset algorithm is used to check the RAM. If a ROM is selected, the applied algorithm will be standard one without PMOS test. ***This bit overwrites the PMOSEN feature***.
29:31 CLK_CFG	Logic, memory BIST and STCU2 core clock configuration. CLK_CFG defines the ratio between the STCU2 core clock and the TCK used to program the LBIST, the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 PBRIDGE_CLK 001 PBRIDGE_CLK/2 010 PBRIDGE_CLK/3 011 PBRIDGE_CLK/4 100 PBRIDGE_CLK/5 101 PBRIDGE_CLK/6 110 PBRIDGE_CLK/7 111 PBRIDGE_CLK/8 **Note:** refer to Clocking chapter for PBRIDGE_CLK clock frequency value.

90.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the offline LBISTs or MBISTs are performed and STCU_RUN[MBPLLEN] = 1 or STCU_RUN[LBPLLEN] = 1.

In the online state, these bits are not effective. It is also possible to set the PLL during active online mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is active.

Offset: 0x0010 Access: User read/write

Figure 2369. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Note: f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.

Table 2256. STCU_PLL_CFG field descriptions

Field	Description
2:7 PLLODF	PLL Output Division Factor. The value of this field drives the output division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the respective PLL's output division factor.
13:15 PLLIDF	PLL Input Division Factor. The value of this field drives the input division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the respective PLL's input division factor.
25:31 PLLLDF	PLL Loop Division Factor. The value of this field drives the loop division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the respective PLL's loop division factor.

90.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for LBIST and MBIST execution, providing protection against dead-locks or infinite loop conditions during the self-test procedure. When the offline self-test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15 to 0 define the timeout before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the offline or online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active
- Online self-test phase is active and STCU_CFG[WRP] = 0

Offset: 0x0014 Access: User read/write

Figure 2370. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 2257. STCU_WDG field descriptions

Field	Description
0:31 WDGEOC	Watchdog End of Count Timer. This value must be set in order to define the time budget respective to the offline and online self-test execution and check that everything is working correctly in this timeslot. The allowed time delays are: 0x00000000 1*k*STCU2 core clock cycles 0x00000001 2*k*STCU2 core clock cycles 0x00000002 3*k*STCU2 core clock cycles … 0xFFFFFFFD 4294967294*k*STCU2 core clock cycles 0xFFFFFFFE 4294967295*k*STCU2 core clock cycles 0xFFFFFFFF 4294967296*k*16 STCU2 core clock cycles where k is: – ‘1’ for offline self-test – ‘16’ for online self-test **Note:** STCU2 core clock is specified through STCU_CFG[CLK_CFG] field.

90.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST and LBIST interrupt pending bits. These bits are effective only during the online self-test phase and managed only when the respective control bit in the STCU_RUNSW register (MBIE and LBIE) enabled.

Offset: 0x0018 Access: User read/write

Field	Description
30 MBIFLG	MBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled MBIST is completed is pending. Write 1 to clear the bit.
31 LBIFLG	LBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled LBIST is completed is pending. Write 1 to clear the bit.

90.5.8 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the self check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

CRC-32 (ethernet protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

Field	Description
0:31 CRCE	CRC expected signature

90.5.9 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the offline and online self-test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Field	Description
0:31 CRCR	Read CRC signature

90.5.10 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the online and offline self-test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 90.6.4: Design implementation information*.

Access to this register is described in *Figure 2374* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

Offset: 0x0024 Access: User read/write

Figure 2374. STCU2 Error Register (STCU_ERR_STAT)

Table 2261. STCU_ERR_STAT field descriptions

Field	Description
6 ABORTHW	Online hardware abort flag. 0 No hardware abort was requested during the online self-test sequence 1 A hardware abort was detected during the online self-test sequence
11 LOCKESW	Online LOCK Error. 0 If PLL is enabled, it is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the online self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW[LBSWPLLEN] is set or during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1, or during both.
12 WDTOSW	Online Watchdog timeout. 0 LBIST and MBIST time slots have completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not completed in the assigned watchdog time or there are internal mismatches in the end of execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 CRCSSW	Online CRC Status. This flag is activated *only* when online self-test is performed and STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to 0) 1 Failed CRC comparison
14 ENGESW	Online Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	Online Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the unrecoverable faults condition 1 There are errors that trigger the unrecoverable faults condition

Table 2261. STCU_ERR_STAT field descriptions (continued)

Field	Description
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the recoverable faults condition 1 There are errors that trigger the recoverable faults condition
27 LOCKE	Offline LOCK Error 0 The PLL is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the offline self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLLEN] = 1 or during the MBIST run when STCU_RUN[MBPLLEN] = 1, or during both.
28 WDTO	Offline Watchdog timeout. 0 LBIST and MBIST time slots have been completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not been completed within the assigned watchdog time or there are internal mismatches among end of execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the watchdog reach the end of count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Offline CRC status. This flag is activated *only* when offline self-test is performed STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
30 ENGE	Offline Engine Error. 0 Valid engine execution 1 Invalid engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Offline Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)

90.5.11 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of Unrecoverable or recoverable faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Field	Description
16:31 LBESW[7:0]	LBESW*x*: online LBIST End status. 0 LBIST execution not yet completed 1 LBIST execution finished

90.5.16 STCU2 Online LBIST Reset Management (STCU_LBRMSW)

The STCU_LBRMSW register defines the online reset mapping for each LBIST. Global or specific functional resets can be programmed depending on the online Self Test requirements and top level integration architecture.

The size of the register depends on the number of LBISTs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x003C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																

Reset: The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

W																

Reset: The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

Figure 2380. STCU2 Online LBIST Reset Management (STCU_LBRMSW)

Table 2267. STCU_LBRMSW field descriptions

Field	Description
16:31 LBRMSW[7:0]	Online LBIST Reset Management. **Note:** If one of the selected LBIST has this bit set to '1', then only the Global functional reset will be pulsed. 0 Dedicated functional reset is pulsed at the end of LBIST run 1 Global functional reset is pulsed at the end of LBIST run

90.5.17 STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)

The STCU_LBUFM register defines the fault mapping of each LBIST in terms of unrecoverable or recoverable fault. The size of the register depends on the number of LBISTs.

Note: On this device, the LBISTs are 7.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0040 Access: User read/write

Figure 2391. STCU2 Online MBIST 2 Status Register (STCU_MBS2SW)

1. The availability of this field is based on the number of NMCUT available in this device. For details, refer to *Table 114: MBIST registers in STCU2 with available fields* in *Chapter 7: Device configuration*.

Table 2278. STCU_MBS2SW field descriptions

Field	Description
0:31 MBSSW[63:32]	MBSSW*x*: online status (NMCUT range = 32 to 63) of the selected MBIST. 0 Failed NMCUT BIST execution 1 No fault detected during the NMCUT BIST execution

90.5.28 STCU2 Online MBIST 3 Status Register (STCU_MBS3SW)

The STCU_MBS3SW register includes the results corresponding to the execution of the selected online MBIST in the range NMCUT = 64 to 95. The size of the register depends on the amount of RAM or ROM subject to BIST. The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Note: Refer to Section 7.10.6: STCU2 configuration in Chapter 7: Device configuration for the number of NMCUT available in this device.

90.5.38 STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

The STCU_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0100 + *n* * 0x40 (*n* = 0 to 6) Access: User read/write

Figure 2402. STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

Table 2289. STCU_LB_CTRL*n* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer, the CSM bit has to be set Sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current LBIST has been completed. (0x0 to NLBIST - 1) pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
13:15 SHS	Shift Speed 000 Shift at full rate (STCU core clock) 001 Shift at 1/2 rate (STCU core clock) 010 Shift at 1/3 rate (STCU core clock) 011 Shift at 1/4 rate (STCU core clock) 100 Shift at 1/5 rate (STCU core clock) 101 Shift at 1/6 rate (STCU core clock) 110 Shift at 1/7 rate (STCU core clock) 111 Shift at 1/8 rate (STCU core clock)

Table 2289. STCU_LB_CTRL*n* field descriptions (continued)

Field	Description
16:19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
20:23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
26 PFT	Past Flush Test The LBIST controller, by default apply 32 flush test patterns. This bit allows to skip/apply the flush test pattern sequence. 0 Apply flush test patterns 1 Skip flush test patterns
27:31 CWS	Capture window size 00000 Controller waits 16 shift cycle for capture to finish. 00001 Controller waits 1 shift cycle for capture to finish. 00010 Controller waits 2 shift cycles for capture to finish. … 00111 Controller waits 7 shift cycles for capture to finish.

90.5.39 STCU2 LBIST PC Stop *n* Register (STCU_LB_PCS*n*)

The STCU_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0104 + n * 0x40 (n = 0 to 6) Access: User read/write

Field	Description
6:31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

90.5.40 STCU2 LBIST PRPG Low *n* Register (STCU_LB_PRPGL*n*)

The STCU_LB_PRPGL register defines the LSB part (31 to 0) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0108 + n * 0x40 (n = 0 to 6) Access: User read/write

Figure 2404. STCU2 LBIST PRPG Low *n* Register (STCU_LB_PRPGL*n*)

Table 2291. STCU_LB_PRPGL*n* field descriptions

Field	Description
0:31 PRPG[31:0]	PRPG LBIST low bits This field defines the low part (31 to 0) of the LBIST PRPG start value.

90.5.41 STCU2 LBIST PRPG High *n* Register (STCU_LB_PRPGH*n*)

The STCU_LB_PRPGH register defines the MSB part (63 to 32) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x010C + n * 0x40 (n = 0 to 6) Access: User read/write

Field	Description
0:31 PRPG[63:32]	PRPG LBIST High Bits This field is the high part (63 to 32) of the LBIST PRPG start value.

90.5.42 STCU2 Offline LBIST MISR Expected Low *n* Register (STCU_LB_MISREL*n*)

The STCU_LB_MISREL register defines the LSB part (31 to 0) of the expected MISR of the offline LBIST controller. The size of the register depends on the number of MISR bits of the respective LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Offset: 0x0110 + n * 0x40 (n = 0 to 6) Access: User read/write

Figure 2414. STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

Table 2301. STCU_MB_CTRL*k* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current MBIST has been completed. (0x00 to LBIST - 1) — pointer to LBIST PTR = 0x10 + $MBIST_i$ (Pointer to MBIST) for i = 0 to XX: please refer to the MBIST partitions table for the $MBIST_i$ code. PTR = 0xFF: Pointer to NIL. No additional MBIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode

90.6 Use cases and limitations

The STCU2 module is designed to give high flexibility during the online and offline self-test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Offline self-test sequence after a reset trigger event
- Bypass mode of the self-test sequence after a reset trigger event
- Online self-test sequence

The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.

90.6.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and LBIST or MBIST execution parameters stored in the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the system RAM or ROM according to the system specifications. The sequence is the following:

- Unlock the offline STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFM1/2/3/4 registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, the STCU_LB_PRPGL/H can also be programmed to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the offline self-test sequence in the STCU_CRCE register.
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.
- Program the RUN bit in the STCU_RUN register to enable the offline self-test execution and the LM/BPLLEN bits to enable the PLL during LBIST or MBIST execution according to STCU_PLL_CFG register content.
- Start the offline self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the self-test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application read the STCU_LBS flag register to check the failed LBIST when UF or RF conditions are detected.

- The software application read the STCU_LBE flag register to check the LBIST still on-going when UF or RF are detected.
- The software application read the STCU_MBS1/2/3/4 flag registers, depending on the number of memories, to check the failed RAM or ROM memory BIST when UF or RF are detected.
- The software application read the STCU_MBE1/2/3/4 flag registers, depending on the number of memories, to check the RAM or ROM memory BIST still running when UF or RF are detected.
- The software application read the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- For each LBIST, the software application reads the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

90.6.2 Online self-test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the LBIST or MBIST execution. Since the online operations clean up the content of the respective digital logic (LBIST) or RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the online STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 online self-test registers.
- The LBIST, MBIST and STCU2 internal fault reaction should already be programmed during the offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_LBUFM, STCU_MBUFM1/2/3/4 and STCU_ERR_FM.
- Program the Reset management during online LBIST execution setting the STCU_LBRMSW register.
- The STCU_LB_CTRL, STCU_LB_PCS should already be programmed during offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.

- Overwrite/Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBISTs are running simultaneously to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the online self-test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the online self-test execution, the L/MBIE to enable the Interrupt requests, and the L/MBSWPLLEN bits to enable the PLL lock signal monitor during LBIST or MBIST execution.
- Start the online self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- If the L/MBIE are enabled, an interrupt is generated at the end of all the LBIST or MBIST runs. The software application has to manage these interrupt signals and clean up the respective flags (L/MBIFLG) in the STCU_INT_FLG register.
- The STCU2 switches off the core clock at the end of the self-test run.
- The activated functional reset is managed by the STCU_LBRMSW.
- If at least one of the selected LBISTs enables the global functional reset, the STCU2 requests a functional reset which restarts the system. If all the selected LBISTs enable their own dedicated functional reset, only these local reset lines are applied and only the respective LBIST partitions are cleaned up.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBESW flag register to check the LBIST is still running when UFs or RFs are detected.
- The software application reads the STCU_MBS1SW/2SW/3S+W/4SW flag registers, depending on the number of memories, to check the failed RAM/ROM memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBE1SW/2SW/3SW/4SW flag registers, depending on the number of memories, to check the RAM/ROM memory BIST is still running when UFs or RFs are detected.
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.

- For each LBIST, the software application reads the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after online self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

90.6.3 Bypass USER Mode

In this mode, the user application parameters stored in Flash and read by SSCM are written to skip the self-test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the offline Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the self-test sequence is not applied and the system can wake up and start the user application.

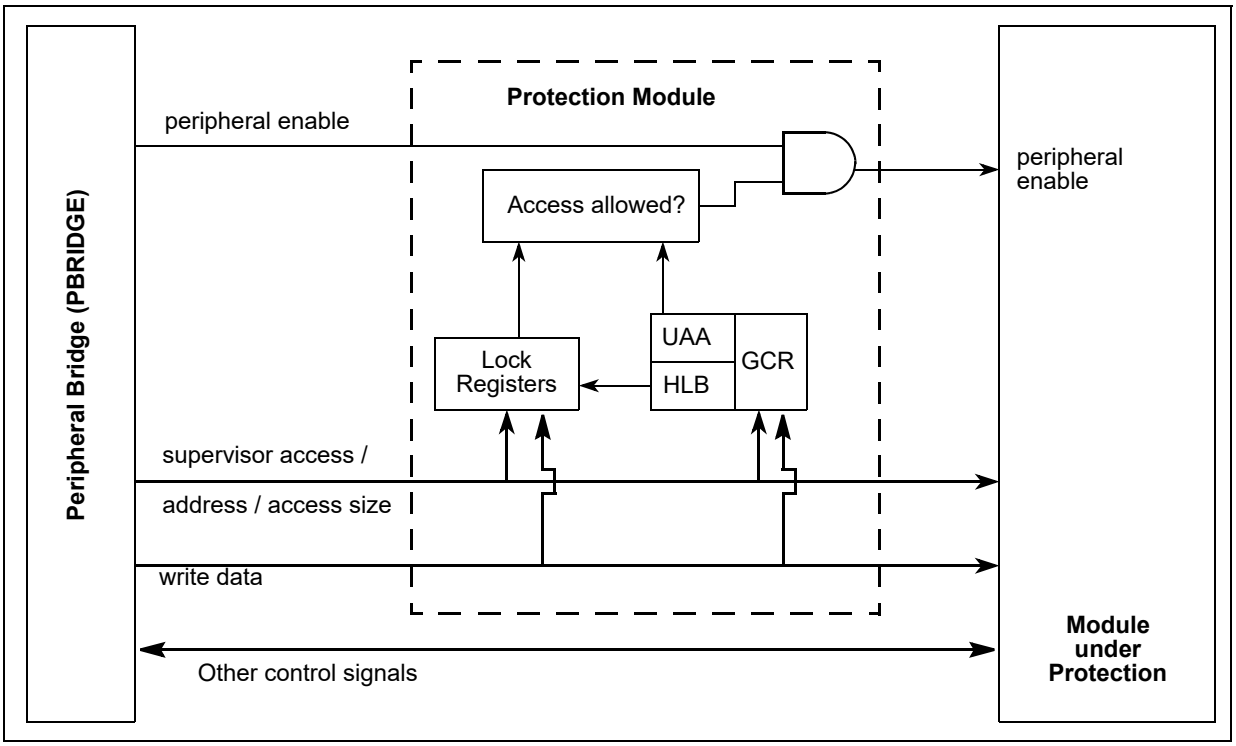
90.6.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the on/offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- As the software has full control of the system while applications are running during the online self-test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

91 Register Protection (REG_PROT)

91.1 Introduction



91.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Refer to the Chapter 7: Device configuration for device-specific details of the protected registers and bytes.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 2415*.

Figure 2415. REG_PROT block diagram

91.1.2 Features

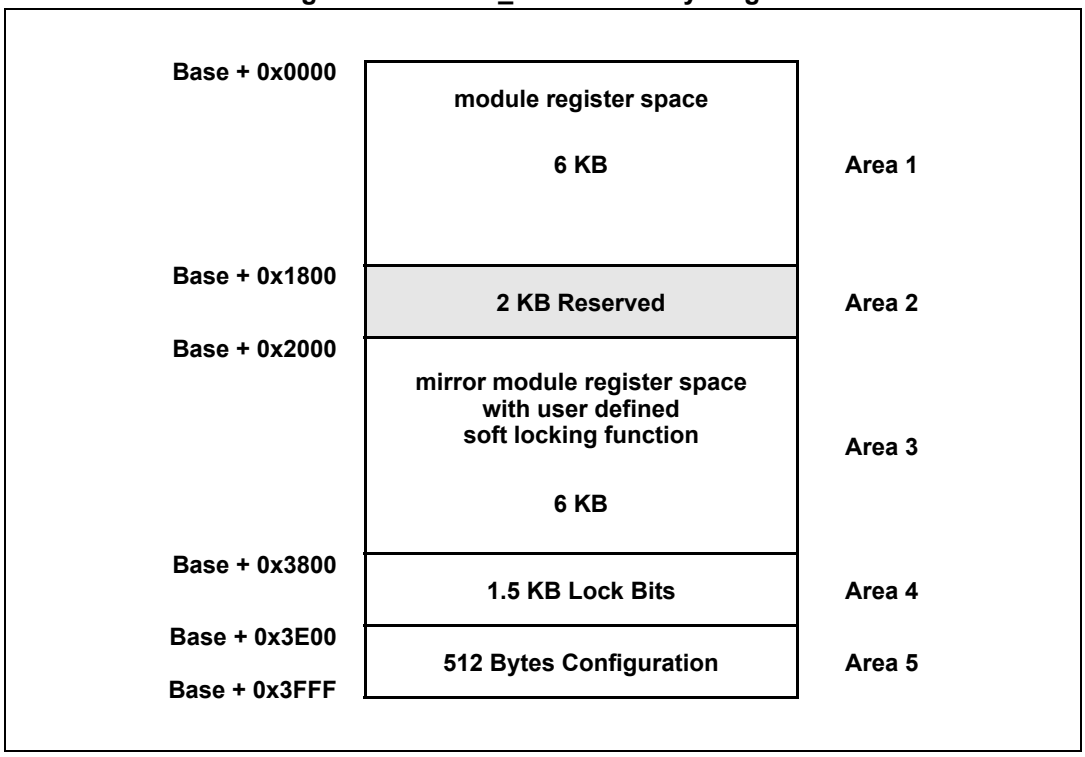
Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set.

91.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.



91.2 External signal description

There are no external signals.

91.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 2416*.

Figure 2416. REG_PROT memory diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

91.3.1 Memory map

Table 2302 shows the memory map for a module which is protected via a REG_PROT module.

Table 2302. REG_PROT memory map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*Section 91.3.2.1*
0x0001	Module Register 1 (MR1)	*Section 91.3.2.1*
0x0002	Module Register 2 (MR2)	*Section 91.3.2.1*
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	*Section 91.3.2.1*
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	*Section 91.3.2.2*
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	*Section 91.3.2.2*
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	*Section 91.3.2.2*
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3	*Section 91.3.2.3*
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	*Section 91.3.2.3*
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	*Section 91.3.2.3*
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	*Section 91.3.2.4*

Note: Reserved registers in area #1 will be handled as specified in the protected module's documentation.

91.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

91.3.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

91.3.2.2 Module Register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 2304*.

91.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 2303. Soft lock bits vs. protected address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

Note: As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3800-0x3DFF

Access: Read always
Supervisor write

	0	1	2	3	4	5	6	7
R	0	0	0	0	SLB0	SLB1	SLB2	SLB3
W	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

Figure 2417. Soft Lock Bit Register (SLBR*n*)

Table 2304. SLBR*n* field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR*n* register: SLB0 can block accesses to MR[*n* *4 + 0] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[*n* *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[*n* *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[*n* *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable

91.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3FFC

Access: Read Always

Figure 2418. Global Configuration Register (GCR)

Table 2305. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register cannot be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and cannot be modified 0 All SLB bits are accessible and can be modified.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

91.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

91.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size is device and module specific, refer to the *Chapter 7: Device configuration for details.*

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

91.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

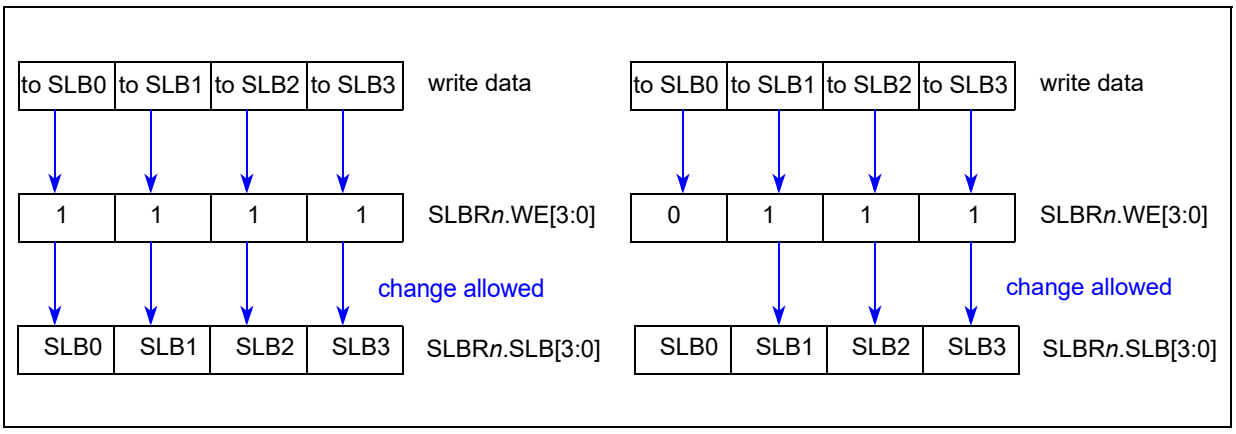
Both methods are explained in the following sections.

91.4.2.1 Change lock settings directly via area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 2419 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 2419. Change lock settings directly via Area #4



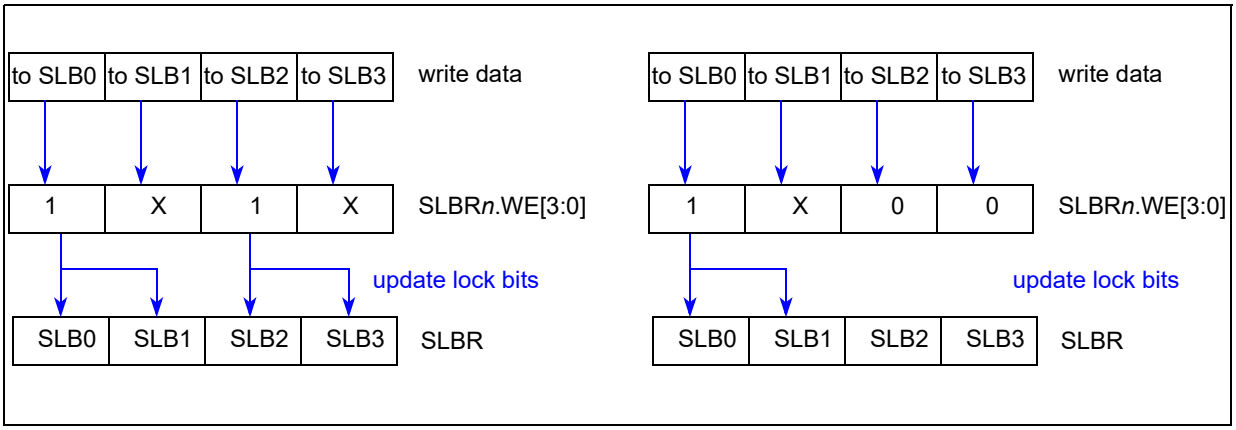


Figure 2419 shows four registers that can be protected 8-bit wise. In *Figure 2420* registers with 16-bit protection and in *Figure 2421* registers with 32-bit protection are shown:

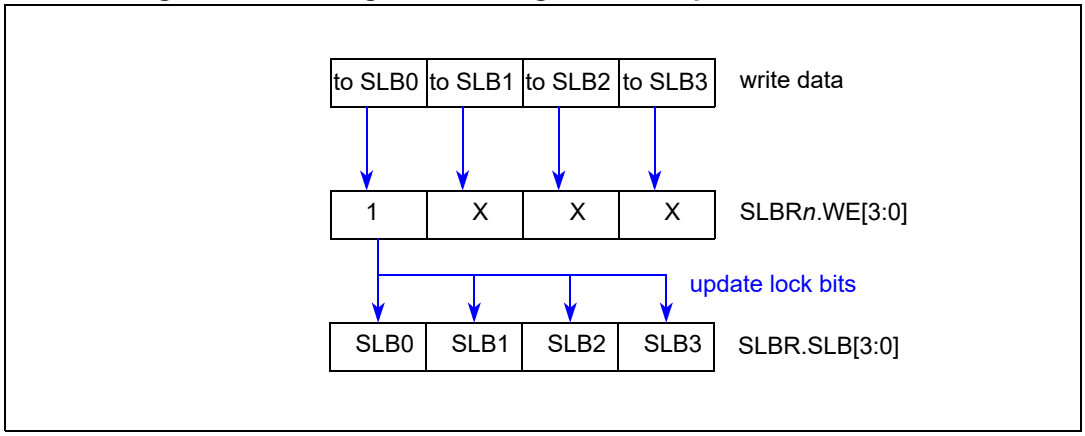
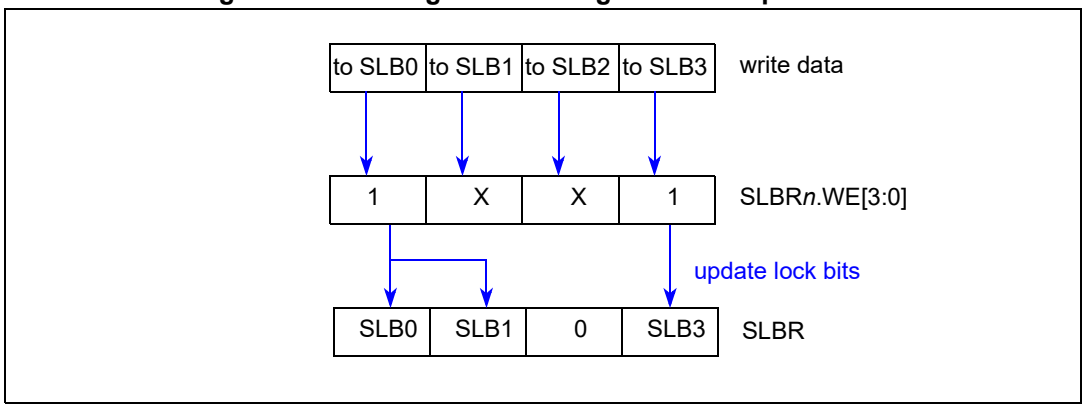
Figure 2420. Change lock settings for 16-bit protected addresses



On the right side of *Figure 2420* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 2420* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

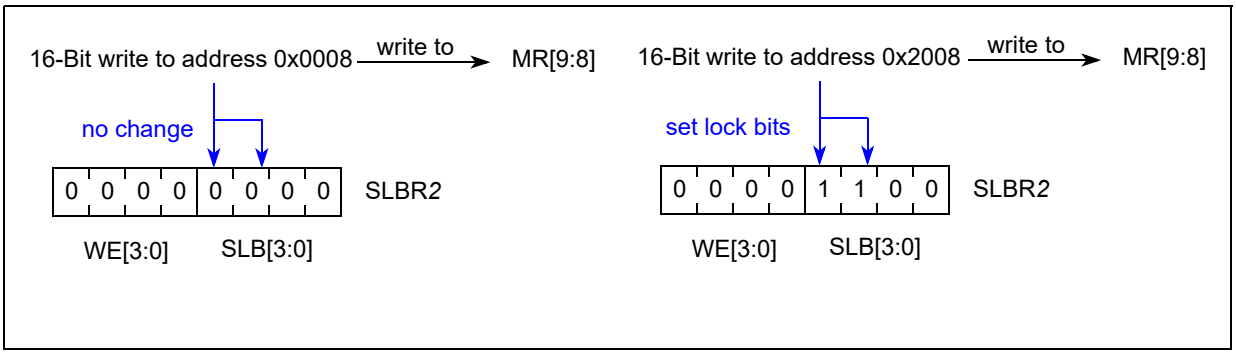


In *Figure 2421* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 2421. Change lock settings for 32-bit protected addresses

In *Figure 2422* an example is shown which has a mixed protection size configuration:

Figure 2422. Change lock settings for mixed protection

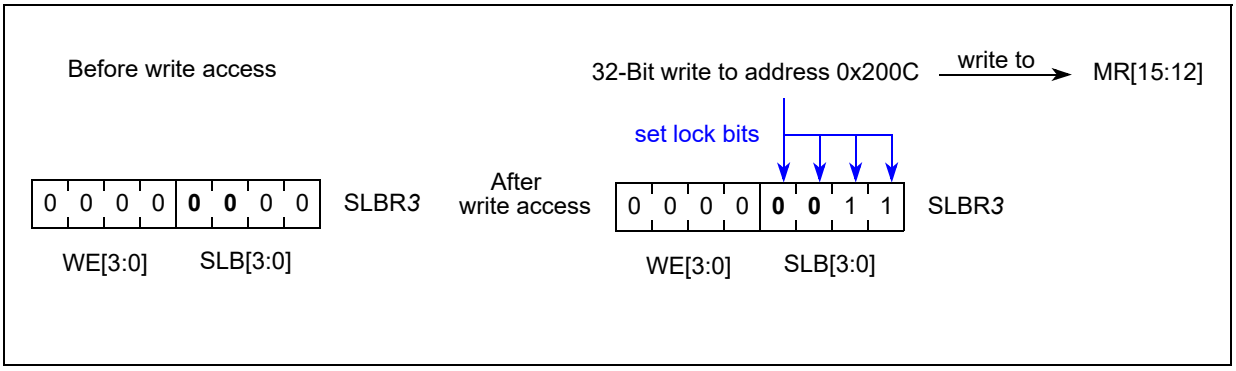


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

91.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 2423* shows one example:

Figure 2423. Enable locking via mirror module space (Area #3)



When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 2420*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 2420*).

Figure 2424 shows an example where some addresses are protected and some are not:

Figure 2424. Enable locking for protected and unprotected addresses

In the example in *Figure 2424* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

91.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 91.4.2.1: Change lock settings directly via area #4* and *Section 91.4.2.2: Enable locking via mirror module space (Area #3)* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

91.4.3 Access errors

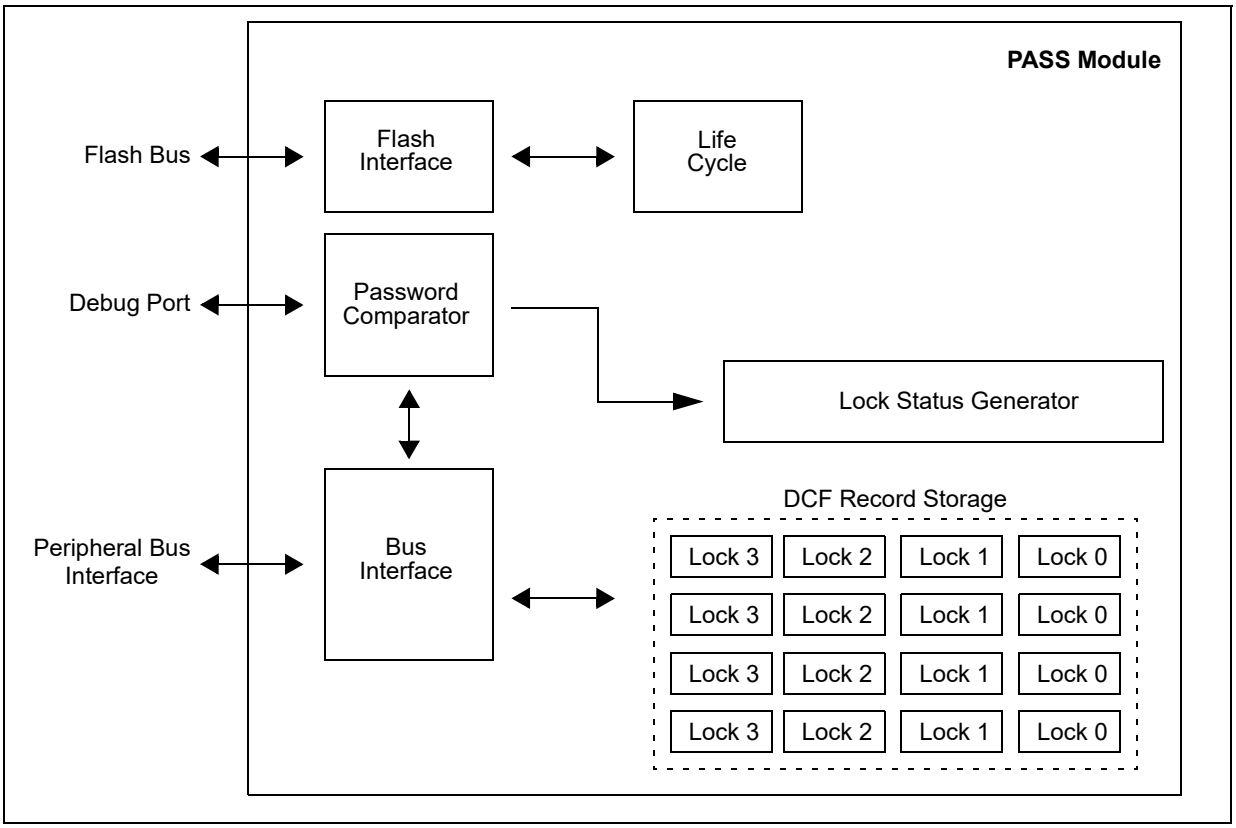
The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 2416*

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR is set.

91.5 Initialization/application information

91.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (refer to *Section 91.3.2: Register descriptions*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.



92 Password and Device Security Module (PASS)

92.1 Introduction

92.1.1 Overview

The Password and Device Security (PASS) module shown in *Figure 2425* receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 2425. PASS module block diagram

92.1.2 Features

The PASS includes these distinctive features:

- Lifecycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Fuse Bypass Configuration and Password Comparison

92.1.3 Modes of operation

The PASS operates identically in all system modes.

92.2 External signal description

The PASS has 1 external pin that is used for Production Disable control (refer to *Section 92.4.2: Production Disable*).

92.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 92.4: DCF clients*.)

Table 2306 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

Do not write to address 0x00D0 with bit value 0.

Table 2306. PASS memory map

Offset	Register	Access	Reset Value	DCF Client Address(1) (ADDR[14:0])	Section
0x0000	Lifecycle Status Register (LCSTAT)	R	0xX0000007	None	*Section 92.3.1.1*

0x013C	Lock 3 Status Register (LOCK3_PG3)	R/W	0xXFXXXXXX[2]	0x013C	*Section 92.3.1.9*

1. DCF Client Address column shows what is the DCF used to preload the register value during reset. If the column value is “None”, it means that the register value at reset is fixed in hardware.
2. Reset value depends on password group lock state.

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

92.3.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

92.3.1.1 Lifecycle Status register (LCSTAT)

The Lifecycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device lifecycle forward), but never to revert the lifecycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external lifecycle management module (like SSCM). It is a 3-bit lifecycle. This register simply displays the lifecycle input from external blocks.

Offset: 0x0000 Access: Software Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	FBE	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	x(1)	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

1. Reset value depends on the Censorship DCF client.

Figure 2426. Lifecycle Status register (LCSTAT)

PASS_LCSTAT register functions are as shown in *Table 2307*.

Table 2307. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the state of the Censorship DCF Client. The bit can be set (or cleared) via DCF Record in UTEST Flash. Refer to *Section 92.6.3: Censoring and uncensoring the device*. 0 Device is uncensored 1 Device is censored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit. **Note:** Refer to the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual for details.

Table 2307. LCSTAT register field descriptions (continued)

Field	Description
2 FBE	Fuse Bypass enable This field indicates whether the Fuse Bypass DCF Client is set to Fuse Bypass Enable. 0 No Fuse Bypass 1 Fuse Bypass Enable **Note:** Refer to *Section 92.4.3* for details.
29:31 LIFE	The lifecycle setting is manipulated externally (SSCM). Pass displays a 3-bit input lifecycle. 000 Failure Analysis mode 001 Reserved 010 OEM Production 011 Customer Delivery 110 ST Production 111 In Field

92.3.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.

The ID of the accessing master sets the CMST field of the Challenge Status register.

Offset: 0x0008 Access: Software Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2429. Challenge Input register (CIN*n*)

CIN register functions are as shown in *Table 2310*.

Table 2310. CIN*n* register field descriptions

Field	Description
0:31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

92.3.1.5 Clock Jitter Enable (CJE)

Software accessible one time writable register. This register stores the jitter enable status for the Pseudo Random Clock Divider Module (PRCD). The default value of this register if '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial communications modules includes large amounts of pseudo random clock edge jitter, making the serial communications modules unusable. For details about which serial communications modules are affected, refer to the clocking section of the Reference Manual.

For more information on Production disable, refer to *Section 92.5.5: Production Disable*

Debug access is blocked when Production disable bit[0] (Gated Debug Enable) is asserted, the Chip is *In Field* and Clock Jitter is not enabled.

Offset: 0x00D0 Access: Software Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2430. Clock Jitter Enable (CJE)

Table 2311. CJE field descriptions

Field	Description
31 CJE	Clock Jitter Enable 0 Clock Jitter is enabled. The baud rate clock to Serial communications modules includes large amounts of pseudo random clock edge jitter. 1 Clock Jitter is disabled. The baud rate clocks function normally.

92.3.1.6 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the lifecycle has matured to *OEM Production* or older.

Offset: 0x0100 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MIDLOCK															
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2431. Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

LOCK0_PG*n* register functions are as shown in *Table 2312*.

Table 2312. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTEST NVM Lock. This bit is used to lock the UTEST NVM block from programs on the alternate interface (erase protection not needed since UTEST NVM is OTP and not erasable).
2:15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16:31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', indicating that a block is locked.

Warning: **When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.**
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

When Production Disable register bit[1](BAF PLock Hardware Interlock enable) is asserted and lifecycle is *In Field*, then the external signal is ORed with BAF_plock(low_lock[0]) of LOCK0_PGx.

92.3.1.7 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x0104 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2432. Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

LOCK1_PG*n* register functions are as shown in *Table 2313*.

Table 2313. LOCK1_PG*n* register field descriptions

Field	Description
16:31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is '1', which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

92.3.1.8 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle is matured to *OEM Production* or older.

Offset: 0x0108 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit resets to ‘1’.

Figure 2433. Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 2314*.

Table 2314. LOCK2_PG*n* register field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

92.3.1.9 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x010C + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Not all devices include this field. Refer to the device reference manual's chip configuration chapter for details.
2. Reset value depends on lifecycle. If lifecycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2434. Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

LOCK3_PG*n* register functions are as shown in *Table 2315*.

Table 2315. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally (if lifecycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked).
1 DBL	Debug Interface Lock The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM). 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked.

Table 2315. LOCK3_PG*n* register field descriptions (continued)

Field	Description
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared. 1 Only the Master which unlocked the passgroup can change the passgroup settings.
4:7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
11 RL4	Read Lock Region 4 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
12 RL3	Read Lock Region 3 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
13 RL2	Read Lock Region 2 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
14 RL1	Read Lock Region 1 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
15 RL0	Read Lock Region 0 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
16:31 A256KLOCK	256K address space block lock A256KLOCK[47:32] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: **When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.**
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to *Section 92.5.3: Flash Memory Read Protection*.

Once a censored device enters the *Failure Analysis* lifecycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash UTest region controlled by LOCK3[0]is read unlocked in Failure Analysis lifecycle.

92.4 DCF clients

Where a DCF client is listed, the reset value of that register may automatically be preloaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

92.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Censorship DCF client defines whether the MCU is censored or not (Refer to *Table 2306*).

DCF Client Address: 0x00B0 Censorship Access: DCF Record Write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 2435. Censorship register (not accessible)

Table 2316. Censorship register field descriptions

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored. If this value is anything other that 0x55AA, the MCU is censored.

92.4.2 Production Disable

Note: Production Disable is a DCF client that is not accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable and Hardware Interlock aspects of the Production Disable feature (refer to Table 2306).

Note: The DCF client implements 2 bits with a default value of '0'. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, refer to *Section 92.5.5: Production Disable*

DCF Client Address: 0x00C0 Production Disable — Access: DCF Record Write Once Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2436. Production Disable DCF client

Table 2317. Production Disable DCF Client field descriptions

Field	Description
HI	Hardware Interlock 0 BAF Flash block programming is controlled by PASS_LOCK0[BAF] bits. 1 BAF Flash block is locked for programming while external hardware pin is asserted '0'.
DD	Debug disable 0 Debug Interface is Enabled and Disabled using Censorship, JTAG password & PASS_LOCK3[DBL] bit as described elsewhere. 1 Debug Interface is disabled while Clock Jitter is NOT enabled.

92.4.2.1 Debug Disable (DD)

Note: Debug Disable is an optional feature that, once the Lifecycle is In Field or beyond, overrides all other debug controls and disables the debug interface (refer to Table 2320).

92.4.2.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the lifecycle is In Field or beyond, prevents programming of the BAF Flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

92.4.3 Fuse Bypass DCF Client

This DCF client is used to configure the password protected Fuse bypass feature. Refer to *Section 92.5.6: Fuse Bypass* for details.

The Fuse Bypass DCF Client is not directly readable in software, but the state of the Fuse Bypass bit can be read in the LCSTAT register (refer to *Section 92.3.1.1: Lifecycle Status register (LCSTAT)*).

The DCF client is written during Destructive Reset Phase 3 and compared during Functional Reset Phase 3; if this compare does not match the data already written, the logic will decode No fuse bypass.

DCF Client Address: 0x00E0 Fuse Bypass — Access: DCF Record Write Once Only

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 2437. Fuse Bypass DCF Client

Table 2318. Fuse Bypass register field descriptions

Field	Description
31 FB	Fuse Bypass enable 0 The Fuse can NOT be Bypassed 1 Bypass of the fuse is possible with a password

92.4.4 Password Slot Access

Password Slot Access is a write-once DCF client. The DCF controls access for both read and write starting from Lifecycle = OEM Production. If the bit is 1, the slot is still accessible when Life Cycle = OEM Production (and blocked starting from Life Cycle = In Field). Otherwise if the bit is set to 0, the slot is blocked starting from Life Cycle = OEM Production.

DCF Client Address: : 0x00B4 Password Slot Access — Access: DCF Record Write Once

Figure 2438. Password Slot Access DCF Client

Table 2319. Password Slot Access DCF Client field descriptions

Field	Description
28:31	Password Slot Access per password group

92.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

92.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (refer to *Section 92.4.1: Censorship*).

92.5.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (refer to *92.3.1.9: Password Group n - Lock 3 status register (LOCK3_PGn)*). Both of these debug enabling options are further conditioned by lifecycle and Production Disable.

The following table describes all options for enabling/blocking Debug Interface access.

Table 2320. Debug Interface Enable Truth table

Input Conditions						Outcome
Lifecycle	**Production Disable mode**	**Clock Jitter Enable**	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
In Field	Disabled	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Disabled
	Enabled	Jitter enabled	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not matched	Disabled
		Jitter disabled		Don't Care	Don't Care	Disabled
Failure Analysis	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled

The HSM can also block Debug Interface Access, even if it enabled by PASS. This allows HSM to granted Debug Interface Access after an encrypted secure challenge/response protocol with an external tool (refer to the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual).

92.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

92.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 2321: Flash Memory Read Protection truth table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The Flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (refer to *Chapter 7: Device configuration*, *Section 7.11.1: Password and Device Security Module (PASS) configuration*).

Table 2321. Flash Memory Read Protection truth table

INPUTS				OUTPUTS	
Lifecycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
STMicroelectronics Production / Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable

92.5.4 UTEST protection

During the *Customer Delivery* lifecycle, the user must program a valid password or a DCF record that writes LOCKm_PGn registers to unprotect the UTest for each password group in order to prevent permanent and irreversible locking of Flash blocks.

92.5.5 Production Disable

Production disable activation protocol and implementation is described in *Chapter 65: Boot Assist Flash (BAF)*, *Section 65.3.6: Production disable activation protocol and implementation*.

92.5.5.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

Note: Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (CAN and FlexRay). This jitter means those serial communications modules are not able to communicate on the network.
As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted (refer to Section 92.4.2: Production Disable for details).

92.5.5.2 Enabling

Note: The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. Bit 1 enables the Hardware Interlock pin.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

Note: If no DCF Record writes to this client, the default state of both features is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature cannot be Enabled accidentally.

92.5.5.3 Clock jitter activation

The BAF code copies the ‘Clock Jitter Activation’ constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (refer to *Section 92.3.1.5: Clock Jitter Enable (CJE)* for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF Flash is 0xFFFF_FFFF (erased state).

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF Flash should be programmed to make the most significant bit ‘0’. After the next reset, the BAF copies this updated value to the Clock Jitter Register and the feature is activated.

92.5.5.4 Clock Jitter Truth table

Table 2322 shows the relationship between Lifecycle, Production Disable & Clock Jitter enable input conditions versus the state of the Baud Rate Clock.

Table 2322. Clock Jitter Truth Table

Lifecycle	Production Disable [Debug Disable]	Clock Jitter Enable	Baud Rate Clock State
STMicroelectronics_ Production Customer_Delivery In_Field	Don’t Care	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
Failure_Analysis	Off[0]	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
	On[1]	Don’t Care	Jitter

92.5.6 Fuse Bypass

92.5.6.1 Fuse

Some devices include an additional security feature, whereby a silicon fuse is used to gate access to Flash Test Mode when the device is in Failure_Analysis lifecycle. The fuse must be blown, creating physical damage to the silicon, before access is granted to Flash Test Mode. The PASS implements a configurable feature to bypass the requirement to blow the fuse to enter flash test mode, by entering a password instead. This feature is called Fuse Bypass.

92.5.6.1.1 Use Case: No Fuse Bypass

Customers who want no alternative to the Fuse to enter Flash Test Mode in FA lifecycle:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 0.
- And as a back-up, during customer assembly, the customer could program the Fuse Bypass Password to a random value.

92.5.6.1.2 Use Case: Fuse Bypass Password

Customers who require a password to enter Flash Test Mode in FA lifecycle, but do not require the added sophistication of blowing a fuse:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 1.
- During customer assembly, the customer programs the Fuse Bypass Password into Flash.
- The customer maintains a system for retrieving these passwords for the life of the module.
- If the part is returned to STMicroelectronics for FA, the customer must provide the Fuse Bypass password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA can only be performed if the die is removed from the package and the fuse blown.

92.5.6.1.3 Use Case: No Fuse. No Password

Customers who are less concerned with security and will accept neither fuse nor password to enter Flash Test Mode in FA lifecycle:

- Customer need do nothing special for this mode in customer assembly.
- When the part is returned to STMicroelectronics for FA, The DCF Client is still in the default state of 1. This is Fuse Bypass.
- The Fuse Bypass password should still be in the erased state (all 1). The tester can enter all 1 as the password to gain access to Flash Test Mode.

92.5.6.2 Fuse Bypass Password

The Fuse Bypass Password is a password entered by the STMicroelectronics via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA lifecycle. Flash blocks that are assigned as sealed during production

are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

92.5.6.2.1 Fuse Bypass Password Generation

The Fuse Bypass password is created by the customer during their module assembly process. It must be programmed into UTest Flash while in CUSTOMER_DELIVERY lifecycle.

When an MCU is returned to STMicroelectronics for FA, the MCU must be in FA lifecycle and this password must also be provided to STMicroelectronics to allow access to Flash Test Mode without blowing the fuse. Therefore the customer should develop a process for managing Fuse Bypass passwords for the life of the module.

If the password is not available when a device is returned for FA, STMicroelectronics must remove the die from the package and blow the fuse before entry is possible to Flash Test Mode and Flash FA can be undertaken.

92.5.6.2.2 Fuse Bypass Password storage

The Fuse Bypass Password is 224 bits (28 bytes) wide and is to be stored in UTest Flash at a fixed location. Refer to the device reference manual for the address of the Fuse Bypass password.

The password region of UTest Flash is readable only when in CUSTOMER_DELIVERY lifecycle. In any lifecycle after this (including FA lifecycle), this region is read protected.

92.5.6.2.3 Fuse Bypass Password Challenge entry

The Fuse Bypass password challenge is entered by an external tool to the password register in JTAGC.

As the Fuse Bypass Password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

92.5.6.2.4 Fuse Bypass Password compare

The Fuse Bypass Password challenged, is compared against the password stored in UTest Flash. Only the least significant 224 bits are compared.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

92.6 Initialization/application information

92.6.1 Reset

The reset state of each individual bit is shown within *Section 92.3.1: Register descriptions*. However, many bits receive their values based on DCF records stored in the UTest Flash memory block.

92.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 2323. CS/ADDR values for Lock registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xXXXX0100(1)
Lock1	0xXXXX0104(1)
Lock2	0xXXXX0108(1)
Lock3	0xXXXX010C(1)
PW Group 1	
Lock0	0xXXXX0110(1)
Lock1	0xXXXX0114(1)
Lock2	0xXXXX0118(1)
Lock3	0xXXXX011C(1)
PW Group 2	
Lock0	0xXXXX0120(1)
Lock1	0xXXXX0124(1)
Lock2	0xXXXX0128(1)
Lock3	0xXXXX012C(1)
PW Group3	
Lock0	0xXXXX0130(1)
Lock1	0xXXXX0134(1)
Lock2	0xXXXX0138(1)
Lock3	0xXXXX013C(1)

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 2324*.

Table 2324. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA55AF	Start Record
0x04	0x00000000	
0x08	0x000000FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xXXXX0110(1)	

Table 2324. Setting some bits in the MIDLOCK field (continued)

ADDR offset	DATA	Description
0x10	0xFFFFFFFF	Stop Record
0x14	0xFFFFFFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

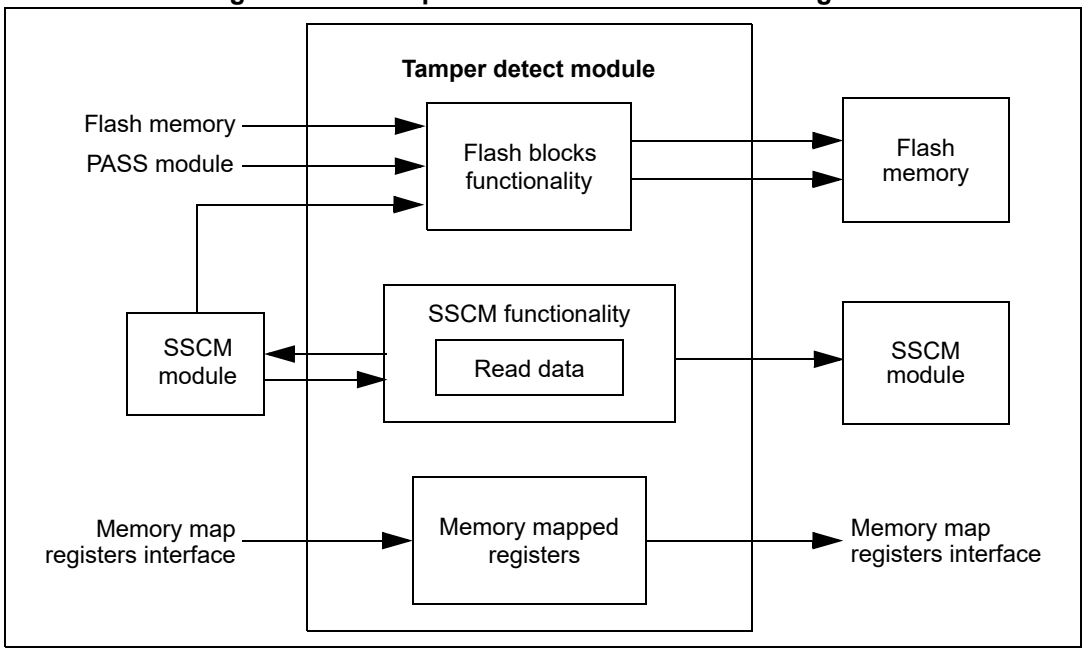
92.6.3 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTest Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS) and the address 0x00B0. Therefore 0xXXXX00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is censored.

93 Tamper Detection Module (TDM)



93.1 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR: it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

Figure 2439 shows the block diagram of the TDM and its interface to other system components.

Figure 2439. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One-Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information (via the DCF bus)
- Software tamper region override

The TDM module controls the flash blocks for erase operations and sets them as OTP

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programed. Over-programming is not possible.

Note: The PASS module provides the control for erase operation for each flash block as well as for each region of the flash memory, and the PASS settings have priority over the settings of the TDM.

The flash block indicates to the TDM the address of the programed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

93.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 128-bit records
  - The diary block should be assigned as OTP region in flash
  - The diary area can store any type of relevant information
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled
- 32-bit Erase Lock DCF clients for each flash memory TDR defined
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records(35)
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation
- Memory Map Registers Interface for reading via software of specific registers

93.3 External signal description

There are no external signals driving or being driven by the TDM.

93.4 DCF client

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

35. The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 2325. DCF client address map

DCF client name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write-once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR – "*n*" specifies a TDR – "*m*" specifies the flash blocks as per the LOCK registers of the flash memory	write 0 to 1 only

93.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. *Figure 2440* shows the diagram for this register.

Caution: This DCF client is implemented as Write Once and is writable from 1 to 0 only. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0000 Access: DCF write

Table 2326. DBA field descriptions

Field	Description
0:31 DBA	Diary Base Address This field holds the base address of the diary. This information is then used to verify if the diary being programed matches any TDR region. **Note:** Diary Base Address must be on a 16KB boundary.

93.4.2 Tamper Region Override (TO) DCF client

This DCF client holds overriden information for each TDR. *Figure 2441* shows the diagram for this register.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

26:31 TOE[5:0]	TDR Override Enable Each TOE field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written 1 Diary override. The diary for this TDR can be erased WITHOUT writing to the diary

93.4.3 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. *Figure 2442* depicts this client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash block to OTP irreversible.

Field	Description
16–31 256KBOTPEN	256 KB Block OTP Enable (256KBOTPEN[47:32]) This field affects flash memory blocks in the upper range of 256 KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

93.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0)

This DCF client holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF client however holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. Therefore, the diagram of this register mirrors the LOCK0 register in the flash memory. *Figure 2446* depicts the TDR*n*_LOCK0 DCF client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

DCF client Address: 0x14 + ((n * 4) + 0) Access: DCF write

93.5 Memory map and registers

Note: The Tamper Detection Module's memory-mapped registers are read-only. Any attempted write generates a transfer error.

Table 2336. TDM memory map

Address offset (hex)	Register name	Location
0x00	TDR Status Register (TDM_TDRSR)	*Section 93.5.1*
0x04	Last Flash Programed Address Register (TDM_LFPAR)	*Section 93.5.2*
0x08	Diary Base Address (TDM_DBA)	*Section 93.5.3*
0x10–0x24	Software Tamper Override Key Region (TDM_STO_KEY0–TDM_STO_KEY5)	*Section 93.5.4*

93.5.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, such as locked or unlocked, of each tamper region, such as TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

Note: TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.

If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Offset: 0x00 Access: User read

Figure 2450. TDR Status and Diary Override Register (TDM_TDRSR)

Table 2337. TDM_TDRSR field descriptions

Field	Description
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

Table 2337. TDM_TDRSR field descriptions (continued)

Field	Description
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

93.5.2 Last Flash Programed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Offset: 0x04 Access: User read

Figure 2452. Diary Base Address Register (TDM_DBA)

1. Reset value depends on the Diary Base Address (DBA) DCF client

Table 2339. TDM_DBA field descriptions

Field	Description
0:31 DBA	Diary Base Address These bits represent the address of the diary location in the flash. **Note:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

93.5.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)

The STO_KEYn register holds the service key for overriding the Tamper Detect Region *n*, where *n* denotes the Tamper Detect Region number.

Caution: The STO_KEY*n* registers can only be written once.
The associated DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Offset: 0x10 + *n* * 0x4 (*n* = 0 to 5) Access: User read/write

Figure 2453. Software Tamper Override Key Region (TDM_STO_KEY*n*)

Table 2340. TDM_STO_KEY*n* field descriptions

Field	Description
0:31 STO_KEY	Software Tamper Override Key Diary *n* This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Note:** The STO_KEYn registers can only be written once. **Note:** Refer to *Section 65.3.7: TDM Diary Operation* for programming details

93.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

93.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Dairy is defined by a DCF Record .

The diary is divided into 6 parts where each part consists of 256 × 128-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region . These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM , which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR.As the diary should be OTP, successive writes are allowed on unprogramed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

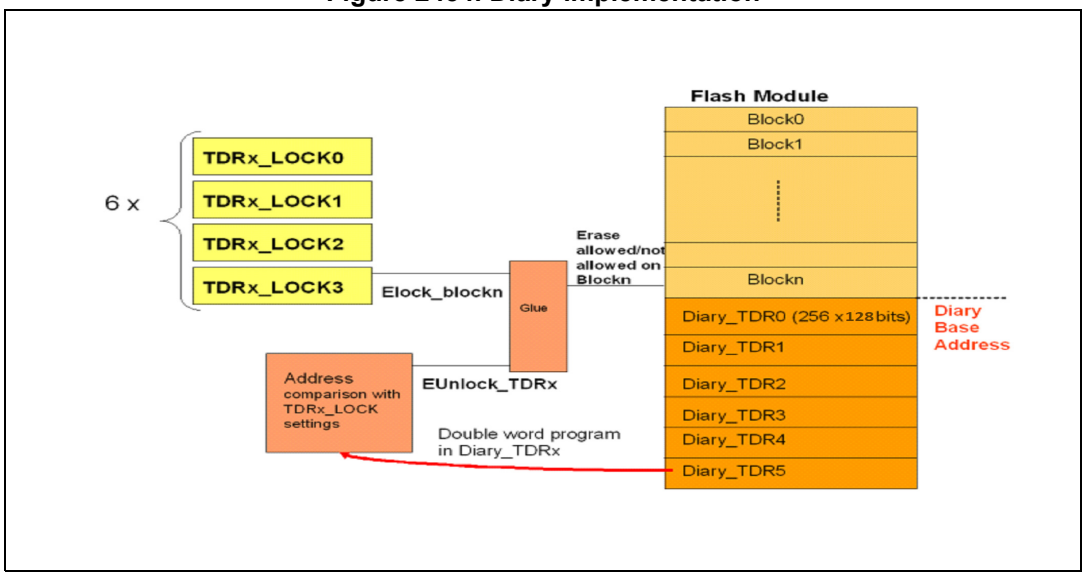
At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programed double word. TDM determines whether the programed data was written to the correct TDR Diary Location and then unlocks the blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the next program operation on any block, other than Diary, is performed with program completion interrupt enabled or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programed in

the diary. If diary is detected to be full, TDM provides a means to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programed in the diary location is flexible, and may include count information or other important customer information.



Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from “override tamper region lock” DCF record (refer to *Section 93.6.3: Diary*) has priority over the settings in the TDRn_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDRn_LOCK*m* settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in *Figure 2454*.

Figure 2454. Diary implementation

Note: The settings in the Tamper Region Override Register have priority over the TDRn_LOCKm Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

93.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 × 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as

TDRn_LOCKm where n is the number of a tamper region, that is, 0-5 and m varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They cannot be read nor written. They can only be initialized by DCF record within the UTEST flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

Note: No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

93.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 4 KB, and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector to honor OTP restrictions. Therefore, each diary can hold a maximum of two-hundred and fifty-six 128-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients cannot be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

93.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is ‘0’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 4 KB section of the diary. With 6 TDRs, 24 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b000_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b001_0000_0000_0000
- TDR2 = Diary_Base_Address + 0b010_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b011_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b100_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b101_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b110_0000_0000_0000

93.6.5 Diary base address verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as “TDR Erase Blocked”. Refer to *Section 93.5.1: TDR Status Register (TDM_TDRSR)* for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning “TDR Erase Enabled”.

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. Refer to *Section 93.5.1: TDR Status Register (TDM_TDRSR)*. The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. Refer to *Section 93.5.2: Last Flash Programed Address Register (TDM_LFPAR)*.

93.6.5.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location can be written. After a maximum of 256 records are programed to the diary, a TDR diary is full. Full means that at least 1 bit has been programed to ‘0’ in each record within the 4 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

93.6.6 One Time Programmable (OTP)

93.6.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programed. Over-programming is not possible.

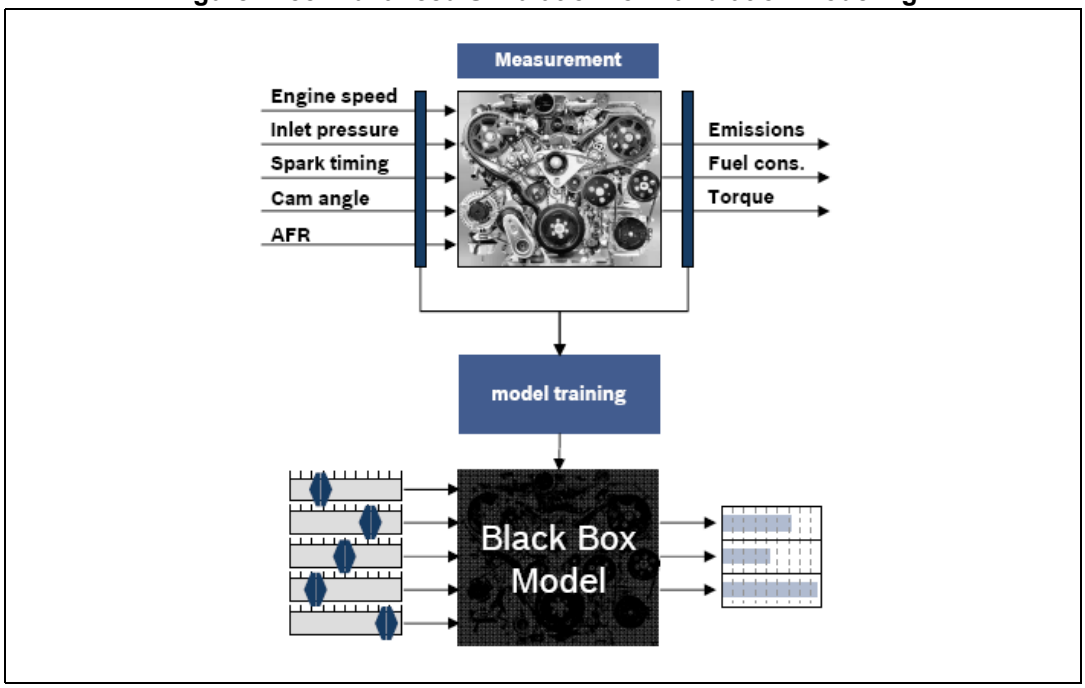
Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

94 ASC Modeling Unit version 2 (AMU2)

94.1 Introduction

The Advanced Simulation for Calibration (ASC) Modeling Unit (AMU) is a high performance floating-point arithmetic calculation engine implementing a specific pre-defined algorithm (see *Section 94.3.1: AMU2 algorithm* for details). This is a second generation implementation.

This computation unit is used to describe unknown systems using a model that is based on measured data. The model is based on mathematical approximations such that no physical description is necessary. Additionally, this approach minimizes the required number of measurements of the system through the use of a statistically optimal distribution.



There are various modeling algorithms typically used for this type of system analysis. Examples include classic polynomial descriptions and neural networks. The statistical machine learning method implemented by the AMU offers a number of significant improvements versus previous approaches, including:

- Ability to describe complex behaviors with very high accuracy
- No model parameterization is necessary
- Robust against measurement errors and data “outliers”
- Provides best trade-off between measurement number and model accuracy

In the past, a significant drawback to this approach was the high computational power necessary for this type of modeling. The AMU, which is a compact hardware implementation of a specific algorithm, provides the needed calculation capabilities within the context of a general purpose microcontroller.

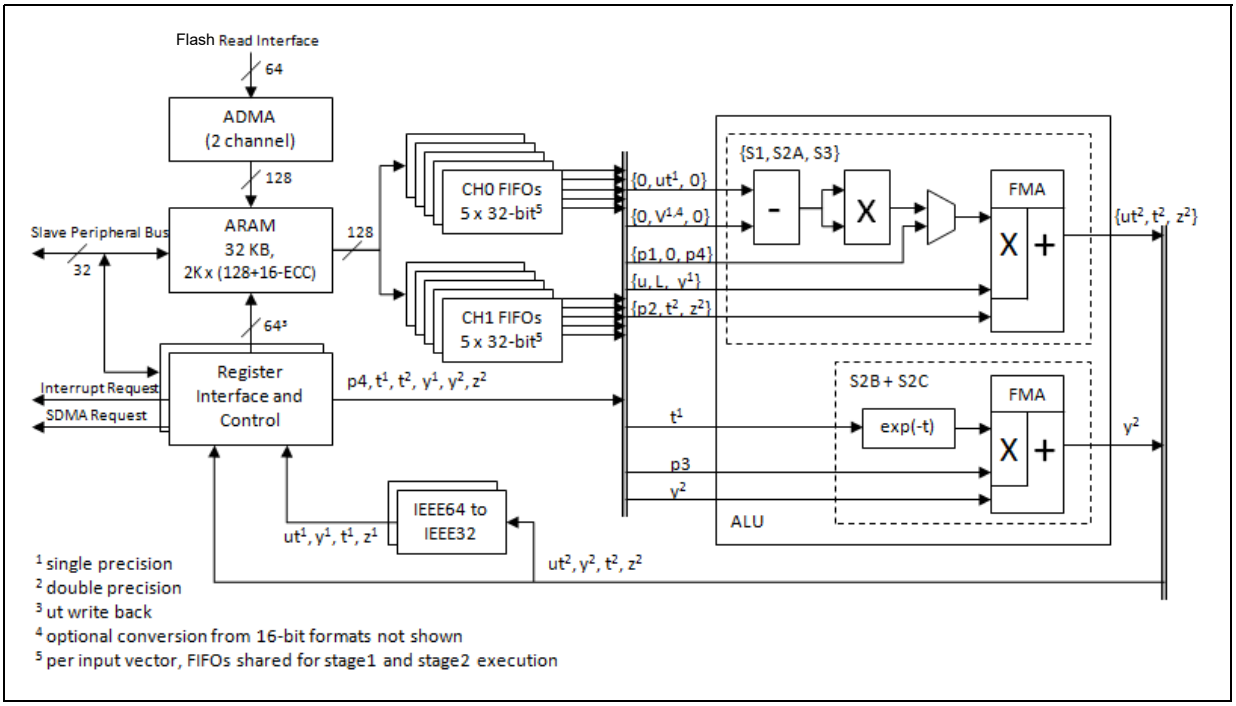
See *Figure 2455* for a simplified diagram of the intended use of the ASC Modeling Unit.

Figure 2455. Advanced Simulation for Calibration Modeling

Note the module names AMU and AMU2 are meant to be completely synonymous and are used here interchangeably.

94.1.1 Overview

The AMU2 implementation includes the pre-defined floating-point algorithm that includes:



- Multiple loop constructs with extensive vectored multiply-accumulate operations
- Single-precision exponential function, exp(x)
- 32 Kbytes of memory-mapped local RAM for parameter and coefficient storage
- Local DMA (ADMA) with private connection into system Flash for fetching data into the local memory
- Local RAM (ARAM) accessible via local DMA and system bus interface

The AMU contains two separate channels, which are timing-independent and register-independent. Each channel logically includes a calculation engine and a DMA channel. The calculation engines both share the same arithmetic logic using a time multiplexed scheme. Likewise, the DMA channels use a time multiplexed scheme to share common interfaces for fetching from the system Flash memory (or the calibration remapped destination memories, or both) and writing into the local RAM.

Within each calculation engine, there are two pipelined floating-point engines: one performs the stage 1, 2a and 3 calculations using a subtracter, a multiplier and an FMA (fused multiply-add), while the second performs the stage 2b and 2c operations using the exp(x) function and an FMA. This structure was selected to allow stage2a to be computed continuously in one pipeline, while stages 2b and 2c are computed in parallel in the other pipeline to maximize overall performance. Operations from the two channels are interleaved on the calculation engines and also include a number of blocks to feed these arithmetic blocks with data. The interleaving of the channels is such that operations on one channel do not influence the timing on the other channel. This includes a 128-bit read interface from the ARAM to dedicated input data FIFOs to source data to the ALU.

A block diagram of the AMU2 is shown in *Figure 2456*. The module consists of a local 32 KB RAM with a SEC-DED Error Correcting Code (ECC) organized on 64-bit doublewords, that is, 8 check bits per 64 bits of data, 2 DMA channels to support data transfers from Flash to the AMU local RAM, dedicated data FIFOs for input data and the hardwired data path to calculate the AMU2 function. The AMU local RAM is also visible over the peripheral bus to the system.

Figure 2456. AMU2 block diagram(36)

The AMU2's system interfaces and local RAM, along with the register interface and control, are shown on the left side, and the two floating-point ALU pipelines on the right side of *Figure 2456*. The top pipeline calculates the results from stages 1, 2a and 3 using a generic function of the form:

result = ((in1 - in2) * (in1 - in2) + in3) * in4 + in5

where the inputs are simply labeled in1, in2, …, in5 from top to bottom. As shown in *Table 2341*, a different input operand set is sent into this pipeline structure for each stage, producing the required result calculations.

Table 2341. Stage 1, 2a, 3 Input Operands and Results

stage	in1	in2	in3	in4	in5	result, ((in1 - in2)*(in1 - in2) + in3) * in4 + in5
1	0	0	p1[*]	u[*]	p2[*]	p1[*] * u[*] + p2[*]
2a	ut[*]	V[*]	0	L[*]	t	((ut[*] - V[*]) * (ut[*] - V[*])) * L[*] + t
3	0	0	p4	y	z	p4 * y + z

For the stage 2b + 2c pipeline, the single input operand set produces the required calculation:

(exp(-t) * p3[*]) + y

36. Refer to the device block diagram for the AMU2 connection to the Flash Controler

94.1.2 Features

- High performance floating-point calculation of pre-defined algorithm with extensive vectored multiply accumulate operations and an exp(x) evaluation
- Time multiplexed hardware structure for the calculation engine to minimize die size while still maintaining execution speed
- Two independent calculation channels
  - The two independent channels allow two concurrent processes to use the AMU to perform calculations; no interference between the two processes is guaranteed by the hardware.
- Two independent AMU DMA (ADMA) channels
  - The ADMA channels are high-bandwidth 64-bit direct memory access channels, supporting transfer of Flash (or remapped calibration) data to local AMU RAM
- 32 KB of local AMU RAM (ARAM) memory storage
  - Logically dual ported
  - Connected to system peripheral bus, ADMA channels and internal AMU calculation engines
- Programming model located in peripheral address space of system memory map
  - Includes ARAM memory space and registers
  - Optimized for system DMA result & save, data reload and calculation initiation
- Support for multiple use cases involving system DMA or local ADMA, or both

94.1.3 Modes of operation

The AMU2 module does *not* support any special modes of operation. As a memory-mapped device located on the peripheral bus as a slave module, the AMU2 responds strictly based on accesses to its programming model via the peripheral bridge bus controller. The module generates a number of control output signals that can be configured to generate processor core interrupts (to either the main core(s) or I/O Processor) or system DMA requests in response to changes in the AMU2's calculation state.

The module optionally supports the ability to run or stall the calculation engine if a processor core is halted due to a debug event; for the AMU2, this function is programmable. By default, the AMU2 stalls in response to a debug event as signaled by a module input signal. See the AMU2_CCR1CH*n*[DDSL] description in *Section 94.2.3.21: AMU Control & Configuration 1 Channel n Register (AMU2_CCR1CHn)* for more details.

The functionality associated with the AMU2 resides in two clock domains: the module operates at the frequency of the main cores while its peripheral bus interface to the programming model operates at the same speed as that domain (typically 0.5x the speed of the main cores).

94.2 Memory map and register definition

The AMU module supports its programming model mapped to standard 16 KB on-platform peripheral slots. The local AMU RAM is accessible for read and write via the slave peripheral bus interface and is mapped to four contiguous and properly aligned 16 KB peripheral slots for a maximum size of 64 KB. The programming model, including the ARAM, can only be referenced in supervisor mode using 32-bit (word) accesses, either as single or burst transfers. It implements a big-endian memory organization. Attempted

references while in user mode, using different access sizes, writing to a read-only address, or to *reserved* addresses generate an error termination. It should also be noted that byte and halfword-sized accesses can be emulated using the Decorated Storage Memory Controller to perform bit field inserts for writes, and simple processor loads with shift or masking operations for reads, or both. Unless noted otherwise, *unused* addresses are treated as RAZ/WI: read-as zero, writes ignored. There are specific unused addresses that are located in read-only space and are therefore marked as “RAZ”; attempted writes to these locations generate an error termination.All programming model register reads and writes complete in a single peripheral bus clock cycle.

94.2.1 AMU memory map

Table 2342 shows the memory map for the AMU module.This address space is partitioned into 3 regions: local ARAM, channel 0 registers and channel 1 registers.

Table 2342. AMU memory map

Address Offset	Register	Access	Reset Value	Section
Local ARAM Address Space

94.2.2 ARAM memory map details

The 32 KB physical address space allocated to the AMU's local RAM (ARAM) is segmented into 2 regions. The first, a 31 KB space (offset addresses = 0x0_0000 - 0x0_7BFF), is intended for user-defined storage of the AMU input data. The second, a 1 KB space (offset addresses = 0x0_7C00 - 0x0_7FFF) is used by the AMU2 for temporary storage. This RAM space is used by the calculation engines to temporarily store the UT[*] vector generated as the stage1 output; additionally, it implements small FIFO memories to store "streamed data" associated with the V[*] and P3[*] vectors. The specific memory allocation within this 1 KB space is shown in *Table 2343*. Note if the streaming feature for the V[*] and P3[*] vectors is not enabled, the first 768 bytes of this 1 KB space can be used for general purpose ARAM data storage.

Table 2343. 1 KB ARAM Space Reserved for the Calculation Engines

Offset Start Address	Offset End Address	Size	Purpose
0x0_7C00	0x0_7CFF	256 bytes	Channel 0 Streaming v[*] FIFO
0x0_7D00	0x0_7DFF	256 bytes	Channel 1 Streaming v[*] FIFO
0x0_7E00	0x0_7E7F	128 bytes	Channel 0 Streaming p3[*] FIFO
0x0_7E80	0x0_7EFF	128 bytes	Channel 1 Streaming p3[*] FIFO
0x0_7F00	0x0_7F7F	128 bytes	Channel 0 ut[*] Storage
0x0_7F80	0x0_7FFF	128 bytes	Channel 1 ut[*] Storage

Given the 32 KB physical address space associated with the ARAM, all the pointers for this memory are implemented as 15-bit byte addresses that define the offset into the local memory. These local memory pointers are restricted to reference data items on their natural size boundaries, for example, with a 0-modulo-2 byte addresses (2-byte aligned) for 16-bit data, 0-modulo-4 byte addresses (4-byte aligned) for 32-bit data and 0-modulo-8 byte addresses (8-byte aligned) for 64-bit data. Additionally, software must manage the pointer values near the end of the address ranges as the hardware pointer calculations do *not* perform any special handling near the 31 KB or 32 KB boundaries.

Concerning the alignment of streamed V[*] or P3[*] data in their FIFOs, it should be noted that if the streamed data starts at offset 8 or 24 within the 32-byte Flash page, the first doubleword of data is stored at offset 8 in the associated FIFO, else it is stored at offset 0. During normal usage, this is completely transparent, but may be of interest during AMU debug if the contents of the FIFOs are examined.

If the ARAM is protected from single bit errors by enabling the ECC logic, it is the system's responsibility to initialize its contents with correct ECC before any AMU calculations are performed. This initialization can be performed by the system DMA performing 16-byte burst transfers to write the entire contents of the ARAM, using the memory initialization feature of the ADMA, or using the ADMA to load the entire memory from Flash. If the system DMA is used for ARAM initialization, both AMU2_CCR1CH{0,1}[EECC] configuration bits must be cleared until the initialization is complete.

Finally, it should be noted that the two 32-bit Control & Configuration Registers are treated in a special manner when configured as the last destination of an ADMA transfer. The AMU2_DCCRCH*n*[DARU] provides this specific configuration. For example, when configured with DARU = 0b01, the last 64-bit ADMA transfer associated with channel 0 writes to the CCR{1,2}CH0 registers to initiate an ALU calculation. Likewise, the last 64-bit ADMA transfer associated with channel 1 could write to the CCR{1,2}CH1 registers. This mechanism allows the basic data block transfer controlled by the ADMA to load new input data into the ARAM and then initiate a calculation by writing to the CCR{1,2}CH*n* registers.

94.2.3 Register descriptions

94.2.3.1 AMU ID and Version Channel *n* Register (AMU2_IDVCH*n*)

This read-only register provides information on the AMU channel number and revision.

28:31 VER	AMU version number This implementation is Version 2.

94.2.3.2 AMU N crossing Channel *n* Register (AMU2_NCH*n*)

This register provides a debug capability for the algorithm's stage2 calculation. If properly enabled (AMU2_CCR2CH*n*[ENCRS] = 1), when the outer loop in the stage2 calculation *completes* the iteration count defined by this register, the calculation engine stops (if AMU2_CCR2CH*n*[SNCRS] = 1) and optionally generates an interrupt request or system DMA request (based on AMU2_CCR1CH*n*[NCICFG]). If the calculation engine stops, the p8 outer loop count is NCRS+1.

The register also provides an optional bit masking capability so that multiple "N crossing" events can occur as the result of a single register write. As a limit, this mechanism could be used to stop the calculation after every iteration of the stage2 outer loop.

Offset: 0x1000C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2458. AMU N crossing Channel *n* Register (AMU2_NCH*n*)

Table 2345. AMU2_NCH*n* field descriptions

Field	Description
0:15 NMSK	N crossing Mask. This field provides the ability to mask individual bits in the N crossing comparison. If set, the bit is ignored in the equality comparison comparing the N crossing value and the outer loop iteration count from stage2 of the algorithm. if NMSK[i] == 0, then the corresponding bit in NCRS[i] is included in the comparison if NMSK[i] == 1, then the corresponding bit in NCRS[i] is excluded (masked) in the comparison
16:31 NCRS	N crossing value (unsigned integer). When enabled by AMU2_CCR2CH*n*[ENCRS], the stage2 calculation is stopped *after* the masked NCRS iterations of the outer loop. After the calculation is stopped, the p8 outer loop count contains an NCRS+1 value in this register. The intermediate value contained in the y64 register is consistent with this p8/NCRS value. Additionally, if the AMU2_CCR1CH*n*[NCICFG] is set to an appropriate value, an interrupt or a DMA request is triggered when the outer loop count reaches the masked NCRS value. The interrupt enable/disable control is independent of the AMU2_CCR2CH*n*[ENCRS] setting. The equality comparison is defined as: N crossing_event = ((p8[15:0] | NMSK[15:0]) == (NCRS[15:0] | NMSK[15:0])) where "|" is the boolean OR operator.

94.2.3.3 AMU P1 Pointer Channel *n* Register (AMU2_P1PTRCH*n*)

This register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit P1[*] input vector. This input vector is used in the stage1 calculation.

Table 2347. AMU2_P2PTRCH*n* field descriptions

Field	Description
17:29 PTR	Pointer into ARAM for the p2[*] vector. PTR[14:0] is a byte address. Since this array contains aligned 32-bit data elements, the two least significant address bits are fixed at zero.

94.2.3.5 AMU P3 Pointer Channel *n* Register (AMU2_P3PTRCH*n*)

In the normal operating mode, this register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit P3[*] input vector. This input vector is used in the

stage2 outer loop calculation as a scale factor in the accumulation of results from the exp(x) evaluation.

Due to its size, there are two methods for accessing this vector. In normal mode (AMU2_DCCRCH*n*[STMP3] = 0), the entire contents of the vector are written into the ARAM before the stage2 calculation begins; for this mode, the standard PTR[14:2] field defines the offset pointer into the ARAM. In the data streaming mode (AMU2_DCCRCH*n*[STMP3] = 1), PTR[31:2] defines a starting system Flash address for the P3[*] input. Note this mode requires the system Flash address be 8-byte aligned like all the other ADMA source data addresses. As data values are fetched, they are temporarily stored in the last 1 KB region of the ARAM, an area managed by the AMU2 for special data handling. For both modes of operation, the pointer value remains unchanged, even when data streaming. Finally, the pointer must reference the 0th element in the data array, even when starting or resuming a calculation with a non-zero P8 value. To summarize:

- if AMU2_DCCRCH*n*[STMP3] = 0, then PTR[14:2] defines P3 offset pointer into the ARAM.
- if AMU2_DCCRCH*n*[STMP3] = 1, then PTR[31:3] defines P3 pointer as a system Flash address.

Offset: 0x10018 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2461. AMU P3 Pointer Channel *n* Register (AMU2_P3PTRCH*n*)

Table 2348. AMU2_P3PTRCH*n* field descriptions

Field	Description
0:29 PTR	Pointer for the p3[*] vector. Depending on the data mode for the p3[*] vector, this field is used in two different ways: if AMU2_DCCRCH*n*[STMP3] = 0, then PTR[14:2] defines offset pointer into ARAM if AMU2_DCCRCH*n*[STMP3] = 1, then PTR[31:3] defines system Flash address PTR[31:0] is a byte address. The two least significant address bits are fixed at zero to enforce 4-byte (32 bit) alignment for the non-streaming configuration and the low-order three bits are forced to zero for the streaming configuration.

94.2.3.6 AMU P4 Channel *n* Register (AMU2_P4CH*n*)

This is the P4 data register. It is a 32-bit single-precision value used as a scale factor at the stage3 output normalization calculation.

Offset: 0x1001C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

94.2.3.10 AMU P8 Channel *n* Register (AMU2_P8CH*n*)

The P8 register contains two 16-bit unsigned integers related to the outer loop at the stage2 calculation. The upper halfword contains the threshold count for the ALU's speed control (see *Section 94.3.5.2: ALU speed control*), while the lower halfword is the starting value for the stage2 outer loop calculation.

As the stage2 outer loop iterates, the lower halfword of the AMU2_P8CH*n* register is incremented. If the calculation is stopped or halted, the register reflects the incremented loop count value. When the outer loop completes execution, it is restored to its initial value. This provides hardware support for the loop control such that this register does *not* have to be explicitly re-initialized for every calculation.

There is also an aliased read-only copy of this register available so that intermediate results associated with Y64 and P8 can be retrieved by the system DMA (SDMA) in a simple, sequential block transfer.

94.2.3.13 AMU V Pointer Channel *n* Register (AMU2_VPTRCH*n*)

In the normal operating mode, this register is a 4-byte aligned pointer into the ARAM defining the starting location for the 16-bit or 32-bit V[*] input array. It is used in the inner loop of the stage2 calculation in a difference evaluation.

The V[*] array supports three data formats as defined by the AMU2_CCR1CH*n*[V16, VFH, CMEXP] fields. The formats include a 32-bit single-precision floating-point, a 16-bit half-precision floating-point, and a 16-bit fixed-point format with a common 7-bit biased exponent. See *Section 94.2.3.21: AMU Control & Configuration 1 Channel n Register (AMU2_CCR1CHn)* for details on the selection of the formats and *Section 94.3.3.1: Floating-point data formats* and *Section 94.3.3.2: 16-bit fixed-point with common exponent* for information on these number formats.

The V[*] array is the only 2-dimensional data array used in the algorithm and is defined as V[p6, p7]. Its memory organization follows the standard C definition with a row-major ordering, that is, the sequential data elements as [0,0], [0,1], [0,2], …, [p6-1, p7-2], [p6-1, p7-1].

Due to its size, there are two methods for accessing this array. In normal mode (AMU2_DCCRCH*n*[STMV{32,16}] == 00), the entire contents of the array are written into the ARAM before the stage2 calculation begins; for this mode, the standard PTR[14:2] field defines the offset pointer into the ARAM. In the data streaming mode (AMU2_DCCRCH*n*[STMV{32,16}] != 00), PTR[31:3] defines a starting system Flash address for the V[*] input. Note this mode requires the system Flash address be 8-byte aligned like all the other ADMA source data addresses. As data values are fetched, they are temporarily stored in the last 1 KB region of the ARAM, an area managed by the AMU2 for special data handling. For both modes of operation, the pointer value remains unchanged, even when data streaming. Finally, the pointer must reference the [0,0] element in the data array, even when starting or resuming a calculation with a non-zero P8 value. To summarize:

- if AMU2_DCCRCH*n*[STMV{32,16}] = 00, then PTR[14:2] is V offset pointer into the ARAM.
- if AMU2_DCCRCH*n*[STMV{32,16}]!= 00, then PTR[31:3] is V pointer as Flash address.

Offset: 0x10038 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2469. AMU V Pointer Channel *n* Register (AMU2_VPTRCH*n*)

Table 2356. AMU2_VPTRCH*n* field descriptions

Field	Description
0:29 PTR	Pointer for the v[*] array. Depending on the data mode for the v[*] array, this field is used in two different ways: – if AMU2_DCCRCH*n*[STMV{32,16}] == 00, then PTR[14:2] is offset pointer into ARAM. – if AMU2_DCCRCH*n*[STMV{32,16}] != 00, then PTR[31:3] is system Flash address. PTR[31:0] is a byte address. The two least significant address bits are fixed at zero to enforce 4-byte (32 bit) alignment for the non-streaming configuration and the low-order three bits are forced to zero for the streaming configuration.

94.2.3.14 AMU L Pointer Channel *n* Register (AMU2_LPTRCH*n*)

This register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit L[*] input vector. It is used in the inner loop of the stage2 calculation as a scale factor in the accumulation of squared differences.

Offset: 0x1003C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Field	Description
17:29 PTR	Pointer into ARAM for the L[*] vector. PTR[14:0] is a byte address. Since this array contains aligned 32-bit data elements, the two least significant address bits are fixed at zero.

94.2.3.15 AMU U Pointer Channel *n* Register (AMU2_UPTRCH*n*)

This register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit single-precision U[*] input vector. It is used in the stage1 calculation.

94.2.3.16 AMU DMA Source Address Channel *n* Register (AMU2_DSACH*n*)

This is the ADMA's source 8-byte aligned pointer into the system Flash region (including remapped accesses into on- and off-chip calibration memories or system RAM, or both). Depending on configuration information in the AMU2_DCCRCH*n* register, this register may be automatically updated during a data transfer, or left unchanged.

Table 2359. AMU2_DSACH*n* field descriptions

Field	Description
0:28 PTR	ADMA source address in Flash region of the system memory map. For best performance and efficiency, this byte address is forced to doubleword (8-byte aligned) alignment, matching the AMU's private interface to the Flash controller.

94.2.3.17 AMU DMA Destination Address Channel *n* Register (AMU2_DDACH*n*)

This is the ADMA's destination 8-byte aligned offset pointer into the ARAM. Depending on configuration information in the AMU2_DCCRCH*n* register, this register may be automatically updated during a data transfer, or left unchanged.

The ADMA also supports a mode where the last 8 bytes are written directly into the AMU2_CCR{1,2}CH*n* registers so that a data transfer can be coupled with the initiation of a calculation in the context of a single transfer. This mode is enabled by the AMU2_DCCRCH*n*[DARU] register field and affects the final value of the AMU2_DDACH*n* register.

Table 2360. AMU2_DDACH*n* field descriptions

Field	Description
17:28 PTR	ADMA destination address in the ARAM. For best performance and efficiency, this byte address is enforced to a doubleword (8-byte aligned) alignment, matching the AMU's private interface to the Flash controller.

94.2.3.18 AMU DMA Transfer Count Channel *n* Register (AMU2_DCNTCH*n*)

This register contains two unsigned 16-bit byte counts associated with the current ADMA transfer operation. The upper halfword contains the threshold byte count associated with the ADMA's speed control function (see *Section 94.3.6.5: ADMA speed control*). The lower halfword defines the number of bytes to be transferred in the current ADMA operation. Based on ADMA address alignments, both counts are forced to be a multiple of 8 bytes.

Offset: 0x1004C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

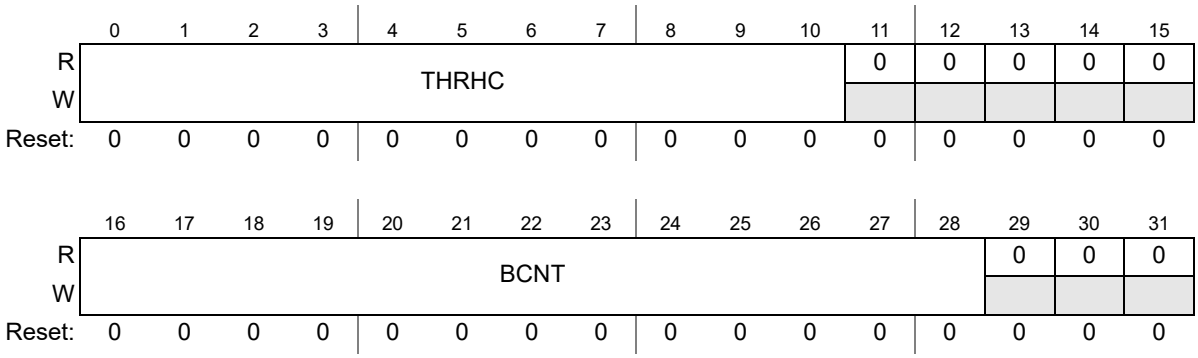

Figure 2474. AMU DMA Transfer Count Channel *n* Register (AMU2_DCNTCH*n*)

Table 2361. AMU2_DCNTCH*n* field descriptions

Field	Description
0:10 THRHC	Threshold Count. This 16-bit unsigned integer defines the threshold count used in the ADMA speed control function. There are additional control fields associated with this function in the AMU2_DCCRCH*n* register. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. The count is forced to be 32-byte aligned to match the ADMA's fetch size from the system Flash private connection.
16:28 BCNT	ADMA transfer byte count in a 16-bit unsigned integer format and forced to be an 8-byte aligned count.

94.2.3.19 AMU DMA Checksum Channel *n* Register (AMU2_DCKSCH*n*)

This is the expected ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the expected checksum result. If enabled, the checksum accumulated by the ADMA is compared to this value at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

Offset: 0x10050 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Table 2362. AMU2_DCKSCH*n* field descriptions

Field	Description
0:31 UINT	Expected ADMA checksum in a 32-bit unsigned integer format.

94.2.3.20 AMU DMA Control & Configuration Channel *n* Register (AMU2_DCCRCH*n*)

The AMU2_DCCRCH*n* register defines the operating configuration for the ADMA. It includes a speed control function, fields that configure the operation of the source and destination ADMA addresses, CRC configuration controls, fields to configure data streaming for the P3 and V vectors, an enable for an ARAM initialization function, conditional and unconditional start flags, plus stop and resume controls.

The conditional start flags (AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI]) can be used to trigger ADMA transfers after the ALU completes execution of specific parts of the algorithm.

Offset: 0x10054 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Table 2363. AMU2_DCCRCH*n* field descriptions

Field	Description
1:3 SRTSP	Start Speed This 3-bit encoded value defines the start speed for the ADMA channel. It is used with the MAXSP field and AMU2_DCNTCH*n*[THRHC] with the current speed of the ADMA is reported in AMU2_SEIRCH*n*[DCURSP]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
5:7 MAXSP	Maximum Speed This 3-bit encoded value defines the maximum speed for the ADMA channel. It is used with the SRTSP field and AMU2_DCNTCH*n*[THRHC] with the current speed of the ADMA is reported in AMU2_SEIRCH*n*[DCURSP]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. This field uses the same definition as SRTSP above.
8:9 ADICFG	ADma Interrupt ConFiGuration This 2-bit field provides the reporting mechanism associated with the ADMA complete indicator flag (AMU2_SEIRCH*n*[ADIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ADMA completion 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement 11 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement
10:11 SARU	Source Address Register Update This 2-bit field controls the updating of the AMU2_DSACH*n* register. 00 ADMA does not modify the original starting value of AMU2_DSACH*n* 01 ADMA does not modify the original starting value of AMU2_DSACH*n* 10 ADMA increments the AMU2_DSACH*n* as the data transfer occurs. The final value points to the next 8-byte aligned system Flash address 11 ADMA increments the AMU2_DSACH*n* as the data transfer occurs and, after the final transfer, “rounds up” to the next 32-byte aligned system Flash page address

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
12:13 DARU	Destination Address Register Update This 2-bit field controls the updating of the AMU2_DDACH*n* register. 00 ADMA does not modify the original starting value of AMU2_DDACH*n* 01 ADMA uses AMU2_DDACH*n* + the current byte counter as the ARAM write address as each data transfer occurs *except for the final 8-byte transfer*. Both the AMU2_DDACH*n* and AMU2_DCNTCH*n* register values are unchanged. This value enables the special ADMA transfer where the last 8 bytes are *not* written into the ARAM, but instead are written into the AMU2_CCR{1,2}CH*n* registers. For this mode, the contents of AMU2_DCNTCH*n* defines the total number of data bytes to be transferred + 8 (for the final 8-byte transfer to the AMU2_CCR{1,2}CH*n*). Additionally, if DCCRCH*n*[DECC] = 0, any required single-bit corrections on the fetched data, including that destined for AMU2_CCR{1,2}CH*n*, are performed before being forwarded to the destination (either the ARAM or the control & configuration registers). If a non-correctable ECC event is detected on the last 64-bit data fetch, the update of the AMU2_CCR{1,2}CH*n* registers is not performed to avoid any inadvertent ALU activity 10 ADMA increments the AMU2_DDACH*n* as each data transfer occurs *including* the last transfer. The final value points to the next 8-byte aligned ARAM address 11 ADMA increments the AMU2_DDACH*n* as each data transfer occurs *including* the last transfer. The final value points to the next 8-byte aligned ARAM address
14 HCRCE	Halt on Cyclic Redundancy Check Error This bit determines the AMU2's response to a properly-enabled (ECRC == 1) CRC checksum error. 0 AMU2 continues calculation regardless of the error status associated with a CRC checksum 1 AMU2 halts execution if a CRC checksum error is detected when DCCRCH*n*[ECRC] = 1
15 ECRC	Enable Cyclic Redundancy Check This bit enables the ADMA's calculation of a CRC checksum as data is written into the ARAM. The expected 32-bit checksum result is defined in the AMU2_DCKSCH*n* register. 0 ADMA checksum is disabled 1 ADMA checksum is enabled
16 CADS	Clear ADMA State Setting this bit resets the DMA status state machine (AMU2_SEIRCH*n*[ADMAS]) to idle. The use of this bit is intended for situations where halted or stopped data transfers are *not* continued. This bit always reads as a zero. See *Section 94.3.6.2: ADMA execution states* for more information. 0 Do not reset the ADMA status state machine to idle 1 Reset the ADMA status state machines to idle
17 DECC	Disable ADMA ECC single bit corrections Setting this bit disables the ADMA's ECC logic from performing single-bit corrections and double-bit detections on data to be written into the ARAM and optionally sent to the CRC logic for checksum generation. This bit is intended for test and debug purposes. 0 Enable single-bit corrections and double-bit detections on corrupted data fetched from the system Flash address space 1 Disable single-bit corrections and double-bit detections on corrupted data fetched from the system Flash address space

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
18 STMP3	Stream the P3 vector into a 128-byte ARAM circular FIFO When enabled, the P3 vector is fetched from the system Flash using the AMU2_P3PTRCH*n* register (which is incremented) and written into a dedicated 128-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual P3 vector in Flash are likely - the AMU2_P3PTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is *not* supported. The streaming of P3 data is initiated when STMP3 = 1 and SRT = 1. Concurrent streaming of the V array can be supported by also setting STMV{32,16} != 00. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports either normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC18] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMP3] = AMU2_CCR2CH*n*[ADCCR18]. 0 P3 streaming mode is disabled 1 P3 streaming mode is enabled
19 STMV32	Stream the 32-bit V array into a 256-byte ARAM circular FIFO When enabled, the 32-bit V array is fetched from the system Flash using the AMU2_VPTRCH*n* register (which is incremented) and written into a dedicated 256-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual V array in Flash are likely - the AMU2_VPTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is *not* supported. The separate STMV{32,16} are required so the ADMA can begin the appropriate data transfer *before* the AMU2_CCR1CH*n*[V16] is configured. It is software's responsibility to insure the STMV{32,16} and AMU2_CCR1CH*n*[V16] settings are consistent. The definition of the 2-bit {STMV32, STMV16} configuration bits is: (00) All V streaming is disabled (01) 16-bit V streaming is enabled (10) 32-bit V streaming is enabled (11) 32-bit V streaming is enabled The streaming of V data is initiated when STMV{32, 16} != 00 and SRT = 1. Concurrent streaming of the P3 vector can be supported by also setting STMP3 = 1. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports *either* normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC19] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMV32] = AMU2_CCR2CH*n*[ADCCR19]. 0 V32 streaming mode is disabled 1 V32 streaming mode is enabled

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
20 STMV16	Stream the 16-bit V array into a 256-byte ARAM circular FIFO When enabled, the 16-bit V array is fetched from the system Flash using the AMU2_VPTRCH*n* register (which is incremented) and written into a dedicated 256-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual V array in Flash are likely - the AMU2_VPTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is not supported. The separate STMV{32,16} are required so the ADMA can begin the appropriate data transfer *before* the AMU2_CCR1CH*n*[V16] is configured. It is software's responsibility to insure the STMV{32,16} and AMU2_CCR1CH*n*[V16] settings are consistent. 0 V16 streaming mode is disabled 1 V16 streaming mode is enabled The definition of the 2-bit {STMV32, STMV16} configuration bits is: (00) All V streaming is disabled (01) 16-bit V streaming is enabled (10) 32-bit V streaming is enabled (11) 32-bit V streaming is enabled The streaming of V data is initiated when STMV{32,16} != 00 and SRT = 1. Concurrent streaming of the P3 vector can be supported by also setting STMP3 = 1. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports *either* normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC20] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMV16] = AMU2_CCR2CH*n*[ADCCR20].
21 EHP	Enable High Priority The ADMA's private connection with the platform Flash controller includes a signal that elevates the priority of a data request versus requests from the other system bus masters. By default, the ADMA's priority is lower than the other system bus masters. However, when this control signal is asserted, the ADMA's request is given highest priority within the platform Flash controller. The assertion of this high priority signal is controlled by three mechanisms: (1) For non-streamed ADMA transfers, the high priority control signal is asserted based on the setting of the ADMA speed control and the platform Flash controller's response time. If the responses are too slow, the ADMA asserts the high priority signal. (2) For streamed ADMA transfers, the high priority control signal is asserted based on the setting of the ALU speed control and the platform Flash controller's response time. Again, if the responses are too slow based on the ALU's need for new data, the ADMA asserts the high priority signal. (3) If this EHP bit is set, the high priority control signal is unconditionally asserted. 0 ADMA does not unconditionally assert the high priority signal to the platform Flash controller 1 ADMA does unconditionally assert the high priority signal to the platform Flash controller

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
22 DSAS	ADMA Stop if Alu Stops. This bit provides a mechanism to automatically stop the ADMA channel transfer requests if the ALU stops for any reason. This bit applies to non-streamed ADMA transfers. When streaming P3 or V, or both, the ADMA automatically stops streaming if/when the ALU is stopped or halted, and automatically resumes streaming when the calculation is resumed. 0 ALU stops do not affect the ADMA 1 ALU stops force the ADMA to also stop
23 STP	ADMA Stop request The setting of this indicator bit signals the ADMA to stop at the next appropriate point. The ADMA run status is available in AMU2_SEIRCH*n*[ADMAS]. If the P3 vector or V array, or both, are being streamed, the ADMA data transfers are paced by the ALU calculation speed, so any stop or halt condition to the ALU automatically stalls the ADMA. Note the simultaneous assertion of the STP and any conditional (WFS1D, WFS23D, WFDNI) or unconditional (SRT) start indicators causes the attempted ADMA initiation to *effectively be ignored* with no change in the AMU2_SEIRCH*n*[ADMAS] status. 0 No ADMA stop request; it operates normally 1 ADMA stop request; stop data transfer at the next appropriate point. Once the ADMA stops, this indicator is cleared.
24 DEICFG	ADMA Error Interrupt Conflguration This field controls the reporting mechanism associated with the ADMA error indicator flag (AMU2_SEIRCH*n*[DEIRQ]). 0 If an ADMA error is detected, set the indicator flag; the flag is explicitly cleared by software. 1 If an ADMA error is detected, set the indicator flag and assert core interrupt request; the flag is explicitly cleared by software.
25 WFDNI	Wait For ALU Done Interrupt request This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage2 + 3 calculations complete and set the AMU2_SEIRCH*n*[DNIRQ] indicator. This condition is signaled by (AMU2_SEIRCH*n*[DNIRQ] = 1'b1). If the ALU is idle when the AMU2_DCCRCH*n* register is loaded and a conditional ADMA start after the next ALU calculation completes is desired, the WFDNI indicator should be used. Once the ADMA transfer begins, this indicator bit is automatically cleared. Writes to AMU2_CCR2CH*n*[ADCC25] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFDNI] = AMU2_CCR2CH*n*[ADCCR25]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage2 + 3 calculations complete, and set AMU2_SEIRCH*n*[DNIRQ]

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
26 WFS23D	Wait For Stage23 Done This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage2 + 3 calculations are complete. This condition is signaled by (AMU2_SEIRCH*n*[S23XS] == 2'b00). Once the ADMA transfer begins, this indicator bit is automatically cleared. If the ADMA's data transfer must be delayed until the entire ALU calculation is complete, then both WFS1D and WFS23D must be asserted. Alternatively, the WFDNI flag can be used as the conditional ADMA start condition. Writes to AMU2_CCR2CH*n*[ADCC26] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFS23D] = AMU2_CCR2CH*n*[ADCCR26]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage2 + 3 calculations are complete
27 WFS1D	Wait For Stage1 Done This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage1 calculation is complete. This condition is signaled by (AMU2_SEIRCH*n*[S1XS] == 2'b00). Once the ADMA transfer begins, this indicator bit is automatically cleared. If the ADMA's data transfer must be delayed until the entire ALU calculation is complete, then both WFS1D and WFS23D must be asserted. Alternatively, the WFDNI flag can be used as the conditional ADMA start condition. Writes to AMU2_CCR2CH*n*[ADCC27] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFS1D] = AMU2_CCR2CH*n*[ADCCR27]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage1 calculation is complete
28 RSM	ADMA ReSuMe The assertion of a properly-qualified resume condition ((RSM == 1) && (STP == 0)) resumes the data transfer defined by the contents of the ADMA's registers, exiting from the stopped state. This bit applies to non-streamed ADMA transfers. When streaming P3 or V, or both, the ADMA automatically stops streaming if/when the ALU is stopped or halted, and automatically resumes streaming when the calculation is resumed. Once the ADMA resumes execution, this indicator bit is automatically cleared. 0 Do not resume the ADMA 1 Resume the ADMA's data transfer

Table 2363. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
30 FARZ	Force ARAM to Zero The assertion of this indicator flag enables a special ADMA mode of operation where up to 16 bytes of zero data (with the appropriate ECC check bits) are written into the ARAM destination defined by AMU2_DDACH*n* on alternating cycles. This ARAM initialization mode functions in a manner similar to a normal ADMA data transfer. Instead of fetching data from the Flash (or one of its remapped destination memories), the ADMA forces all zero data with correct ECC to be written into the ARAM. The AMU2_DSACH*n* register is *not* used, but the starting destination address is defined by AMU2_DDACH*n* and the size of the memory to be cleared by AMU2_DCNTCH*n*[BCNT]. The CRC is not supported in this mode, and AMU2_DCCRCH*n*[DARU] must be 0b00. The ARAM initialization is initiated by setting AMU2_DCCRCH*n*[SRT] = 1. All the ADMA status reporting operates like a normal data transfer. It is recommended that the other ADMA channel be idle during this initialization function. 0 The zeroing of the ARAM by the ADMA is disabled 1 The zeroing of the ARAM by the ADMA is enabled
31 SRT	ADMA Start request. This assertion of a properly-qualified start condition ((SRT == 1) && (STP == 0)) initiates the data transfer defined by the contents of the ADMA's registers. Once ADMA starts execution, this indicator bit is automatically cleared. Writes to AMU2_CCR2CH*n*[ADCC31] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[SRT] = AMU2_CCR2CH*n*[ADCCR31]. 0 Do not unconditionally start the ADMA 1 Unconditionally start the ADMA

94.2.3.21 AMU Control & Configuration 1 Channel *n* Register (AMU2_CCR1CH*n*)

AMU2_CCR1CH*n* is the first of two control and configuration registers defining the operation of the ALU.

Table 2364. AMU2_CCR1CH*n* field descriptions

Field	Description
1:3 SRTSP	Start Speed This 3-bit encoded value defines the start speed for the ALU engine. It is used with the MAXSP field and AMU2_P8CH*n*[THRHC] with the current speed of the ALU is reported in AMU2_SEIRCH*n*[ACURSP]. The ALU speed control provides a mechanism to control the operation efficiency of the engine for coarse power control of the AMU. See *Section 94.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
5:7 MAXSP	Maximum Speed This 3-bit encoded value defines the maximum speed for the ALU engine. It is used with the SRTSP field and AMU2_P8CH*n*[THRHC] with the current speed of the ALU is reported in AMU2_SEIRCH*n*[ACURSP]. The ALU speed control provides a mechanism to control the operation efficiency of the engine for coarse power control of the AMU. See *Section 94.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models. 000 Maximum speed 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
8:9 AEICFG	ALU Error Interrupt ConFiGuration This 2-bit field provides the reporting mechanism associated with the ALU error indicator flag (AMU2_SEIRCH*n*[ERIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU error condition 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU error condition 11 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software

Table 2364. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
10:11 OVICFG	Overflow Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU overflow indicator flag (AMU2_SEIRCH*n*[OVIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU overflow condition. 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software. 10 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU overflow condition. 11 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software.
12:13 NCICFG	N Crossing Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU N crossing indicator flag (AMU2_SEIRCH*n*[NCIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU N crossing condition 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement.The AMU2_CCR2CH*n*[SNCRS] indicator should be set so the ALU stops its calculation so the correct intermediate result is available for the SDMA 11 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement.The AMU2_CCR2CH*n*[SNCRS] indicator should be set so the ALU stops its calculation so the correct intermediate result is available for the SDMA
14:15 DNICFG	ALU Done Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU done, that is, a calculation has successfully completed, indicator flag (AMU2_SEIRCH*n*[DNIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU done condition. 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software. 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement 11 Set indicator flag, initiate an ADMA transfer if one of the conditional start flags (AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI]) is also asserted. The AMU2_SEIRCH*n*[DNIRQ] flag is cleared by the AMU
16 BPRI	Bus Priority This indicator bit controls the bus arbitration priority associated with the ARAM and the programming model registers. Recall from *Figure 2456: AMU2 block diagram*, there are multiple master devices that can access the ARAM and programming model registers, specifically, the ADMA and ALU as well as system bus transfers routed via slave peripheral bus. This indicator bit controls the arbitration policy for selecting one master's request when concurrent accesses occur; idle cycles from the selected master provide opportunities for stalled accesses from other masters to be granted and complete. 0 ADMA has higher arbitration priority than the ALU which has higher priority than slave peripheral bus accesses (ADMA > ALU > slave peripheral bus) 1 ADMA has higher arbitration priority than slave peripheral bus accesses which have higher priority than the ALU (ADMA > slave peripheral bus > ALU)

Table 2364. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
17 EECC	Enable Error Correcting Code (ECC) in the ARAM This bit controls the checking of data read from the ARAM by the ALU and the slave peripheral bus. Note, ECC is generated on all writes to the ARAM from either the ADMA or the slave peripheral bus. If a single-bit error is detected by the ECC logic on an ARAM read, the corrected data is written back into the ARAM *only* in response to the read-modify-write sequence needed on all slave peripheral write accesses. 0 ECC checking of ARAM reads is disabled 1 ECC checking of ARAM reads is enabled If the system DMA is used for ARAM initialization, the EECC bits for *both* channels must be cleared until the initialization is complete.
18 DDSL	Disable Debug Stall This bit disables the AMU from stalling when an MCU debug event is underway. 0 All debug events, as signaled by an input signal, stall the AMU. The stall globally affects both channels of the ADMA and ALU 1 Debug events do not affect the AMU

19
SETZ
	Set Z result
	This bit controls the first operation performed in the ALU's stage3 output normalization. As the name implies, if this bit is asserted, the final result (z64) is set to the P5 data value, else it is unaffected. The second operation in stage3 involves a final accumulation with the result plus the product of y64 and p4.
	The stage3 output normalization pseudo-code is:
	`/* stage 3: output normalization */`
	`if (setz) {`
	`z64 = (ieee64) p5;`
	`}`
	`z64 = z64 + (ieee32) y64 * p4; // 32 x 32 -> 64 FMA`
	0 z64 is unaffected
	1 z64 is set to the 64-bit double-precision value of p5

20 ESTZC	Enable SETZ Clear If set, this bit forces the SETZ flag to be automatically cleared after a stage3 calculation as indicated by the assertion of AMU2_SEIRCH*n*[DNIRQ]. 0 SETZ flag is not cleared by the hardware. 1 SETZ flag is automatically cleared by the hardware after the stage3 calculation completes.
23 V16	V is a 16-bit data format This bit, along with VFH, defines the format for the V array: if V16 = 0, then V[*] is 32-bit single-precision format (ieee32) if V16 = 1 && VFH = 0, then V[*] is 16-bit half-precision format (ieee16) if V16 = 1 && VFH = 1, then V[*] is 16-bit fixed-point format with a common 7-bit biased exponent This bit cannot be changed while the ADMA is streaming V[*] data. See *Section 94.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.

Table 2364. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
24 VFH	V is Fixed Halfword format This bit, along with V16, defines the format for the V array: if V16 = 0, then V[*] is 32-bit single-precision format (ieee32) if V16 = 1 && VFH = 0, then V[*] is 16-bit half-precision format (ieee16) if V16 = 1 && VFH = 1, then V[*] is 16-bit fixed-point format with a common 7-bit biased exponent See *Section 94.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.
25:31 CMEXP	Common Exponent This 7-bit field defines the common exponent using an excess-63 format for the V array's 16-bit fixed-point format. See *Section 94.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.

94.2.3.22 AMU Control & Configuration 2 Channel *n* Register (AMU2_CCR2CH*n*)

AMU2_CCR2CH*n* is the second of two control and configuration registers defining the operation of the ALU.

Offset: 0x1005C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2478. AMU Control & Configuration 2 Channel *n* Register (AMU2_CCR2CH*n*)

Table 2365. AMU2_CCR2CH*n* field descriptions

Field	Description
1 ADCCRE	Alternate DCCR write Enable This bit enables all the aliased AMU2_DCCRCH*n* indicators (AMU2_CCR2CH*n*[ADCR18, ADCCR19, ADCCR20, ADCCR25, ADCCR26, ADCCR27]) to be written when this register is updated. Clearing this bit allows software to write the AMU2_CCR2CH*n* without affecting the aliased control bits in the AMU2_DCCRCH*n*. The ADCCRE indicator always reads as a zero. 0 Contents of the write data for AMU2_CCR2CH*n*[ADCCR{18,19,20,25,26,27}] do not affect the AMU2_DcCRCH*n* 1 Contents of the write data for AMU2_CCR2CHn[ADCCR{18,19,20,25,26,27}] are loaded into AMU2_DCCRCH*n*
2 ADCCR18	Alternate AMU2_DCCRCH*n*[STMP3] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMP3], that is, AMU2_DCCRCH*n*[STMP3] = AMU2_CCR2CH*n*[ADCCR18], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMP3 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
3 ADCCR19	Alternate AMU2_DCCRCH*n*[STMV32] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMV32], that is, AMU2_DCCRCH*n*[STMV32] = AMU2_CCR2CH*n*[ADCCR19], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMV32 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
4 ADCCR20	Alternate AMU2_DCCRCH*n*[STMV16] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMV16], that is, AMU2_DCCRCH*n*[STMV16] = AMU2_CCR2CH*n*[ADCCR20], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMV16 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
9 ADCCR25	Alternate AMU2_DCCRCH*n*[WFDNI] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFDNI], that is, AMU2_DCCRCH*n*[WFDNI] = AMU2_CCR2CH*n*[ADCCR25], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFDNI indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
10 ADCCR26	Alternate AMU2_DCCRCH*n*[WFS23D] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFS23D], that is, AMU2_DCCRCH*n*[WFS23D] = AMU2_CCR2CH*n*[ADCCR26], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFS23D indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
11 ADCCR27	Alternate AMU2_DCCRCH*n*[WFS1D] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFS1D], that is, AMU2_DCCRCH*n*[WFS1D] = AMU2_CCR2CH*n*[ADCCR27], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFS1D indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.

Table 2365. AMU2_CCR2CH*n* field descriptions (continued)

Field	Description
12 ADCCR31	Alternate AMU2_DCCRCH*n*[SRT] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[SRT], that is, AMU2_DCCRCH*n*[SRT] = AMU2_CCR2CH*n*[ADCCR31], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the SRT indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
14 ENCRS	Enable N CRoSsing event This bit enables the occurrence of an N crossing event. 0 The ALU's N crossing logic is disabled 1 The ALU's N crossing logic is enabled
15 SNCRS	Stop on N CRoSsing event This bit forces the ALU to stop execution on the occurrence of an N crossing event. 0 The ALU does not stop execution when an N crossing event occurs 1 The ALU stops execution when an N crossing event occurs
16 CSXXS	Clear Stage "X" eXecution State Setting this bit resets both the ALU execution state machines (AMU2_SEIRCH*n*[S1XS, S23XS]) to idle. The use of this bit is intended for situations where halted or stopped calculations are *not* continued. This bit always reads as a zero. 0 Do not reset the ALU execution state machines to idle 1 Reset both of the ALU execution state machines to idle See *Section 94.3.5.1: ALU execution states* for more information.
23 S23STP	Stage23 STop request The setting of this indicator bit signals the ALU to stop at the completion of the current outer loop execution. If asserted *after* the final stage2 outer loop completes, stage3 also finishes and S23STP remains asserted indicating the stop request was not granted.The ALU's stage23 status is available in AMU2_SEIRCH*n*[S23XS]. Once the ALU is stopped, this indicator bit is automatically cleared. 0 No stage23 stop request; the ALU operates normally 1 Stage23 stop request; stop execution at the completion of the current outer loop iteration
25 WFSS23	Wait For Sdma complete before starting Stage23 This is a conditional start bit for stage23. It signals the stage23 execution start is enabled by the completion of an SDMA data transfer. This indicator is used when the SDMA is used to copy an AMU result into system memory. The setting of this flag means the SDMA result retrieval must be finished before a stage23 calculation is initiated. Once stage23 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage23 start condition 1 Initiate stage23's execution when the SDMA completes its current data transfer

Table 2365. AMU2_CCR2CH*n* field descriptions (continued)

Field	Description
26 WFDS23	Wait For aDma complete before starting Stage23 This is a conditional start bit for stage23. It signals the stage23 execution start is enabled by the completion of the ADMA data transfer. The WFDS23 indicator is automatically cleared if the ADMA halts due to a bus or non-correctable ECC error, or if a checksum error is detected. This prevents the ALU stage23 execution from starting after the ADMA halt condition is processed by a service routine. The WFDS23 conditional start indicator can be combined with WFDS1. If both bits are asserted, as the ADMA completes its data transfer, the ALU begins execution of stage1, followed by stage23. Once stage23 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage23 start condition 1 Initiate stage23's execution when the ADMA completes its current data transfer
27 WFDS1	Wait For aDma complete before starting Stage1 This is a conditional start bit for stage1. It signals the stage1 execution start is enabled by the completion of the ADMA data transfer. The WFDS1 indicator is automatically cleared if the ADMA halts due to a bus or non-correctable ECC error, or if a checksum error is detected. This prevents the ALU stage1 execution from starting after the ADMA halt condition is processed by a service routine. The WFDS1 conditional start indicator can be combined with WFDS23. If both bits are asserted, as the ADMA completes its data transfer, the ALU begins execution of stage1, followed by stage23. Once stage1 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage1 start condition 1 Initiate stage1's execution when the ADMA completes its current data transfer.
28 S23RSM	Stage23 ReSuMe This bit resumes a stopped stage23 calculation. If stage23 is not stopped at the time of an attempted write to assert this bit, it is ignored. Once stage23 resumes execution, this indicator bit is automatically cleared. 0 Do not resume a stopped stage23 calculation 1 Resume a stopped stage23 calculation
30 S23SRT	Stage23 StaRT request. This assertion of a properly-qualified start condition ((S23SRT == 1) && (S23STP == 0)) initiates the ALU's stage23 execution. If S1SRT is also asserted, the ALU hardware sequences through the execution, first of stage1 and then stage23. Once stage23 starts execution, this indicator bit is automatically cleared. 0 Do not unconditionally start ALU's stage23 execution 1 Unconditionally start ALU's stage23 execution, either immediately or after stage1 completes
31 S1SRT	Stage1 StaRT request. This assertion of this start condition initiates the ALU's stage1 execution. Once stage1 starts execution, this indicator bit is automatically cleared. 0 Do not unconditionally start ALU's stage1 execution 1 Unconditionally start ALU's stage1 execution

94.2.3.23 AMU RES64M Channel *n* Register (AMU2_RES64MCH*n*)

This is the read-only final 64-bit double-precision result register. It is the z64 final accumulation from the stage3 output normalization calculation and is loaded into this register as the calculation completes. It is described here as the concatenation of two 32-bit words with RES64{M,L} defining the most significant and least significant words.

Figure 2480. AMU RES64L Channel *n* Register (AMU2_RES64LCH*n*)

Table 2367. AMU2_RES64LCH*n* field descriptions

Field	Description
0:31 IEEE64	Least significant word of the final result value in IEEE 64-bit floating-point format. This is the RES64LCH*n* register.

94.2.3.25 AMU Status, Error & Interrupt Channel *n* Register (AMU2_SEIRCH*n*)

This is the AMU's status register. The most significant three bytes contain read-only status and error flags, while the low-order byte contains the interrupt flag bits. Specifically, there are 15 status bits signaling the state of the ADMA, stage1 and stage23 ALU calculations, along with the current speed settings, 9 error flags signaling arithmetic faults in the ALU or other error conditions, and 6 interrupt request flags.

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address) and this status register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Certain error flag indicators in this register are cleared by a read of the register; there is an alternate location of this register (see *Section 94.2.3.33: AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)*) where a read does not affect these status flags. Accordingly, software polling of the CHBSY flag should use the alternate AMU2_SEINCCH*n* register so that no fault status bits are inadvertently cleared.

It should be noted the interrupt flags are intended to record the completion of an event or the occurrence of an error condition. These flags are set when the event occurs, while the subsequent reporting of the event is defined by the corresponding interrupt configuration field, specifically AMU2_DCCRCH*n*[ADICFG, DEICFG] and AMU2_CCR1CH*n*[AEICFG, OVICFG, NCICFG, DNICFG]. The event's reporting can be configured to *not* perform any type of asynchronous notification (intended for software polling applications), a processor interrupt, or depending on the event, a system DMA or ADMA request. For DMA requests (both system and AMU), the hardware clears the indicator event flag as the request is acknowledged; for the software polling configuration or processor interrupts, a service routine or another software task must explicitly clear the event flag by writing a logical 1 to the corresponding interrupt flag. This is a "write 1" clear protocol.

Figure 2481. AMU Status, Error & Interrupt Channel *n* Register (AMU2_SEIRCH*n*)

Table 2368. AMU2_SEIRCH*n* field descriptions

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. This flag is asserted when ((AMU2_SEIRCH*n*[ADMAS] == 0b11) || (AMU2_SEIRCH*n*[S1XS] == 0b11) || (AMU2_SEIRCH*n*[S23XS] == 0b11)). 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled

Table 2368. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
4:5 S1XS	Stage1 eXecution Status This read-only 2-bit field defines the execution status of the ALU's stage1 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execution cannot be stopped via a request 11 Running or stalled
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 94.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event.
9:11 ACURSP	Alu Current Speed This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.

Table 2368. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32. 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value.
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation. 1 Arithmetic fault associated with the ALU's stage3 calculation was detected.
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation. 1 Arithmetic fault associated with the ALU's stage1 calculation was detected.
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data 1 Arithmetic fault associated with the input data was detected

Table 2368. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such as bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does not include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other errors, was detected
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected

Table 2368. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error
27 ADIRQ	ADMA Interrupt ReQuest. This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2384: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition

Table 2368. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

94.2.3.26 AMU Actual Checksum Channel *n* Register (AMU2_ACKSCH*n*)

This is the actual read-only ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the actual checksum result. If enabled, this register is cleared at the beginning of the ADMA transfer, the actual checksum accumulated by the ADMA in this register and then compared to expected value contained in the AMU2_DCKSCH*n* register at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address), the status register and this register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Offset: 0x1008C + n * 0x100 (n = 0 to 1) Access: Supervisor Read

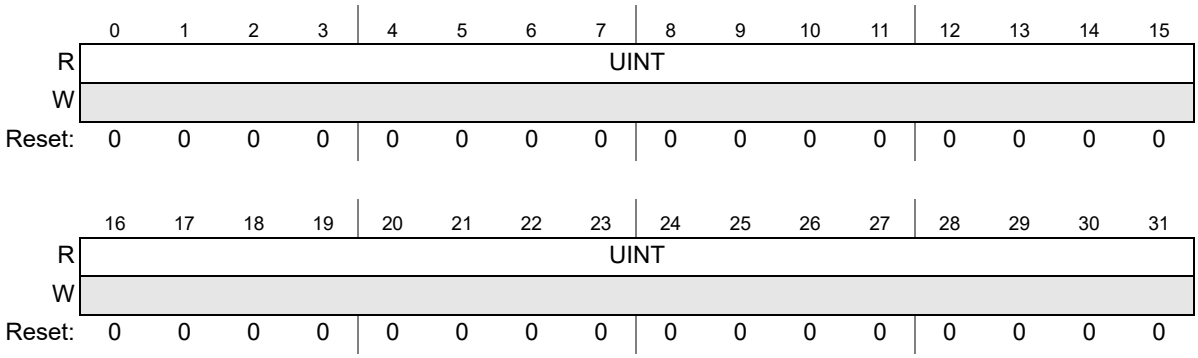

Figure 2482. AMU Actual Checksum Channel *n* Register (AMU2_ACKSCH*n*)

Table 2369. AMU2_ACKSCH*n* field descriptions

Field	Description
0:31 UINT	Actual ADMA checksum in a 32-bit unsigned integer format.

94.2.3.27 AMU RES32 Channel *n* Register (AMU2_RES32CH*n*)

This is the read-only 32-bit single-precision version of the final 64-bit double-precision result register, that is, this is “z32”, derived from the z64 final accumulation from the stage3 output normalization calculation.

Offset: 0x10090 + n * 0x100 (n = 0 to 1) Access: Supervisor Read

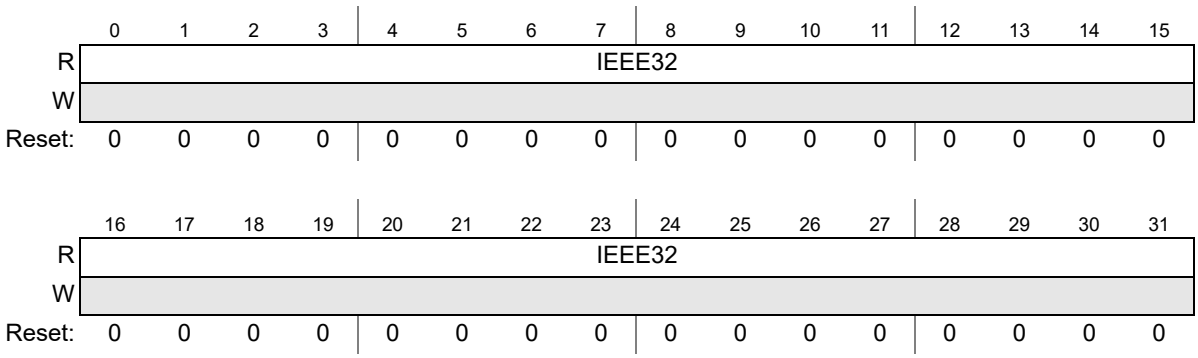

Figure 2483. AMU RES32 Channel *n* Register (AMU2_RES32CH*n*)

Table 2370. AMU2_RES32CH*n* field descriptions

Field	Description
0:31 IEEE32	Single-precision version (IEEE 32-bit floating-point format) of the final 64-bit result (z64) value.

94.2.3.28 Aliased copy of AMU Status, Error & Interrupt Channel *n* Register (AMU2_ASEIRCH*n*)

This is the AMU's status register. The most significant three bytes contain read-only status and error flags, while the low-order byte contains the interrupt flag bits. Specifically, there are 15 status bits signaling the state of the ADMA, stage1 and stage23 ALU calculations, along with the current speed settings, 9 error flags signaling arithmetic faults in the ALU or other error conditions, and 6 interrupt request flags.

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address) and this status register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Certain error flag indicators in this register are cleared by a read of the register; there is an alternate location of this register (see *Section 94.2.3.33: AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)*) where a read does not affect these status flags. Accordingly, software polling of the CHBSY flag should use the alternate AMU2_SEINCCH*n* register so that no fault status bits are inadvertently cleared.

It should be noted the interrupt flags are intended to record the completion of an event or the occurrence of an error condition. These flags are set when the event occurs, while the subsequent reporting of the event is defined by the corresponding interrupt configuration field, specifically AMU2_DCCRCH*n*[ADICFG, DEICFG] and AMU2_CCR1CH*n*[AEICFG, OVICFG, NCICFG, DNICFG]. The event's reporting can be configured to *not* perform any type of asynchronous notification (intended for software polling applications), a processor interrupt, or depending on the event, a system DMA or ADMA request. For DMA requests (both system and AMU), the hardware clears the indicator event flag as the request is acknowledged; for the software polling configuration or processor interrupts, a service routine or another software task must explicitly clear the event flag by writing a logical 1 to the corresponding interrupt flag. This is a "write 1" clear protocol.

Table 2371. AMU2_ASEIRCH*n* field descriptions

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled

Table 2371. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
4:5 S1XS	Stage1 Execution Status This read-only 2-bit field defines the execution status of the ALU's stage1 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execution cannot be stopped via a request 11 Running or stalled
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 94.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event.
9:11 ACURSP	ALU Current Speed This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.

Table 2371. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation 1 Arithmetic fault associated with the ALU's stage3 calculation was detected
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation 1 Arithmetic fault associated with the ALU's stage1 calculation was detected
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data. 1 Arithmetic fault associated with the input data was detected.

Table 2371. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such as bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does *not* include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other rerrors, was detected
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected

Table 2371. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error
27 ADIRQ	ADMA Interrupt Request This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error

Table 2371. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2384: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

94.2.3.29 Aliased copy of AMU Actual Checksum Channel *n* Register (AMU2_AACKSCH*n*)

This is the actual read-only ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the actual checksum result. If enabled, this register is cleared at the beginning of the ADMA transfer, the actual checksum accumulated by the ADMA in this register and then compared to expected value contained in the AMU2_DCKSCH*n* register at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address), the status register and this register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Field	Description
0:31 UINT	Actual ADMA checksum in a 32-bit unsigned integer format.

94.2.3.30 AMU Y64M Channel *n* Register (AMU2_Y64MCH*n*)

This is the read-only 64-bit double-precision register containing the y64 value at the completion of each iteration of the outer (stage 2) loop. It is described here as the concatenation of two 32-bit words with Y64{M,L} defining the most significant and least significant words.

Figure 2487. AMU Y64L Channel *n* Register (AMU2_Y64LCH*n*)

Table 2374. AMU2_Y64LCH*n* field description

Field	Description
0:31 IEEE64	Least significant word of the y64 value in IEEE 64-bit floating-point format at the completion of the stage2 outer loop. This is the Y64LCH*n* register.

94.2.3.32 Aliased copy of AMU P8 Channel *n* Register (AMU2_AP8CH*n*)

The P8 register contains two 16-bit unsigned integers related to the outer loop at the stage2 calculation. The upper halfword contains the threshold count for the ALU's speed control (see *Section 94.3.5.2: ALU speed control*), while the lower halfword is the starting value for the stage2 outer loop calculation.

As the stage2 outer loop iterates, the lower halfword of the AMU2_P8CH*n* register is incremented. If the calculation is stopped or halted, the register reflects the incremented loop count value. When the outer loop completes execution, it is restored to its initial value. This provides hardware support for the loop control such that this register does *not* have to be explicitly re-initialized for every calculation.

There is also an aliased read-only copy of this register available so that intermediate results associated with Y64 and P8 can be retrieved by the system DMA (SDMA) in a simple, sequential block transfer.

Offset: 0x100A8 + n * 0x100 (n = 0 to 1) Access: Supervisor Read

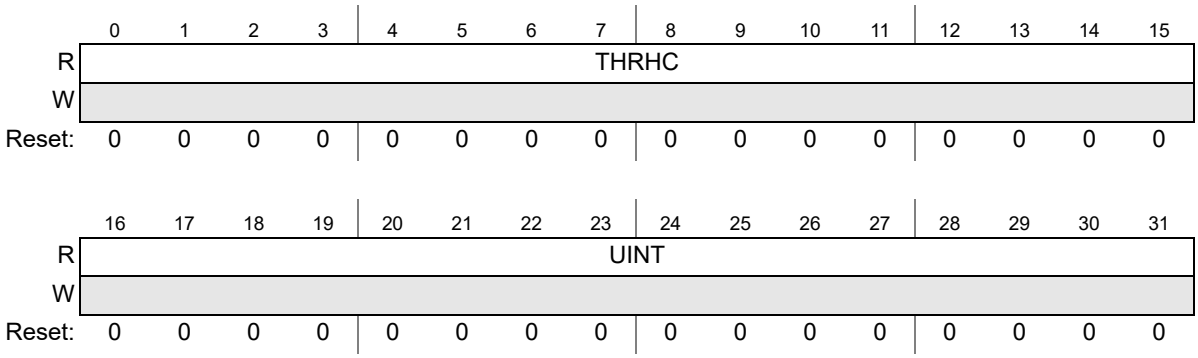

Figure 2488. AMU P8 Channel *n* Register (AMU2_AP8CH*n*)

Table 2375. AMU2_AP8CH*n* field descriptions

Field	Description
0:15 THRHC	Threshold Count This 16-bit unsigned integer defines the threshold count used in the ALU speed control function. There are additional control fields associated with this function in the AMU2_CCR1CH*n* register. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models.
16:31 UINT	Parameter p8 value in a 16-bit unsigned integer format.

94.2.3.33 AMU Status, Error & Interrupt No Clear Channel *n* Register (AMU2_SEINCCH*n*)

This is an alternate view of the AMU's status register. It contains read-only status (SEIRCH*n*[31:16]) and error flags (SEIRCH*n*[15:7]), plus the module's interrupt bits (SEIRCH*n*[4:0]).

For this version of the register, specific error status indicators are not cleared by a read of the register. This specifically affects the operation of AMU2_SEINCCH*n*[YCAFLT, ZCAFLT, S23AFLT, S1AFLT, IDVERR, ADMERR, CKSERR, ECCERR, RGCERR].

This register is read-only. When clearing the state of the interrupt request flags, use the AMU2_SEIRCH*n* registers.

Offset: 0x100AC + n * 0x100 (n = 0 to 1) Access: Supervisor Read

Figure 2489. AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)

Table 2376. AMU2_SEINCCHn field descriptions

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
4:5 S1XS	Stage1 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage1 logic. See *Section 94.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execu tion cannot be stopped via a request 11 Running or stalled

Table 2376. AMU2_SEINCCHn field descriptions (continued)

Field	Description
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 94.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event
9:11 ACURSP	Alu CURrent SPeed. This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 94.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value

Table 2376. AMU2_SEINCCHn field descriptions (continued)

Field	Description
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32. 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value.
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation 1 Arithmetic fault associated with the ALU's stage3 calculation was detected
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation 1 Arithmetic fault associated with the ALU's stage1 calculation was detected
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data 1 Arithmetic fault associated with the input data was detected
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does *not* include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other errors, was detected

Table 2376. AMU2_SEINCCHn field descriptions (continued)

Field	Description
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 ("write 1 clear") to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error.

Table 2376. AMU2_SEINCCHn field descriptions (continued)

Field	Description
27 ADIRQ	ADMA Interrupt Request This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – -Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2384: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition

Table 2376. AMU2_SEINCCHn field descriptions (continued)

Field	Description
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

94.2.3.34 AMU Y32 Channel *n* Register (AMU2_Y32CH*n*)

This is a read-only 32-bit single-precision (“y32”) version of the 64-bit double-precision y64 value at the completion of each iteration of the outer (stage 2) loop.

0:31 IEEE32	Single-precision version (IEEE 32-bit floating-point format) of the 64-bit result (y64) value.

94.3 Functional description

The AMU2 includes two independent channels, named channel 0 (ch0) and channel 1 (ch1), and featuring independent registers. Each channel logically includes a calculation engine and a DMA channel. The calculation engines share the same arithmetic logic using a time multiplexed scheme. Likewise, the DMA channels use a time multiplexed scheme to share common interfaces for fetching from the system Flash memory and writing into the ARAM. Once a calculation is initiated, the ALU engine executes the defined algorithm using data from the local ARAM (which is visible in the system memory map via the peripheral bus) or data streamed into the module from the private Flash connection by the ADMA. The ADMA executes data transfers from the system Flash (or the calibration remapped destination memories, or both) to the ARAM using a private interconnect.

94.3.1 AMU2 algorithm

As mentioned previously, the defined floating-point algorithm includes several loops with vector multiply-accumulate operations plus an evaluation of an exponential function while calculating a single double-precision output value. The algorithm is partitioned into 3 stages:

- Stage1: Input normalization within a single for() loop
- Stage2: Within two nested for() loops, accumulation of t in the inner loop, followed by calculation of exp(-t) and accumulation of y in the outer loop
- Stage3: Output normalization using y

The AMU2's hardware structure segments the algorithm into two parts for implementation: stage1 and stage23, where the latter includes both stage2 + stage3. The terms stage1, stage2 and stage23 are used throughout the document.

The stage1 and stage23 algorithms are defined in the following C pseudo-code. This description uses explicit references to `ieeexy` tags where *xy* = {16, 32, 64} defines the cast (and associated rounding) to the indicated precision in the subsequent floating-point calculations and `uintxy` defines an unsigned *xy*-bit integer.

94.3.1.1 Stage1 of the algorithm

```
void amuStage1(
    ieee32*  u,             // pointer to  u[p7] 32-bit single data array
    ieee32*  p1,            // pointer to p1[p7] 32-bit single data array
    ieee32*  p2,            // pointer to p2[p7] 32-bit single data array
    ieee32*  ut,            // pointer to ut[p7] 32-bit single data array
    uint05   p7             // dimension of the ASC function
) {
    uint16   k;             // local loop counter

    /* stage 1 */
    for (k = 0; k < p7; k++) {
        ut[k] = (ieee32) (u[k] * p1[k] + (ieee64) p2[k]); // 32x32 -> 64 FMA
    }
}
```

94.3.1.2 Stage23 (2 & 3) of the algorithm

```
void amuStage23(
    ieee32*  ut,            // pointer to ut[p7] 32-bit single data array
    uint01   v16,           // v[p6*p7] is 16-bit data array
    uint01   vfh,           // v[p6*p7] is 16-bit half precision float
    ieee32*  v32f,          // pointer to v[p6*p7] as ieee32
    ieee16*  v16h,          // pointer to v[p6*p7] as ieee16
    uint16*  v16x,          // pointer to v[p6*p7] as 16-bit fixed-point
    uint07   cmExp,         // v[p6*p7] common exponent for 16-bit fixed
    ieee32*  L,             // pointer to  L[p7] 32-bit single data array
    ieee32*  p3,            // pointer to p3[p7] 32-bit single data array
    ieee32   p4,            // scalar factor in the output normalization
    ieee32   p5,            // optional start value in the output
normalization
    uint16   p6,            // size of the ASC function
    uint05   p7,            // dimension of the ASC function
    uint16   &p8,           // outer stage2 "for" loop count
    ieee64   p9,            // starting value of double-precision y
accumulator
    uint01   setz,          // configuration to define initial z64 value
    ieee64   y64,           // 64-bit double-precision outer loop output
value
    ieee32   y32,           // 32-bit single-precision version of y64
    ieee64   z64,           // 64-bit double-precision final output value
    ieee32   z32            // 32-bit single-precision version of final
output
) {
    ieee32   d, e, v_ieee32;// internal stage23 local single-precision
variables
    ieee64   t;             // internal stage23 local double-precision
accumulator
    uint16   p8_init;       // internal unsigned integer variable
    uint16   i,j,k;         // internal unsigned integer array index (i),
loop count variables (j,k)

    /* data initialization */
    y64 = p9;
    p8_init = p8;

    /* stage 2: t accumulation, exp(-t), y accumulation */
    for (j = p8; j < p6; j++) {
        i = j * p7;

        /* stage 2a: t accumulation */
        t = (ieee64) 0.0;
```

```
            for (k = 0; k < p7; k++) {
                switch ((v16 << 1) + vfh) {
                    case 0:
                    case 1:                 // V array = ieee32 format
                        v_ieee32 = v32f[i+k];
                        break;
                    case 2:                 // V array = ieee16 format
                        v_ieee32 = (ieee32) v16h[i+k];
                        break;
                    case 3:
                        v_ieee32 = convertFixedPoint (cmExp-63, v16x[i+k]);
                        break;
                }
                d = ut[k] - v_ieee32;
                d = (ieee32)(d * d);
                t += (L[k] * d);            // 32 x 32 -> 64 FMA
            }

            /* stage 2b: exp() */
            e = amuExp(-(ieee32)t);         // amu exp()

            /* stage 2c: y64 accumulation */
            y64 += p3[j] * e;               // 32 x 32 -> 64 FMA
            p8++;                           // update global loop counter

        // user stop requests pause the algorithm in-place at this point
        }

        y32 = (ieee32) y64;                 // ieee32 version of y

        /* stage 3: output normalization */
        if (setz) {
            z64 = (ieee64) p5;
        }

        z64 = z64 + y64 * p4;               // 32 x 32 -> 64 FMA
        z32 = (ieee32) z64;

        p8 = p8_init;                       // return p8 to original value

    }
```

94.3.2 The exp(x) function and implementation

As previously described, a single-precision evaluation of the exp(x) is a key function in the defined algorithm (part of the stage2 outer loop calculations). The AMU2's implementation consists of four steps:

1. Special case analysis, for example, value out of range produces +Inf
2. Argument reduction
3. Function evaluation
4. Range reconstruction

94.3.2.1 Special case analysis

The first step of the exp(x) function consists of a series of conditional tests to filter out these special cases and perform the proper operation, for example returning an infinity when the input argument is too large.

94.3.2.2 Argument reduction

Standard algorithms for exp(x) typically approximate e^x in a bounded domain, typically defined as [-ln(2)/2, ln(2)/2] or [0, ln(2)]. The AMU2 implementation uses the [0, ln(2)) range. Further, the following mathematical identity is applied to the function definition:

$e^x = e^{E*\ln(2)+z} = (e^{\ln(2)})^E * e^z = 2^E * e^z$

where E is a signed *integer* and z is such that $|z| < \ln(2)$. After a series of arithmetic manipulations, z and E can be computed as:

$E = \text{int}(x / \ln(2))$

$z = x - E * \ln(2)$

where E is the integer part of the (x/ln(2)) computation with the same sign.

Further, the e^z computation can be rewritten as:

$e^z = e^{(A+B)} = e^A * e^B$

The range of the input argument can be further reduced by rewriting z as the sum of two fixed-point numbers such that z = A + B. This can be accomplished trivially by assigning the first *n* bits of z to A and the remaining bits of z to B. For the AMU2, the first 6 bits of the input argument are assigned to A, and the remaining 17 bits to B, thus allowing the use of a simple 64-element lookup table to compute e^A and a polynomial approximation for e^B.

94.3.2.3 Function evaluation

The next step is the selection of a polynomial approximation of e^B that is sufficiently accurate in the range [0, ln(2)/64]. In the AMU2, a Minimax approximation is used to model the e^x function with a low-degree polynomial. Minimax approximations are polynomials of degree N that calculate a given function within a given interval such that the absolute maximum error is minimized. This allows an error bound on the approximation *without* incurring unnecessary terms in the polynomial.

The difficult part of finding a Minimax polynomial is the iterative nature of the algorithm to compute the coefficients. For this, the Remez Algorithm as implemented in an indefinite precision solver is applied. The form of the polynomial is:

$f(x) = a_0 + a_1 * x + a_2 * x^2 + a_3 * x^3 + ...$

Using the Remez Algorithm, the function implements a three-term expression of the form:

$exp(x) = 1 + x * (C_0 + x * (C_1 + x* C_2))$

where C_n represent the required coefficients and x is the range-limited input argument. This produces the following expression in a more typical polynomial form:

$exp(x) = 1 + C_0 * x + C_1 * x^2 + C_2 * x^3$

In solving for the C_n coefficients to provide the minimum error, it becomes obvious that C_0 is very close to 1.0 and C_1 is reasonably close to 0.5. Since the assignment of these two coefficients to these constants allows a simplified hardware implementation, the next step is calculation of a revised C_2 coefficient to account for the simplifications involving C_0 and C_1. This calculation produces the following coefficient values:

$C_0 = 1.0$

$C_1 = 0.5$

$C_2 = 0.167876224340382$

Using this form of the exp(x) function and comparing its precision and accuracy versus Excel's computation of e^x over the range [0, ln(2)/64] shows the following results:

- Error terms approximately bounded as [-7.0E-10, +7.0E-10]
- > 30 bits of precision across the entire input range

The AMU2 limits the datapath width to 25 bits to minimize the exp() implementation cost.

94.3.2.4 Range reconstruction

The final step in the exp(x) function is the use of multiplicative range reconstruction to return the answer back into the proper range. Recall the equations of interest are:

$e^x = 2^E * e^z$

$e^z = e^{(A + B)} = e^A * e^B$

$exp(x) = 2^E * e^A * e^B$

where E was calculated during argument reduction, e^A from a table lookup and e^B using the polynomial evaluation. Finally, the result must be converted into a single-precision floating point number. Due to the nature of floating point numbers, this is a simple step; because the range of z is [0, ln(2)), the range of e^z is [1, 2). Since floating point numbers must be normalized to the range [1, 2), the result is guaranteed to be normalized, and in the proper range. The calculated e^z is stored as the single-precision mantissa and E as the exponent.

Note: If the exp(x) evaluation generates an overflow, the single-precision function result is set to positive infinity (+Inf = 0x7F800000). Likewise, if an underflow is generated, the result is set to a positive zero (+0 = 0x00000000).

The AMU2 includes a single instance of the exp(x) hardware function which is shared via time-multiplexing across the two calculation channels.

94.3.3 AMU data types and formats

The algorithm calculations performed by the AMU2 use floating-point values for the parameters and data, and unsigned integers for all memory pointers and loop counts. This section provides details on the supported floating-point data types as well as one additional format available for the V[*] array.

As an example of the data set size, consider the following two variables as a typical use case:

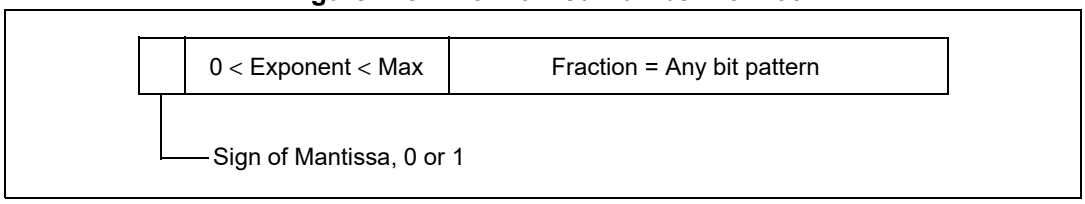
- Dimensionality of the ASC function, p7, with an example value of 10
- Size of the ASC function, p6, with an example value of 500

Based on these two variables, the input vector data can be categorized into three sizes:

- The V[*] array has a size of p6 * p7 = 500 * 10 = 5000 elements
- The P3[*] vector has a size of p6 = 500 elements
- All remaining vectors (L[*], P1[*], P2[*], u[*], ut[*]) have a size of p7 = 10 elements

94.3.3.1 Floating-point data formats

The AMU2 uses 16-bit half-, 32-bit single- and 64-bit double-precision floating-point data formats as defined in the IEEE 754-2008 “Standard for Floating-Point Arithmetic” specification. These formats are described in the following subsections. The multiple floating-point formats are used to minimize the data memory storage requirements for input operands and increase computational accuracy while allowing a reasonable module implementation size.



Each floating-point format supports five unique data types: normalized numbers, zeros, infinities, NaNs, and denormalized numbers. The normalized data type, as depicted in *Figure 2491*, never uses the maximum or minimum exponent value for a given format.

94.3.3.1.1 Normalized numbers

Normalized numbers include all positive or negative numbers with exponents between the maximum and minimum values. For half-, single- and double-precision normalized numbers, the implied integer bit (the so-called “hidden bit”, see more in the next paragraph) is one and the biased exponent cannot be zero.

In IEEE 754-2008, all normalized numbers are represented in sign-magnitude format as +/- 1.fff...fff * 2^e, where fff...fff is called the significant (or mantissa; it represents the fractional portion of the number), and e is called the exponent. Since all normalized numbers have a “1” as the first bit, it need not be stored in memory, and thus is often called the “hidden bit.” Implementations detect whether a number is normal or denormal by inspecting the exponent value. Denormalized numbers always have a zero exponent, and normalized numbers always have a non-zero exponent.

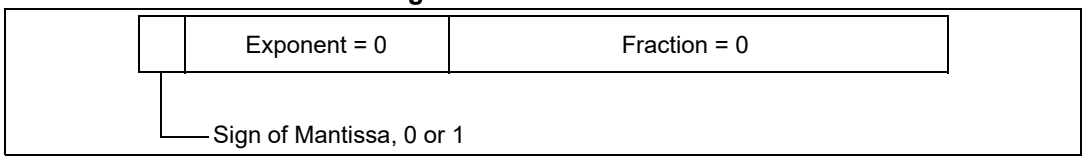


Figure 2491. Normalized Number Format

94.3.3.1.2 Zeros

Zeros can be positive or negative and represent real values, +0.0 and –0.0. See *Figure 2492*. The difference between +0.0 and -0.0 is significant: +0.0 is used to represent values that approach zero from the positive direction, and -0.0 is used to represent values that approach zero from the negative direction.

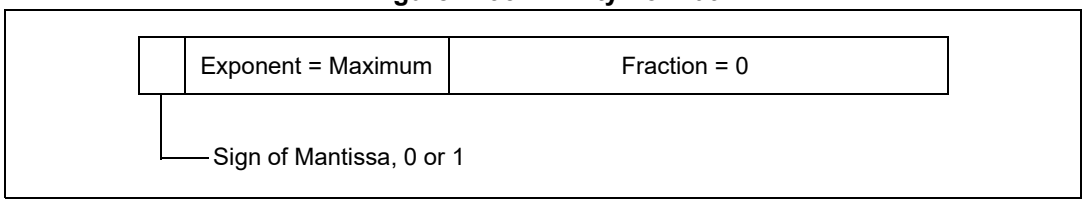

Figure 2492. Zero Format

94.3.3.1.3 Infinities

Infinities can be positive or negative and represent real values that exceed the overflow threshold. A result's exponent greater than or equal to the maximum exponent value indicates an overflow for a given data format and operation. This overflow description ignores the effects of rounding. For half-, single- and double-precision infinities, the fraction is a zero. See *Figure 2493*.

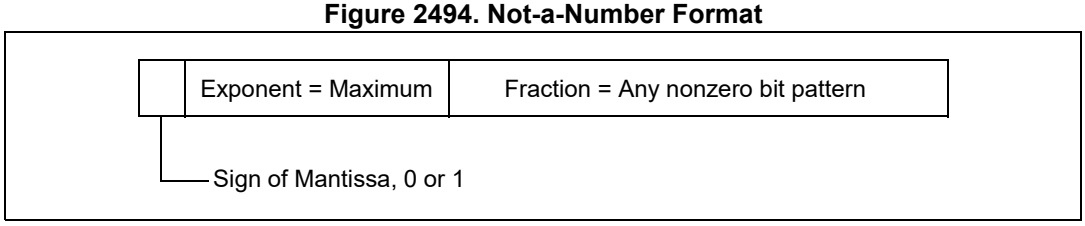

Figure 2493. Infinity Format

94.3.3.1.4 Not-A-Number

NaNs represent the results of operations having no mathematical interpretation, such as infinity divided by infinity. Operations using a NaN operand as an input return a NaN result. User-created NaNs can protect against uninitialized variables and arrays. See *Figure 2494*.

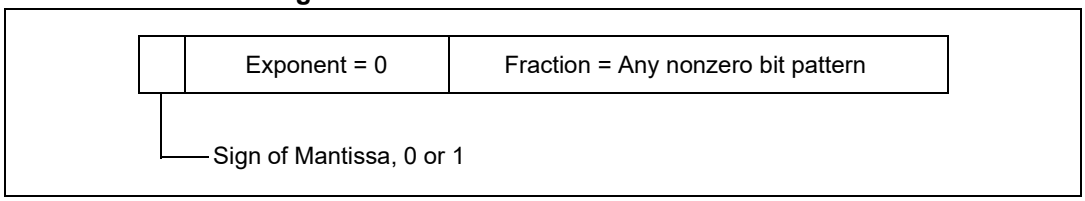
Figure 2494. Not-a-Number Format

The IEEE 754 specification defines quiet and signaling NaNs, based on the state of the most significant bit of the fraction. If set, the NaN is quiet, else it is a signaling NaN.

As the AMU2 performs each algorithm calculation, if one (or more) input operand is a NaN, the logic selects one NaN input and passes it as the result of that computation. Accordingly, if any input operand is a NaN, the result of the ALU calculation is also a NAN.

The IEEE 754 specification also defines a calculation producing an invalid operation should generate a quiet NaN that provides some diagnostic information. Accordingly, the AMU2 produces the following quiet NaN results from these invalid operations:

```
Inf - Inf// ieee32 = 0x7fc0_0001, ieee64 = 0x7ff8_0000_0000_0001
Inf * 0// ieee32 = 0x7fc0_0002, ieee64 = 0x7ff8_0000_0000_0002
0   * Inf// ieee32 = 0x7fc0_0003, ieee64 = 0x7ff8_0000_0000_0003
FMA(0,  Inf,  x)// ieee32 = 0x7fc0_0004, ieee64 = 0x7ff8_0000_0000_0004
FMA(Inf,  0,  x)// ieee32 = 0x7fc0_0005, ieee64 = 0x7ff8_0000_0000_0005
FMA(Inf,  0, -Inf)// ieee32 = 0x7fc0_0006, ieee64 = 0x7ff8_0000_0000_0006
FMA(x,  Inf, -Inf)// ieee32 = 0x7fc0_0006, ieee64 = 0x7ff8_0000_0000_0006
```



The following definition is used when converting an ieee64 NaN into an ieee32 NaN:

```
ieee32[31] = ieee64[63]// copy the sign bit
ieee32[30:23] = 0xff    // exponent = maximum
ieee32[22] = ieee64[51]// copy (signaling, quiet) bit from the ieee64 NaN
ieee32[21:0]  = if (ieee64[50:22] == 0) then ieee64[21:0], else 0x3f_ffff
```

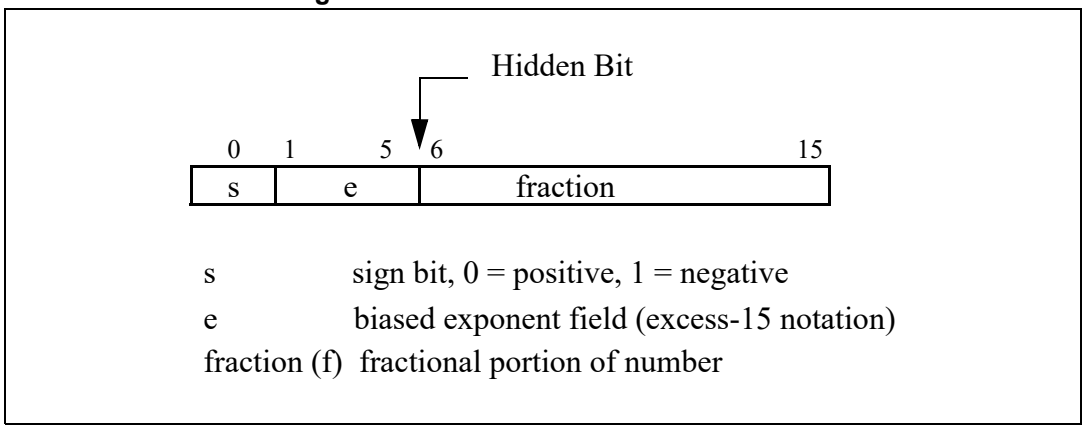
94.3.3.1.5 Denormalized numbers

Denormalized numbers represent real values near the underflow threshold. Denormalized numbers can be positive or negative. For denormalized numbers in half-, single- and double-precision, the implied (hidden) integer bit is a zero and the biased exponent is zero. See *Figure 2495*.

Figure 2495. Denormalized Number Format

Traditionally, the detection of underflow causes floating-point number systems to perform a flush-to-zero. The IEEE 754 standard implements gradual underflow: the result mantissa is shifted right (denormalized) while the result exponent is incremented until reaching the minimum value. If all the mantissa bits of the result are shifted off to the right during this denormalization, the result becomes zero.

In the AMU2, all denormalized numbers are treated as zeros.



94.3.3.1.6 Half-precision floating-point format

Half-precision (16-bit) floating-point storage format is supported by the AMU2 only for the V[*] array with automatic conversion to the 32-bit single-precision floating-point format. No computational operations are defined for half-precision numbers as this format is supported *to minimize the memory storage associated with the V[*] array*. Recall the V array is two dimensional of size [p6 * p7].

Each half-precision floating-point data element is 16 bits wide with one sign bit (s), 5 bits of biased exponent (*e*) and 10 bits of fraction (*f*).

In the IEEE 754-2008 specification, half-precision floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2496. Half-Precision Data Format

For normalized numbers, the biased exponent value '*e*' lies in the [1 - 30] range corresponding to an actual exponent value E in the [-14 - +15] range, the hidden bit is a '1', and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

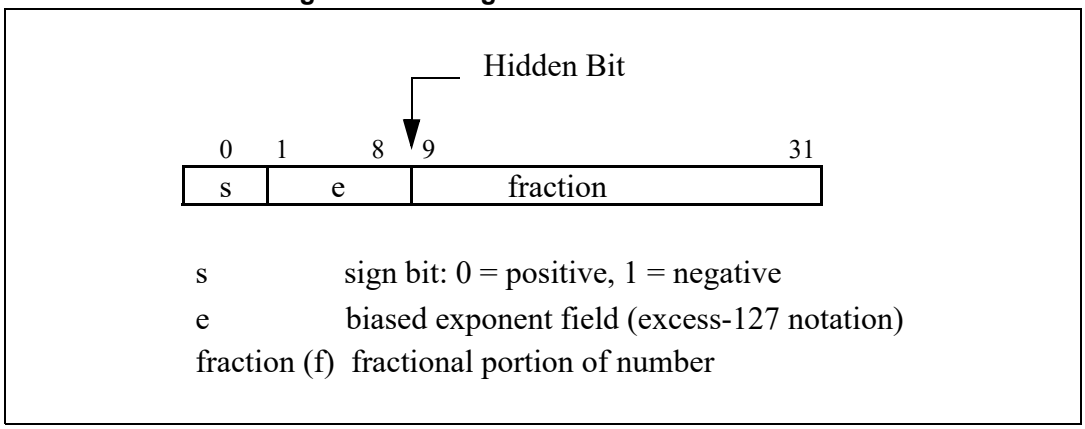
where E is the unbiased exponent and 1.fraction is the significand consisting of a leading '1' (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number ($pmax_{hp}$) is represented by the encoding `0x7bff` which is 65504, and the minimum positive normalized number ($pmin_{hp}$) is represented by the encoding `0x0400` which is approximately 6.1E-5.

Two specific values of the biased exponent are reserved: 0 and 31, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 31 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined to be '0'. This number type is not directly supported in hardware and is converted to zero by the AMU2.



Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 31 and a fraction *f* which is non-zero.

94.3.3.1.7 Single-precision floating-point format

Each single-precision floating-point data element is 32 bits wide with one sign bit (s), 8 bits of biased exponent (*e*) and 23 bits of fraction (*f*).

In the IEEE-754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2497. Single-Precision Data Format

For normalized numbers, the biased exponent value '*e*' lies in the [1 - 254] range corresponding to an actual exponent value E in the [-126 - +127] range, the hidden bit is a '1', and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

where E is the unbiased exponent and 1.fraction is the significand consisting of a leading '1' (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number (*pmax*) is represented by the encoding `0x7f7fffff` which is approximately 3.4E+38, and the minimum positive normalized number (*pmin*) is represented by the encoding `0x00800000` which is approximately 1.2E-38.

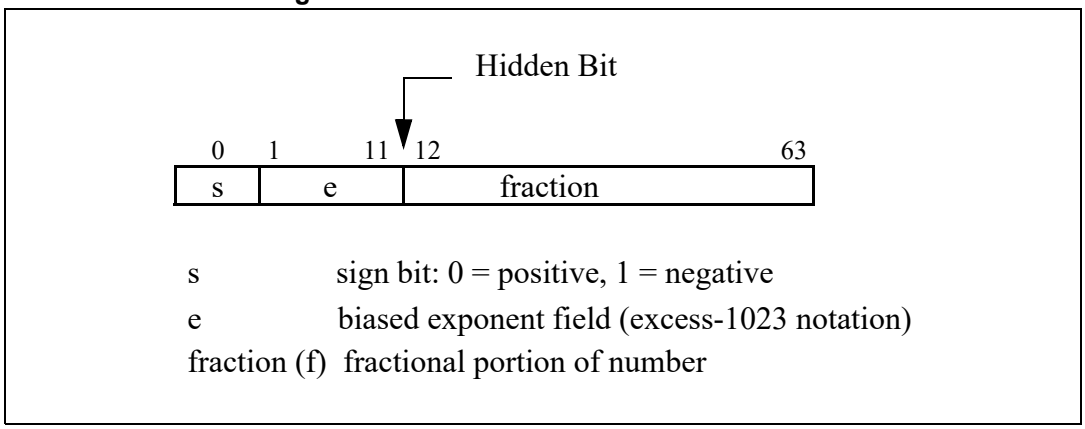
Two specific values of the biased exponent are reserved: 0 and 255, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction *f* which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 255 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined by the IEEE-754 standard to be '0'. This number type is not directly supported in hardware and is converted to zero by the AMU2.

Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 255 and a fraction *f* which is non-zero.



Defining *pmax* to be the most positive normalized number (farthest from zero), *pmin* the smallest positive normalized number (closest to zero), *nmax* the most negative normalized number (farthest from zero) and *nmin* the smallest normalized negative number (closest to zero), an overflow is said to have occurred if the numerically correct result (r) of an operation is such that r > *pmax* or r < *nmax*. An underflow is said to have occurred if the numerically correct result of an operation is such that 0 < r < *pmin* or *nmin* < r < 0. In this case, r may be denormalized, or may be smaller than the smallest denormalized number.

94.3.3.1.8 Double-precision floating-point format

Each double-precision floating-point data element is 64 bits wide with one sign bit (s), 11 bits of biased exponent (*e*) and 52 bits of fraction (*f*).

In the IEEE-754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2498. Double-Precision Data Format

For normalized numbers, the biased exponent value ‘*e*’ lies in the [1 - 2046] range corresponding to an actual exponent value E in the [-1022 - +1023] range, the hidden bit is a ‘1’, and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

where E is the unbiased exponent and 1.fraction is the significand consisting of a leading ‘1’ (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number (*pmax*) is represented by the encoding `0x7feeffff_ffffffff` which is approximately 1.8E+308, and the minimum positive normalized number (*pmin*) is represented by the encoding `0x00100000_00000000` which is approximately 2.2E-308.

Two specific values of the biased exponent are reserved: 0 and 2047, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction *f* which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 2047 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined by the IEEE-754 standard to be ‘0’. This number type is not directly supported in hardware and is converted to zero by the AMU2.

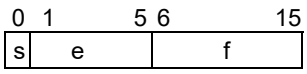
Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 2047 and a fraction *f* which is non-zero.

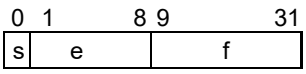
Defining *pmax* to be the most positive normalized value (farthest from zero), *pmin* the smallest positive normalized value (closest to zero), *nmax* the most negative normalized value (farthest from zero) and *nmin* the smallest normalized negative value (closest to zero), an overflow is said to have occurred if the numerically correct result (r) of an operation is such that r > *pmax* or r < *nmax*. An underflow is said to have occurred if the numerically correct result of an operation is such that 0 < r < *pmin* or *nmin* < r < 0. In this case, r may be denormalized, or may be smaller than the smallest denormalized number.

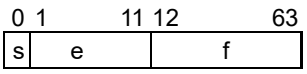
94.3.3.1.9 Floating-point data format summary

Table 2378 summarizes the data type specifications for the three supported floating-point formats.

Table 2378. Floating-point Format Summary







Parameter	Half-Precision	Single-Precision	Double-Precision
Data Format			
Field Size in Bits			
Sign (s)	1	1	1
Biased exponent (e)	5	8	11
Fraction (f)	10	23	52
Total	16	32	64
Interpretation of Sign			
Positive fraction	s = 0	s = 0	s = 0
Negative fraction	s = 1	s = 1	s = 1
Normalized Numbers			
Bias of biased exponent	+15 (0xf)	+127 (0x7F)	+1023 (0x3FF)
Range of biased exponent	0 < e < 31 (0x1F)	0 < e < 255 (0xFF)	0 < e < 2047 (0x7FF)
Range of fraction	Zero or Nonzero	Zero or Nonzero	Zero or Nonzero
Mantissa	1.f	1.f	1.f
Relation to representation of real numbers	$(-1)^s \times 2^{e-15} \times 1.f$	$(-1)^s \times 2^{e-127} \times 1.f$	$(-1)^s \times 2^{e-1023} \times 1.f$
Denormalized Numbers			
Biased exponent format minimum	0 (0x0)	0 (0x00)	0 (0x000)
Bias of biased exponent	+14 (0xE)	+126 (0x7E)	+1022 (0x3FE)

Table 2378. Floating-point Format Summary (continued)

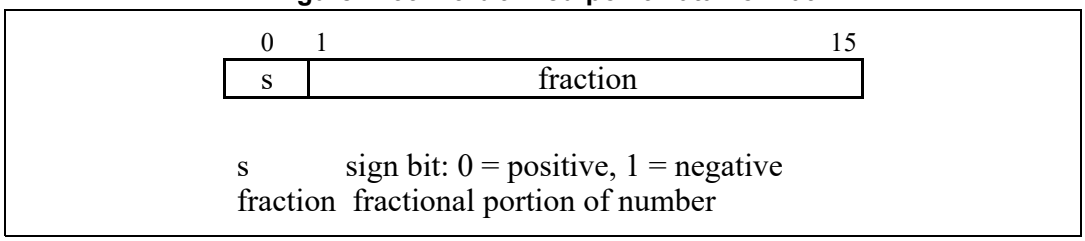
Parameter	Half-Precision	Single-Precision	Double-Precision
Range of fraction	Nonzero	Nonzero	Nonzero
Mantissa	0.f	0.f	0.f
Relation to representation of real numbers	$(-1)^s \times 2^{-14} \times 0.f$	$(-1)^s \times 2^{-126} \times 0.f$	$(-1)^s \times 2^{-1022} \times 0.f$
Signed Zeros			
Biased exponent format minimum	0 (0x0)	0 (0x00)	0 (0x00)
Mantissa	0.f = 0.0	0.f = 0.0	0.f = 0.0
Signed Infinities			
Biased exponent format maximum	31 (0x1F)	255 (0xFF)	2047 (0x7FF)
Mantissa	0.f = 0.0	0.f = 0.0	0.f = 0.0
NaNs			
Sign	0 or 1	0 or 1	0 or 1
Biased exponent format maximum	31 (0x1F)	255 (0xFF)	2047 (0x7FF)
Fraction	Nonzero	Nonzero	Nonzero
Representation of fraction Nonzero bit pattern created by user Fraction when created by AMU2	xxxxx…xxxx N/A	xxxxx…xxxx 10000…0[001-110]	xxxxx…xxxx 1000…0[001-110]

Table 2378. Floating-point Format Summary (continued)

Parameter	Half-Precision	Single-Precision	Double-Precision
Approximate Ranges			
Maximum positive normalized	6.5×10^{4}	3.4×10^{38}	1.8×10^{308}
Minimum positive normalized	6.1×10^{-5}	1.2×10^{-38}	2.2×10^{-308}

94.3.3.1.10 Calculation Precision

The AMU2 implementation uses the IEEE 754 floating-point precisions explicitly defined in *Section 94.3.1: AMU2 algorithm*. Other details include:



- The AMU2 supports the standard IEEE 754 “round-to-nearest, ties-to-even” mode for all rounding operations, including all conversions from double-precision to single-precision. Denormalized numbers are not supported. Denormalized numbers are interpreted as zero. Input NaNs are passed as the result of a computation and certain operations producing an invalid result generate a quiet NaN with a diagnostic value embedded in the fraction. More details on the handling of NaNs is presented in *Section 94.3.3.1.4: Not-A-Number*.
- If an overflow condition is detected, the result is forced to (+/-) Inf value before the ALU is halted.
- The exponential function inputs a 32-bit converted *t* operand and produces an IEEE 32-bit floating-point result. The externally-observable exp(x) precision is 24 bits, ± 1 ULP.

94.3.3.2 16-bit fixed-point with common exponent

The AMU2 also supports a fixed-point format for the V[*] array. This format specifies a signed 16-bit two’s complement fixed-point fraction in the [-1, 1.0) range with a common 7-bit exponent using an excess-63 format. This format provides more bits of fraction precision versus the IEEE 754 half-precision floating-point format at the cost of a reduced dynamic range within the same memory footprint.

In this format, values are represented with two explicit fields (sign field and fraction field) along with a 7-bit common biased exponent field (AMU2_CCR1CH*n*[CMEXP]) applied to all elements in the V[*] array.

Figure 2499. 16-bit fixed-point Data Format

Note that the 7-bit common biased exponent is not shown in *Figure 2499*.

Using the same variables as the floating-point data types, the biased exponent value '*e*' lies in the [0 - 127] range corresponding to an actual exponent value E in the [-63 to +64] range, the hidden bit is a '0', and the value of this 2's complement number is interpreted as:

((-1 x *s*) + 0.*fraction*) x 2^E

where E = CMEXP - 63.

When the V[*] array is specified in this format, the AMU2 automatically converts the number into a single-precision floating-point value before it is used in the stage2 calculation. This transformation is described by the following C language *convert fixed halfword-to-single precision floating-point* function:

```
ieee32 convertFixedPoint(uint07 cmExp, uint16 v16x)
{
    int i, s;

    if (v16x & 0x8000) {
        s = 1;
        v16x = (~v16x + 1) & 0xffff;              // same as v16x = -v16x
    } else
        s = 0;

    if (v16x & 0x8000)
        ieee32Result = 1<<31 | (64+cmExp)<<23;    // minimum value
    else if (v16x == 0)
        ieee32Result = 0x00000000;
    else {
        for (i = 0; i < 16; i++) {
            v16x <<= 1;
            if (v16x & 0x8000)
                break;
        }
        ieee32Result = s<<31 | (63+cmExp-i)<<23 | (v16x & 0x7fff)<<8;
    }

    return ieee32Result;
}
```

94.3.4 Register format and data types

As described in the pseudo-code of *Section 94.3.1: AMU2 algorithm*, the programming model provides address pointers and data values. The register types are defined in *Table 2379* and presented in their order of appearance in the pseudo-code.

Table 2379. Data types in registers

Operand	AMU2 Register	Data Type
u_pointer(1)	UPTRCH*n*	ARAM pointer to ieee32 floating-point data
p1_pointer(1)	P1PTRCH*n*	ARAM pointer to ieee32 floating-point data

Table 2379. Data types in registers (continued)

Operand	AMU2 Register	Data Type
p2_pointer(1)	P2PTRCH*n*	ARAM pointer to ieee32 floating-point data
ut_pointer(1)	Implicit	Special ARAM pointer to ieee32 floating-point data
p9	P9{M,L}CH*n*	ieee64 floating-point data
p8	P8CH*n*	Unsigned int16 data
p7	P7CH*n*	Unsigned non-zero int6 data (if value ==0, then p7 = 32)
p6	P6CH*n*	Unsigned int16 data
v_pointer(2)	VPTRCH*n*	ARAM or system pointer to ieee32 floating-point data, or ieee16 floating-point data, or 16-bit fixed-point data with 7-bit common exponent
L_pointer(1)	LPTRCH*n*	ARAM pointer to ieee32 floating-point data
p3_pointer(2)	P3PTRCH*n*	ARAM or system pointer to ieee32 floating-point data
y64	Y64{M,L}CH*n*	ieee64 floating-point data
y32	Y32CH*n*	ieee32 floating-point data
p5	P5CH*n*	ieee32 floating-point data
p4	P4CH*n*	ieee32 floating-point data
result, z64	RES64{M,L}CH*n*	ieee64 floating-point data
res32, z32	RES32CH*n*	ieee32 floating-point data

1. All pointers reference the AMU local RAM (ARAM), and are limited to 15 bits in size as the RAM is a maximum of 32 KB.
2. For “normal” operations, the v_pointer and p3_pointer are like the other pointers and reference the ARAM and are limited to 15 bits in size. When ADMA data streaming is enabled, these same registers are configured as a 8-byte aligned 32-bit system Flash address.

94.3.5 ALU calculation engine

The ALU calculation engine supports a time-multiplexed hardware computation pipeline supporting 2 execution channels. This structure implements the algorithm detailed in *Section 94.3.1: AMU2 algorithm* including the transcendental function described in *Section 94.3.2: The exp(x) function and implementation*.

94.3.5.1 ALU execution states

The ALU maintains two finite state machines that record the execution state of the stage1 and stage23 calculations and is visible in the AMU2_SEIRCH*n*[S23XS, S1XS] fields. The execution states and their descriptions are detailed in *Table 2380*.

Table 2380. ALU S1, S23 Execution States

State	AMU2_SEIRCH*n*[S{1,23}XS]	Description
Idle or Pending Start	0b00	Idle or pending start. A pending start is created when any of the conditional start bits, AMU2_CCR2CH*n*[WFS1D, WFS23D, WFSS23], are set.
Halted	0b01	Halted after detection of an error condition or arithmetic fault.
Stopped	0b10	Stopped due to an explicit request (AMU2_CCR2CH*n*[S23STP]) or a properly-enabled N crossing event. Note the stage1 execution cannot be stopped via either of these mechanisms and stage23 is stopped after the current iteration of the outer loop. N crossing events also stop at the same point in the algorithm execution.
Running or Stalled	0b11	Actively executing or stalled due to a properly-enabled debug event (AMU2_CCR1CH*n*[DDSL] = 0). The presence of a properly-qualified debug event is reflected in the AMU2_SEIRCH*n*[QDSL] indicator.

Once a state machine enters the halted state, the state needs to be cleared by starting a new calculation, or by explicitly resetting it by a register write with AMU2_CCR2CH*n*[CSXXS] = 1. Likewise, once the status signals a stopped state, it can be resumed by a register write with AMU2_CCR2CH*n*[S23RSM] = 1, cleared by starting a new calculation or explicitly reset by a register write with AMU2_CCR2CH*n*[CSXXS] = 1.

94.3.5.2 ALU speed control

The ALU includes a “speed control” function that can be used to throttle the execution rate of the channel. There are four registers associated with this function: three 3-bit registers defining the starting, maximum and current speed settings plus a threshold count. The 3-bit settings define a fractional operation “speed” as {1/8, 2/8, 3/8,..., 7/8, 8/8} where 8/8 represents the maximum, that is full speed. The registers for this function include:

AMU2_CCR1CH*n*[SRTSP] // start speed

AMU2_CCR1CH*n*[MAXSP] // maximum speed

AMU2_SEIRCH*n*[ACURSP] // ALU current speed

AMU2_P8CH*n*[THRHC] // threshold P8 count

The ALU controls its execution speed by stalling the calculation engine pipeline as defined by the current speed. As the ALU executes, the operation speed is increased by 1/8 from the starting value to the maximum value each time a multiple of the P8 threshold count is reached. As an example, if SRTSP = 1/8 and MAXSP = 8/8 (full speed), then the current speed reflected in the ACURSP field follows the following sequence:

For the 1st THRHC loops of stage 23 calculation, ACURSP = 1/8

For the 2nd THRHC loops of stage 23 calculation, ACURSP = 2/8

For the 3rd THRHC loops of stage 23 calculation, ACURSP = 3/8

For the 4th THRHC loops of stage 23 calculation, ACURSP = 4/8

For the 5th THRHC loops of stage 23 calculation, ACURSP = 5/8

For the 6th THRHC loops of stage 23 calculation, ACURSP = 6/8

For the 7th THRHC loops of stage 23 calculation, ACURSP = 7/8

For the 8th THRHC loops of stage 23 calculation until complete, ACURSP = 8/8

It is software's responsibility to initialize the three controlling registers (SRTSP, MAXSP, THRHC) with appropriate values (SRTSP < MAXSP) else the speed control behavior may be indeterminate.

Note: Recall the pipelined calculation engine hardware is shared by the two channels via a time multiplexing scheme. To make the speed control of the calculation engine manageable, there is a single ALU speed control mechanism implemented, affecting both channels. Note the four registers associated with this function are multiply-mapped into the programming models of both channels, but only a single function is implemented. Accordingly, the global values of the speed control registers are used if one (or both) channels are executing. If both channels are idle and one begins execution, the speed ramps up from SRTSP to MAXSP as described. If the other channel begins execution while the first channel is already executing, the second channel begins its execution at ACURSP. The speed is only returned to the SRTSP value when both channels are idle and one (or both) becomes active.

94.3.6 AMU Direct Memory Access (ADMA)

94.3.6.1 Basic ADMA data transfer capabilities

Each AMU2 channel is equipped with an ADMA channel. This allows optimized block copying of data from Flash and system calibration memories (if applicable) to the local RAM (ARAM).

The programming model associated with each ADMA channel contains five registers: source and destination addresses, transfer count, expected checksum and control & configuration. Since the AMU2 supports the ADMA transfers using a private 64-bit interface to the platform Flash memory controller, all addresses and transfer counts must be 8-byte aligned values.

The control & configuration register (AMU2_DCCRCH*n*) supports the ability to separately update the source or destination address registers, or both, so repeated ADMA transfers can sequence through a Flash data structure while keeping the local ARAM structure constant. See the AMU2_DCCRCH*n*[SARU, DARU] fields. The DARU register field supports the ability to transfer the last 64 bits fetched from the Flash source memory location to the two AMU Control & Configuration Registers (AMU2_CCR{1,2}CH*n*). This provides the ADMA with the ability to load a new vector data set from Flash, followed by writes to initiate a calculation. This special "last write to CCR{1,2}" mode is enabled when AMU2_DCCRCH*n*[DARU] = 0b01.

94.3.6.2 ADMA execution states

The ADMA maintains a finite state machine that records its current operating condition and is visible in the AMU2_SEIRCH*n*[ADMAS] field. These execution states and their descriptions are detailed in *Table 2381*.

Table 2381. ADMA Execution States

State	AMU2_SEIRCH*n* [ADMAS]	Description
Idle or Pending Start	0b00	Idle or pending start. A pending start is created when any of the conditional start bits, AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI], are set.
Halted	0b01	Halted after detection of an error condition, such as a bus error, illegal address, multi-bit ECC event.

Table 2381. ADMA Execution States (continued)

State	AMU2_SEIRCH*n* [ADMAS]	Description
Stopped	0b10	Stopped due to an explicit request (AMU2_DCCRCH*n*[STP]) or an implicit request caused by an ALU stop condition enabled by AMU2_DCCRCH*n*[DSAS] = 1.
Running or Stalled	0b11	Actively executing the data transfer or stalled due to a properly-enabled debug event (AMU2_CCR1CH*n*[DDSL] = 0). The presence of a properly-qualified debug event is reflected in the AMU2_SEIRCH*n*[QDSL] indicator.

Once a state machine enters the halted state, the state needs to be cleared by starting a new data transfer or by explicitly resetting it by a register write with AMU2_DCCRCH*n*[CADS] = 1. Likewise, once the status signals a stopped state, it can be resumed by a register write with AMU2_DCCRCH*n*[RSM] = 1, cleared by starting a new data transfer or explicitly reset by a register write with AMU2_DCCRCH*n*[CADS] = 1.

94.3.6.3 Cyclic redundancy checking

The ADMA optionally supports a standard CRC checksum on transfers into the ARAM. If enabled (AMU2_DCCRCH*n*[ECRC] = 1), the checksum is calculated by the ADMA on each data transfer and accumulated. When the data transfers are complete, the final actual CRC value is compared against the expected checksum value contained in the AMU2_DCKSCH*n* register. If the checksums are identical, the AMU operation continues. However, if the checksums are not equal, a data transmission error has occurred and is signaled by AMU2_SEIRCH*n*[CKSERR] = 1. In the case of an enabled CRC checksum error, any ALU calculation which depends on the completion of the ADMA transfer (as defined by AMU2_CCR2CH*n*[WFDS1] == 1 or AMU2_CCR2CH*n*[WFDS23] == 1) is aborted and the corresponding AMU2_CCR2CH*n*[WFDS1, WFDS23] indicators cleared.

The ADMA supports the standard “Ethernet” CRC32 polynomial, which is defined as:

$$CRC32 = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + x^{0}$$

The checksum calculation initializes the CRC to 0xFFFF_FFFF, and processes the fetched data beginning with the most significant bit of the most significant byte. The C code in *Figure 2500* mirrors the ADMA’s hardware implementation. It uses a 256-entry table lookup function (containing unique 32-bit words based on the combined CRC state and a data byte) and is based on the algorithm detailed in “Byte-wise CRC Calculations”, Aram Perez, IEEE Micro June 1983. The `gen_crc_table()` function is executed once to populate the `crc_table[]` array; the `update_crc()` function is called for each CRC to be calculated.

Figure 2500. ADMA CRC32 C Language Function

```
#define POLYNOMIAL 0x04c11db7L
static unsigned long crc_table[256];
void gen_crc_table()
{
    /* generate the table of CRC remainders for all possible bytes */
    register int i, j;
    register unsigned long crc_accum;

    for (i = 0; i < 256; i++) {
        crc_accum = ((unsigned long) i << 24);
        for (j = 0; j < 8; j++) {
            if (crc_accum & 0x80000000L)
                crc_accum = (crc_accum << 1) ^ POLYNOMIAL;
            else
                crc_accum = (crc_accum << 1);
        }
        crc_table[i] = crc_accum;
    }
}

unsigned long update_crc(unsigned long crc_accum,
                         char *data_blk_ptr,
                         int data_blk_size)
{
    /* update the CRC on the data block one byte at a time */
    register int i, j;

    for (j = 0; j < data_blk_size; j++) {
        i = ((int)(crc_accum >> 24) ^ *data_blk_ptr++) & 0xff;
        crc_accum = (crc_accum << 8) ^ crc_table[i];
    }
    return crc_accum;
}
```

The actual checksum value calculated by the ADMA is available in the AMU2_ACKSCH*n* register or the aliased AMU2_AACKSCH*n*.

94.3.6.4 ADMA V and P3 Data Streaming Modes

Recall the V[*] and P3[*] input data vectors have larger array dimensions compared to all the other input data vectors. Accordingly, the ADMA supports a special type of data streaming for these 2 input vectors. At any point in time, the ADMA supports *either* normal data transfers *or* the special streaming modes.

Specifically, *it is not necessary to pre-load the contents* of V[*] or P3[*], or both, into the ARAM before initiating the ALU's stage23 calculation if one of the special data streaming modes is enabled. When enabled by AMU2_DCCRCH*n*[STMP3, STMV{32,16}], the ADMA

manages the streamed input vector(s) using the circular data FIFO(s) implemented in the ARAM. The ADMA prefetches the streamed data and writes it into the FIFOs and the FIFO contents are read based of the ALU's stage23 calculation speed.

The V[*] *and* P3[*] input data vectors can be streamed at the same time, if both AMU2_DCCRCH*n*[STMP3, STMV{32,16}] are [1, != 00]. Typically, the execution time of the ALU calculation engine increases when streaming P3 or V, or both, due to Flash arbitration delays as the AMU streaming traffic may be stalled due to requests from other bus masters.

When operating in the data streaming mode, certain register fields associated with a normal ADMA transfer are ignored, or are interpreted in a special manner. See *Table 2382*.

Table 2382. ADMA Register Definitions when V or P3 Data Streaming is Enabled

Register/Field	Used when Data Streaming	Description when Data Streaming
AMU2_P3PTRCH*n*	Yes	if AMU2_DCCRCH*n*[STMP3] = 1, this register defines the 32-bit system address for the P3[*] input data vector.
AMU2_VPTRCH*n*	Yes	if AMU2_DCCRCH*n*[STMV{32,16}] != 00, this register defines the 32-bit system address for the V[*] input data vector.
AMU2_DSACH*n*	No	The normal ADMA source address register is *not* used when data streaming is enabled; the AMU2_{P3,V}PTRCH*n* registers are used instead.
AMU2_DDACH*n*	No	The normal ADMA destination address register is *not* used when data streaming is enabled. The ADMA uses a reserved space within the ARAM to implement circular data FIFOs (256 bytes for V[*], 128 bytes for P3[*]). The offset ARAM addresses of interest are: 0x0_7C00 - 0x0_7CFF Channel 0 V[*] FIFO 0x0_7D00 - 0x0_7DFF Channel 1 V[*] FIFO 0x0_7E00 - 0x0_7E7F Channel 0 P3[*] FIFO 0x0_7E80 - 0x0_7EFF Channel 1 P3[*] FIFO
AMU2_DCNTCH*n*	No	The ADMA's fetching of V[*] or P3[*] data, or both, is paced by the ALU's stage23 calculation speed. Due to the execution pipeline structure, there may be speculative data fetches that are not actually used in the calculation.
AMU2_DCKSCH*n*	No	Due to the speculative, ALU-paced data transfers, CRC checking is not supported while data streaming. Note the data fetches from system Flash are still protected by the standard single-error correction, double-error detection ECC. A multi-bit non-correctable ECC event during a streaming operation causes the AMU2_SEIRCH*n*[ADMERR] bit to be set and the ADMA to be halted. The ALU calculation then stalls due to the lack of input data.
AMU2_DCCRCH*n*[SRTSP], AMU2_DCCRCH*n*[MAXSP]	No	Since the ADMA transfers are ALU-paced when data streaming, the normal "speed control" function is ignored.
AMU2_DCCRCH*n*[ADICFG]	No	Since the ADMA transfers are ALU-paced when data streaming, the normal interrupt configurations are ignored.
AMU2_DCCRCH*n*[SARU], AMU2_DCCRCH*n*[DARU]	No	Since the ADMA transfers use different source and destination addresses when data streaming, these fields are ignored.

Table 2382. ADMA Register Definitions when V or P3 Data Streaming is Enabled (continued)

Register/Field	Used when Data Streaming	Description when Data Streaming
AMU2_DCCRCH*n*[HCRCE], AMU2_DCCRCH*n*[ECRC]	No	Due to the speculative, ALU-paced data transfers, CRC checking is not supported while data streaming.
AMU2_DCCRCH*n*[STMP3]	Yes	When asserted in conjunction with AMU2_DCCRCH*n*[SRT] = 1, this bit enables the P3[*] data streaming mode.
AMU2_DCCRCH*n*[STMV{32,16}]	Yes	When asserted in conjunction with AMU2_DCCRCH*n*[SRT] = 1, this bit enables the V[*] data streaming mode.
AMU2_DCCRCH*n*[DSAS]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, stopping the ALU also stops the ADMA.
AMU2_DCCRCH*n*[STP]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, stopping the ALU also stops the ADMA, given AMU2_DDCRCH*n*[DSAS] = 1.
AMU2_DCCRCH*n*[WFS23], AMU2_DCCRCH*n*[WFS1]	No	Since the ADMA data transfers are paced by the ALU stage23 execution speed, these bits are ignored when data streaming is enabled.
AMU2_DCCRCH*n*[RSM]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, resuming the ALU also resumes the ADMA.
AMU2_DCCRCH*n*[SRT]	Yes	The simultaneous assertion of SRT = 1 and (STMV{32,16} != 00 or STMP3 = 1) initiates an ADMA transfer with data streaming enabled.

94.3.6.5 ADMA speed control

The ADMA includes a “speed control” function that can be used to throttle its access rate. There are four register fields associated with this function: three 3-bit registers defining the starting, maximum and current speed settings plus a threshold count. The 3-bit settings define a fractional operation “speed” as {1/8, 2/8, 3/8,..., 7/8, 8/8} where 8/8 represents the maximum, that is full speed. The registers for this function include:

AMU2_DCCRCH*n*[SRTSP] // start speed

AMU2_DCCRCH*n*[MAXSP] // maximum speed

AMU2_SEIRCH*n*[DCURSP] // ADMA current speed

AMU2_DCNTCH*n*[THRHC] // threshold byte count (32-byte aligned)

The ADMA controls the transfer speed by inserting idle states between the receipt of data and the initiation of the next Flash read. As the ADMA fetches data, the operation speed is increased by 1/8 from the starting value to the maximum value each time a multiple of the byte threshold count is reached. As an example, if SRTSP = 1/8 and MAXSP = 8/8 (full

speed), then the current speed reflected in the DCURSP field follows the following sequence:

For the 1st THRHC bytes, DCURSP = 1/8

For the 2nd THRHC bytes, DCURSP = 2/8

For the 3rd THRHC bytes, DCURSP = 3/8

For the 4th THRHC bytes, DCURSP = 4/8

For the 5th THRHC bytes, DCURSP = 5/8

For the 6th THRHC bytes, DCURSP = 6/8

For the 7th THRHC bytes, DCURSP = 7/8

For the 8th THRHC bytes until the transfer is complete, DCURSP = 8/8

It is software's responsibility to initialize the three controlling registers (SRTSP, MAXSP, THRHC) with appropriate values (SRTSP < MAXSP) else the speed control behavior may be indeterminate.

Note: Recall the ADMA hardware is shared by the two channels via a time multiplexing scheme. To make the speed control of the ADMA manageable, there is a single ADMA speed control mechanism implemented, affecting both channels. Note the four registers associated with this function are multiply-mapped into the programming models of both channels, but only a single function is implemented. Accordingly, the global values of the speed control registers are used if one (or both) channels are executing. The speed is only returned to the starting value when both channels are idle and one (or both) becomes active.

94.4 Use case examples

This section presents overviews of multiple use cases describing different scenarios for data loading, ALU calculation and post-processing of the result. This is *not* intended to provide a complete list, but rather examples of the types of configurations supported by the AMU2.

In general, there are three distinct phases associated with an AMU2 calculation: data loading, the ALU calculation and result retrieval & post-processing. The data loading can be performed by any processing element, such as a processor core, the system DMA or the ADMA, or both. The actual algorithm execution is always performed by the AMU2's ALU calculation engine. The retrieval of results and status can be performed by a processor core or the system DMA, while the post-processing is typically handled by a processor core. Recall, the AMU2's programming model is specifically organized in a manner that promotes the use of a DMA, either the system DMA or the ADMA, to handle the data loading operations.

In general, the relative data load speeds among the possible masters are:

CPU < SDMA < ADMA

that is, the CPU is the slowest, the system DMA is faster and the ADMA is the fastest. Additionally, for certain scenarios, the ADMA's data transfers can be overlapped with the ALU calculation to further reduce the execution times for multiple algorithm evaluations.

Consider the following use case examples presented in order of increasing complexity.

94.4.1 Single calculation using a CPU as the master device

For this scenario, a processor core performs *all the required data loading*, moving the coefficients and parameters from system Flash into the ARAM and then initializing all the

corresponding pointer and parameter registers. Once the data load and register initialization are completed, the calculation is started by writing the AMU2_CCR{1,2}CH*n* registers. In this case, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the AMU2_CCR2CH*n*[S1SRT, S23SRT] bits are set.

The AMU2 performs the calculation and then typically generates an interrupt, signaling successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a “1” to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

The preceding description assumes the processor is interrupted when the AMU2 completes as this would be the typical scenario. The AMU2 also provides a channel busy flag (AMU2_SEIRCH*n*[CHBSY]) that the processor can poll to determine whether the calculation is finished.

94.4.2 Single calculation using SDMA for data load, CPU for post-processing

In this example, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA can perform the data load into the ARAM plus the initialization of the pointer and parameter registers.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move “links” to the second channel performing the register loads. In any case, the second data transfer loads the programming model using an 80-byte block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation.

It should be noted the programming model of the AMU2 is organized such that an optimized 80-byte burst transfer (5 x 8-byte 8-beat bursts) can be used to load the registers. The optimized block transfer does not include the AMU2_NCH*n* register for two reasons:

1. The use of the N crossing functionality is a debug feature and not intended for normal system operation;
2. The inclusion of the AMU2_NCH*n* functionality must be properly enabled by setting AMU2_CCR2CH*n*[ENCRS] = 1. Stated differently, the AMU2_NCH*n* functionality is completely disabled if AMU2_CCR2CH*n*[ENCRS] = 0. In the optimized block transfer, the AMU2_NCH*n* register does not need to be initialized, and AMU2_CCR2CH*n* register (with ENCRS = 0) is always the last register written.

Note, the AMU2_NCH*n* register can be included in the sequential data transfer for the register writes by increasing the total number of bytes to be transferred to 84 and using 32-bit writes.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the AMU2_CCR2CH*n*[S1SRT, S23SRT] bits are set by the SDMA's last transfer.

The channel performs the calculation and generates an interrupt, signaling a successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a "1" to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

94.4.3 Single calculation using SDMA + ADMA for data load, CPU for post-processing

For this case, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA and the ADMA collectively can perform the data load into the ARAM plus the initialization of the pointer and parameter registers.

In this example, let the ADMA move the U[*] vector into the ARAM and the SDMA move all the rest of the data.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move "links" to the second channel performing the register load. The second data transfer loads the programming model using an 80-byte (5 x 16 byte 4-beat bursts) block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation. In this example, the programming model initialization configures the ADMA to move the U[*] vector into the ARAM and the AMU2_CCR2CH*n*[WFDS1, WFDS23] conditional start bits are set (and [S1SRT, S23SRT] cleared) to signal the start of the calculation engine is dependent on the completion of the ADMA.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the ADMA completes the data transfer of the U[*] vector into the ARAM.

The channel performs the calculation and generates an interrupt, signaling a successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a "1" to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

94.4.4 Single calculation using SDMA for partial data load, streaming ADMA for V[*], CPU for post-processing

For this case, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA can perform the partial data load into the ARAM plus the initialization of the pointer and parameter registers.

In this example, let the ADMA use the special data streaming mode to fetch the V[*] array into the ARAM with the SDMA moving all the rest of the data including the programming model register initialization.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move “links” to the second channel performing the register load. In any case, the second data transfer loads the programming model using an 80-byte (5 x 16 byte 4-beat bursts) block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation. In this scenario, the programming model initialization configures the ADMA to stream the V[*] array into the ARAM by setting both AMU2_DCCRCH*n*[STMV{32,16}, SRT] and the AMU2_CCR2CH*n*[S1SRT, S23SRT] indicators set to signal the start of the calculation engine for this special data streaming mode.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation is paced by the availability of V[*] input data being managed by the ADMA.

The channel performs the calculation and generates an interrupt, signaling successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a “1” to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

As detailed in *Section 94.3.6.4: ADMA V and P3 Data Streaming Modes*, the AMU2 supports streaming of V or P3, or both, concurrently. Additionally, neither the checksum nor the ADMA speed control is supported in this mode. Additionally for this case, the AMU2_VPTRCH*n* register must be reloaded before the next calculation.

94.4.5 Multiple calculations using ADMA for partial data load, SDMA for result retrieval

For this example, let a processor or system DMA perform the *initial* data and programming model register load, and configuring the AMU2 for the first calculation. Next, configure the ADMA to perform repeated loads of the second, third, fourth, … last U[*] vectors and the SDMA to retrieve results as each calculation is finished.

For this scenario, the ADMA would load a data structure from Flash (or a calibration remapped destination memories, or both) having the U[*] vectors and the values for the AMU2_CCR{1,2}CH*n* registers. The configuration sequences through the Flash data

structure and loads each U[*] vector into the same ARAM locations for all calculations. Consider the following sequence of events:

1. A processor or system DMA loads the initial data set and initializes the programming model registers. The initial register load sets AMU2_DCCRCH*n*[WFDNI] to delay the fetching of the next (2nd) U[*] until the first calculation is complete. Additionally, the ADMA is configured to load the next U[*] input vector and the AMU2_CCR{1,2}CH*n* registers by setting AMU2_DCCRCH*n*[SARU, DARU] = [0b10, 0b01]. Finally, as part of the initial register writes, AMU2_CCR1CH*n*[DNICFG] = 0b10 to generate a SDMA request after the ALU calculation completes, and AMU2_CCR2CH*n*[S1SRT, S23SRT] = 1,1 to start the first calculation.
2. As the first complete calculation finishes, the assertion of AMU2_SEIRCH*n*[DNIRQ] is configured to assert an SDMA request and initiate the ADMA to fetch the next U[*] vector from Flash and writing it into the same ARAM locations. Since AMU2_DCCRCH*n*[DARU] = 0b01, the last 64 bits of fetch data are written into the AMU2_CCR{1,2}CH*n* registers. The write sets AMU2_CCR2CH*n*[WFDS1, WFSS23] = 1,1 to conditionally start the second calculation when the ADMA completes the new U[*] fetch. The ADMA fetch also needs to set AMU2_CCR2CH*n*[ADCCR25] = AMU2_DCCRCH*n*[WFDNI] = 1 on all data sets *except* the final iteration. The SDMA responds by copying the AMU2_RES64{M,L}CH*n* and AMU2_SEIRCH*n* registers into system RAM; the AMU2_SEIRCH*n*[DNIRQ] indicator is cleared by the SDMA acknowledge.
3. The process continues with the ALU performing the calculation, the ADMA fetching a new U[*] vector, and the SDMA copying the 64-bit result and status into system RAM until the last U[*] vector is fetched from Flash. The final value loaded into AMU2_CCR1CH*n*[DNICFG] = 0b01 to generate a processor interrupt request when the final calculation completes.

94.5 Operation details

94.5.1 Details on operation completion status indicators

Recall the AMU2_SEIRCH*n* register provides a sizable number of status flags. See *Section 94.2.3.25: AMU Status, Error & Interrupt Channel n Register (AMU2_SEIRCHn)* for the details. This section provides information on the detailed bit status based on a number of expected operation completion states. For ADMA completion state information, see *Table 2383*, while *Table 2384* contains the ALU completion state details.

Table 2383. ADMA Completion State Details in AMU2_SEIRCH*n*

ADMA Completion State	ADMAS	ADMERR	CKSERR	DEIRQ	ADIRQ
Completed error-free	00	0	0	0	1
Error (Bus error, non-correctable ECC event)	01	1	0	1	0
Checksum error with AMU2_DCCRCHn[HCRCE] = 0	00	0	1	0	1
Checksum error with AMU2_DCCRCHn[HCRCE] = 1	01	0	1	1	0

Table 2384. ALU Completion State Details in AMU2_SEIRCH*n*

ALU Completion State	S23XS	S1XS	YCAFLT	ZCAFLT	S23AFLT	S1AFLT	IDVERR	ECCERR	RGCERR	ERIRQ	OVIRQ	NCIRQ	DNIRQ
S1 error-free completion	00	00	0	0	0	0	0	0	0	0	0	0	1(1)
S1 input data validation error	00	01	0	0	0	0	1	0	0	1	0	0	0
S1 ECC error	00	01	0	0	0	0	0	1	0	1	0	0	0
S1 register conflict error	00	01	0	0	0	0	0	0	1	1	0	0	0
S1 overflow	00	01	0	0	0	1	0	0	0	0	1	0	0
S1 underflow	00	00	0	0	0	1	0	0	0	0	0	0	1(1)
S23 error-free completion	00	00	0	0	0	0	0	0	0	0	0	0	1
S23 N crossing	10	00	0	0	0	0	0	0	0	0	0	1	0
S23 input data validation error	01	00	0	0	0	0	1	0	0	1	0	0	0
S23 ECC error	01	00	0	0	0	0	0	1	0	1	0	0	0
S23 register conflict error	01	00	0	0	0	0	0	0	1	1	0	0	0
S23 overflow	01	00	0	0	1	0	0	0	0	0	1	0	0
S23 underflow	00	00	0	0	1	0	0	0	0	0	0	0	1
Final Y32 overflow	01	00	1	0	0	0	0	0	0	0	1	0	0
Final Y32 underflow	00	00	1	0	0	0	0	0	0	0	0	0	1
Z32 overflow	01	00	0	1	0	0	0	0	0	0	1	0	0
Z32 underflow	00	00	0	1	0	0	0	0	0	0	0	0	1

1. For these completion states, if there is a pending Stage23 calculation, the AMU2_SEIRCH*n*[DNIRQ] indicator does *not* set until and unless that calculation completes error-free or with any underflow.

94.5.2 Details on operation stop/resume

The AMU2 supports the ability to temporarily stop an operation and later resume execution. Consider the following examples of the required operations to support this stop/resume control.

94.5.2.1 Stop ALU calculation, check progress, then resume

For this basic stop/resume sequence, the following steps are needed:

1. Set AMU2_CCR2CH*n*[S23STP] = 1.
2. Wait for AMU2_CCR2CH*n*[S23STP] to (auto)clear, indicating the stop request has been processed and the ALU has entered the stopped state. The ALU's stopped state is signaled by AMU2_SEIRCH*n*[S23XS] = 2 (stopped).
3. Check calculation progress as needed.
4. Resume the calculation by setting AMU2_CCR2CH*n*[S23RSM] = 1. As the ALU continues the calculation, AMU2_SEIRCH*n*[S23XS] = 11 (running).

This sequence can be used whether P3[*] or V[*], or both, streaming is enabled or not. If data streaming is enabled, the stopping of the ALU automatically causes the ADMA to stop fetching data since the data transfers are paced by the ALU execution.

If a stop request is made during the final iteration of the stage2 outer loop, the AMU honors the request and stops prior to executing stage3.

94.5.2.2 Stop ALU calculation, perform a new calculation, then restore and resume the original calculation

For this stop/resume sequence, the following steps are needed:

1. Set AMU2_CCR2CH*n*[S23STP] = 1.
2. Wait for AMU2_CCR2CH*n*[S23STP] to (auto)clear, indicating the stop request has been processed and the ALU has entered the stopped state. The ALU's stopped state is signaled by AMU2_SEIRCH*n*[S23XS] = 2 (stopped).
3. Temporarily save the contents of the required programming model. This includes the AMU2_{P3PTR, P4, P5, P6, P7, P8, VPTR, LPTR, CCR{1,2}, Y64, RES32} registers as well as the CH*n* UT[*] in the ARAM data FIFO.
4. Load the new data set, execute the calculation, store the results as required.
5. Restore the saved data contents from Step 3, including restoring the saved Y64 to P9 and RES32 to P5 (see Note below).
6. Continue the calculation by setting AMU2_CCR2CH*n*[S23SRT] = 1. As the ALU continues the calculation, AMU2_SEIRCH*n*[S23XS] = 11 (running).

Again, this sequence can be used whether P3[*] or V[*], or both, streaming is enabled or not. This sequence assumes the two calculations *do not corrupt each other's input data in ARAM*, otherwise software must save/restore the ARAM contents as required.

Note: In the case where the interrupted calculation is configured to initialize Z to P5 as indicated by AMU2_CCR1CHn[SETZ] = 1, then P5 is restored to the original P5 value. Otherwise, P5 is restored to the saved RES32 value. Note that in the latter case, the double precision RES64 value is lost when resuming the interrupted calculation as only the single-precision RES32 can be saved and restored using P5.

94.5.3 AMU2 Performance

The execution time for the M=p7=10, N=p6=500 test case is 10,084 cycles with all the operands pre-loaded into the ARAM. At 200 MHz, this corresponds to an execution time of 50.42 microseconds. This time applies for both a single or two simultaneous channel execution.

The AMU2 execution time, when all operands are pre-loaded into the ARAM, can be approximated by the equation:

Estimated AMU2 Execution Time [cycles] ~= 66 + 2*M + 2*M*(N + (N & 1))

where the constant represents the summation of the time associated with the stage1 and stage2 startup including the initial data FIFO loading and filling the execution pipeline plus the stage3 execution, the second term represents the stage1 time, and the third term represents the stage2 time. The stage1 and stage2 times include the "2*" multiplier since these operations are time-multiplexed across the two ALU channels.

See *Table 2385* for a few estimated and measured execution times with varying M and N values.

Table 2385. AMU2 Execution Times, all data pre-loaded into ARAM

M (p7)	N (p6)	Estimated Execution Time [cycles]	Measured Execution Time [cycles]	Measured Execution Time [usec @ 200 MHz]
10	500	10086	10084	50.42
10	250	5086	5084	25.42
5	500	5076	5076	25.38
5	250	2576	2576	12.88
5	249	2576	2576	12.88
5	248	2556	2556	12.78
5	247	2556	2556	12.78
5	246	2536	2536	12.68

For a 200 MHz operating speed, the Flash access time set to the normal value (RWSC=6) and an otherwise idle Flash, if both P3[*] *and V[*] are streamed by the ADMA* with all the *other* input data already loaded in the ARAM, the incremental execution time is estimated at 1000 cycles producing a total execution time of 11,084 cycles.

Table 2386. Single Channel AMU2 Performance for M=p7=10, N=p6=500

Input Operand Mode	Execution Cycles	Execution Time @ 200 MHz
All pre-loaded into ARAM	10084	50.42 usec
ADMA load of new P3[*] + V32[*][*], all else pre-loaded into ARAM	16959	84.80 usec
ADMA load of new P3[*] + V16[*][*], all else pre-loaded into ARAM	13834	69.17 usec
Stream V32[*][*], all else pre-loaded into ARAM	10086	50.43 usec
Stream V16[*][*], all else pre-loaded into ARAM	10086	50.43 usec
Stream P3[*] + V32[*][*], all else pre-loaded into ARAM	11524	57.62 usec
Stream P3[*] + V16[*][*], all else pre-loaded into ARAM	10090	50.45 usec

95 Real Time Clock / Autonomous Periodic Interrupt (RTC/API)

95.1 Overview

The RTC is a free running counter used for time keeping applications. The RTC may be configured to generate an interrupt at a predefined interval independent of the mode of operation (run mode or low power mode). When the RTC interval is reached, the RTC will generate a wakeup request to the wakeup unit. The RTC can be configured to generate an interrupt on the RTC interval timeout.

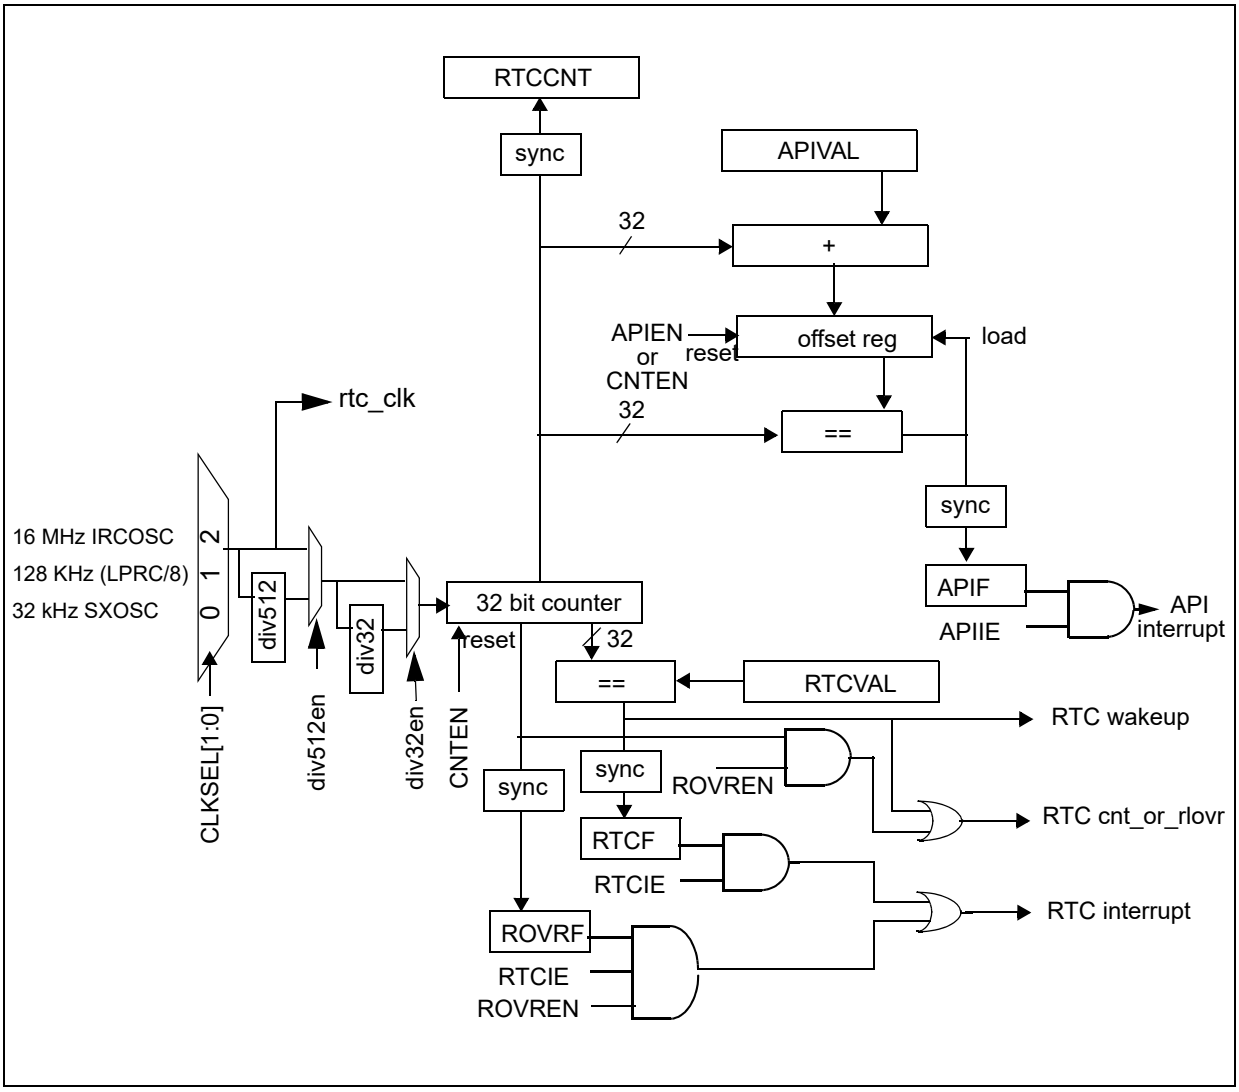
The RTC also supports an autonomous periodic interrupt (API) function which can be used to generate a periodic event to the wakeup unit or an interrupt request.

95.2 Features

Features of the RTC/API include:

- 3 selectable counter clock sources:
  - LPRC prescaled by 8 (128 kHz)
  - SXOSC (32 kHz)
  - IRCOSC (16 MHz)
- Clock sources can optionally be prescaled by 512 or 32
- 32-bit counter
  - Supports times up to 1.5 months with 1 ms resolution
  - Runs in all modes of operation, including normal RESET
  - Reset when disabled by software and by POR
- 12-bit compare value to support an extended range of interrupt intervals
- RTC compare value changeable while counter is running
- RTC status and control register are reset only by POR
- Autonomous periodic interrupt (API) to support an extended range of inerrupt intervals
- Configurable interrupt for RTC match, API match, and RTC rollover
- Configurable wakeup event for RTC match, API match, and RTC rollover

Figure 2501. RTC/API block diagram



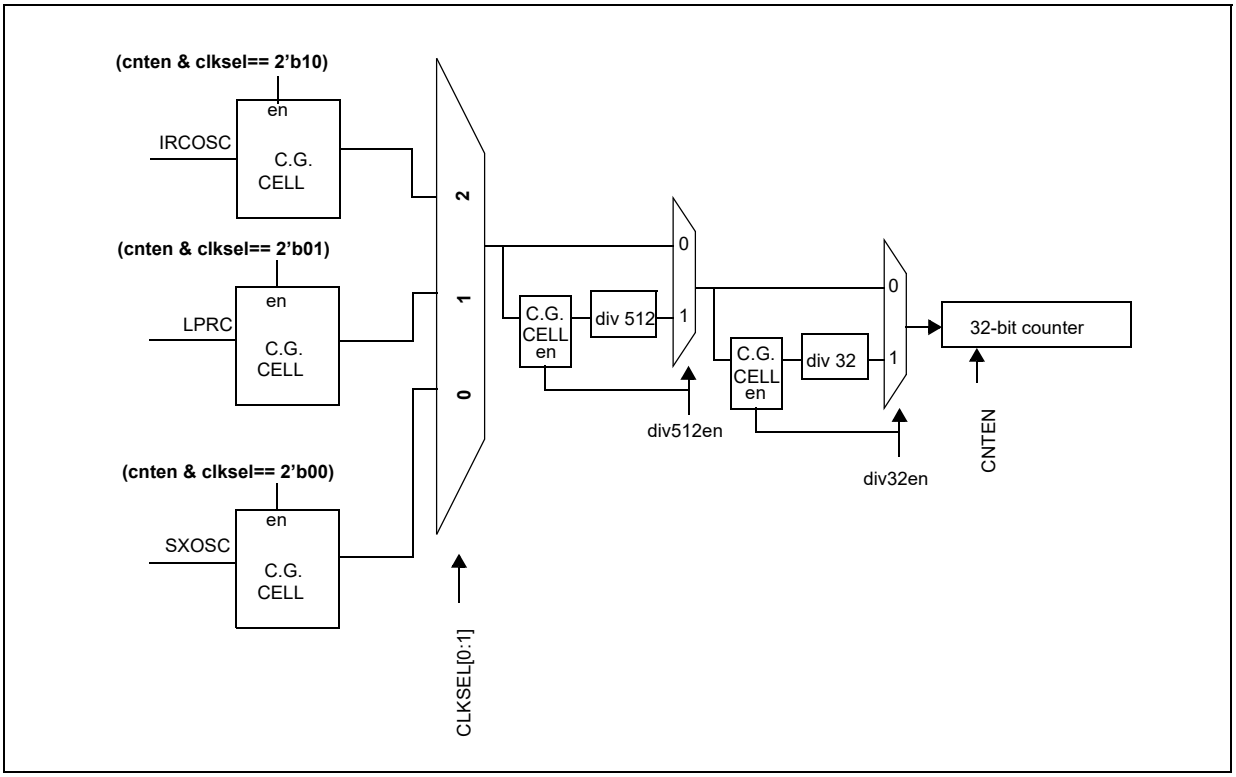


Figure 2502. Clock gating for RTC clocks

95.3 Modes of operation

95.3.1 Functional mode

There are two functional modes of operation for the RTC: normal operation and low power mode. In normal operation, all RTC registers can be read or written. The RTC/API and associated interrupts are optionally enabled. In low power mode, the bus interface is disabled and no configuration changes are permitted. The RTC/API is enabled if enabled prior to entry into low power mode.

95.3.2 Debug mode

If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. If RTCC[FRZEN] is clear, the counter will continue counting (and set flags accordingly) when the device is in debug mode.

95.4 Register descriptions

The registers listed in *Table 2387* are described in the following sections.

Table 2387. RTC/API register map

Address offset	Register	Location
0x0000	RTC Supervisor Control Register (RTCSUPV)	*Section 95.4.1*
0x0004	RTC Control Register (RTCC)	*Section 95.4.2*
0x0008	RTC Status Register (RTCS)	*Section 95.4.3*
0x000C	RTC Counter Register (RTCCNT)	*Section 95.4.4*
0x0010	API Compare Value Register (RTC_APIVAL)	*Section 95.4.5*
0x0014	RTC Compare Value Register (RTC_RTCVAL)	*Section 95.4.6*

95.4.1 RTC Supervisor Control Register (RTCSUPV)

The RTCSUPV register contains the SUPV bit which determines whether other registers are accessible in supervisor mode or user mode.

Note: RTCSUPV register is accessible only in supervisor mode.

Offset: 0x0000 Access: Supervisor R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SUPV	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2503. RTC Supervisor Control Register (RTCSUPV)

Table 2388. RTCSUPV register field descriptions

Field	Description
0 SUPV	RTC Supervisor Bit 0 All registers are accessible in both user as well as supervisor mode. 1 All other registers are accessible in supervisor mode only.

95.4.2 RTC Control Register (RTCC)

The RTCC register contains:

- RTC counter enable
- RTC interrupt enable
- RTC clock source select
- RTC compare value
- API enable
- API interrupt enable
- API compare value

Offset: 0x0004 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNTEN	RTCIE	FRZEN	ROVREN	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2504. RTC Control Register (RTCC)

Table 2389. RTCC register field descriptions

Field	Description
0 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Clearing CNTEN has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic as well as resetting the 32-bit counter. This allows for the RTC configuration and clock source selection to be updated without causing synchronization issues. 0 Counter disabled and reset 1 Counter enabled
1 RTCIE	RTC Interrupt Enable The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0 RTC interrupts disabled 1 RTC interrupts enabled
2 FRZEN	Freeze Enable Bit If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. 0 Counter running in debug mode 1 Counter stops (freezes) in debug mode
3 ROVREN	Counter Roll Over Interrupt Enable The ROVREN enables interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0 RTC rollover interrupt disabled 1 RTC rollover interrupt enabled
16 APIEN	Autonomous Periodic Interrupt Enable The APIEN bit enables the autonomous periodic interrupt function. 0 API disabled 1 API enabled

Table 2389. RTCC register field descriptions (continued)

Field	Description
17 APIIE	API Interrupt Enable The APIIE bit enables interrupts requests to the system if APIF is asserted. 0 API interrupts disabled 1 API interrupts enabled
18:19 CLKSEL	Clock Select The CLKSEL[0:1] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. 00 SXOSC 01 LPRC prescaled by 8 10 IRCOSC 11 Reserved
20 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0 Divide by 512 is disabled. 1 Divide by 512 is enabled.
21 DIV32EN	Divide by 32 enable The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0 Divide by 32 is disabled. 1 Divide by 32 is enabled.
31 TRIG_EN	Trigger enable Used for self clearing of WKPU API event. This bit is required in case API event is being used to trigger SSWU eCTU commands. 0 Trigger enable is disabled. 1 Trigger enable is enabled.

95.4.3 RTC Status Register (RTCS)

The RTCS register contains:

- RTC interrupt flag
- API interrupt flag
- ROLLOVR Flag

Offset: 0x0008 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	RTCF	0	0	0	0	0	0	0	0	0	0	INV_RTC	INV_API	INV_ANL
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	APIF	0	0	ROVRF	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2505. RTC Status Register (RTCS)

Table 2390. RTCS register field descriptions

Field	Description
2 RTCF	RTC Interrupt Flag The RTCF bit indicates that the RTC counter has reached the counter value matching RTCVAL. RTCF is cleared by writing a 1 to RTCF. Writing a 0 to RTCF has no effect. 0 RTC counter is not equal to RTCVAL. 1 RTC counter matches RTCVAL.
13 INV_RTC	Invalid RTC write This bit becomes value 1 after a value has been written to the RTCVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the RTCVAL register again will be ignored.
14 INV_API	Invalid APIVAL write This bit becomes value 1 after a value has been written to the APIVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the APIVAL register again will be ignored.
15 INV_ANL	Invalid ANLCMP write This bit becomes value 1 after a value has been written to the ANLCMP_CNT register and the synchronization process is continuing. During this synchronization period, any attempt to write to the ANLCMP_CNT register again will be ignored.
18 APIF	API Interrupt Flag The APIF bit indicates that the RTC counter has reached the counter value matching API offset value. APIF is cleared by writing a 1 to APIF. Writing a 0 to APIF has no effect. 0 No API interrupt 1 API interrupt
21 ROVRF	Counter Roll Over Interrupt Flag The ROVRF bit indicates that the RTC has rolled over from 0xffff_ffff to 0x0000_0000. ROVRF is cleared by writing a 1 to ROVRF. 0 RTC has not rolled over. 1 RTC has rolled over.

95.4.4 RTC Counter Register (RTCCNT)

The RTCCNT register contains the current value of the RTC counter.

Offset: 0x000C Access: User read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RTCCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RTCCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2506. RTC Counter Register (RTCCNT)

Table 2391. RTCCNT register field descriptions

Field	Description
0:31 RTCCNT	RTC Counter Value Due to the clock synchronization, the RTCCNT value may actually represent a previous counter value.

95.4.5 API Compare Value Register (RTC_APIVAL)

The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted.

Offset: 0x0010 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	APIVAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	APIVAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2507. API Compare Value Register (RTC_APIVAL)

Table 2392. RTC_APIVAL register field descriptions

Field	Description
0:31 APIVAL	API Compare Value The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted. **Note:** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to rtc clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. Minimum supported value of APIVAL is 4. This is due to synchronization issues.

95.4.6 RTC Compare Value Register (RTC_RTCVAL)

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set.

Note: If RTC counter is reset (RTCC[CTNEN] = 0), it is required to reload the RTCVAL via software to re-enable the RTCVAL match interrupt before starting the RTC counter.

With RTCC[CTNEN] = 1 (RTC running) the user needs to wait the RTCS[RTC_INV] goes to zero (completed the synchronization process) before updating the RTCVAL counter. Otherwise the latter update will have no effect.

Offset: 0x0014 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2508. RTC Compare Value Register (RTC_RTCVAL)

Table 2393. RTC_RTCVAL register field descriptions

Field	Description
0:31 RTCVAL	RTC Compare Value The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. **Note:** Minimum supported value of RTCVAL is 4. This is due to synchronization issues.

95.5 RTC functional description

The RTC consists in a 32-bit free running counter enabled with the RTCC[CNTEN] bit. (When CNTEN is cleared, the counter is asynchronously reset.) The value of the counter may be read via the RTCCNT register. Note that due to the clock synchronization, the RTCCNT value may actually represent a previous counter value. The difference between

the counter and the read value depends on ratio of counter clock and main clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the RTCC[CLKSEL] field, which gives four options for clocking the RTC/API. The three clock sources are:

- LPRC prescaled by 8 (128 kHz)
- SXOSC (32 kHz)
- IRCOSC (16 MHz)

The output of the clock mux can be optionally divided by combination of 512 and 32 to give a 1 ms RTC/API count period for different clock sources. Note that the RTCC[CNTEN] bit must be disabled when the RTC/API clock source is switched.

When the counter value matches the 32-bit value in the RTCC[RTCVAL] field, then the RTCS[RTCF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[RTCIE] interrupt enable bit is set, then the RTC interrupt request is generated. If there is a match while in low power mode then the RTC will first generate a wakeup request to force a wakeup to run mode, then the RTCF flag will be set.

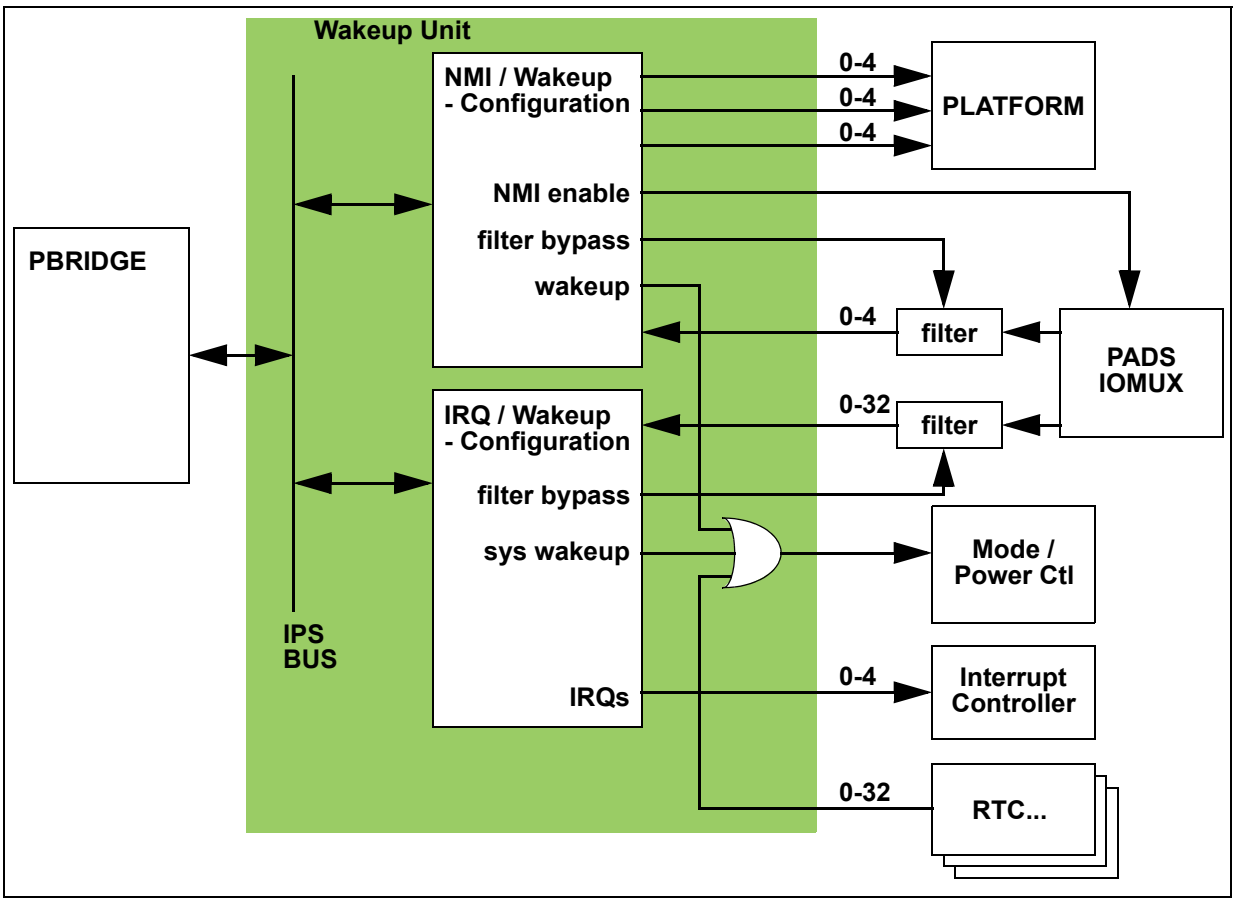
A rollover interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. Rollover events are enabled by setting the RTCC[ROVEN] bit. If this bit is set, an RTC rollover will cause a request. To enable interrupts on a rollover request, the RTCC[RTCIE] bit also needs to be set.

All the flags and counter values are synchronized with ipg_clk the main clock. It is assumed that ipg_clk the main clock frequency is always more than or equal to the rtc_clk RTC clock used to run the counter.

95.6 API functional description

Setting the RTCC[APIEN] bit enables the autonomous interrupt function. The 32-bit RTCC[APIVAL] field selects the time interval for triggering an interrupt and/or wakeup event. Since the RTC is a free running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, a interrupt and/or wakeup request is generated. Then the offset value is recalculated and re-triggers a new request when the new value is reached. APIVAL may only be updated when APIEN is disabled. When a compare is reached, the RTCS[APIF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[APIIE] interrupt enable bit is set, then the API interrupt request is generated. If there is a match while in low power mode, then the API will first generate a wakeup request to force a wakeup into normal operation, then the APIF flag will be set.

96 Wakeup unit (WKPU)



96.1 Introduction

96.1.1 Overview

The Wakeup unit supports up to 32 external sources that can generate CPU exceptions or wakeup events and up to 3 external sources that can cause non-maskable interrupt requests or wakeup events. In addition, it combines its wakeup events with those generated from up to 32 other wakeup sources to supply a single wakeup to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 2509* is a block diagram of the Wakeup unit and its interfaces to other system components.

Note: For the chip-specific implementation details of this module refer to the Device Configuration chapter.

Figure 2509. Wakeup unit block diagram

96.1.2 Features

The Wakeup unit supports these distinctive features:

- Non-maskable interrupt support with:
  - Up to 4 NMI sources
  - Up to 4 analog glitch filters
  - Independent CPU exceptions destination: non-maskable interrupt, critical interrupt, or machine check request
  - Edge detection
  - Configurable system wakeup triggering from all NMI sources
- External wakeup/interrupt support with:
  - Up to 4 system interrupt vectors for up to 32 interrupt sources
  - Up to 32 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable pull functionality
- On-chip wakeup support with:
  - Up to 32 wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status

Note: For the chip-specific feature details of this module refer to the Device Configuration chapter.

96.2 External signal description

The Wakeup unit has 0 to 32 signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

The module has 0 to 4 signal inputs that can be used as non-maskable interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

96.3 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

96.3.1 Memory map

Table 2394 gives an overview on the WKPU registers implemented.

Table 2394. WKPU memory map

Address offset	Registers	Supported access sizes	Location
0x0000	NMI Status Flag Register (NSR)	32/16/8	*Section 96.3.2.1*
0x0004–0x0007	Reserved		
0x0008	NMI Configuration Register (NCR)	32/16/8	*Section 96.3.2.2*

Table 2394. WKPU memory map (continued)

Address offset	Registers	Supported access sizes	Location
0x000C–0x0013	Reserved		
0x0014	Wakeup/Interrupt Status Flag Register (WISR)	32	*Section 96.3.2.3*
0x0018	Interrupt Request Enable Register (IRER)	32	*Section 96.3.2.4*
0x001C	Wakeup Request Enable Register (WRER)	32	*Section 96.3.2.5*
0x0020–0x0027	Reserved		
0x0028	Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)	32	*Section 96.3.2.6*
0x002C	Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)	32	*Section 96.3.2.7*
0x0030	Wakeup/Interrupt Filter Enable Register (WIFER)	32	*Section 96.3.2.8*
0x0034	Wakeup/Interrupt Pullup Enable Register (WIPUER)	32	*Section 96.3.2.9*
0x0038–0x3FFF	Reserved		

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

96.3.2 Register descriptions

This section describes in address order all the Wakeup unit registers.

96.3.2.1 NMI Status Flag Register (NSR)

This register holds the non-maskable interrupt status flags.

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NIF0	NOVF0	0	0	0	0	0	0	NIF1	NOVF1	0	0	0	0	0	0	NIF2	NOVF2	0	0	0	0	0	0	RIF	ROVF	0	0	0	0	0	0
W	w1c	w1c							w1c	w1c							w1c	w1c							w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2510. NMI Status Flag Register (NSR)

Table 2395. NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE0 and NFEE0 has occurred. 0 No event has occurred on the pad.
1 NOVF0	NMI Overrun Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 1 An overrun has occurred on NMI input 0. 0 No overrun has occurred on NMI input 0.
8 NIF1	NMI Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE1 and NFEE1 has occurred. 0 No event has occurred on the pad.
9 NOVF1	NMI Overrun Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 1 An overrun has occurred on NMI input 1. 0 No overrun has occurred on NMI input 1.
16 NIF2	NMI Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE2 and NFEE2 has occurred. 0 No event has occurred on the pad.
17 NOVF2	NMI Overrun Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 1 An overrun has occurred on NMI input 2. 0 No overrun has occurred on NMI input 2.

Table 2395. NSR field descriptions (continued)

Field	Description
24 RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (that is if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An event as defined by RREE and RFEE has occurred. 0 No event has occurred on the pad.
25 ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An overrun has occurred on NMI input. 0 No overrun has occurred on NMI input.

Note: Refer to the Device Configuration chapter to see how the NMI Status Flag Register (NSR) is used in the device.

96.3.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 2396. NCR field descriptions (continued)

Field	Description
3 NWRE0	NMI Wakeup Request Enable 0 1 NMI0 wakeup is enabled. A set NIF0 bit or set NOVF0 bit causes a system wakeup request. 0 NMI0 wakeup is disabled. System wakeup requests from the corresponding NIF0 bit are disabled.
5 NREE0	NMI Rising-edge Events Enable 0 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
6 NFEE0	NMI Falling-edge Events Enable 0 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
7 NFE0	NMI Filter Enable 0 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
8 NLOCK1	NMI Configuration Lock Register 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
9:10 NDSS1	NMI Destination Source Select 1 This value is reset on system reset. 00 non-maskable interrupt 01 critical interrupt 10 machine check request 11 reset request
11 NWRE1	NMI Wakeup Request Enable 1 1 NMI1 wakeup is enabled. A set NIF1 bit or set NOVF1 bit causes a system wakeup request 0 NMI1 wakeup is disabled. System wakeup requests from the corresponding NIF1 bit are disabled
13 NREE1	NMI Rising-edge Events Enable 1 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
14 NFEE1	NMI Falling-edge Events Enable 1 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
15 NFE1	NMI Filter Enable 1 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
16 NLOCK2	NMI Configuration Lock Register 2 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.

Table 2396. NCR field descriptions (continued)

Field	Description
17:18 NDSS2	NMI Destination Source Select 2 This value is reset on system reset. 00 non-maskable interrupt 01 critical interrupt 10 machine check request 11 reset request
19 NWRE2	NMI Wakeup Request Enable 2 1 NMI2 wakeup is enabled. A set NIF2 bit or set NOVF2 bit causes a system wakeup request. 0 NMI2 wakeup is disabled. System wakeup requests from the corresponding NIF2 bit are disabled.
21 NREE2	NMI Rising-edge Events Enable 2 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
22 NFEE2	NMI Falling-edge Events Enable 2 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
23 NFE2	NMI Filter Enable 2 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
24 RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
25:26 RDSS	Reset Destination Source Select This value is reset on system reset. 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request. 0 System wakeup requests from the corresponding RIF bit are disabled. **Note:** To wake up the system from standby by this way, ESR1 option has to be disable in MC_RGM. To disable the MC_RGM ESR1 function, the bit 30 of RGM_FERD and RGM_FEAR registers have to be set.
29 RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.

Table 2396. NCR field descriptions (continued)

Field	Description
30 RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
31 RFE	Reset Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Note: Refer to the Device configuration chapter to see how the NMI Configuration Register (NCR) is used in the device.

Writing a '0' to both NREEx and NFEEx disables the NMI functionality completely (no system wakeup or interrupt will be generated on any pad activity).

96.3.2.3 Wakeup/Interrupt Status Flag Register (WISR)

This register holds the wakeup/interrupt flags.

Offset: 0x0014 Access: User read/write

Figure 2512. Wakeup/Interrupt Status Flag Register (WISR)

Table 2397. WISR field descriptions

Field	Description
0 EIF31	External Wakeup/Interrupt Status Flag 31 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER31), EIF31 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
1 EIF30	External Wakeup/Interrupt Status Flag 30 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER30), EIF30 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
2 EIF29	External Wakeup/Interrupt Status Flag 29 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER29), EIF29 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2397. WISR field descriptions (continued)

Field	Description
3 EIF28	External Wakeup/Interrupt Status Flag 28 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER28), EIF28 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
4 EIF27	External Wakeup/Interrupt Status Flag 27 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER27), EIF27 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
5 EIF26	External Wakeup/Interrupt Status Flag 26 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER26), EIF26 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
6 EIF25	External Wakeup/Interrupt Status Flag 25 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER25), EIF25 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
7 EIF24	External Wakeup/Interrupt Status Flag 24 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER24), EIF24 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
8 EIF23	External Wakeup/Interrupt Status Flag 23 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER23), EIF23 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
9 EIF22	External Wakeup/Interrupt Status Flag 22 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER22), EIF22 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
10 EIF21	External Wakeup/Interrupt Status Flag 21 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER21), EIF21 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
11 EIF20	External Wakeup/Interrupt Status Flag 20 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER20), EIF20 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2397. WISR field descriptions (continued)

Field	Description
12 EIF19	External Wakeup/Interrupt Status Flag 19 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER19), EIF19 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
13 EIF18	External Wakeup/Interrupt Status Flag 18 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER18), EIF18 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
14 EIF17	External Wakeup/Interrupt Status Flag 17 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER17), EIF17 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
15 EIF16	External Wakeup/Interrupt Status Flag 16 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER16), EIF16 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
16 EIF15	External Wakeup/Interrupt Status Flag 15 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER15), EIF15 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
17 EIF14	External Wakeup/Interrupt Status Flag 14 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER14), EIF14 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
18 EIF13	External Wakeup/Interrupt Status Flag 13 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER13), EIF13 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
19 EIF12	External Wakeup/Interrupt Status Flag 12 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER12), EIF12 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
20 EIF11	External Wakeup/Interrupt Status Flag 11 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER11), EIF11 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2397. WISR field descriptions (continued)

Field	Description
21 EIF10	External Wakeup/Interrupt Status Flag 10 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER10), EIF10 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
22 EIF9	External Wakeup/Interrupt Status Flag 9 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER9), EIF9 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
23 EIF8	External Wakeup/Interrupt Status Flag 8 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER8), EIF8 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
24 EIF7	External Wakeup/Interrupt Status Flag 7 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER7), EIF7 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
25 EIF6	External Wakeup/Interrupt Status Flag 6 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER6), EIF6 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
26 EIF5	External Wakeup/Interrupt Status Flag 5 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER5), EIF5 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
27 EIF4	External Wakeup/Interrupt Status Flag 4 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER4), EIF4 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
28 EIF3	External Wakeup/Interrupt Status Flag 3 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER3), EIF3 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
29 EIF2	External Wakeup/Interrupt Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER2), EIF2 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2397. WISR field descriptions (continued)

Field	Description
30 EIF1	External Wakeup/Interrupt Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER1), EIF1 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
31 EIF0	External Wakeup/Interrupt Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER0), EIF0 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Note: Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

96.3.2.4 Interrupt Request Enable Register (IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

Offset: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

26 EIRE5	External Interrupt Request Enable 5 1 A set EIF5 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF5 bit are disabled.
27 EIRE4	External Interrupt Request Enable 4 1 A set EIF4 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF4 bit are disabled.
28 EIRE3	External Interrupt Request Enable 3 1 A set EIF3 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF3 bit are disabled.
29 EIRE2	External Interrupt Request Enable 2 1 A set EIF2 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF2 bit are disabled.
30 EIRE1	External Interrupt Request Enable 1 1 A set EIF1 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF1 bit are disabled.
31 EIRE0	External Interrupt Request Enable 0 1 A set EIF0 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF0 bit are disabled.

96.3.2.5 Wakeup Request Enable Register (WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

Note: Any wakeup pad must be properly driven either externally or internally (enabling weak pull-up/pull-down) before enabling its corresponding WREx bit.

96.3.2.8 Wakeup/Interrupt Filter Enable Register (WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

Note: Glitch filter must be enabled in case the wake-up sources are used to exit from Standby.

96.3.2.9 Wakeup/Interrupt Pull Enable Register (WIPUER)

This register is used to enable a pull on the corresponding interrupt pads. The pull direction (up or down) is selected by SIUL2_MSCR_IO_n.WPDE-WPUE bits.

Note: WIPUER bits related to those bonded LP pads that are used to wake-up the device from STANDBY Mode, should be left at 0 default value.

- *Bits setting has undesired effect in STANDBY mode (extra consumption or anticipated exiting from STANDBY mode)*
- *In running mode, pull-up/down IO configuration shall be done only through SIUL*

96.4 Functional description

96.4.1 General

This section provides a complete functional description of the Wakeup unit.

96.4.2 Non-maskable interrupts

The Wakeup unit supports up to 4 non-maskable interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports the generation of 3 types of interrupts per NMI input to the SoC. The Wakeup unit supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a by-passable analog glitch filter.

Note: Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

96.4.2.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 2511*). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note: After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 2396* for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see *Figure 2510*). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event

is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (it has not yet been cleared).

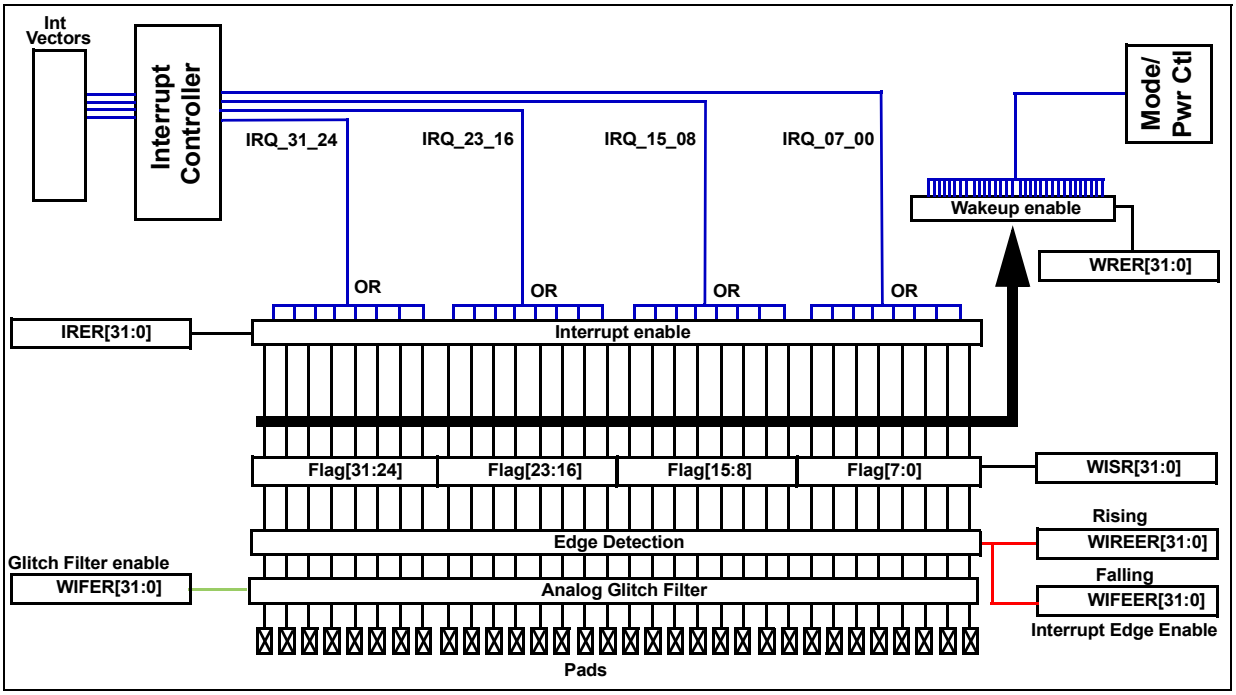
Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

96.4.3 External wakeups/interrupts

The Wakeup unit supports up to 32 external wakeup/interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports up to 4 interrupt vectors to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N - 1, the next is for N through N + M - 1, and so forth.

The parameter IRQ_VEC defines the number of interrupt vectors (the ipi_int_pins output size).



The parameter EIRQ_PER_VEC defines the number of external interrupt sources assigned to each interrupt vector. It is split up into four 6-bit fields, one for each possible interrupt vector, with the lowest field corresponding to ipi_int_pins[0], the second field to ipi_int_pins[1], and so forth.

For example, for EIRQS = 17, IRQ_VEC = 3 and EIRQ_PER_VEC = {6'd0, 6'd5, 6'd3, 6'd9}, ipp_ind_int[8:0] are assigned to ipi_int_pins[0], ipp_ind_int[11:9] are assigned to ipi_int_pins[1], and ipp_ind_int[16:12] are assigned to ipi_int_pins[2]. The signals ipp_ind_int[31:17] and ipi_int_pins[3] do not exist.

Note: If EIRQS = 0, the unused ipp_ind_int[0] input has no effect on the sys_wakeup output.

Refer to *Figure 2519* for an overview of the external interrupt implementation for the example of four interrupt vectors with eight external interrupt sources each.

Figure 2519. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

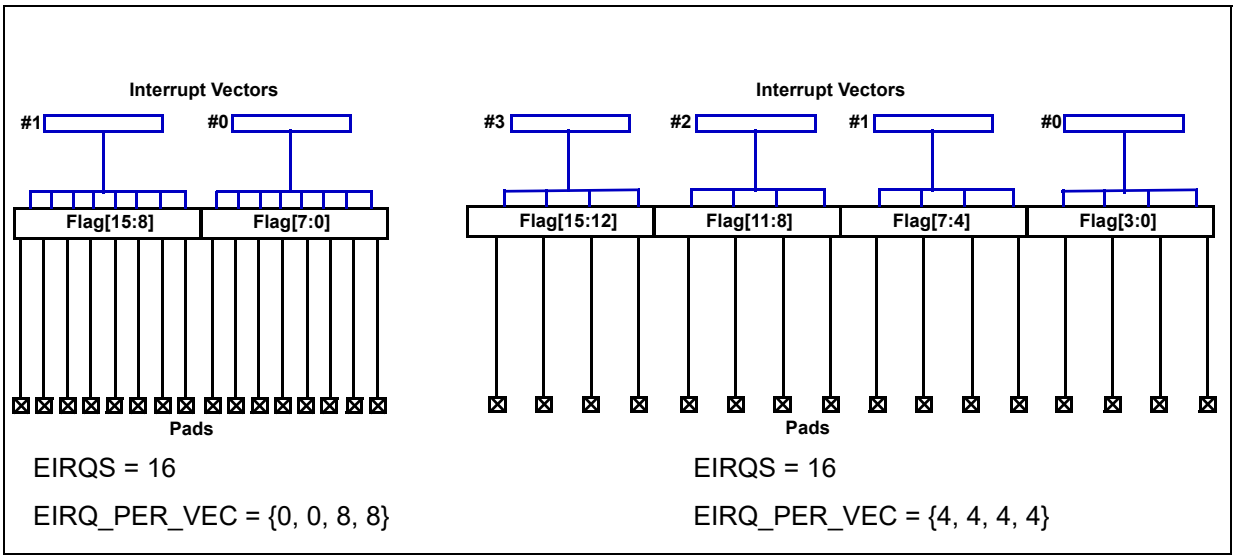
The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

An SoC specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 0 to 32.

Note: Glitch filter control and pad configuration should be done while the external interrupt line is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

96.4.3.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (*Figure 2513*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.



Note: Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (no system wakeup or interrupt will be generated on any activity on that pad)!

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

For devices with less than the maximum number of interrupt sources, it is possible for the SoC to implement either all four interrupt vectors with fewer sources or to reduce the number of vectors as the number of sources are reduced. *Figure 2520* shows two examples of how this could be supported.

Figure 2520. Example of different interrupt to vector mapping at SOC level

96.4.4 On-Chip wakeups

The Wakeup unit supports up to 32 on-chip wakeup sources. It combines the on-chip wakeups with the external ones to generate a single wakeup to the system.

Note: If WUPS = 0, the unused wakeup_in input has no effect on the sys_wakeup output.

96.4.4.1 On-Chip wakeup management

In order to allow software to determine the wakeup source at one location, on-chip wakeups are reported along with external wakeups in the WISR register (see *Figure 2512* for details). Enabling and clearing of these wakeups are done via the on-chip wakeup source's own registers.

97 Emulation and Debug Device Introduction

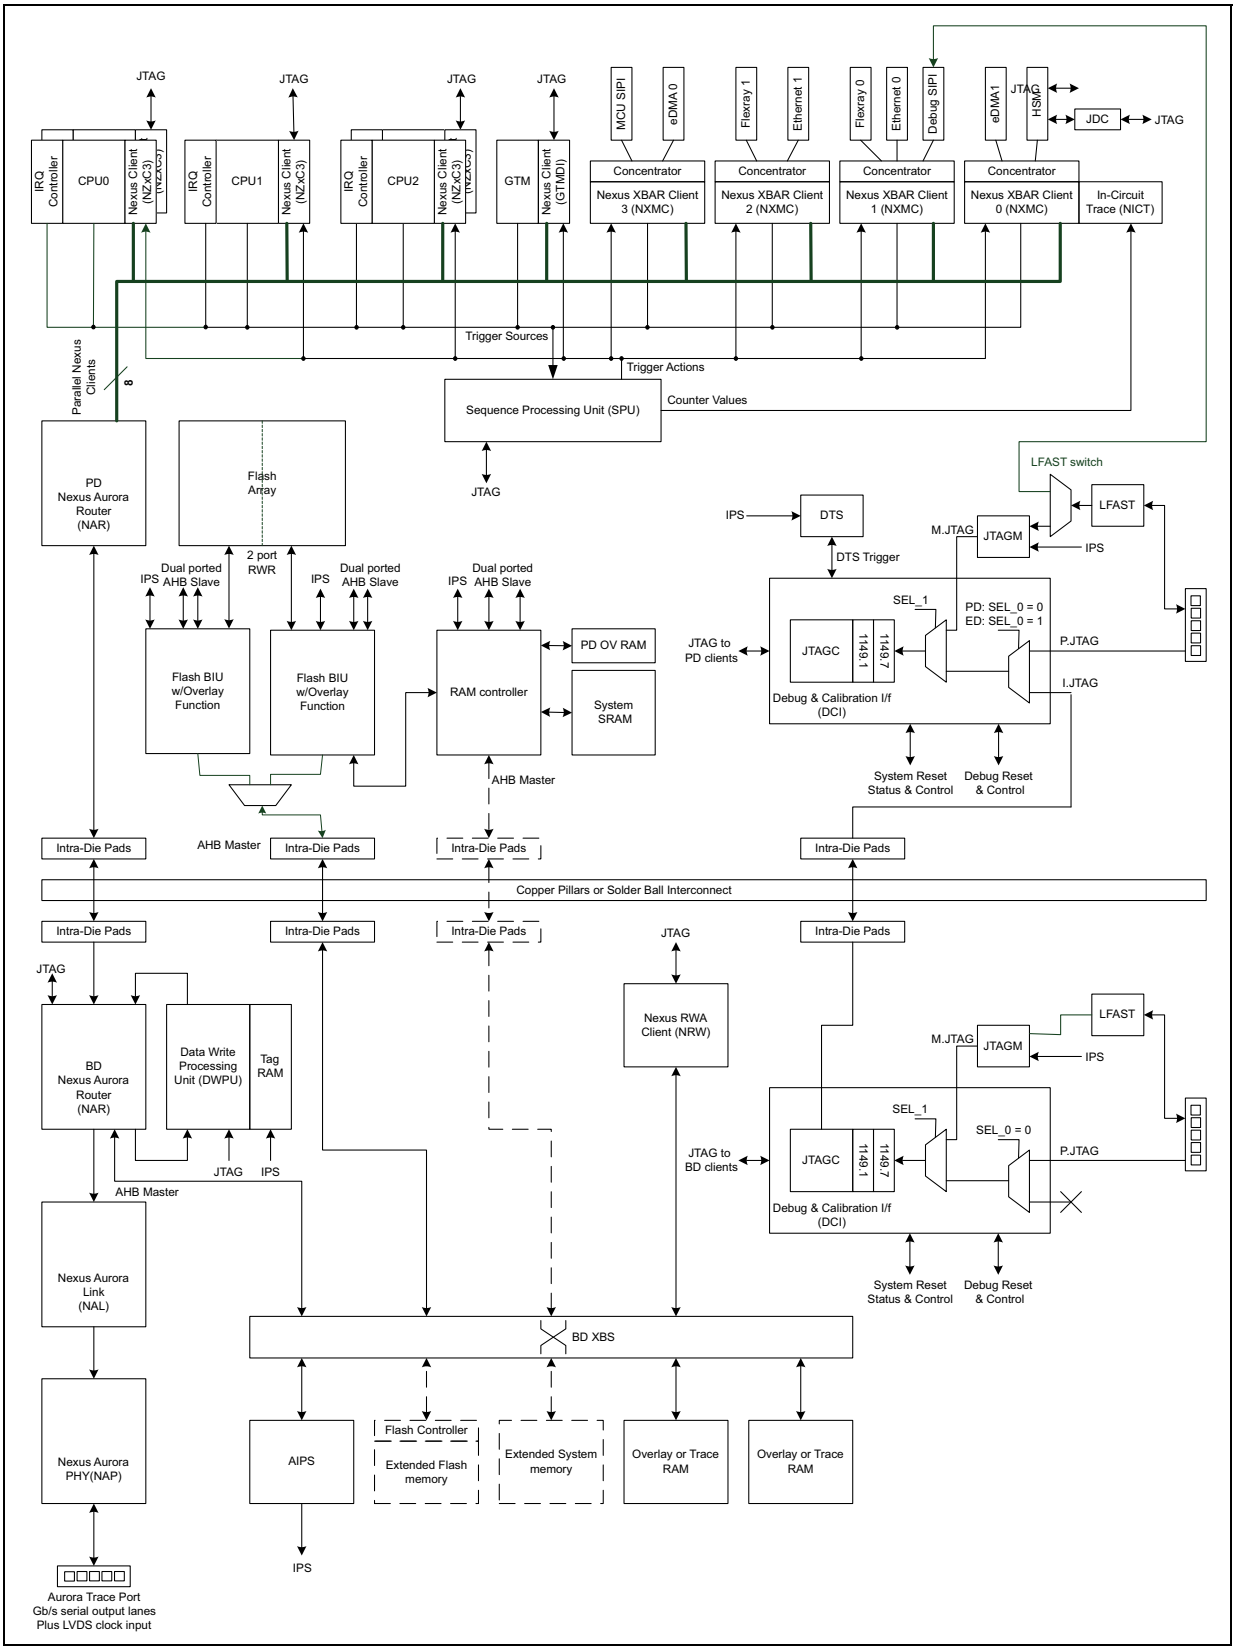
The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD).

97.1 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications for 4- to 8-cylinder engines. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface: it allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the DCI, JTAGM and LFAST functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2012 Nexus Aurora standard)
- 2 MB on-chip SRAM usable as calibration overlay or trace RAM. Entire SRAM contents are maintained as long as ED debug supply is maintained.

97.2 Feature summary



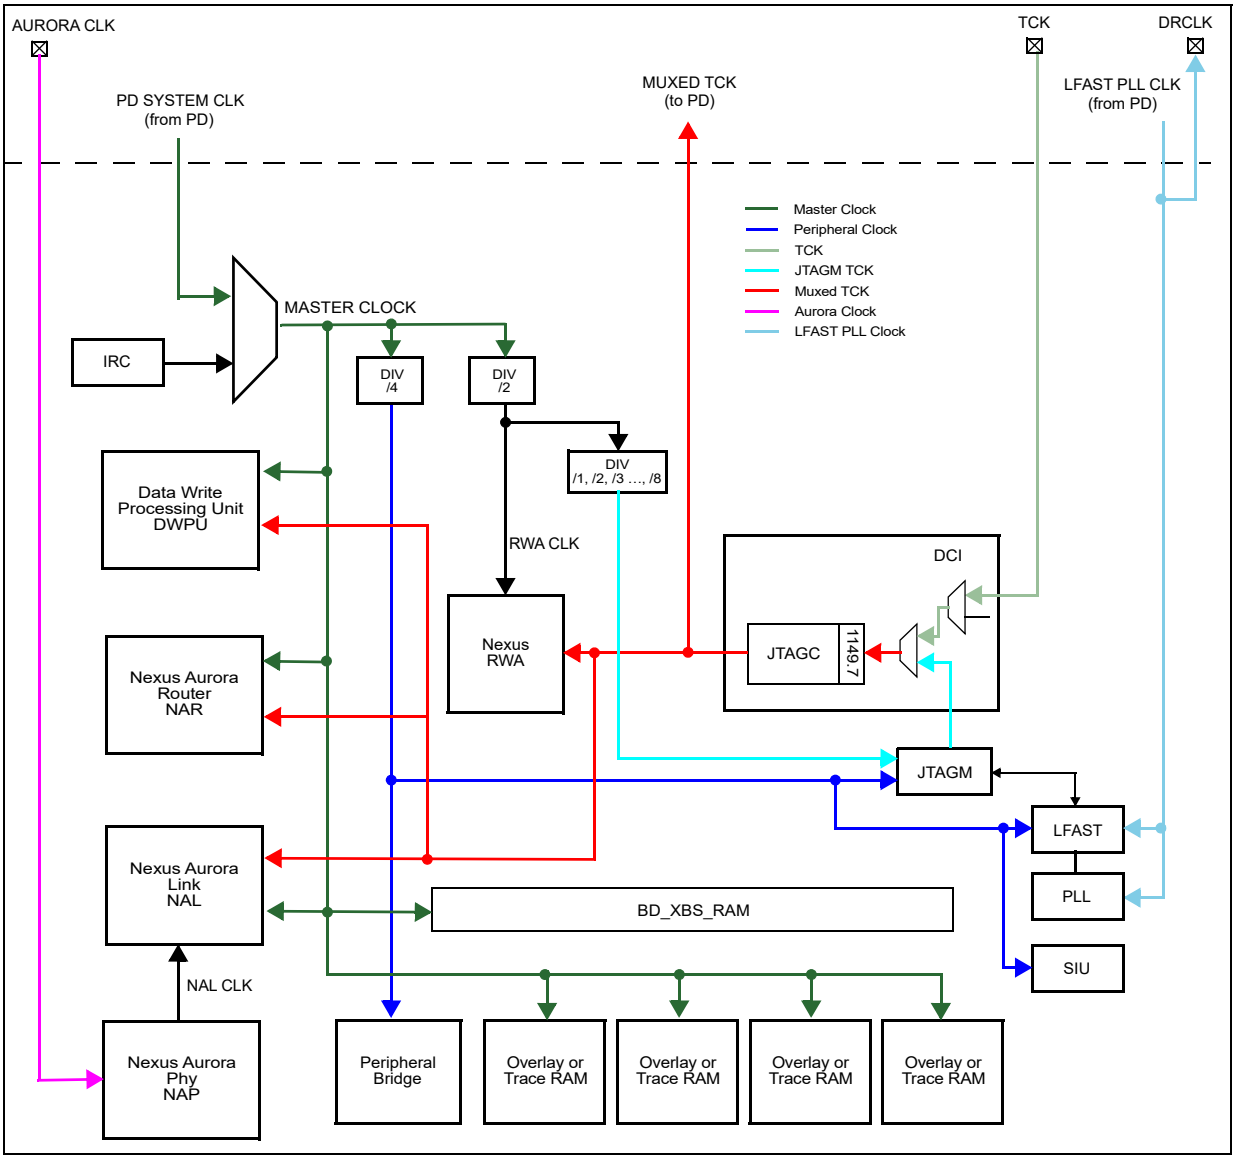
On-chip modules available on the BD include the following features:

- 2 MB on-chip SRAM
  - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
  - Includes ECC
  - Implemented as 4 × 512 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
  - 64-bit data width with ECC checkbits
  - Supports “Early Write” AHB protocol (AHB-EW) for one clock trace data writes
  - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources. Memory-mapped resources include buddy device SRAM and PBRIDGE resources
- Nexus Aurora auxiliary trace port
  - 1.25 Gbit/s maximum data rate per lane
  - Four lanes supported in ED package
  - Port configurable to operate in 2- or 4-lane width
  - One lane LVDS reference clock in
  - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2012 standard
- Data Write Processing Unit (DWPU)
  - Filters data trace stream to retain only writes to user selected locations
  - Detects user configured out of range condition on writes to selected locations
- Debug and Calibration Interface: supports both JTAG (IEEE 1149.1 and IEEE 1149.7) mode and LFAST mode
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)

97.3 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

Figure 2521. Emulation and debug device architecture



97.4 Clocking

Figure 2522 shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- LFAST PLL reference clock coming from the PD (BD LFAST PLL clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Nexus Aurora PHY clock coming from differential LVDS pins in the ED

Figure 2522. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible register and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of ±30%.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 200 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4): Provides the clock to memory mapped registers and other low-speed logic.
- Nexus RWA clock (divided by 2): Provides the clock to the Nexus Read Write Access module.
- JTAGM TCK (divided by 1, 2, …, 8): Provides a high speed TCK clock to the JTAGM module.

The LFAST PLL clock from the PD (also referred to as lfast_sysclk) feeds the LFAST PLL, but it can also directly clock the LFAST in the low data rate mode. This clock is also made available as an output clock to the DRCLK package pin.

The internal TCK clock (referred to as muxed clock in *Figure 2522*) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock can come from two sources (see the Buddy Device–Debug and Calibration Interface (DCI) chapter):

- TCK package pin, when using IEEE 1149.1 or IEEE 1149.7 access
- Divided down version of the master clock to be used in LFAST/JTAGM debug accesses

Note: The division factor for the LFAST/JTAGM clock is defined by the TCKSEL field of the JTAGM_MCR (refer to the JTAGM chapter for more details). However the division factor described there applies to an already divided-by-2 clock, as shown in Figure 2522.

When the PD is unpowered, access through LFAST/JTAGM is not possible. In this case, JTAG accesses can be done only by IEEE 1149.1 or IEEE 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

In the LFAST/JTAGM mode of operation, both RWA clock and internal TCK are synchronous to each other, therefore they can both be the same frequency. This means that TCK frequency can be half of the master clock frequency. *Table 2404* summarizes the frequency restrictions on the Nexus RWA accesses.

Table 2404. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	200	200	27.7	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns)
Powered, out of reset, PLL engaged	LFAST/JTAGM	200	200	100	—

97.5 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described by *Table 2405*:

1. BD power-on reset: asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset: asserts two clock rising edges after assertion of reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset: asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.
4. JTAG controller reset: asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset: asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In *Table 2405*, an ‘X’ indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins. When the debug interface is running through the LFAST interface or by software through JTAGM, those blocks are not reset by the mentioned reset sources.

Table 2405. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
JTAGM	X	—	JTAG mode only	JTAG mode only	—
LFAST	X	—	JTAG mode only	JTAG mode only	—
NAR/DWPU	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

Note: The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

97.6 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as LFAST, JTAGM, XBAR configuration. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 2406. BD memory map

Start address	End address	Allocated size (KB)	Description
BD overlay RAM			
0x0C00_0000	0x0C1F_FFFF	2048	Extended overlay RAM
0x0C20_0000	0x0C3F_FFFF	2048	Reserved BD overlay RAM
0x0C40_0000	0x0C5F_FFFF	2048	Reserved BD overlay RAM
0x0C60_0000	0x0C7F_FFFF	2048	Reserved BD overlay RAM

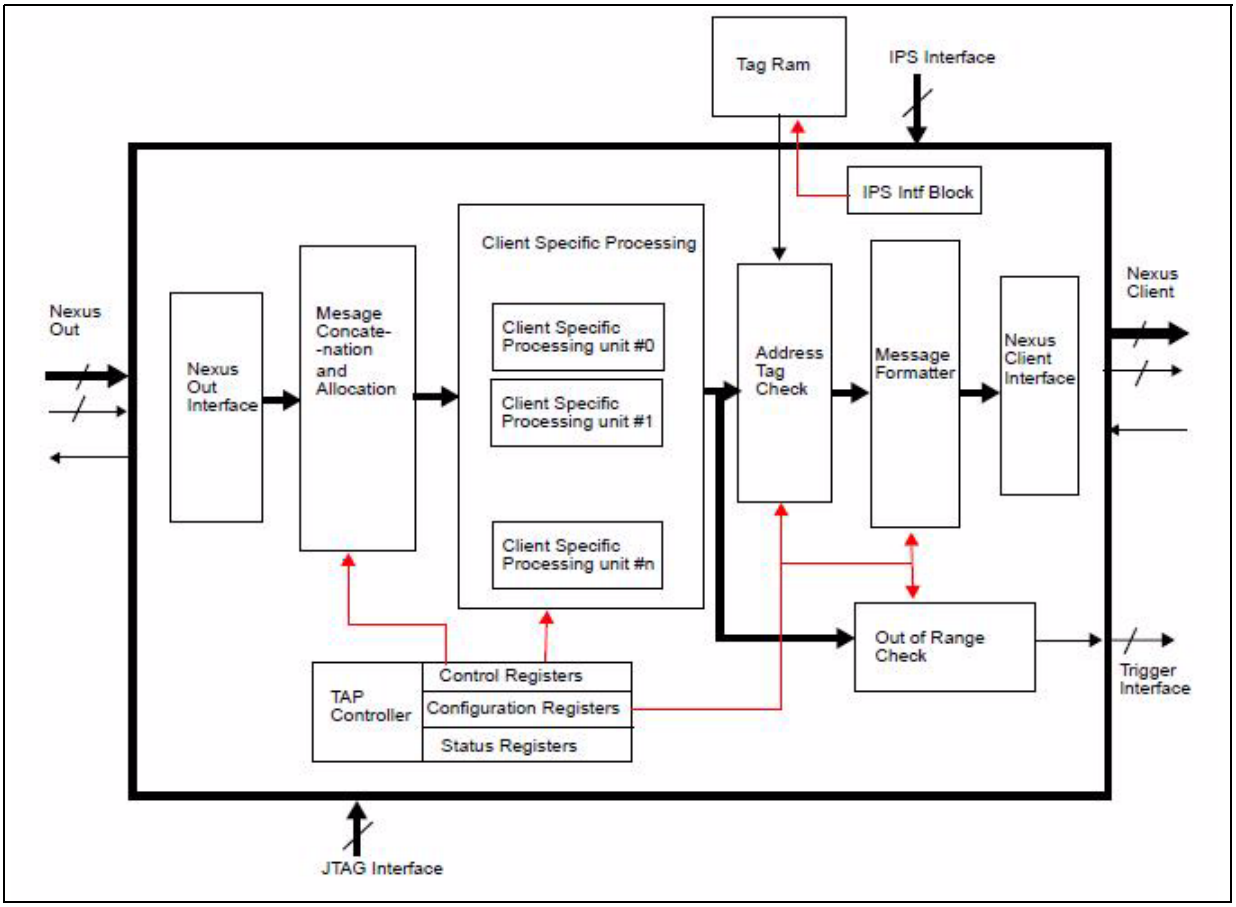
98 Buddy Device—Data Write Processing Unit (DWPU)

98.1 Introduction



The Data Write Processing Unit (DWPU) supports two specific debug and calibration functions:

- Data trace filtering
- Out of range parameter identification

DWPU takes the Nexus standard messages and processes the data write trace messages to filter out messages based on the tagged addressing schema contained in the Tag RAM. DWPU also generates triggers indicating out of range data values for a set of identified addresses and data ranges.

This figure shows the block diagram of the DWPU identifying various functional blocks and the data flows.

Figure 2523. DWPU block diagram

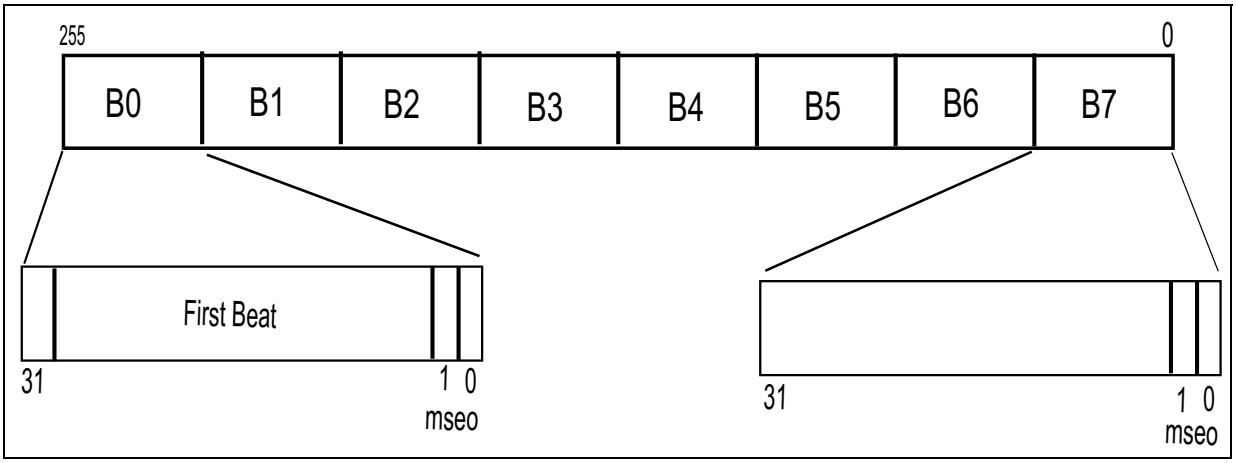
98.2 Features

DWPU supports the following features:

- Out of range data value detection and data write trace filtering simultaneously from up to five Nexus clients
- Filtering operation that can be individually enabled or disabled for each 64-bit word in system RAM or data memory
- High bandwidth throughput
- Filtered trace stream is returned to the BD NAR to allow routing to the trace port or overlay RAM.
- Detection of out of range data values writes within data write trace stream

98.3 Functional description

DWPU includes the following functional blocks:



- Nexus Out Interface (NOI)
- Message Concatenation and Allocation (MCA)
- Client Specific Processing (CSP)
- Address Tag Check (ATC)
- Out of Range Check (ORC)
- Message Formatter (MF)
- Nexus Client Interface (NCI)

98.3.1 Nexus Out Interface (NOI)

The Nexus Out Interface (NOI) enables DWPU to receive Nexus message for data write filtering from NAR. NOI maintains a minimum queue of two buffers to accommodate incoming messages. The NAR only initiates a transfer to the DWPU when it has all the beats of a message. The incoming messages are buffered and then forwarded to the Message Concatenation and Allocation (MCA) for message concatenation and allocation. NOI ensures the temporal order of the incoming messages while forwarding to MCA. NOI also acknowledges the processing of data write messages by MCA.

The format for incoming message with NEXUS_WORD = 32 and NUM_BEAT_IN = 8 is shown below.

Figure 2524. Incoming message format

98.3.2 Message Concatenation and Allocation (MCA)

Message Concatenation and Allocation (MCA) starts concatenating message beats once the NOI has a valid input message to form a complete message. Concatenated messages with selected source IDs contained in Nexus messages are passed over to appropriate Client Specific Processing Unit (CSPU) for further processing. The following messages are dropped by MCA:

- Messages that do not have a selected source ID
- IDLE messages
- Messages with number of beats larger than defined beats for data-write messages

MCA has the capability of providing one fully concatenated message to a CSPU each clock.

98.3.3 Client Specific Processing (CSP)

The Client Specific Processing (CSP) block receives the messages from MCA. The received message are processed after extracting all the relevant fields. Different types of message from various clients are received and processed differently based on their type by a specialized unit called the Client Specific Processing Unit (CSPU).

The CSPU receives concatenated data write messages (including synchronization messages) from MCA and provides the following for the Out of Range Check (ORC) and Address Tag Check (ATC) logic to perform filter checks:

- Reconstructed address
- Data value
- Source ID
- Master ID
- Timestamp

CSPU also confirms that each message is a data write message. All other message types are dropped.

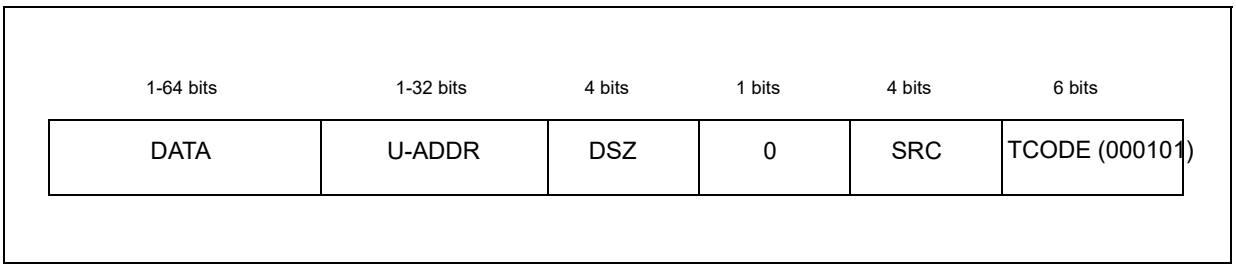
There are two CSPU types, one associated with Core Nexus clients and another associated with NXMC clients. Each CSPU simultaneously supports data write messages with up to four different source IDs.Data write with synchronization message is always required to start an address thread for a particular source ID, then each subsequent data write message

associated with that source ID contains an encoded address. *Table 2407* shows the CSPU type encoding to be used while mapping the source IDs to a CSPU type using SRC_MAP_CTLR.

Table 2407. CSPU encoding

CSTU type	Encoding
Standard	01
NXMC	10

98.3.3.1 Input message formats



DWPU supports various message formats from different source clients. These formats are further processed by the CSPU. The following message formats are supported by the CSPUs, as also described in details the sub-sections:

- Standard data write message format (SDWM)—Includes sync and non-sync type. This is used by most of the clients, such as e200 peripheral and e200 main cores.
- AHBMM (modified) data write message format (MDWM)—Includes both sync and non-sync type of messages. Used by NXMC clients only.

98.3.3.1.1 Standard data trace write message format

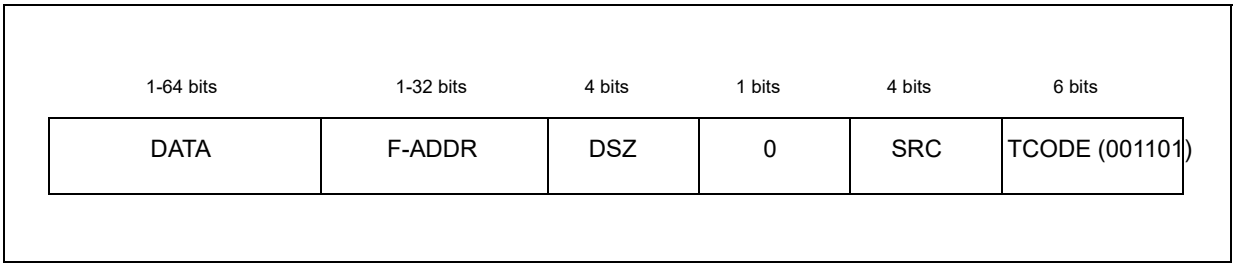
The standard data trace write messages are of two types, sync and non-sync. The non-sync type contains the data write value and the address of the write access, relative to the previous data trace message. The address and DATA field is considered variable. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

Figure 2525. Non-sync data trace write message format

The TSTAMP field not shown is an optional fixed field of 26 bits, is inserted optionally by the core clients based on controls received from the BD NAR.

The second type is the DWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

Figure 2526. Sync data trace write message format



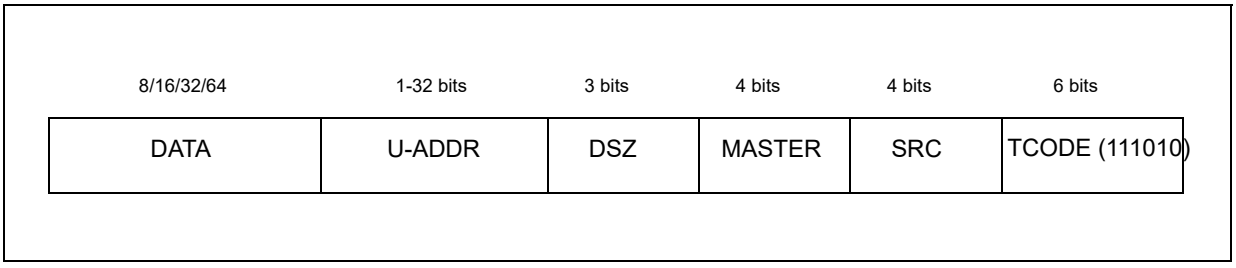


Table 2408 shows the data size (DSZ) encoding for standard data trace message.

Table 2408. Standard DSZ encoding

DSZ	Data size
0000	0-byte
0001	1-byte
0010	2-byte
0011	3-byte
0100	4-byte
0101	5-byte
0110	6-byte
0111	7-byte
1000	8-byte
1001–1111	Reserved

The NXMC (modified) data trace write sync messages contain the data write value and the address of the write access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encoding to either 8, 16, 32 or 64. The TSTAMP field is 26 bits. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

Figure 2527. Non-sync M-Data data trace write message format

The TSTAMP field not shown over here is an optional fixed field of 26 bits, is inserted optionally by the AHBMM clients based on controls received from NAR.

The second type is the MDWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to

ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent MDWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

Figure 2528. Sync M-Data data trace write message format

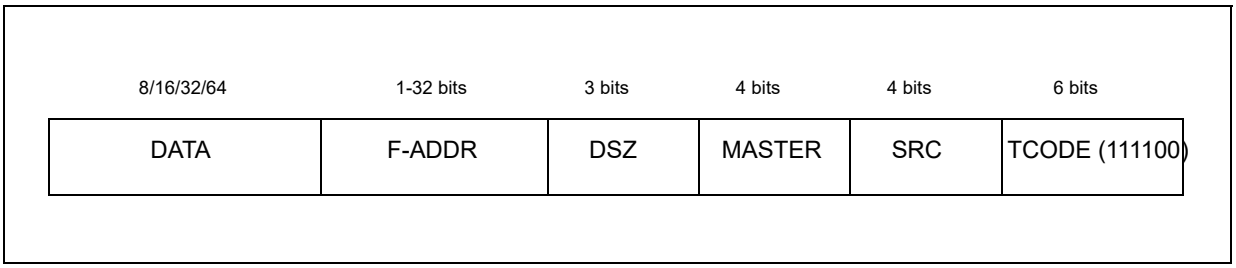

Table 2409 shows the data size (DSZ) encoding for NXMC data trace message.

Table 2409. NXMC DSZ encoding

DSZ	Data size
001	1-byte
010	2-byte
011	3-byte
100	4-byte
000,101–111	Reserved

98.3.4 Address Tag Check (ATC)

DWPU allows filtering operation on data writes to any address within system RAM and tightly coupled data memory. Each 64-bit word in the supported system RAM or data memory address space corresponds to a single bit in Tag RAM; therefore, the required Tag RAM size is $1/64^{th}$ of the address space to be filtered. Data write messages within the supported address range are dropped by ATC if the corresponding bit in Tag RAM is not set. The data write messages with the corresponding Tag bit set are passed over to Message Formatter for further processing.

Writes to addresses outside of the supported address range can be configured to be either removed from the trace stream or retained. This option is controlled by a single user accessible control bit. Data reads and other Nexus message formats submitted in the DWPU trace stream are always dropped by DWPU. Tag RAM is accessible through software (IPS) as well as JTAG interface via PD addressing. All the IPS access is possible in supervisor mode only. The access to Tag RAM is carried out indirectly through three registers: TRC_CTRL, TRC_ADR and TRC_DATA registers. Users should write the TRC_CTRL register followed by the TRC_ADR register before accessing the TRC_DATA register. Any write access to the TRC_ADR register results in a Tag RAM access request. Users should ensure that the Tag RAM request is completed by providing the required TRC_DATA access based on the length of the transfer. In case of block access, the TRC_DATA register is accessed subsequently and users should ensure that the block access length does not cross the region boundary. Deviation in the sequence of register access for Tag RAM access results in erroneous and incomplete transfers.

In PD addressing, the configured PD address in the TRC_ADR register is translated to a Tag RAM address using mapping derived from the FAR_SA_CFGn and FAR_RS_CFGn register. The PD address configured in the FAR_SA_CFG0 register is always translated to the zeroth address of Tag RAM.

The equation to convert system/PD address to Tag RAM address where the System/PD address falls within region n is given below:

Tag RAM address = System/PD address[31:8] - Region n base address[31:8] + Total sum of previous region (n-1) size[31:8]

The Tag RAM address for System/PD address that falls on region 2 is given by:

System/PD address[31:8] - Region 2 base address[31:8] + (region 0 size[31:8] + region 1 size[31:8])

Figure 2529 shows an example of the Tag RAM organization for 8 Kbyte Tag RAM with PD base address configured.

Figure 2529. Tag RAM organization example

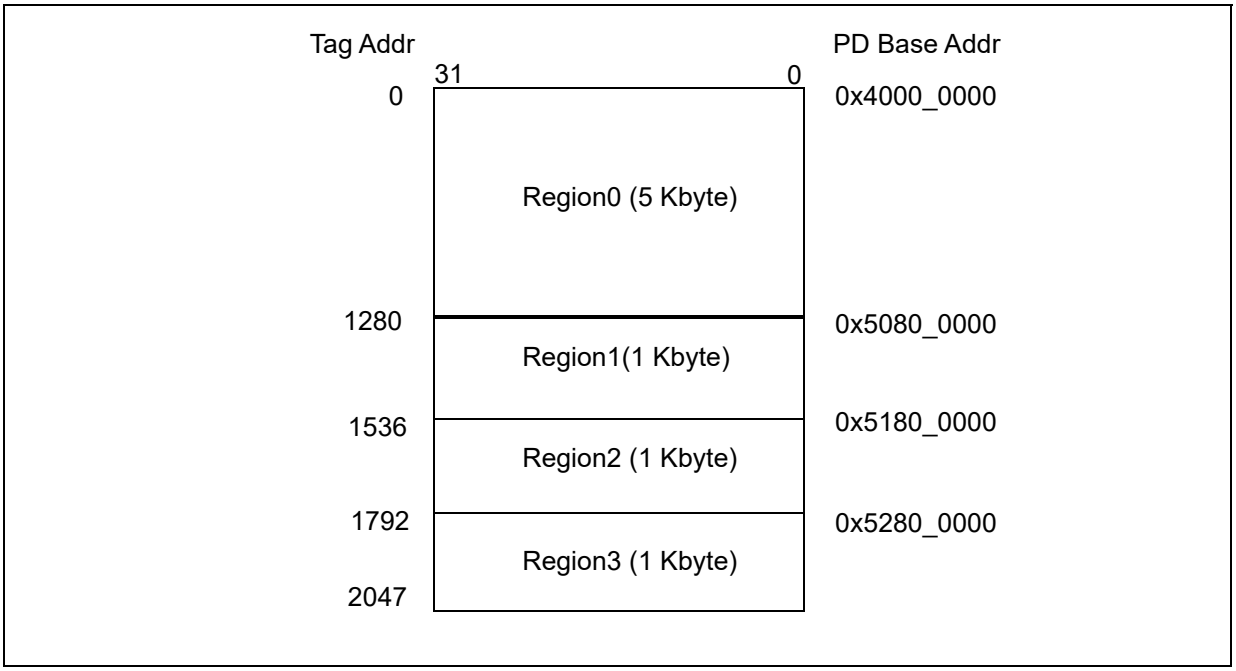

Table 2410 shows an example of address translation from PD addresses to Tag RAM address.

Table 2410. Address translation example

PD address		Tag RAM address
Start	End	
0x4000_0000	0x4000_00FF	0x0
0x4000_0100	0x4000_01FF	0x1
0x4004_FF00	0x4004_FFFF	0x4FF
0x5080_0000	0x5080_00FF	0x500

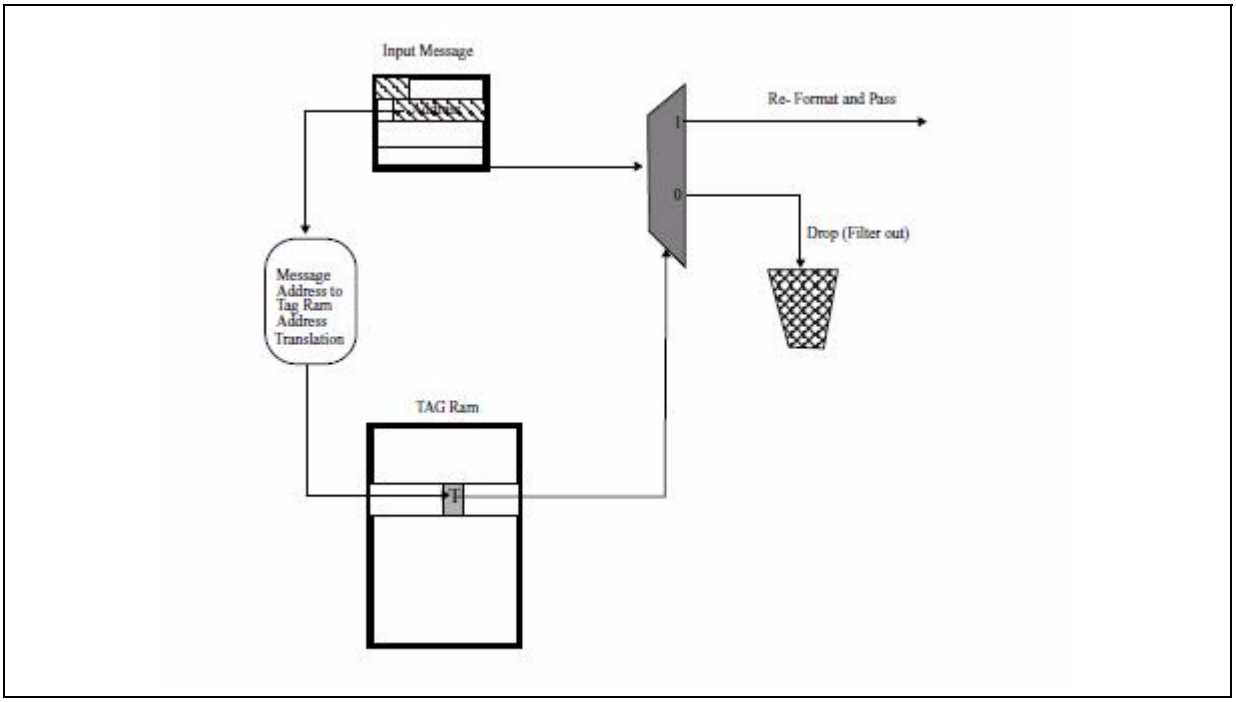

Table 2410. Address translation example (continued)

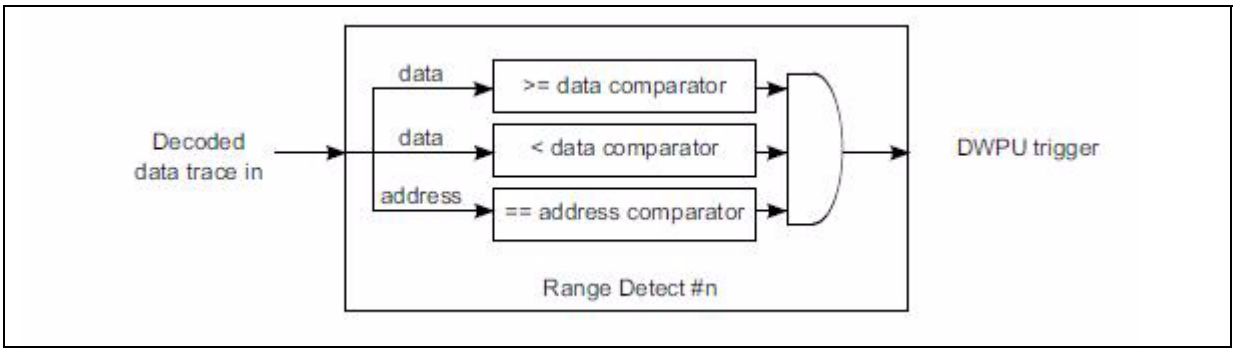
PD address		Tag RAM address
Start	End	
0x5180_0000	0x5180_00FF	0x600
0x5280_0000	0x5280_00FF	0x700
0x5280_FF00	0x5280_FFFF	0x7FF

During the data write filtering operation, the system RAM or data memory address is extracted from the input message. It is then compared to ascertain the address space (whether it is within system RAM space or data memory or outside the supported address range). Finally it is translated to Tag RAM address and initiate a read to Tag RAM. From the Tag RAM 32-bit read accessed, the system/PD address bit [7:3] determine the Tag bit position that is associated with the decoded absolute system/PD address. If the corresponding bit is set, then the input message is passed for message formatting else it is dropped by ATC.

This figure shows the data flow for address Tag filtering.

Figure 2530. Address tag filtering



98.3.5 Out of Range Check (ORC)

In addition to the trace filtering function, the DWPU also supports detection of outside/inside range writes to RAM locations. Both the data range values and address of RAM locations to be checked are user specified. It also has configurable support to detect target inside or outside data range values specified.

A total of four sets of address and data range comparators are supported, where each set of comparators include an address match comparator, a greater than or equal data value comparator and a less than or equal data value comparator. This figure shows the block diagram for range detect comparators.

Figure 2531. Range detect comparators

ORC supports unsigned, signed and floating point data ranges. Signed numbers are represented in 2's complement. 32-bit IEEE-754 single-precision floating-point format is used for floating point representation.

ORC has a configurable option to support for 8/16/32 bit unsigned/signed range detection and 32-bit floating point range comparison. Address comparison is carried out with full the device address. An output signal from DWPU is triggered in response to a detected out of range condition along with a status bit being set in an ORC status register indicating which range comparator has caused the trigger.

98.3.5.1 Comparator capabilities

The primary usage for out of range detect function is to detect out of range conditions on unsigned integer and pointer variables, although it also supports signed and floating point data types comparison. It also has a configurable option to support for 8/16/32 bit unsigned range detection. The unsigned data is directly compared with the stored data ranges.

To support use with signed variables, each data comparator supports 8/16/32 bit signed operation. All the signed numbers are represented in two’s complement. Data comparison happens only when the sign bit matches.

To detect range of floating point variables, each data comparator supports only 32-bit comparison mode. All the floating point numbers are represented in 32-bit IEEE-754 single precision with biased exponent. The floating point data is directly compared with the stored floating point ranges which are also represented in 32-bit IEEE-754 single precision with biased exponent.

98.3.6 Message Formatter (MF)

Message Formatter (MF) module receives message information from ATC and reformats the data write messages to comply with output Nexus message format. A user defined message format is used for sending out the filtered messages as shown in *Figure 2532* below.

Figure 2532. DWPU message format

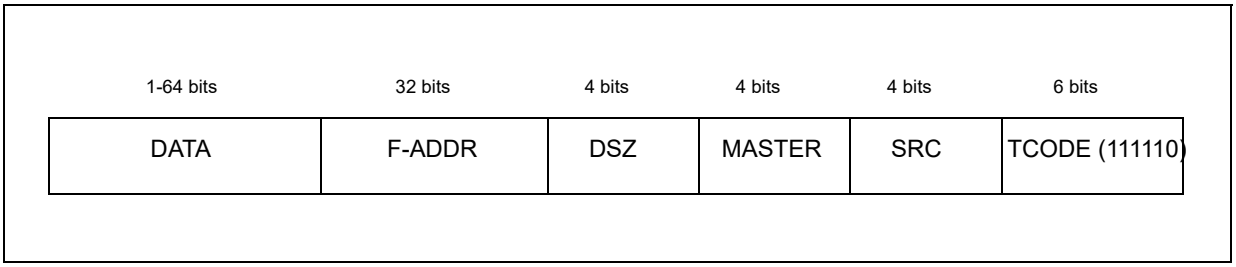


Table 2411. Message field description

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
DWPU message	6	6	TCODE	fixed	TCODE number = 62
	4	4	SRC	fixed	Source client identifier
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access. For core clients 1111 is inserted. For the NXMC clients, same value is inserted as received.
	4	4	DSZ	fixed	Data size
	32	32	F-ADDR	fixed	Full data write address
	1	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	26	26	TSTAMP	fixed	Timestamp (Optional and omitted if there is no valid timestamp)

98.3.7 Nexus Client Interface (NCI)

The Nexus Client Interface (NCI) sends out the formatted filtered data write messages to BD NAR. It also supports the buffer reallocation to increase the Q size.

98.4 Non-memory mapped registers

This section describes the DWPU Nexus register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. In addition, some register are accessible through the IPS interface.

The table below shows the JTAG mapped DWPU registers.

Table 2412. JTAG DWPU registers

Nexus register index	Register	Access	Read address	Write address	Reset value
0x02	Global Control (GLB_CTRL)	R/W	0x04	0x05	0x0000_0002

Figure 2547. Tag RAM Control (DPWU_TRC_CTRL)

Table 2428. DPWU_TRC_CTRL field descriptions

Field	Description
4:15 BAL	Block Access Length.Should not cross the region boundary. Valid only when BAE = 1
21 EXC	Excess Tag RAM access by IPS. Generated when the IPS access to Tag RAM exceeds the configured access length 0 No excess access to Tag RAM 1 Exceeds the configure access length
22 PROG	IPS access to Tag RAM in progress 0 No Tag RAM access by IPS 1 Tag RAM access by IPS is in progress
23 INV	Invalid IPS access. Generated when the targeted PD/system address in the TRC_ADR register falls outside the configured Tag RAM region 0 No error 1 Invalid address
25:27 DSM	Data Size Mode. Valid only for writes, all reads are fixed 32 bits only. 000 Word (32 bit) Access to the Tag RAM. 001 Half-Word (16-bit) access to Tag RAM. 16-bit LSBs of the TRC_DATA is used. 010 Byte (8-bit) access to the Tag RAM. 8-bit LSBs of the TRC_DATA is used. 100 Bit Access to the Tag RAM. LS bit of the TRC_DATA is used.
29 BAE	Block Access Enable. Block access is carried out with 32-bit Data Size Mode only. 0 Block Access disable 1 Block Access enable
30:31 CMD	Read/Write access 00 No read or write access to Tag RAM 01 Read access to Tag RAM. Any write to TRC_ADR register results in read access to the Tag RAM. Read data is stored in the TRC_DATA register. 10 Write access to Tag RAM. Any write to TRC_ADR register results in write access request to the Tag RAM and subsequent TRC_DATA register writes result in actual data to be written into Tag RAM addressed by the TRC_DATA register. 11 Reserved

98.5.2 Tag RAM Configuration Address (DWPU_TRC_ADR)

Tag RAM Configuration Address provides the system address for Tag RAM access. Any write to this register initiates a Tag RAM access request at the address which is being translated from system address configured. It is always accessed in 32-bit only.

Offset: 0x0004 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2548. Tag RAM Configuration Address (DWPU_TRC_ADR)

Table 2429. DWPU_TRC_ADR field descriptions

Field	Description
0:28 ADDR	PD Address. It should be aligned depending on Data Size mode field. DSM = 000, 256 byte aligned DSM = 001, 128 byte aligned DSM = 010, 64 byte aligned DSM = 100, 8 byte aligned (default) **Note:** If the PD address is not aligned to the DSM, this results in a erroneous data read/write.

98.5.3 Tag RAM Configuration Data (DWPU_TRC_DATA)

Tag RAM Configuration read/write data register. Generate ips_xfer_err on accessing this register before configuring the TRC_ADR register. Also on read access to this register while Tag RAM write is in progress and vice versa. Access is always 32-bit. During write, TRC_ADR.DSM determines which part of TRC_DATA should be written irrespective of byte enable.

Offset: 0x0008 Access: Read/Write

Field	Description
0:31 DATA	Reflects the content of Tag RAM on Tag RAM read access. Also provides data for Tag RAM write access.

99 Buddy Device—Nexus Read Write Access (RWA)

99.1 Introduction

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in *Section 99.3: Nexus register access via JTAG*. The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

99.2 Register definition

Table 2431 details the register map for the RWA module.

Table 2431. RWA register map

Register	Nexus access opcode	Read/ write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

99.2.1 Register descriptions

99.2.1.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in *Table 2433*.

Access: Read/Write

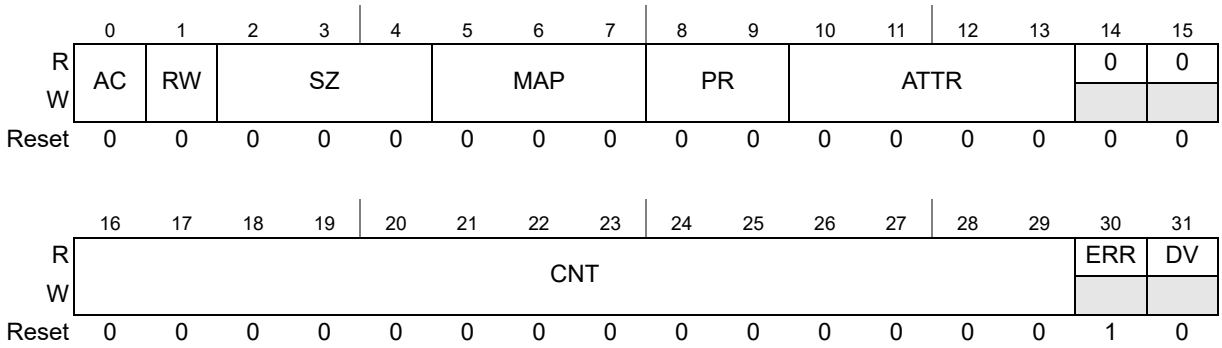

Figure 2550. Read/Write access control/status (RWCS) register

Table 2432. RWCS fields

Field	Description
0 AC	Access Control. 0 End access/ Access has completed 1 Start access
1 RW	Read/Write Select. 0 Read access 1 Write access
2:4 SZ	Word Size. 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 Reserved (default to word) 100 Reserved (default to word) 101 Reserved (default to word) 110 Reserved (default to word) 111 Reserved (default to word)
5:7 MAP	MAP Select. 000 Primary memory map 001 Reserved 010 Reserved 011 Reserved 100 Reserved 101 Reserved 110 Reserved 111 Reserved
8:9 PR	Read/Write Access Priority. 00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority

Table 2432. RWCS fields (continued)

Field	Description
10:13 ATTR	Access Attributes. RWA accesses are run as privileged data non-cacheable accesses by default, and drive the p_d_hprot[5:0] bus access attributes to 6'b000011 accordingly. This field is provided to allow a portion of these default values to be modified when performing read or write accesses using the RWA as shown in *Table 2434*. hprot[1] must be set to one. 0xxx Reserved 1xxx Reserved x0xx p_d_hprot[4] driven to 0 for accesses x1xx p_d_hprot[4] driven to 1 for accesses xx0x p_d_hprot[3] driven to 0 for accesses xx1x p_d_hprot[3] driven to 1 for accesses xxx0 p_d_hprot[2] driven to 0 for accesses xxx1 p_d_hprot[2] driven to 1 for accesses
14:15	Reserved for future functionality.
16:29 CNT	Access Control Count. Number of accesses of word size SZ.
30 ERR	Read/Write Access Error (see *Table 2433*).
31 DV	Read/Write Access Data Valid (see *Table 2433*).

Table 2433. Read/Write access status bit encoding

Read action	Write action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

Table 2434. Protection encoding

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
0	0	0	Cache-inhibited
0	0	1	Guarded, not cache-inhibited
0	1	0	Reserved
0	1	1	Reserved
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

99.2.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.

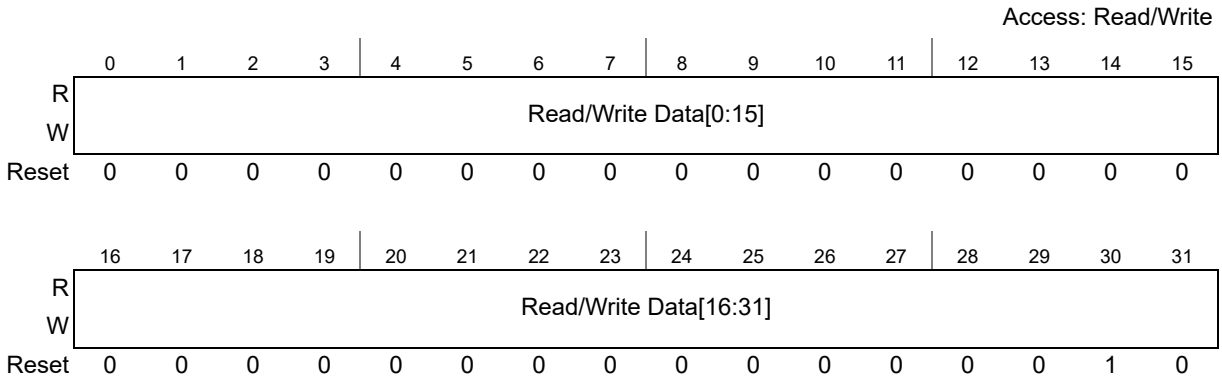

Figure 2551. Read/write access data (RWD) register

Read/write accesses to the memory require that the debug firmware properly retrieve/place the data in the RWD. *Table 2435* shows the proper placement of data into the RWD.

Table 2435. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

Table 2436 shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 2436. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]

Table 2436. RWD byte lane mapping (continued)

Transfer size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—-	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—-	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]
Word @000	0 0 0	XBAR[31:24]	XBAR[23:16]	XBAR[15:8]	XBAR[7:0]
Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

99.2.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.

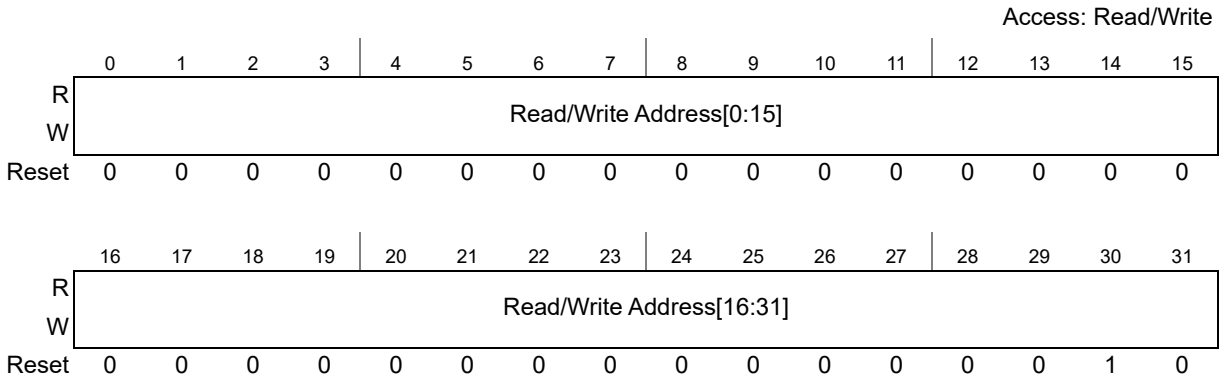

Figure 2552. Read/write access data (RWA) register

99.3 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 2431*.

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in *Table 2431*. This is achieved by loading an 8-bit value into the JTAG data register (DR).

   This register has the following format:

Figure 2553. JTAG DR for Nexus register access

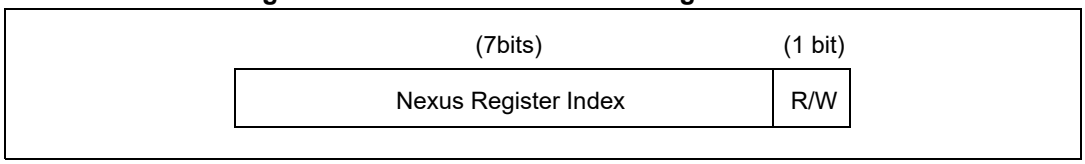

Table 2437. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 2431*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

99.4 Memory access examples

The following subsections describe the steps which are required to access memory.

99.4.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Write Address = 32h’xxxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b’1 (to indicate start access)
   – Map Select (MAP) = 3b’000 (primary memory map)
   – Access Priority (PR) = 2b’00 (lowest priority)
   – Read/Write (RW) = 1b’1 (write access)
   – Word Size (SZ) = 3b’0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h’0000 or 14h’0001(single access)

Note: Access Count (CNT) of 14’h0000 or 14’h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
   – Write Data = 32h’xxxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1’b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

99.4.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 99.4.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in *Section 99.4.1: Single write access* until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note: The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

99.4.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Read Address = 32h'xxxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b'1 (to indicate start access)
   – Map Select (MAP) = 3b'000 (primary memory map)
   – Access Priority (PR) = 2b'00 (lowest priority)
   – Read/Write (RW) = 1b'0 (read access)
   – Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

99.4.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 99.4.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.
4. Repeat Steps 3 and 4 in *Section 99.4.3: Single read access* until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note: The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

100 Buddy Device—Crossbar and RAM (BD_XBS_RAM)

Within the buddy device (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note: Throughout this description, the term "overlay RAM" is applied to the BD memory, even though this memory can be used for both overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
  - Bus masters include the BD's Nexus Aurora Router (BD-NAR), the production device's flash controller (PFLASH) and the BD's Nexus Read/Write Access Client (RWA)
  - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge bus controller
    - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
    - End-to-End ECC32 address and data protection
    - ECC scheme based on 29-bit address and 32-bit data
    - Overlay RAM supports a 64-bit "early write" datapath and a 128-bit read datapath
- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note: Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

100.1 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit "early write" datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, m0 > m1 > m2 (PFLASH > BD-NAR > Nexus RWA). Each slave port is "parked" on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

100.2 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

e2eECC64[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0] ^ ecc_data_lower[7:0]

where `ecc_addr` is H-matrix evaluation of the 29-bit access address (addr[31:3]), `ecc_data_upper` is the H-matrix evaluation of the upper data word (data[63:32]) and `ecc_data_lower` is the comparable evaluation of the lower data word (data[31:0]).

For the BD RAM definition, the following (re)definitions apply:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]; data_lower[31:00] = 0

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]; data_upper[63:32] = 0

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in *Table 2438*. A '*' in *Table 2438* indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

}
```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

101 Buddy Device—System Integration Unit Lite (BD_SIUL2)

101.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

These registers are also indirectly accessible by software via BD_JTAGM in software debug mode.

101.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type.
- A version field that is changed for every major mask revision of the BD.
- A parameterized field that indicates the amount of extended overlay RAM included
  - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps.

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC.
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants).

101.3 Device status information

101.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically.
  - BD_INIT is not cleared by external BD reset input.
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration).
- The calibration tool or calibration software sets BD_INIT.
- After PD POR, the BAF executes and reads BD_INIT.
  - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap.
  - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used).

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

101.3.2 PD reset status

The IPS accessible BD_SIU_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

101.4 Memory map

Table 2439 gives an overview of the BD_SIUL2 registers.

Table 2439. BD_SIUL2 register summary

101.4.1 Register descriptions

This section describes in address order all the BD_SIUL2 registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Note: All registers support 32-bit accesses only.

101.4.1.1 BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)

The BD_SIUL2_DIDR1 contains the part number and mask number.

Offset 0x00 Access: User read

24:31	Reserved.

101.4.1.3 BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset).
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration).
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT.
  - If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap.
  - If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used).

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

31 PD_POR	PD POR Flag Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed. 1 PD is powered and power on reset has completed.

101.4.1.5 BD_SIUL2 Multiplexed Signal Configuration Registers (BD_SIUL2_MSCR1, BD_SIUL2_MSCR2)

The BD_SIUL2_MSCR1–2 registers contain pad multiplexing and control bits. It is reset by system reset.

The debug interface on the BD requires five pins when operating in JTAG 1149.1 and LFAST modes, but can be reduced to three pins when operating in JTAG 1149.7 reduced pin mode, allowing the use of two pins for GPIO. The BD_SIUL2_MSCR registers provides bits to control pad electrical characteristics when the pins are working as GPIO. Note that the registers do not control the multiplexing, but the electrical characteristics for GPIO only. Multiplexing is controlled by the function of the pads. If the debug tool is disconnected and JCOMP negated, the pads are GPIO. When the tool is connected and JCOMP asserted, the pads are automatically assigned to JTAG. If the tool then configures JTAG to work in 1149.7 mode, the pads are assigned back to GPIO. And if the tool selects LFAST mode, the pads are assigned to LFAST.

Note: Multiplexing of GPIO into JTAG pins is not supported.

102 Buddy Device: Debug and Calibration Interface (DCI)

102.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

102.1.1 Features

The ED DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

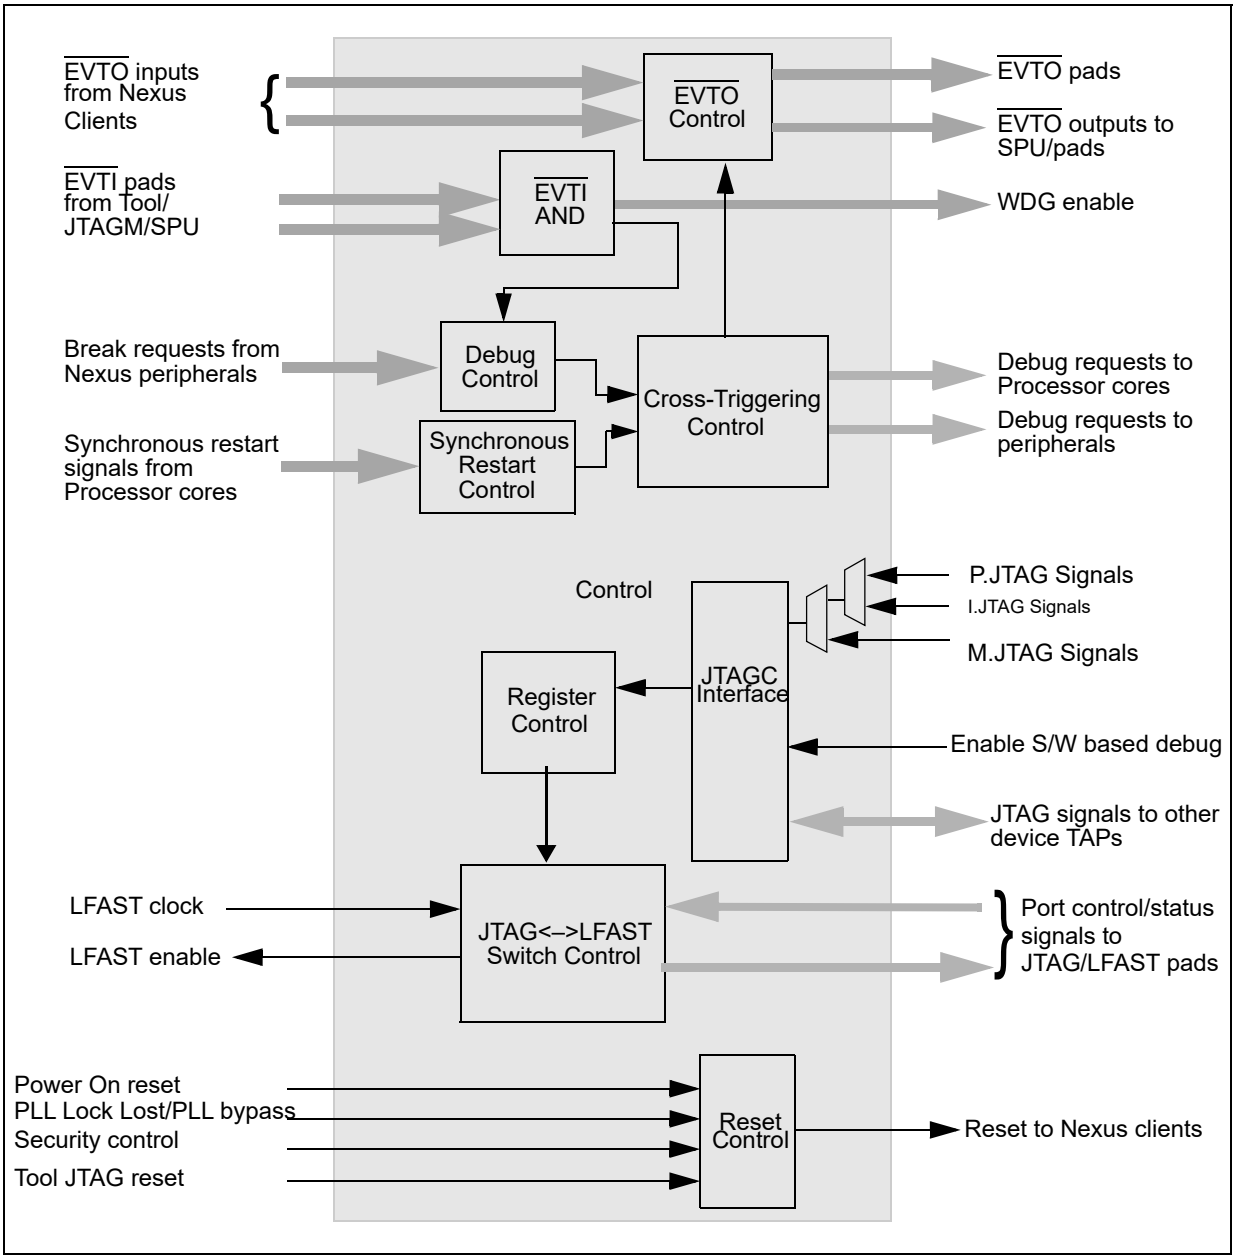
102.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.

  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.
- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.



When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The ED DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as SPU. The ED DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

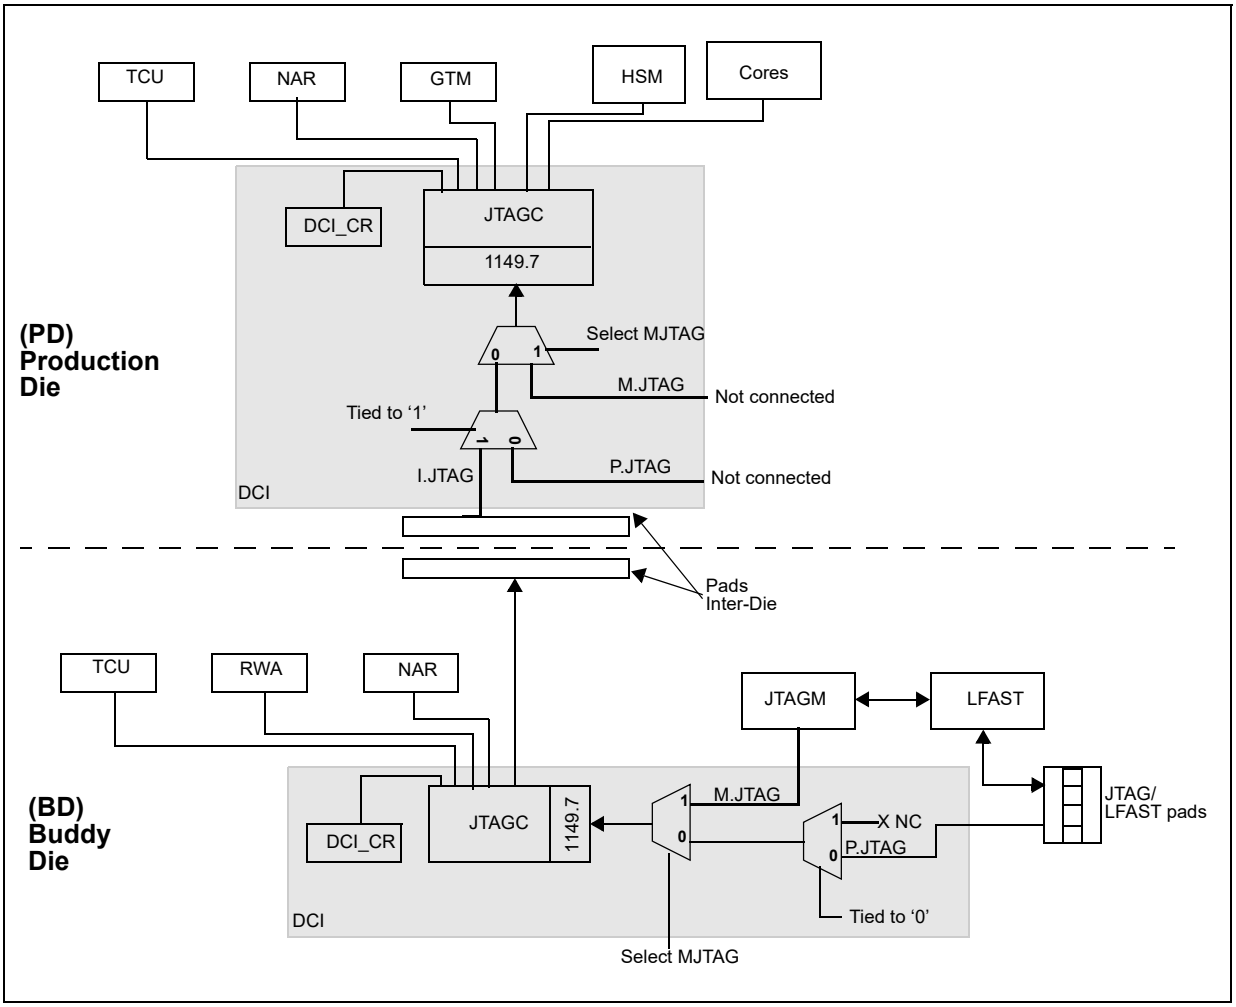


Figure 2563 shows the DCI block diagram.

Figure 2563. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in *Figure 2564*. In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

Figure 2564. DCI in an emulation configuration

102.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 2445 shows a summary of the configuration options.

Table 2445. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

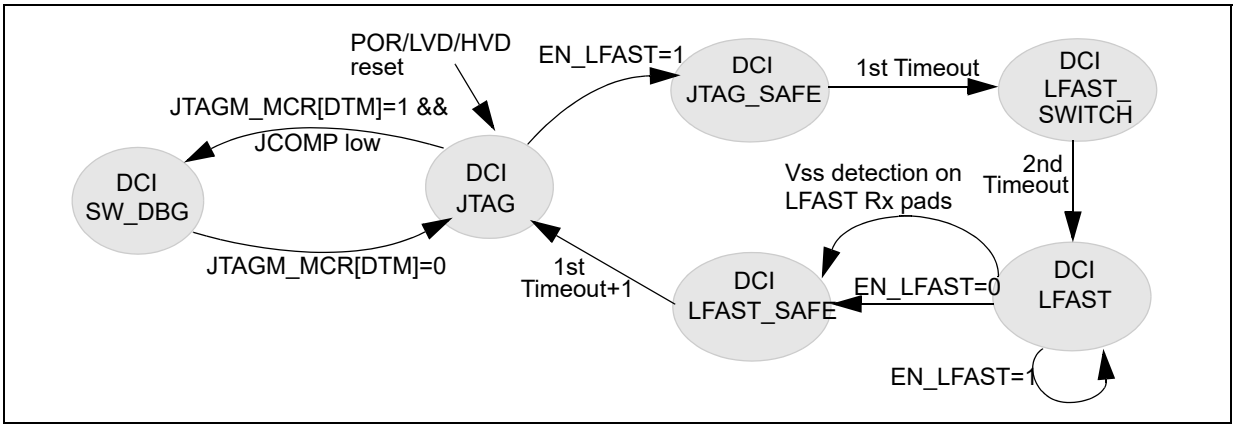
The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the BD LFAST and BD JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 102.1.3.1: Port sharing between JTAG and LFAST modes.* During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 2446* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1’b0). There is no change in port values if no debug tool is connected.

Table 2446. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

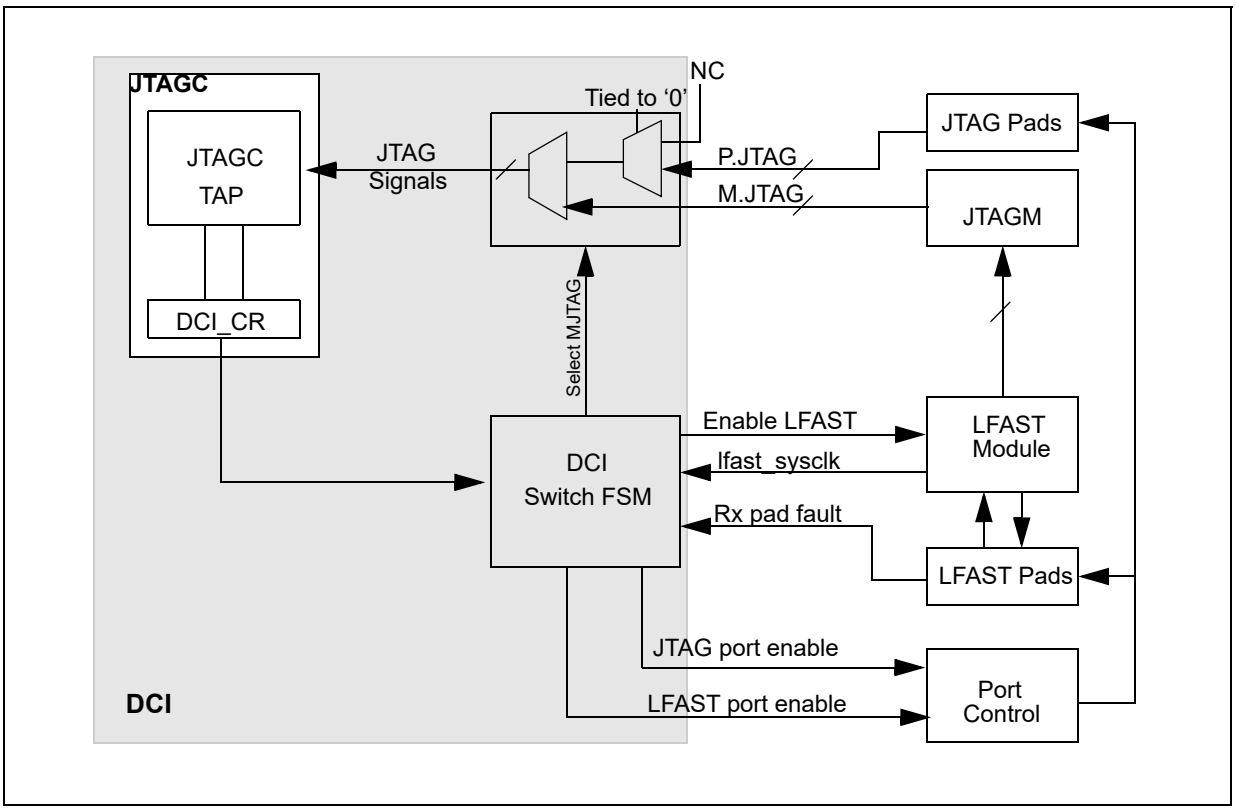
Figure 2565 shows the DCI mode switching operation.

Figure 2565. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

Table 2447 contains the operating mode descriptions.

Table 2447. DCI operating modes



Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.

Table 2447. DCI operating modes (continued)

Mode	Description
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

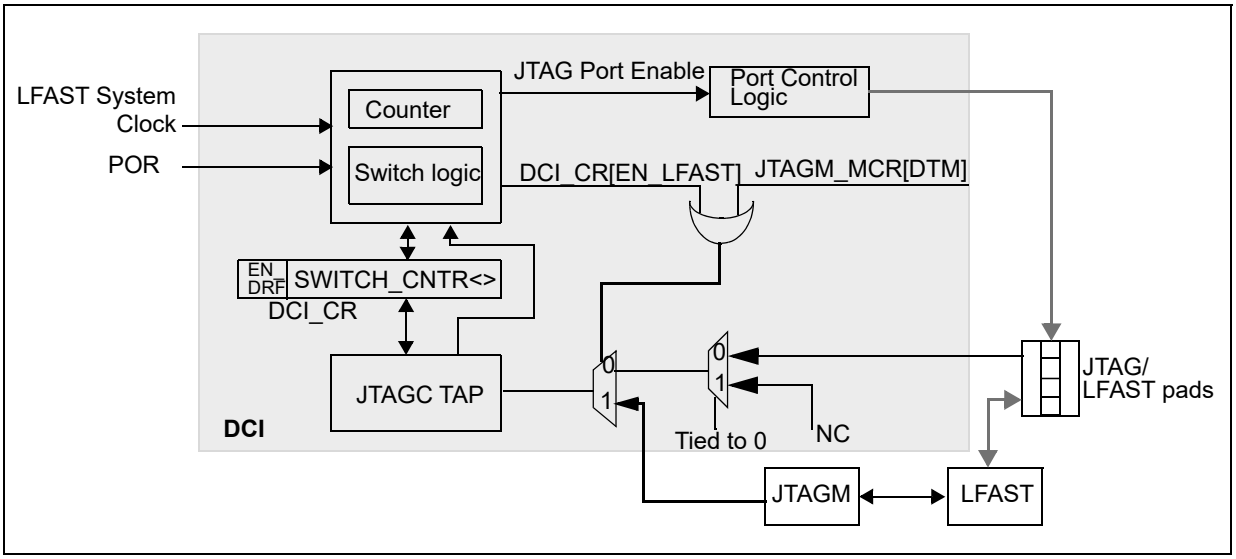
Figure 2566 shows a block diagram of the JTAG/LFAST connections.

Figure 2566. DCI JTAG/LFAST switch integration

102.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch

from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):



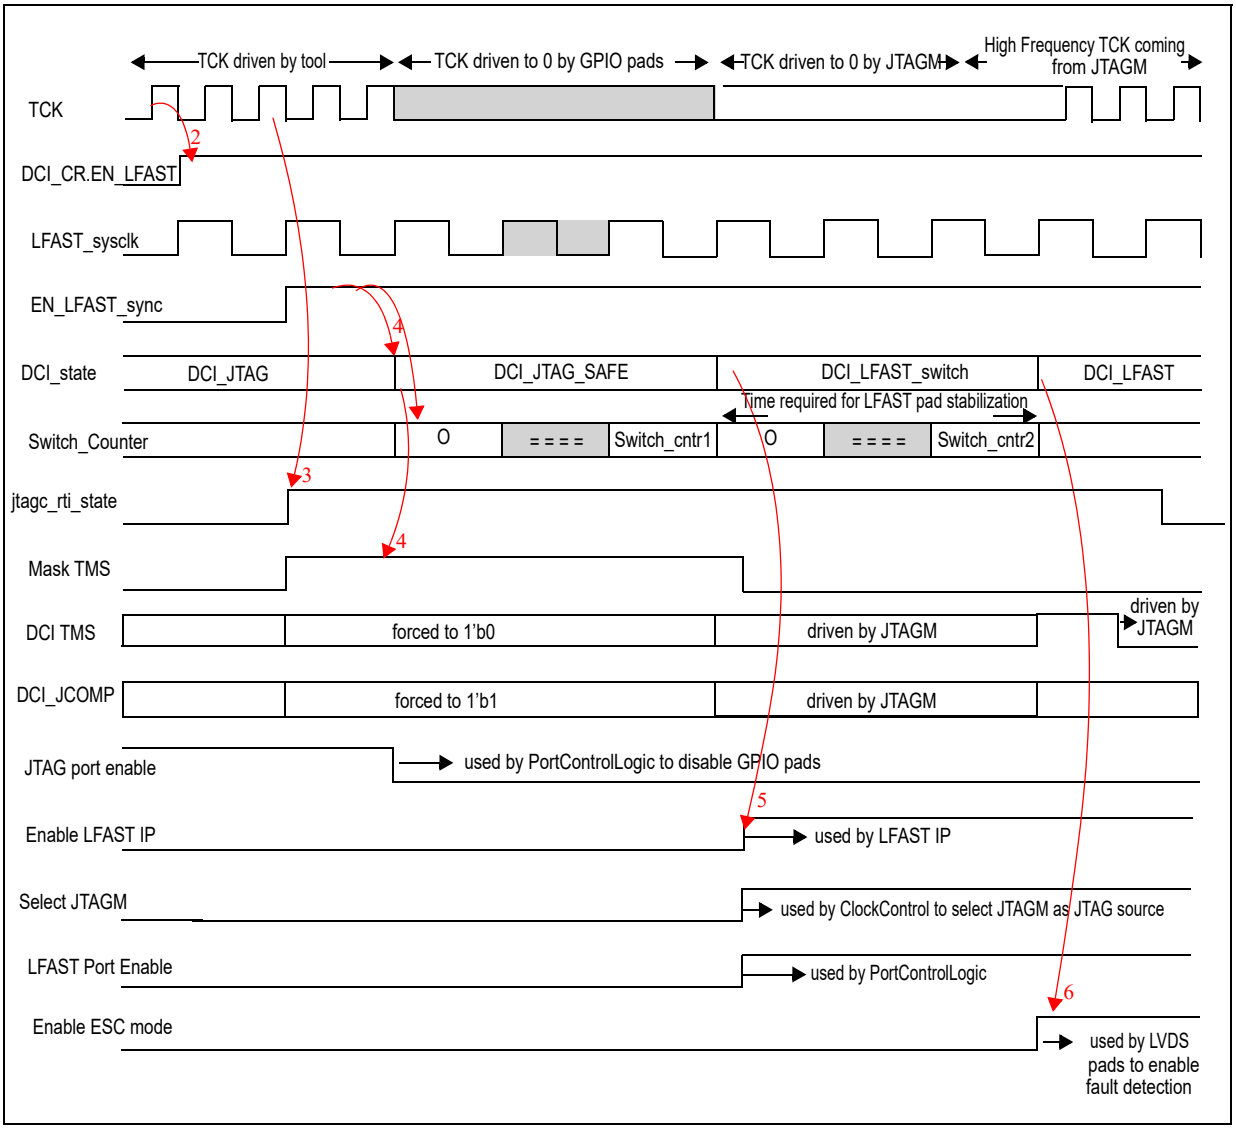
- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 2567*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 2567. DCI switching between JTAG and LFAST modes



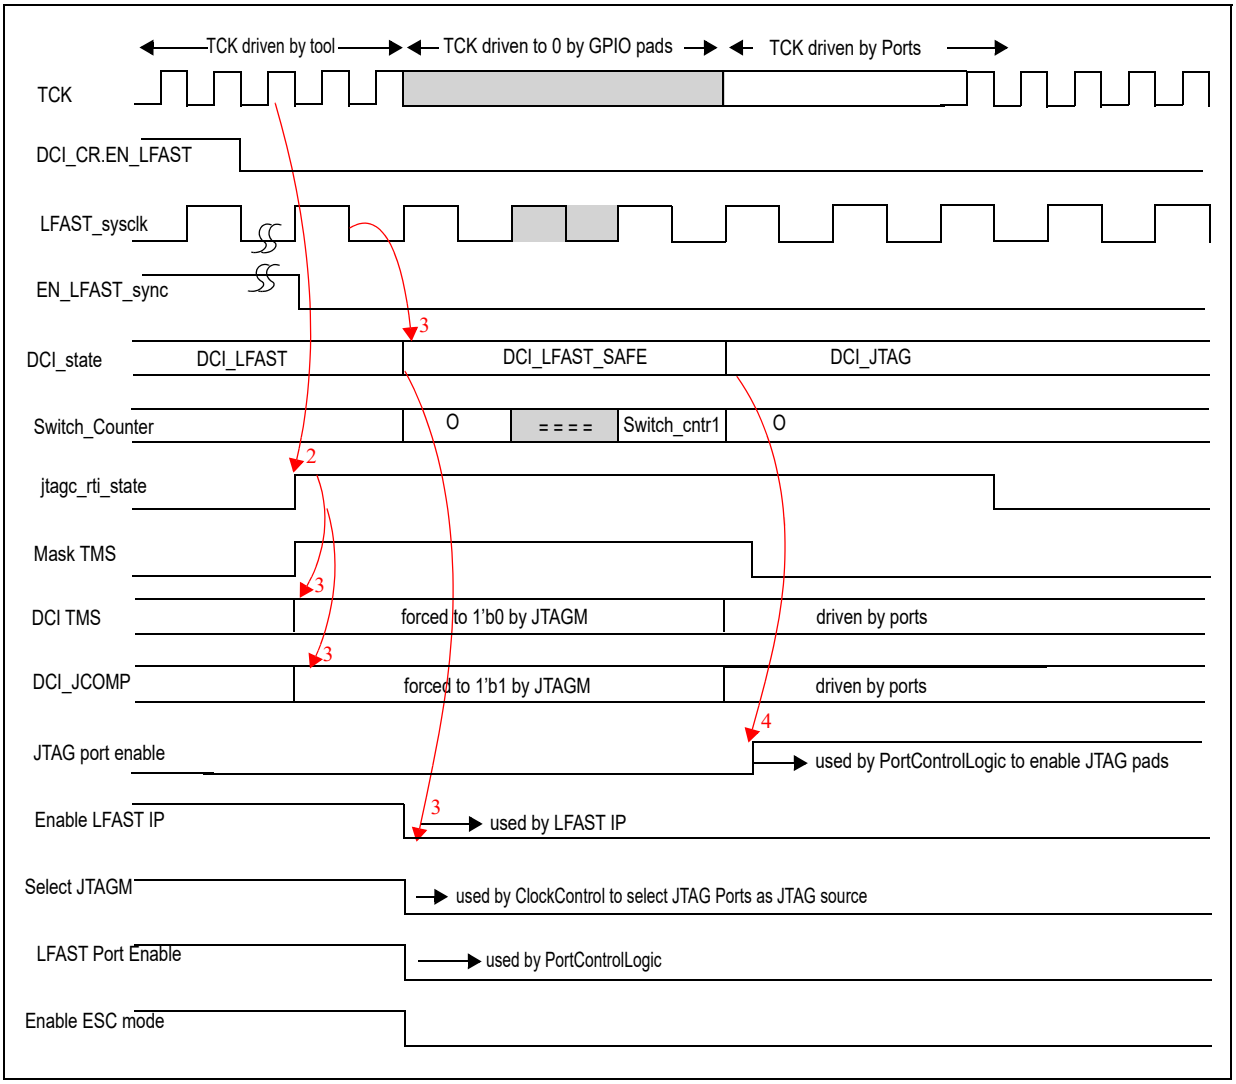
102.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   – EN_LFAST
   – SWITCH_CNTR1
   – SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 2568 shows the timing sequence.

Figure 2568. DCI JTAG to LFAST switching diagram



102.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 2451 and *Table 2453* summarize the MCU and tool behaviors. *Figure 2569* shows the timing sequence.

Figure 2569. DCI LFAST to JTAG switching diagram

102.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

102.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

102.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 2448. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

102.1.3.5 System watchdog control

The BD DCI does not include the Software Watchdog Timer (SWT) disable feature

102.1.3.6 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

102.1.3.7 Security

The SoC security logic provides a Debug_Enable signal to the PD DCI. The PD DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the PD DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

102.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

102.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the

DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

102.3.1 DCI control register (BD_DCI_CR)

The BD_DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 2570* shows the format of the BD_DCI_CR.

Note: The BD version of this register is refered to as DCI_CR in the other sections of this chapter.

In an ED which has both PD and BD instances of the DCI, all bits controlling the switch between LFAST and JTAGM must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

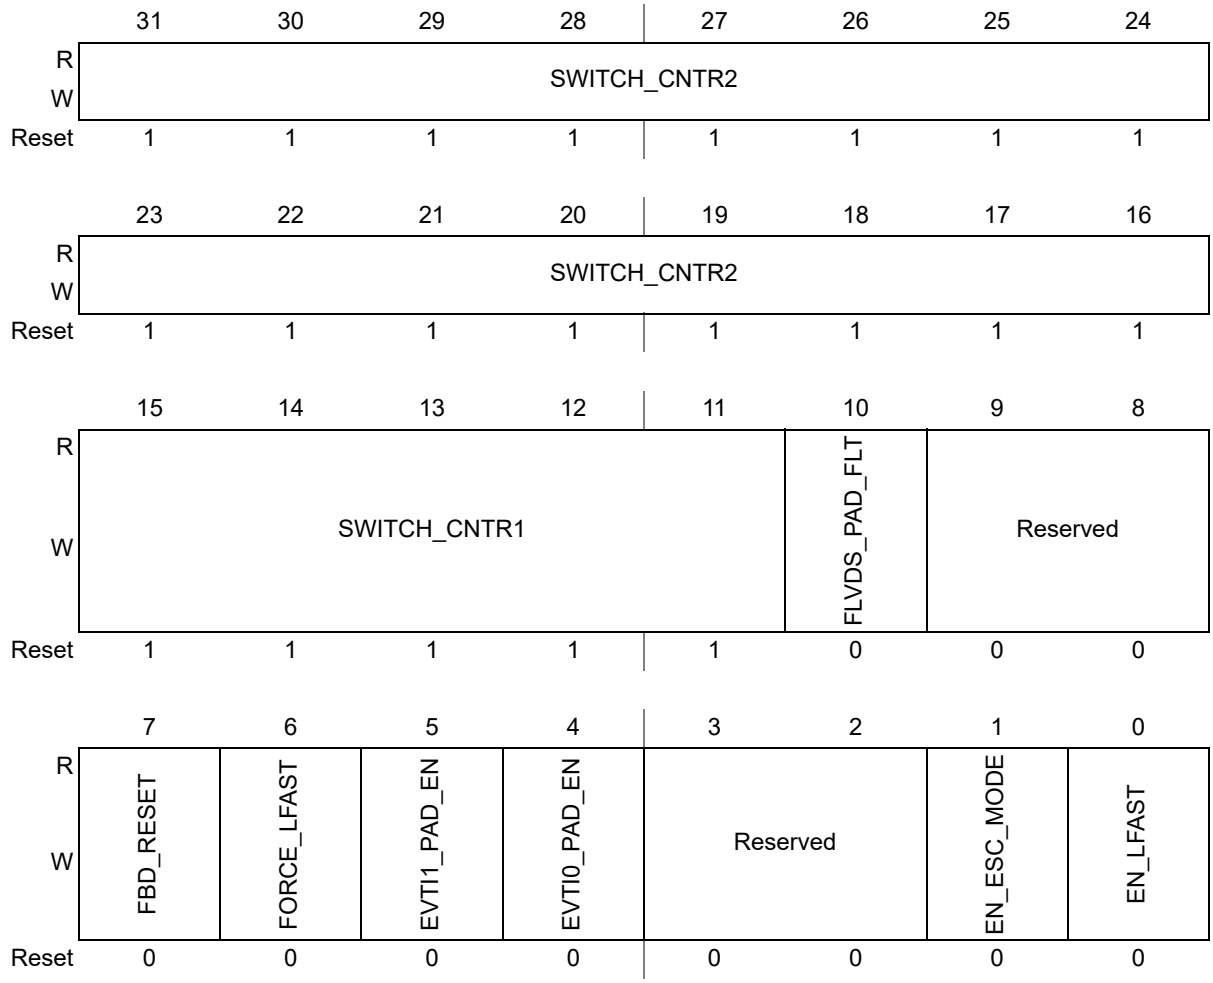


Figure 2570. DCI control register (DCI_CR)

The DCI_CR is described in *Table 2449*.

Table 2449. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2 Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1 Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
7 FBD_RESET	Force Reset 0 Do not force Reset 1 Force Reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN(1)	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN(2)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
1 EN_ESC_MODE	Enable Escape Mode Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(2)	Enable for LFAST-based tool selection This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

102.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter (or the Debug and Trace chapter) which describes how the modules are configured.

102.4 Functional description

102.4.1 DCI mode transition

After power-on reset, the BD DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 2450* and *Table 2451* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 2452* and *Table 2453* contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 2450. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN
TMS	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxP

Table 2451. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP

Table 2451. Tool operation (JTAG to LFAST switching) (continued)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don't Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 2452. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 2453. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

102.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the BD LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the BD DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 2454* and *Table 2455* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 2454. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 2455. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low

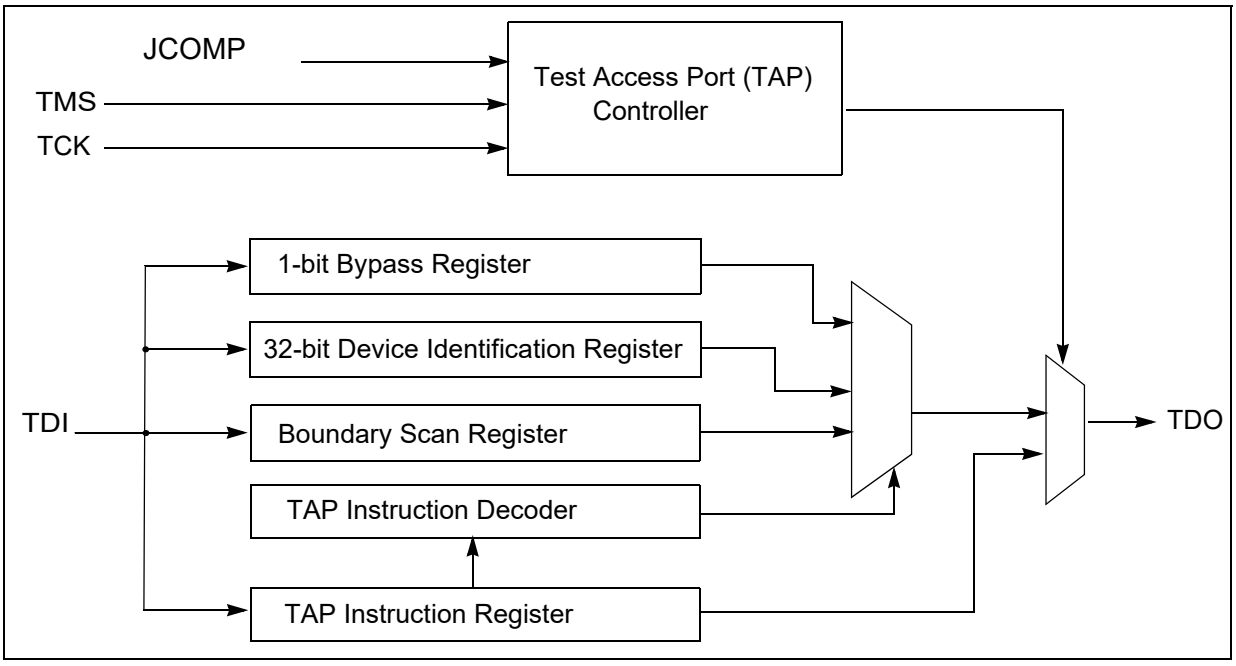
TMS	LVDS TxP	Don’t Care
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don’t Care

103 Buddy Device—JTAG Controller (JTAGC)



103.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

103.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 2571. JTAG (IEEE 1149.1) block diagram

103.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 2459* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

103.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

103.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

103.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 103.4.4: JTAGC block instructions*.

103.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

103.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 2456. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

103.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

103.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

103.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 103.4.3: TAP controller state machine*.

103.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

103.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

103.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

103.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

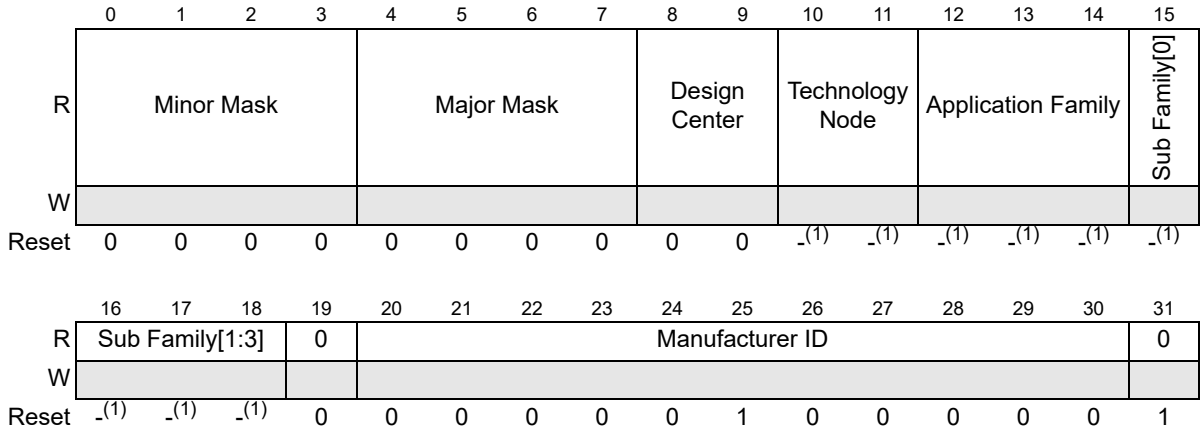


Figure 2572. 6-bit instruction register

103.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

103.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 2457*

Figure 2573. Device identification register

The following table describes the device identification register functions.

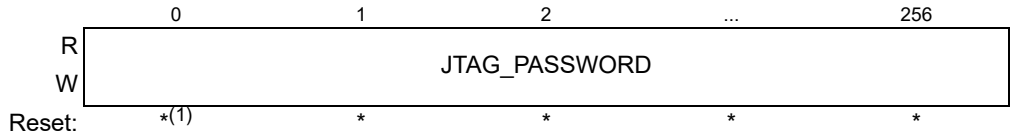

Table 2457. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 00 40nm
12:14 Application Family	Application Family These bits indicate the device application family 101 SPC58N - Chassis & Safety 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 0100 SPC58NE84C3 , SPC58NE84E7
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

103.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the

JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 2574. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 2458. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

103.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 103.4.5: Boundary scan*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

103.4 Functional description

This section explains the JTAGC functional description.

103.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

103.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 103.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

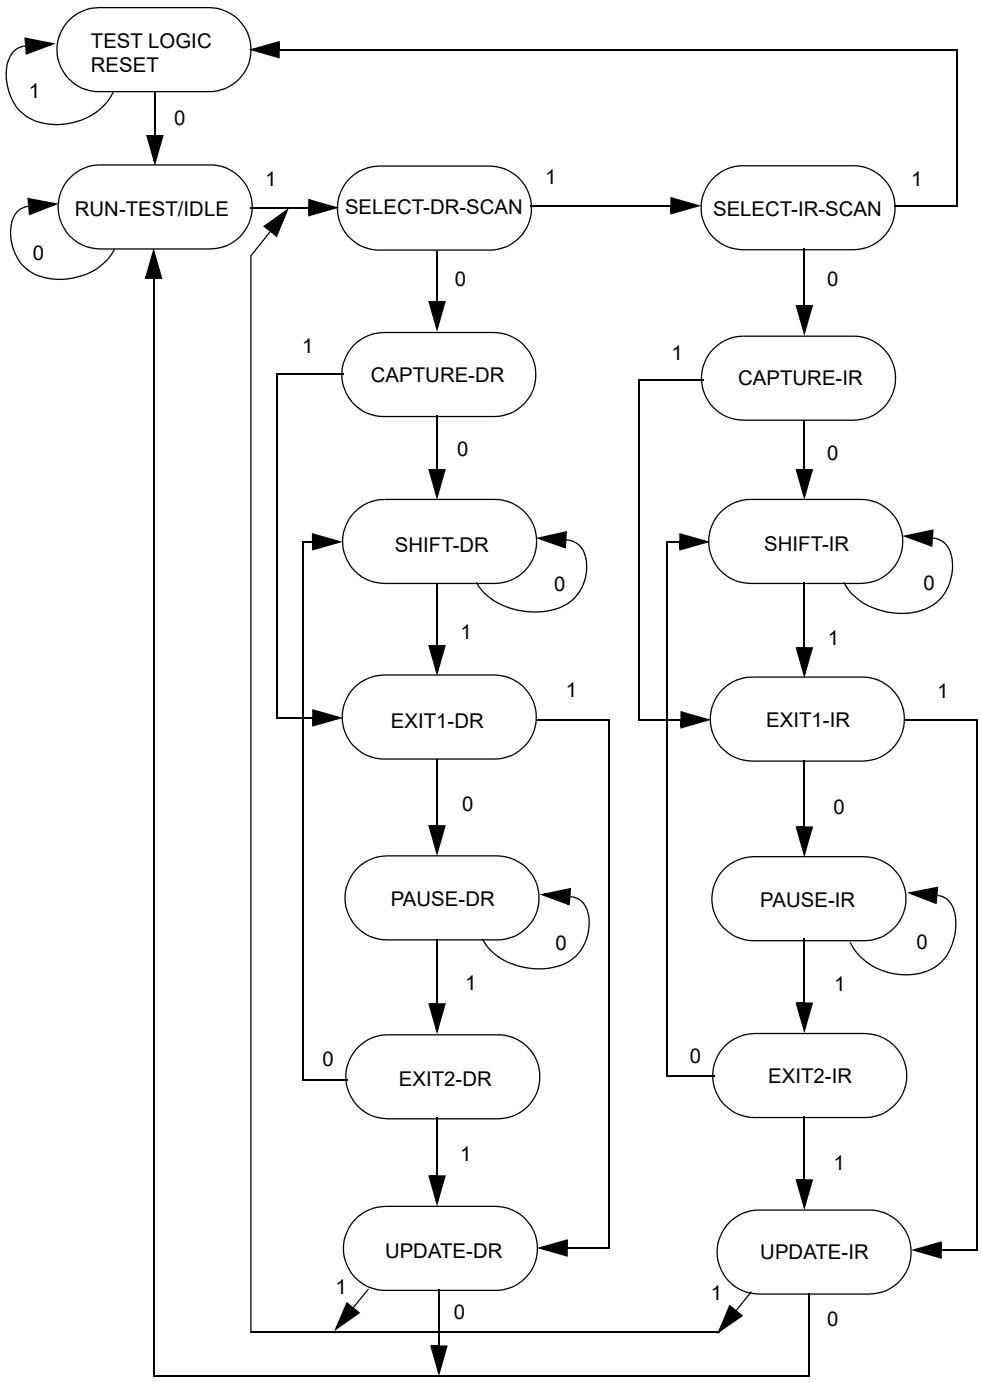

Figure 2575. Shifting data through a register

103.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 2576. IEEE 1149.1-2001 TAP controller finite state machine

Note:

1. The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

103.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

103.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

103.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 2459. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NR_BD	100000	Enables access to the NAR TAP controller on BD
Reserved	100001	Reserved
ACCESS_AUX_NAL	100010	Enables access to the NAL TAP controller

Table 2459. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ACCESS_AUX_RWA_BD	100011	Enables access to the RWA TAP controller
Reserved	100100	Reserved
Reserved	100101	Reserved

ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
ACCESS_AUX_DCI_PD	111110	Enables access to pass control from BD to PD
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

103.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

103.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

103.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

103.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

103.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

103.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

103.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

103.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

103.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

103.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

103.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

104 Buddy Device—JTAG Master (JTAGM)

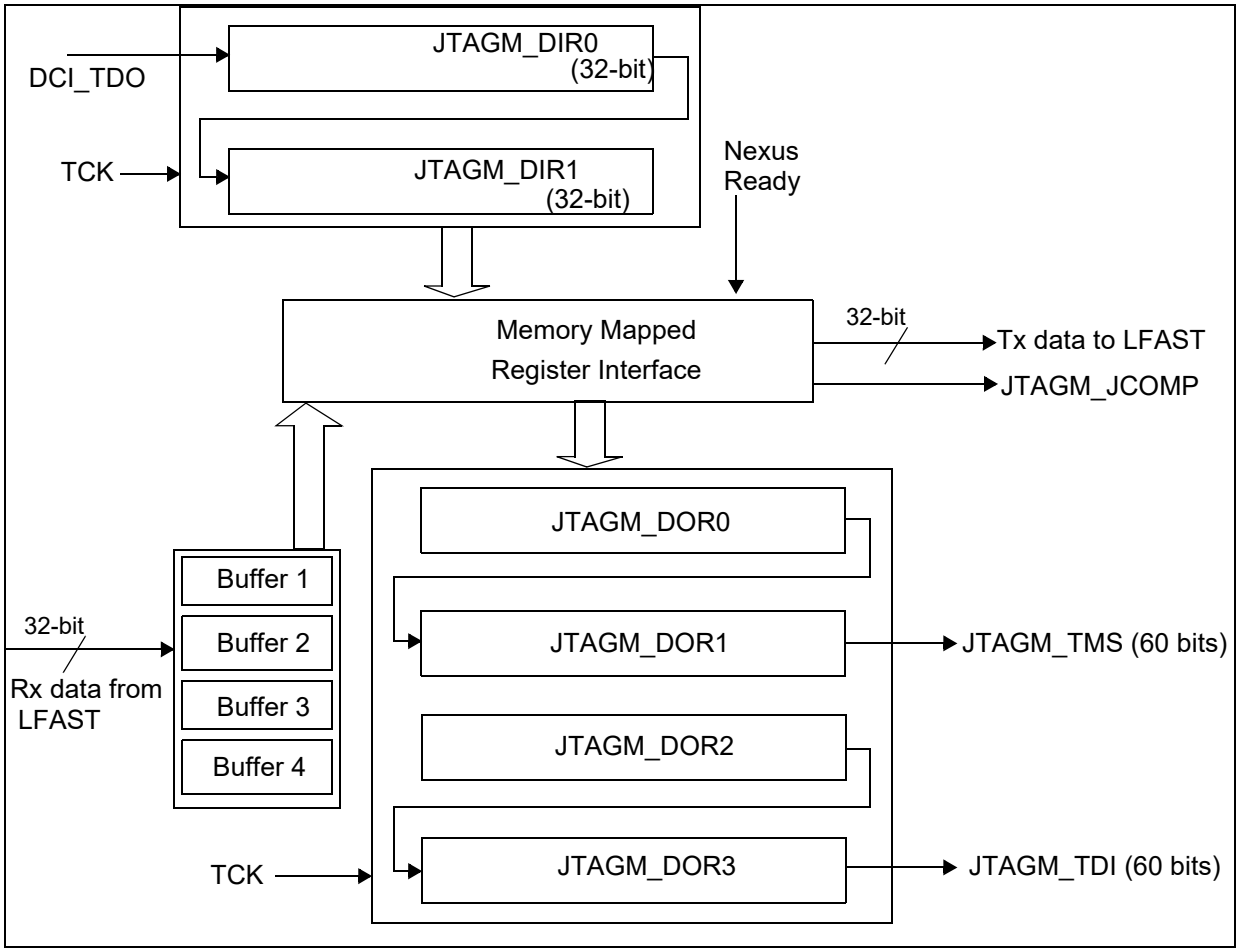
104.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

104.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers, described in detail in *Section 104.4: Memory map and register definition*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 2577 shows the block diagram of the JTAGM.

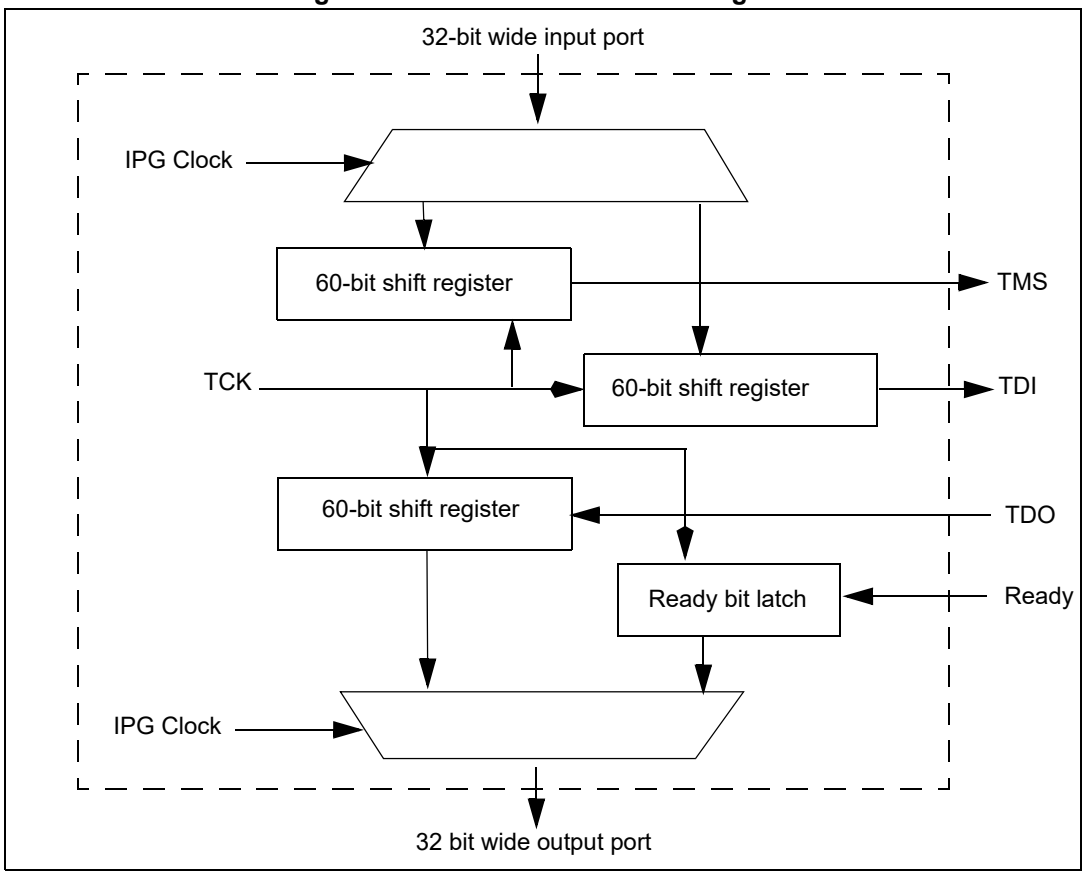
Figure 2577. JTAGM block diagram

104.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

104.2 Functional description



104.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 2578 shows the flow diagram of the LFAST to DCI connection.

Figure 2578. LFAST-to-DCI flow diagram

104.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

104.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

104.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

104.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

104.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

104.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

104.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

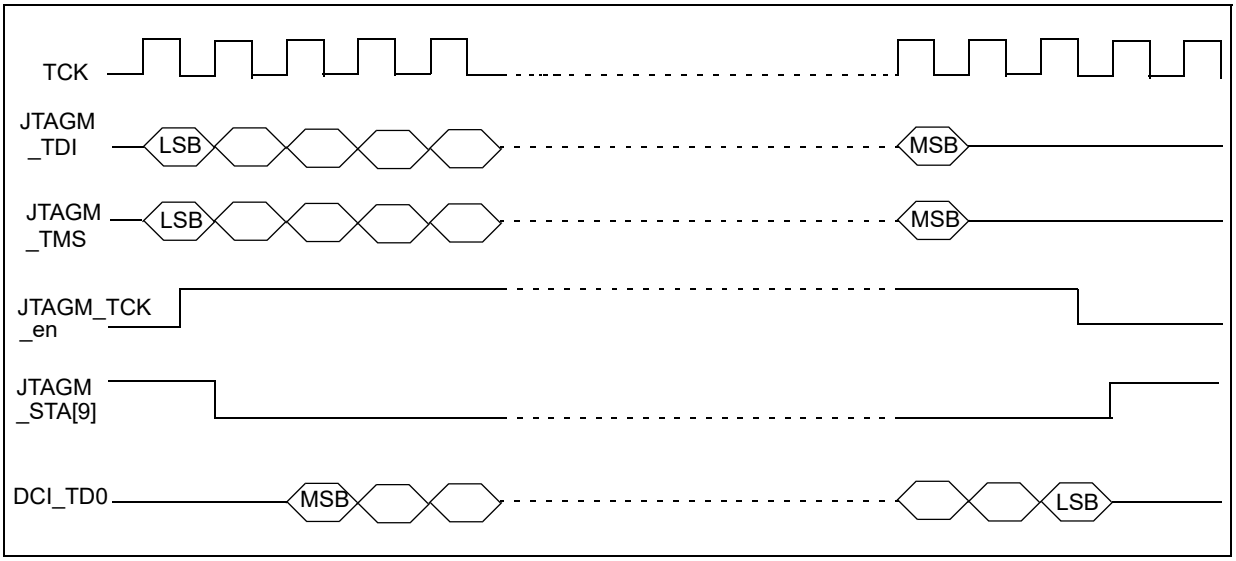
Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.

104.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 104.2.5.1: Status register*

ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written
- 32-bit value to be written to the configuration register
- 24-bit mask of which bits within the status register should be written
- 8 bits of zero-padding
- 24 bits of data to be written to the status register
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data)



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

[BLG_JTAGM_0008][Covers: ADD23.035]While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

104.2.8 JTAGM to DCI serial interface

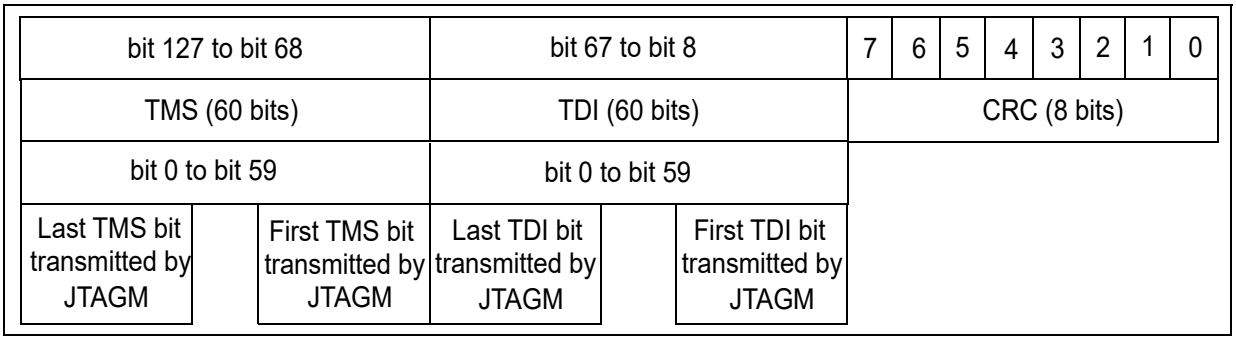
Figure 2579 shows the data transfer timings between JTAGM and DCI.

Figure 2579. JTAGM to DCI serial interface diagram

104.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 2580 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 2580. Bit ordering for LFAST to JTAGM transfer



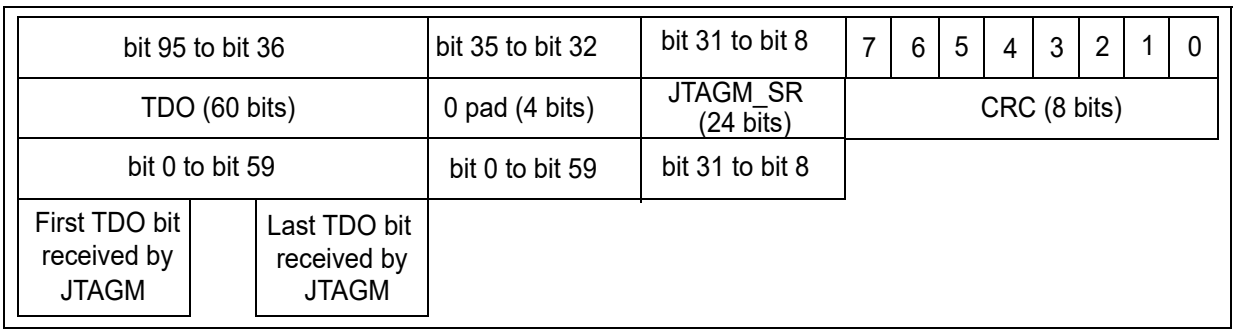


Figure 2581 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 2581. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 2581*).

104.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

104.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

104.4 Memory map and register definition

Table 2460 contains the memory map of the JTAGM registers.

Table 2460. Memory map

104.4.1 Register descriptions

104.4.1.1 Module configuration register (JTAGM_MCR)

This register contains the status bits for the current transfer. *Figure 2582* shows the format of the JTAGM_MCR. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. The only exception is the SIE bit, which always needs to be programmed in the Production Device instance of the JTAGM, regardless of being ED or not.

Figure 2584. JTAGM_SR register in SW mode

The JTAGM_SR register is described in *Table 2462*.

Table 2462. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$0
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1
18 SPU_INT_CLR	Write 1 clears the SPU_INT(1) This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit. (1)
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to ‘1’ when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.

Table 2462. JTAGM_SR register field descriptions (continued)

Field	Description
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode(when DTM =0) , this bit has no effect and acts as a “dont care” . This bit should not be used by the application in the LFAST mode
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

1. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

104.4.1.3 Data out register 0 (JTAGM_DOR0)

Figure 2585 shows the format of the JTAGM_DOR0.

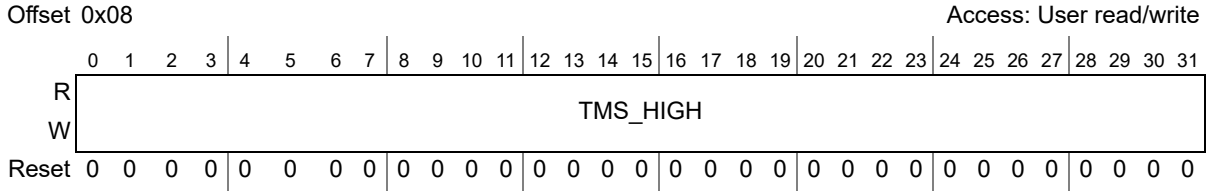

Figure 2585. JTAGM_DOR0 register

The JTAGM_DOR0 register is described in *Table 2463*.

Table 2463. JTAGM_DOR0 register field descriptions

Field	Description
0:31 TMS_HIGH	Higher word of data for TMS, bits 59-28. Writable by software only when DTM = 1

104.4.1.4 Data out register 1 (JTAGM_DOR1)

Figure 2586 shows the format of the JTAGM_DOR1.

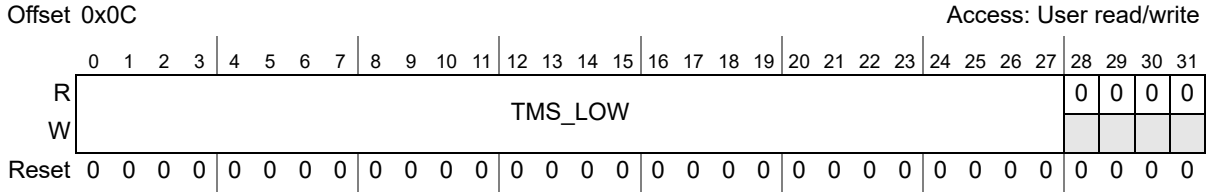

Figure 2586. JTAGM_DOR1 register

The JTAGM_DOR1 register is described in *Table 2464*.

Table 2464. JTAGM_DOR1 register field descriptions

Field	Description
0:27 TMS_LOW	Lower word of data for TMS, bits 27–0. Writable by software only when DTM = 1. TMS_LOW[0] is shifted out first

104.4.1.5 Data out register 2 (JTAGM_DOR2)

Figure 2587 shows the format of the JTAGM_DOR2.

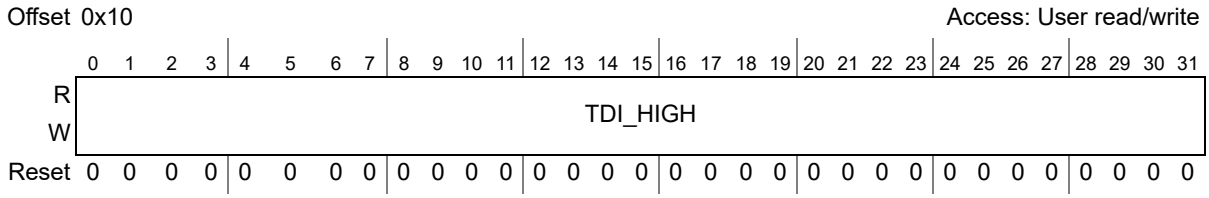

Figure 2587. JTAGM_DOR2 register

The JTAGM_DOR2 register is described in *Table 2465*.

105 Buddy Device—Nexus Aurora Router (NAR)

105.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 2592*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

Figure 2592. NAR top level diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora

formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

- Aurora type interface with clock domain transfer at the same frequency

105.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port or the Trace port, or both The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

105.3 Features

The NAR supports the following features:

- Connects 10 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

105.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 2470. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	on page 4164
NAR_ST—NAR Status Register	R	1	on page 4166
NAR_SFR—Source Filter Register	R/W	2	on page 4168
NAR_TFR—Type Filter Register	R/W	3	on page 4170
NAR_TBALO—Trace memory port base address, low	R/W	4	on page 4171
NAR_TBAHI—Trace memory port base address, high	R/W	5	on page 4171
NAR_TCR—Trace Memory bus control register	R/W	6	on page 4172
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)	on page 4173
NAR_CSSR–Client Suppress Status Register	R	B	on page 4174

Figure 2593. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 2471. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 105.5.2.2: Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). *Note: Some clients may only support timestamps on every message.* 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 1/2 of queue is dedicated to alternate partition 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.

Table 2471. NAR_CR field descriptions (continued)

Field	Description
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications. 00 No message select port. 0–1 port is active. 01 HBDP is the MSP 10 Trace memory bus is the MSP 11 Reserved
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 HBDP is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2 FSD	Frame Serial Data. 0 Framing disabled. Data is streamed through the Aurora out port. 1 Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

105.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				MPF	MLV		APF	ALV		0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 2594. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 2472. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 2487* for coding
23 MPF	MSP Partition Full. 0 MSP partition not full 1 MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled that is the main queue is partitioned. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%
20 APF	ALT Partition Full. 0 ALT partition not full 1 ALT partition full
19–18 ALV	ALT Partition Queue Level. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%

Table 2472. NAR_ST field descriptions (continued)

Field	Description
17–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)

105.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 105.5.6: Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

105.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

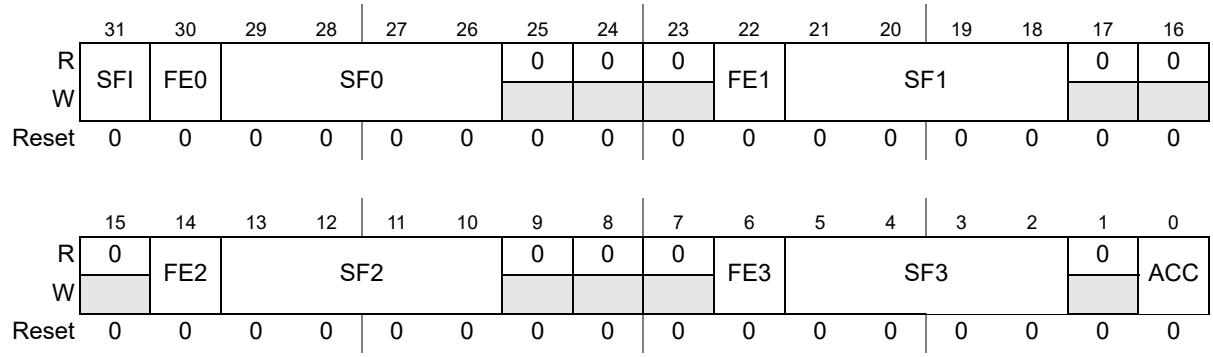

Figure 2595. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2473. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 105.5.6: Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 105.5.6: Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 105.5.6: Output arbitration* for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3

Table 2473. NAR_SFR field descriptions (continued)

5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 105.5.6: Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

105.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 105.5.6: Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 105.5.6: Output arbitration* for an example.

105.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

105.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TBAHI																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2597. Trace memory base address register NAR_TBAHI

Register index: 4

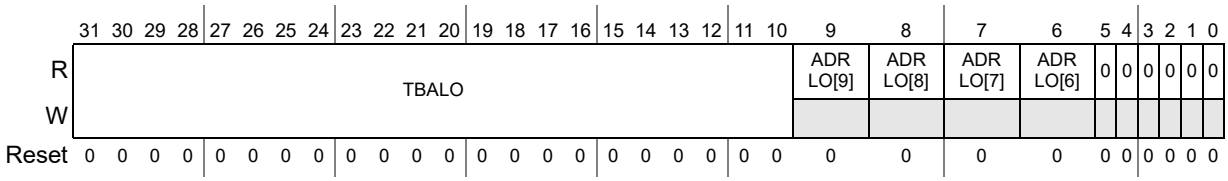

Figure 2598. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 2475. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 2476. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

105.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

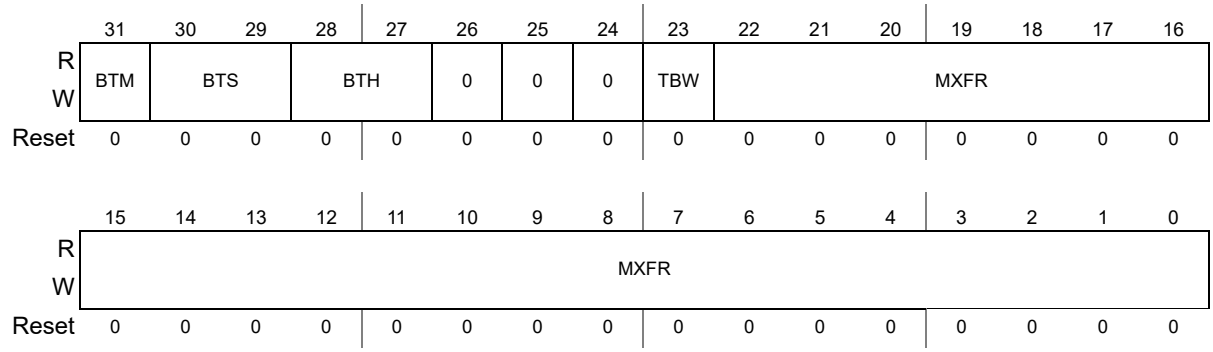

Figure 2599. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 2477. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

105.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 105.5.4: Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each

Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

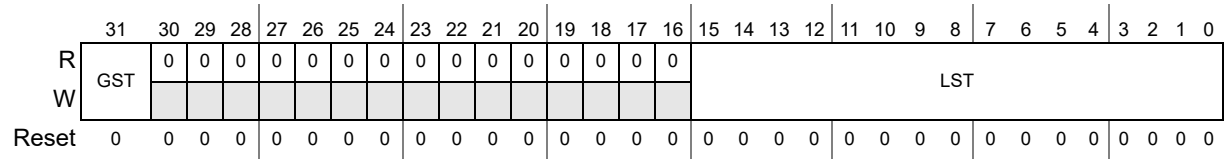

Figure 2600. Suppress trigger control registers (NAR_STCR1–4)

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2478. NAR_STCR field descriptions

105.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status

(NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

105.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note: Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Register index: C

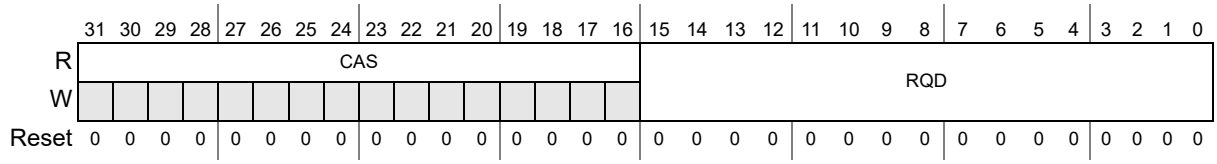

Figure 2602. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

105.4.7 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	GSE	0	0	0	GLOBAL_STALL_COUNT

Figure 2604. Trace memory fill level and partition configuration register (NAR_AHFPAR)

The NAR_AHFPAR is described in the following table.

Table 2482. NAR_AHFPAR field description

Field	Description
31-25	Reserved and must be written with 0s
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on dci_evti[0] event to generate a global stall
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See *Section 105.5.13: Global (Development tool client) stall control*
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 105.5.14: Overlay and internal trace memory full status generation* **Note:** This is used in BD as it has memory ranges from 65K to 983K
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 105.5.14: Overlay and internal trace memory full status generation* **Note:** This is used in PD as it has memory ranges from 1K to 15K

105.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

105.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 105.5.4: Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

105.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 2483. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled

Table 2483. NAR operational modes truth table (continued)

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

105.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

105.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

105.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

105.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

105.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 2484. NAR transmit operations

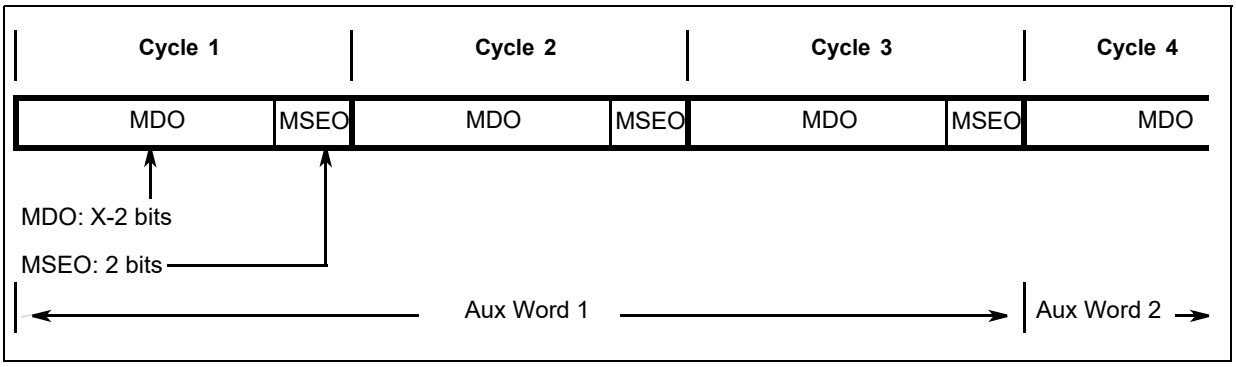
Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

105.5.3 Data reception and arbitration

The BD NAR supports 10 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never

sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn $\times$ 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2605. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request

level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

105.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then

all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

105.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

105.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type or messages from a particular client, or both, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

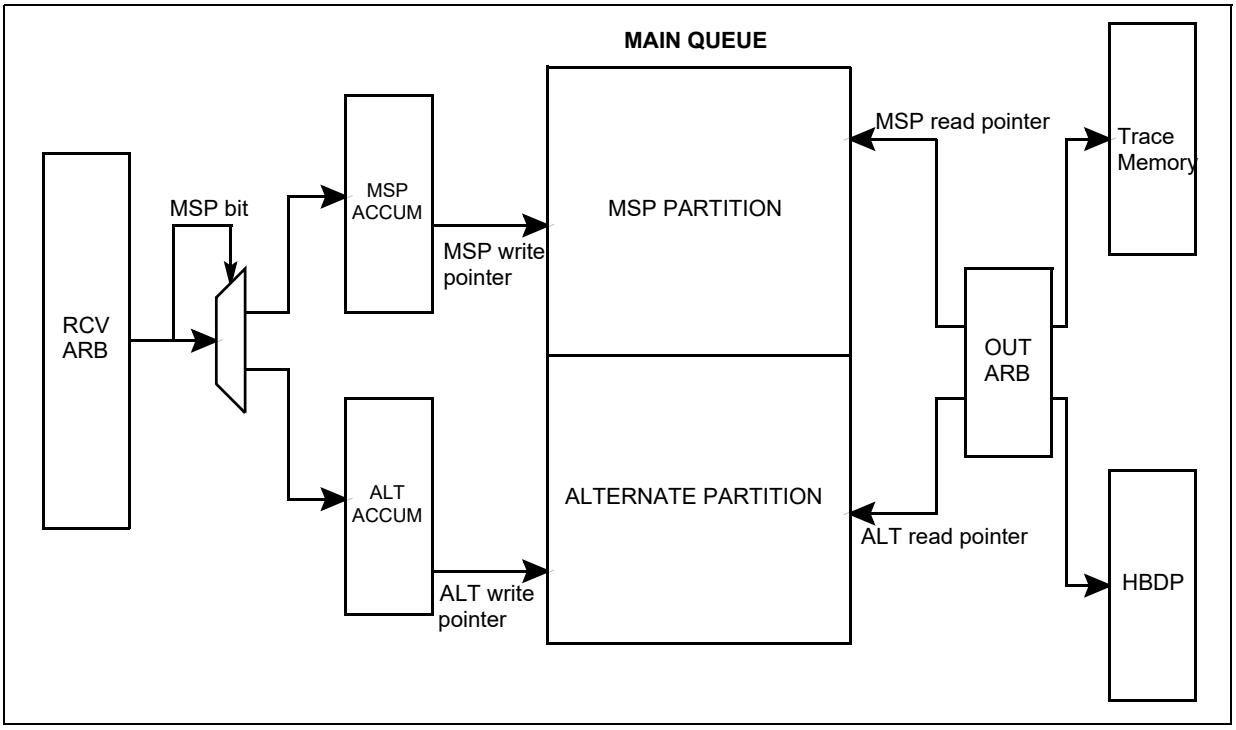
If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types or four sources, or both.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP



Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

105.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in *Figure 2606*. Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

Figure 2606. Queue partitioning

105.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

105.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

105.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and

resizing in the likely case where the trace memory bus width does not equal the queue entry size.

105.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

105.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (that is unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 $\times$ 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

105.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 2488*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 2485. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 2486*
	12	12	fixed	ECODE	See *Table 2487*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC2	NAR source ID
	6	6	fixed	WPHIT	See *Table 2488*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

105.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 2486. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 2487*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 2487*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 2487*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 2487. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering or queue partitioning disabled, or both	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

105.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

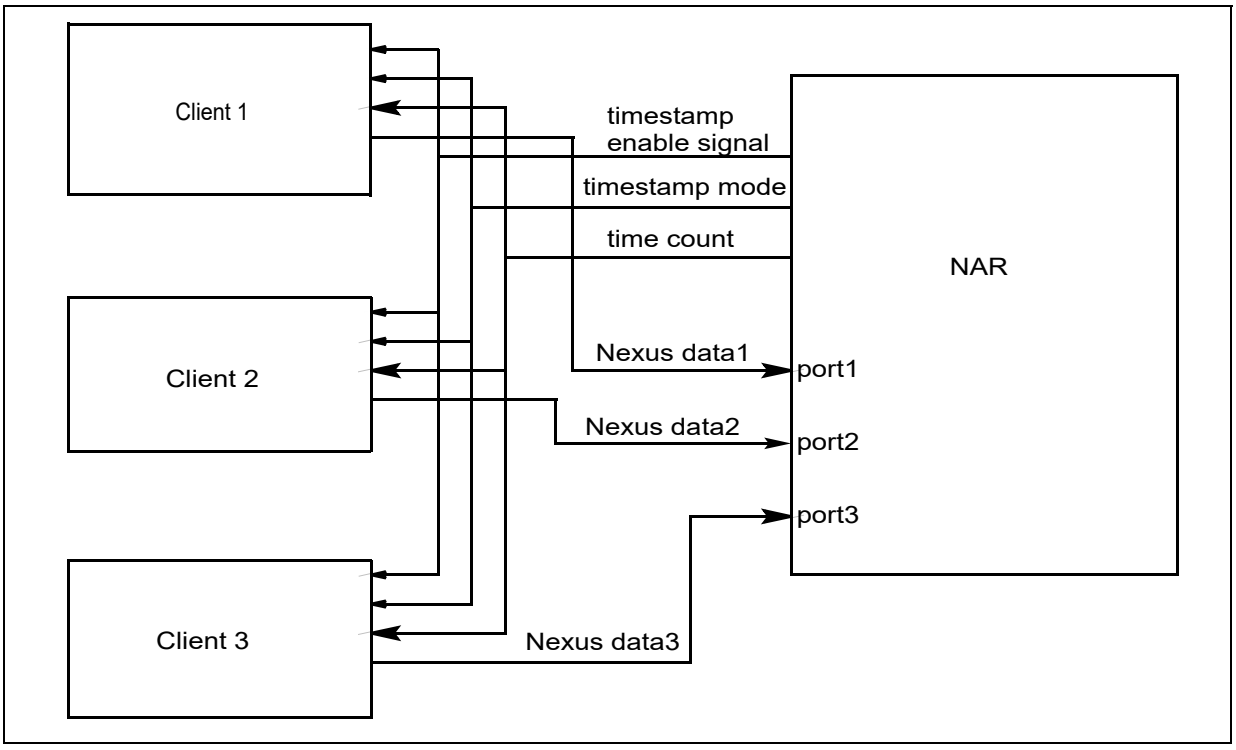


Table 2488. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

105.5.12 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 2607*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2607. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

105.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to NAR block. The dci_evti[0] carries this information. NAR detects the falling edge of dci_evti[1] and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

105.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

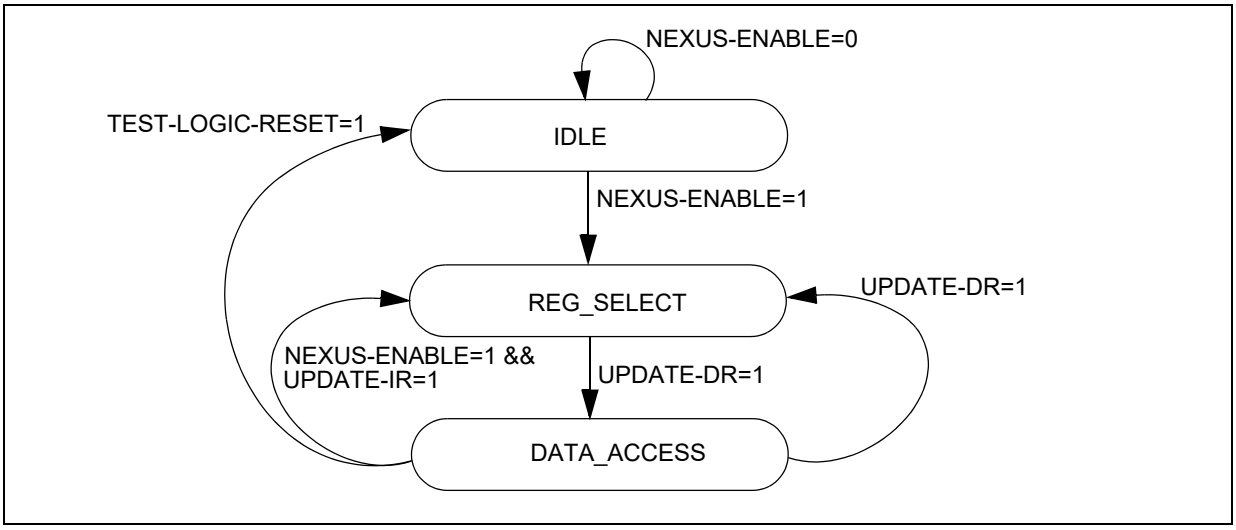
105.5.15 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 2489*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2608. Nexus controller state machine



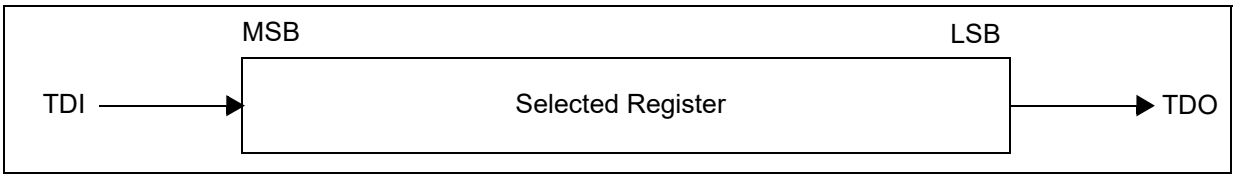


Table 2489. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2609. Shifting data into register

105.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

105.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2608*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 2490. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

105.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2610*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 2470*.

Figure 2610. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 2491. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

105.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

105.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

105.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

105.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

105.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width $\times$ 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as Bn $\times$ 32, where 32 = MDO bits + 2 MSEO bits and Bn is the number of beats.

Thus:Aurora data width = the Nexus client data

Aurora width $\times$ 16 = Bn $\times$ 32

Aurora width = 2 $\times$ Bn.

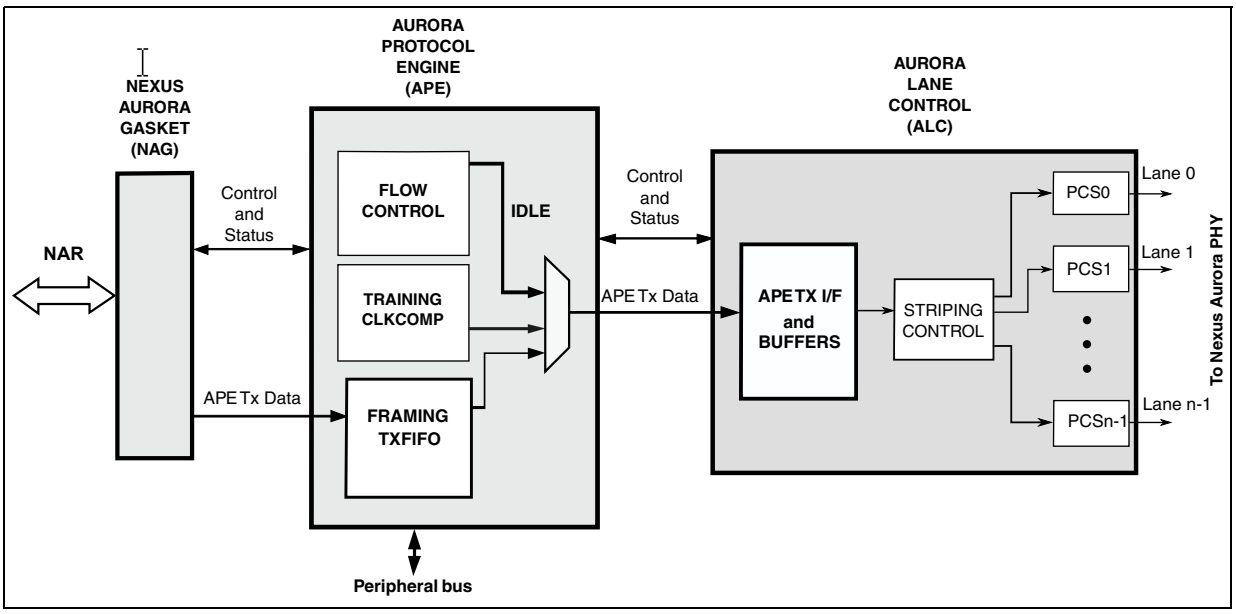
This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block. The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

105.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 105.5.2.1: Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

105.7 Application information



The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 105.5.6: Output arbitration*.

106 Buddy Device—Nexus Aurora Link (NAL)

106.1 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. *Figure 2611* details the NAL block diagram. The number of lanes, n, is 4.

Figure 2611. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Router (NAR); messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. *Table 2492* lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 2492. NAL and NAP feature summary

Sub-component	Feature
NAR Aurora Gasket (NAG)	– Transmit FIFO to buffer data as it crosses the NAR / NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. – Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	– Link training – Per the Aurora Protocol specification, clock-compensation, and data framing – Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	– Striping of data stream from the Aurora core across all available lanes in two-byte chunks – PCS functionality for NAL
Nexus Aurora PHY (NAP)	– Physical transmission of serial data to device pins – External clock source for SerDes clock domain

106.2 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each packet is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each payload transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

Note: Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

106.3 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

106.4 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note: Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

106.5 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 2493. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0x0	NAL General Status Register (NAL_GSR)	32	R	0x0000_8000
0x8	NAL General Control Register (NAL_GCR)	32	R/W	0x0000_0000
0xC	NAL Training Control Register (NAL_TCR)	32	R/W	0x0000_0000

106.5.1 Nexus Aurora Link General Status Register (NAL_GSR)

Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2612. Nexus Aurora Link General Status Register (NAL_GSR)

Table 2494. NAL_GSR field descriptions

Field	Description
0:11	Reserved
12 TXONLY	Transmit Only mode. Indicates that Aurora is configured in a transmit-only mode. 0 Reserved 1 Aurora is configured for transmit-only simplex communication. Training method is configured to use Static Training.
13:18	Reserved
19:21 TXCFG	TX Lane Configuration Number of enabled TX lanes. These bits are read-only and are controlled external to the NAL. 000 Reserved 001 2 TX lanes 010 Reserved 011 4 TX lanes 100 Reserved 101 Reserved 110 Reserved 111 Reserved
22:30	Reserved
31 AS	Aurora Status 0 Aurora is not enabled. 1 Aurora is enabled.

106.5.2 NAL General Control Register (NAL_GCR)

The NAL_GCR configures the behavior of the APE. It can be programmed to reset the Aurora channel, or to configure simplex/duplex initialization and to enable debug features.

Access: Read/Write

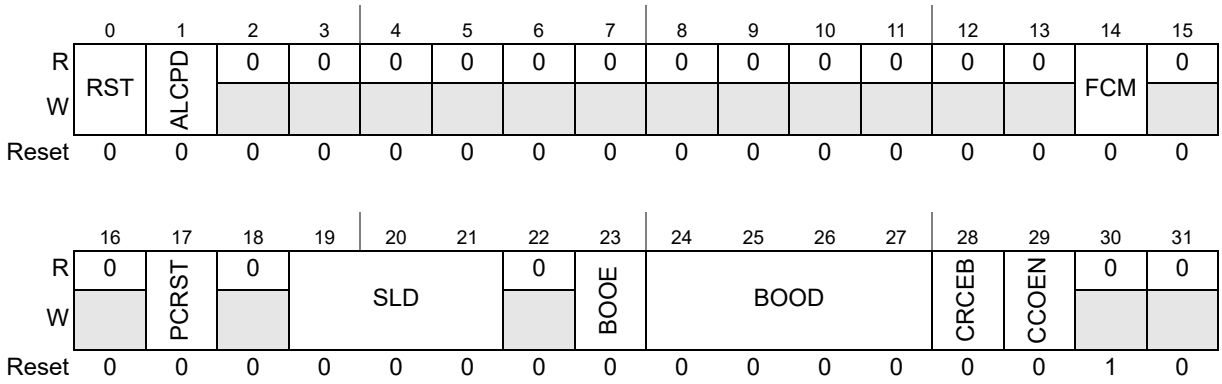

Figure 2613. NAL General Control Register (NAL_GCR)

Table 2495. NAL_GCR field descriptions

Field	Description
0 RST	Reset the Aurora Channel 0 to 1 transition resets the channel and begins the training sequence. 0 normal operation 1 transition from 0 to 1 resets channel and starts training sequence
1 ALCPD	ALC/NAL Power Down Gate off clocks to the NAL blocks (ALC and APE). 0 NAL is enabled with all clocks running provided other mechanisms of powerdown (such as alc_num_lanes) are not in effect. 1 NAL is powered down and inactive.
2:13	Reserved This read-only bitfield is reserved and always has the value zero.
14 FCM	Flow Control Mode 0 Completion Mode 1 Immediate Mode
15:16	Reserved and must be written with zero.
17 PCRST	Protocol Converter Reset Resets the ALC when asserted.
18	Reserved This read-only bit is reserved and always has the value zero.
19:21 SLD	Symbol Lock Delay 000 Allow 3 characters to accumulate in elastic buffer before starting to read 001 Allow 4 characters to accumulate in elastic buffer before starting to read 010 Allow 5 characters to accumulate in elastic buffer before starting to read 011 Allow 6 characters to accumulate in elastic buffer before starting to read 100 Allow 7 characters to accumulate in elastic buffer before starting to read 101 Allow 8 characters to accumulate in elastic buffer before starting to read 110 Allow 9 characters to accumulate in elastic buffer before starting to read 111 Allow 10 characters to accumulate in elastic buffer before starting to read
22	Reserved This read-only bit is reserved and always has the value zero.

Table 2495. NAL_GCR field descriptions (continued)

Field	Description
23 BOOE	Bond Offset Override Enable 0 ALC channel bond attempts to determine channel bond offset. 1 ALC uses user override setting for channel bond offset.
24:27 BOOD	Bond offset override data Only valid when BOOE is set. 0000/1000 use 0-cycle offset 0001 use -7 cycle offset 0010 use -6 cycle offset 0011 use -5 cycle offset 0100 use -4 cycle offset 0101 use -3 cycle offset 0110 use -2 cycle offset 0111 use -1 cycle offset 1001 use +1 cycle offset 1010 use +2 cycle offset 1011 use +3 cycle offset 1100 use +4 cycle offset 1101 use +5 cycle offset 1110 use +6 cycle offset 1111 use +7 cycle offset
28 CRCEB	CRC Enable 0 CRC generation and checking is disabled for TX and RX data. 1 CRC is inserted for TX frames and CRC is checked for RX paths.
29 CCOEN	Clock Compensation Override Enable This is a debug feature which allows the duration between clock compensation sequences to be reduced to 1280 cycles. 0 Clock compensation counter times out at 7424 cycles 1 Clock compensation counter times out at 1280 cycles
29	Reserved and must be written with zero.
30:31	Reserved This read-only bitfield is reserved and always has the value zero.

106.5.3 NAL Training Control Register (NAL_TCR)

The NAL_TCR supports static training as described in *Section 106.4: Static training*.

Access: Read/Write

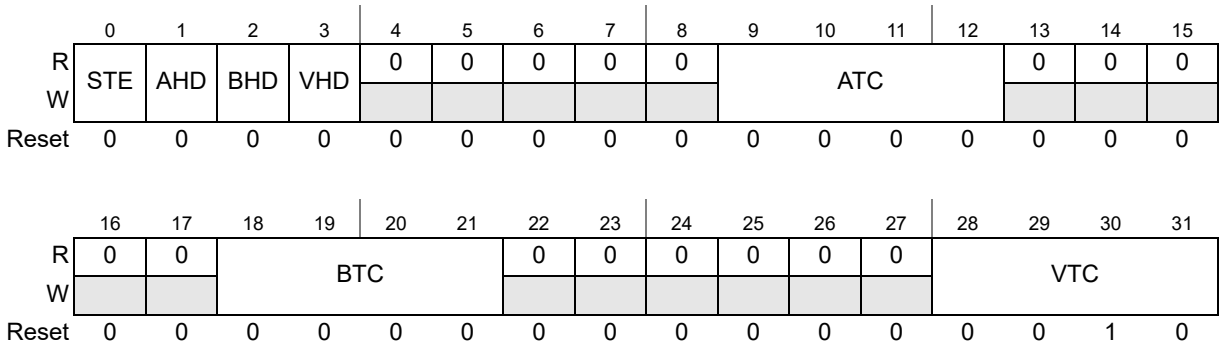

Figure 2614. NAL Training Control Register (NAL_TCR)

Table 2496. NAL_TCR field descriptions

Field	Description
0 STE	Static Training Enable 0 Reserved 1 Timer-based training method is used, ie. RX data is ignored and training is established based on ATC/BTC/VTC timers.

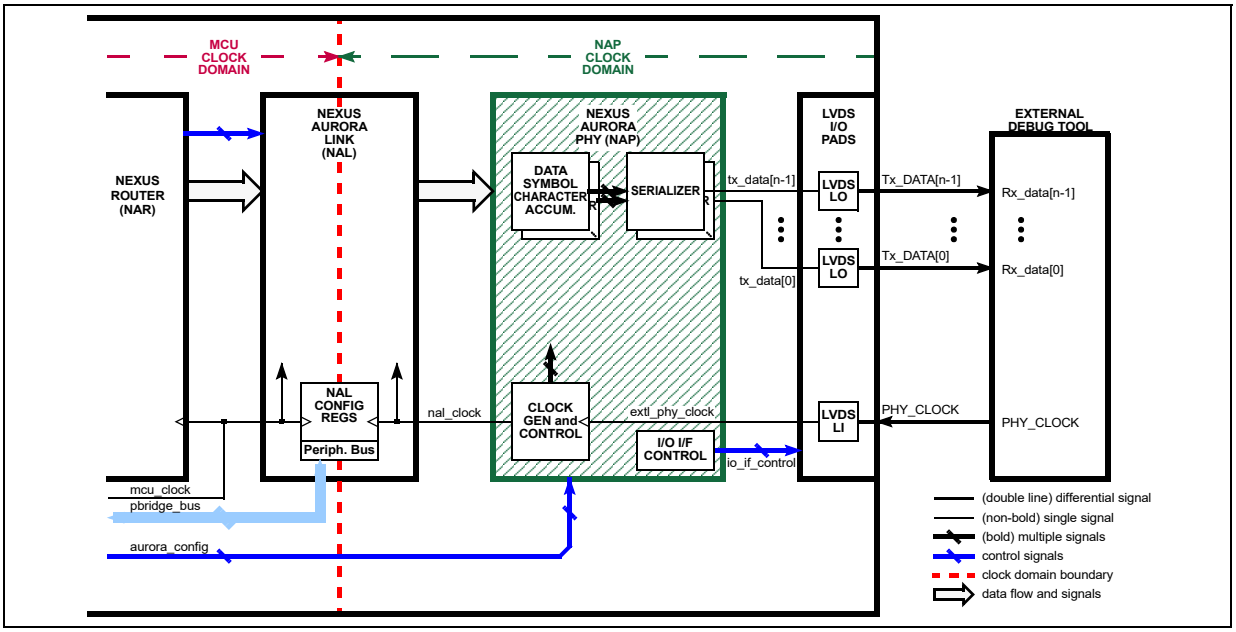
107 Buddy Device—Nexus Aurora PHY (NAP)

107.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.



Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

Figure 2615 shows a high level block diagram of the High Speed Nexus Interface and the NAP.

Figure 2615. High speed Nexus interface block diagram

107.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1 Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

107.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

107.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

107.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

107.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 4 Transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

107.2 External signal description

The external signals of the NAP are listed in *Table 2497*. Each of the NAP signals consists of a positive and negative differential pair.

Table 2497. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2(TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3(TX3P/TX3N)	Output	NAP Tx data for lane 3

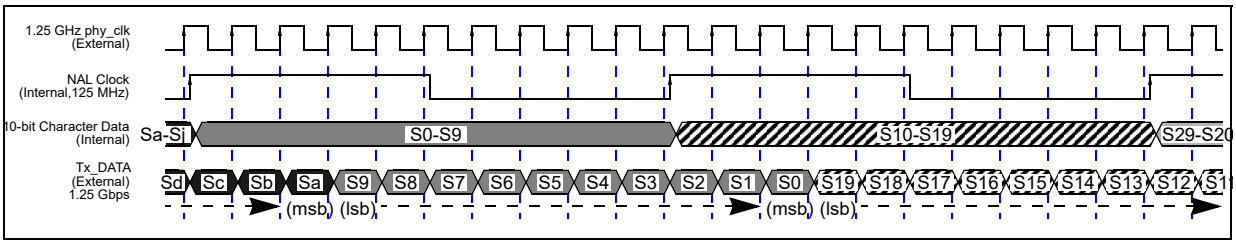
107.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

107.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

107.4.1 Data symbol character accumulator



The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

107.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

Figure 2616 shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

Figure 2616. Serializer timing diagram

107.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

107.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

Appendix A Acronyms and abbreviations

Table 2498 lists acronyms and abbreviations used in this document.

Table 2498. Acronyms and abbreviations

Term	Meaning
AHB	Advanced high-performance bus
AIC	PBRIDGE (AIPS) integrity checker
AMBA	Advanced microcontroller bus architecture
APU	– Advanced protocol unit – Auxiliary processing unit
ASILD	Automotive SIL D
AUTOSAR	Automotive open system architecture
AV	Audio video
BAF	Boot assist flash
BIST	Built-in self test
BIU	Bus interface unit
CAN	Controller area network
CF	Critical fault
CGM	Clock generation module
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check
CSI	Combined serial interface. DSPI configuration that alternates DSI and SPI frames.
CTU	Cross triggering unit
DCB	Data center bridging
DCF	Device configuration format
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DSI	Deserial serial interface. DSPI configuration that serializes and deserializes registers or signals to allow for pin reduction.
ECC	Error correction code
ECSM	Error correction status module
EIM	Error injection module
EMI	Electromagnetic interference
EOUT	Error out

Table 2498. Acronyms and abbreviations (continued)

Term	Meaning
ESD	Electromagnetic static discharge
FCCU	Fault collection and control unit
FMPLL	Frequency-modulated phase-locked loop
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
FTTI	Fault tolerant time interval
GPIO	General-purpose I/O
HVD	High voltage detector
HW	Hardware
ID	LIN identifier field
IEEE	Institute of electrical and electronics engineers
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety
IPS	– Internal peripheral system – IPI slave bus
IRQ	Interrupt request
ISR	Interrupt service routine
JDC	JTAG data communication
JEDEC	Joint electron device engineering council
JTAG	Joint test action group
KGD	Known good die
LBIST	Logic built-in self test
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LLDP	Link layer discovery protocol
LVD	Low voltage detector
LWB	Late-write buffer
MB	Message buffer
MBIST	Memory built-in self test
MBM	Message buffer management
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit
MFD	Multiplication factor divider

Table 2498. Acronyms and abbreviations (continued)

Term	Meaning
Mux	Multiplex
NCF	Non-critical fault
NMI	Non-maskable interrupts
NVM	Non-volatile memory
OPP	Over-program protection
OSC	Oscillator
OTP	One time programmable
PASS	Password and device security module
PBRIDGE	Peripheral bridge
PCM	Platform configuration module
PCU	Power control unit
PFLASH	Platform flash controller
PIT	Periodic interrupt timer
PLL	Phase-locked loop
PMC	Power management controller
PRAM	Platform RAM controller
PWD	Password
RC	– Resistance-capacitance – Resistor-capacitor
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RTL	Register transfer language
RWW	Read-while-write
RX	Receive
SAG	Safety application guide
SAR ADC	Successive approximation register analog-to-digital converter
SIL	Safety integrity level
SIUL	System integration unit lite
SMPU	System memory protection unit
SoC	System-on-chip

Table 2498. Acronyms and abbreviations (continued)

Term	Meaning
SOR	Sphere of redundancy
SPI	Serial peripheral interface
SSCM	System status and configuration module
STCU	Self-test control unit
STM	System timer module
SW	Software
SWT	Software watchdog timer
TBD	To be defined
TCD	Transfer control descriptor
TSENS	Temperature sensor
TX	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault
VCO	Voltage controlled oscillator
VREG	Voltage regulator
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar
XBIC	XBAR integrity checker

Date	Revision	Changes
04-May-2015	1	Initial release.
08-Feb-2016	2	Throughout document: replaced “LINFlex” to “LINFlexD”; editorial and formatting changes *Chapter 1: Preface* *Section 1.4: Reference documents*: – Replaced “http://www.power.org/” by “Power Architecture web site”. *Chapter 2: Introduction* Removed instance of “Checker Core 1”. *Section 2.1.2: Overall architecture*: – “...two pairs of CPUs...” updated to “...one pair of CPU...”. – added “one CPU without lock-step, a DMA move engine”. – “DMA” modified to “a DMA move engine, fast local memories inside the CPU, fast system memories”. *Section 2.1.3: Core features*: – Operating frequency updated to “180 MHz”. – Removed “They include enhancements....(DSP) algorithms”. – Programmable CPU updated from 7 to 6. – CPU frequency updated from “100MHz” to “90MHz”. *Section 2.1.4: Core_2*: – Number of processor cores updated from 7 to 6. – Operating frequency updated from “200MHz” to “180MHz”. – “64-bit address bus and a 32-bit data bus” updated to “64-bit data bus and a 32-bit address bus”. *Section 2.1.5: Memory hierarchy*: – Operating frequency updated from “200MHz” to “180MHz”. – Peripheral frequency updated to “180 MHz or 45MHz”. *Section 2.1.6: Features*: – Replaced “Boot assist Flash (BAF) supports factory programming using a serial bootload through the asynchronous CAN or FlexRay” by “Boot assist Flash (BAF) supports factory programming using a serial bootload through the asynchronous CAN or LIN/UART”. – Added bullet “Standby power domain with smart wake-up sequence”. – Removed last bullet “6582 KB on-chip Flash” as it is redundant. – Added Ethernet controller feature. – Instance of “DSP” updated to read “DSP on Core_2”. – SRAM updated to 608KB. – “64+32 channels per eDMA” updated to “One eDMA with 64 channels; One eDMA with 32 channels”. – Removed “one INTC per computing shell”. – Number of INTC updated to “1”. – “GTM 303” updated to “GTM 343”. – LinFlexD modules updated to “Eighteen”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Table 3: Features List*: – “Number of checker cores” updated to “1”. – “SIMD” updated to “SIMD (LSP)”. – “System RAM” updated to “608 KB (including 256KB of Standby RAM)”. – Removed instance of “External bus”. – “LinFlexD” updated to “18”. – “MCAN/CAN-FD/TTCAN” updated to “M_CAN supporting CAN-FD according to ISO 11898-1 2015 (instances supporting also TTCAN)”. Its value also updated from “7/8/1” to “8 (1)”. – “Microsecond channel downlink” updated to “2”. – “Ethernet” updated to “2”. – “Interrupt controller” updated to “710 sources”. – “integrated switch mode voltage regulator” updated to “yes”. *Section 2.1.8: Packages*: – Replaced “The SPC58NE84/SPC58EG84 is also....device footprint” by “The eLQFP176 and LFBGA292 packages....device footprint”. – 100-pin package removed (eTQFP100). Updated *Figure 2: Block Diagram*. Updated *Figure 3: Periphery allocation*. *Chapter 3: Embedded memories* Added *Section 3.2.2: Standby SRAM regulator*. Updated *Section 3.2.4: Processor core local RAM*. *Section 3.3.2.1: Features*: – Updated ECC bit detection and correction. Modified *Figure 7: Flash memory segmentation and read-while-write partitioning*. Updated error detection and correction setting in *Section 3.3.2.4: Chip-specific C40FMC Flash register information* and *Section 3.4: End-to-end Error Correction Code (e2eECC)*. Updated *Section 3.5: Security features*. *Chapter 4: Signal Description* *Section 4.2: Emulation package*: – Text “A 216 pin.... on the die” updated to “The eLQFP176....device footprint”. *Chapter 5: Memory Map* *Table 7: Overview memory map*: – Used size of “Large Flash Blocks - no overlay” updated to “5888 KB”. – Used size of “Large Flash Blocks - overlay enabled mapping” updated to “5888 KB”. – Footnote “This memory range is applicable on PFLASH_1 and is not accessible by NAR” removed. – Used size of “System RAM” updated to “608 KB”. – Used size of “HSM” updated to “40 KB”. – For “Processor Core local SRAM”, used size updated to “160 KB DMEM, 48 KB IMEM”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Table 8: Peripheral (PBRIDGE_0, PBRIDGE_1, PBRIDGE_2) memory map*: – Corrected the end address of the reserved section before MC_CGM – Added footnotes *Table 9: Flash memory map*: – For “HSM Data Flash Blocks”, Partition ID updated to 4. – Flash 64 KB Data Block 0 merged into a single line. – Flash 64 KB Data Block 1 merged into a single line. – For Flash 64 KB Data Blocks 2 and 3, Partition ID updated to 3. – For Flash 16 KB Code Block 3, Partition ID updated to 1. – For Flash 16 KB Code Block 2, Partition ID updated to 0. – For “Flash 256 KB Code Block 14 to 21”, Partition ID updated to 5. – Added new section “Mirror Low & Mid Flash Blocks”. – Added new section “Mirror Large Flash Blocks”. *Table 10: Emulation and debug map*: – Columns “BD1M” and “BD2M” removed. – Buddy Overlay RM merged into a single row. Updated *Table 11: RAM memory map*. Updated *Table 12: Processor local RAM memory map*. Updated *Table 13: UTest Flash memory map*. *Chapter 6: Functional Safety* Updated *Table 16: Module classification*. Updated *Table 17: FCCU failure inputs*. *Chapter 7: Device configuration* Extensive updates throughout the chapter. *Chapter 8: Reset and Boot* Re-worked the whole chapter according to 40 nm product specifications. *Chapter 9: Device Configuration Format (DCF) Records* Updated *Section 9.1: Introduction*. *Table 132: UTEST Miscellaneous DCF Client field descriptions*: – Updated OPT_RGM_ESR0_HW, ESR0 GATE field descriptions *Table 130: DCF client list*: – Fully checked and updated – Renamed PMC_VREG1P2_EN by PNREG_ENB. – Updated 0x0211 User Serial Boot – Updated 0x0212-0x0214 Reserved – Updated 0x0215 Boot CPU IVPR – Updated 0x0212-0x7FFF Reserved – Removed ESR0_CONFIG Updated *Section 9.4.3: Miscellaneous DCF registers*: – Replaced bit 22 “Reserved” status with “XOSC_AUTOSWITCHB”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 10: Power management* *Section 10.1: Overview*: – Added bullet Smart Standby Wake-up Unit (SSWU). – Removed tables “SYSTEM modes” and “USER modes”, figure “Mode relationships” as these information are present in MC_ME Chapter, added cross-reference to this chapter. *Figure 56: Device power management framework*: – Removed boxes ‘FUSE’ and ‘STANDBY_ECTU_0’; replaced boxes ‘Processor core n’ and ‘IOP’ by ‘Core 0’, ‘Core 1’, ‘Core 2’. – Added PD2 and PD3 power domains. *Section 10.1.3: Power management controller overview*: – Updated bullet “Internal regulator” and added: ‘An internal Switching Mode Power Supply (SMPS) regulator, using external PMOS, NMOS and inductance’. – Updated bullet “Low-power regulator”. – Added in bullet “Auxiliary and clamp regulators“: “Auxiliary and clamp regulators can not be enabled in SMPS regulator mode”. *Table 138: Device power management controller external signals*: – Updated VDD_HV_FLA type and description. – Removed External low voltage power supply for VDD_LV. *Figure 58: Voltage Monitor Coverage*[(1)(2)]: added MVD082_B and MVD270_SB, removed MVD240T_C; fixed Footnote. *Section 10.2: Low power mode support*: replaced sentence “Any register leading to low power entry is triple-voted” by “Inadvertent entry into low power mode is prevented by triple voting of the control flops, both SW readable and otherwise”. *Section 10.2.1: Low power mode (HALT/STOP/STANDBY)*: Section title renamed and content reworked. Added *Section 10.2.1.2: Checker core disabling*. *Table 139: Voltage monitors description*: – Added POR031_C and POR200_C. – Removed VDD_HV_PMC (as well as in *Section 10.6: Power sequence*) – Added rows MVD082_B, MVD270_SB, updated row LVD400_IM with ‘VD14’ (was ‘VD13’), removed row MVD240T_C. *Figure 60: Voltage monitors functionality*: added MVD082_B and MVD270_SB, removed MVD240T_C. *Table 140: Voltage monitors configurability*: added LVD100_SB. *Figure 64: VDD_HV monitored voltages during power-up*: renamed VDD_HV_PMC by VDD_HV_IO. *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* Renamed the title of *Section 11.4: Clocking*. Renamed the title of *Figure 68: SSWU clock architecture*. *Table 160: CTUCR field descriptions*: Renamed CTU_ADC_reset to CTU_FSM_reset. Removed the following register descriptions: CTUEFR, CTU_CFGSR1, CTU_EXPECTED, CTU_CNT_RANGE. Updated register descriptions for: THCR1, THCR2, CLR1-CLR32 (ADC client), CLR1-CLR32 (PDC client), CLR1-CLR32 (TU client).

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	Section 1.5.2.1: PDC channel handling and Section 1.5.2.2: OPC channel handling: inserted reference to “the Excel pinout file attached to the SPC58xEx/SPC58xGx Reference Manual (I/O Signal Table)”. *Section 11.7.2.1: SSWU registers Configuration*: Added CTU FSM reset before next stand-by event. *Section 11.7.2.2: Other IP registers configuration*: – Added trigger mode selection and changed the PWDN to 1. – Removed “for Analog Comparator Block”. – Added Caution. *Chapter 14: e200z4d Core Complex Overview* Changed number of cores from 6 to 5 *Chapter 15: Core (z420n3) Description* Chapter title changed from “Core (z420n3) Overview” to “Core (z420n3) Description”. *Figure 101: Core (z420n3) Supervisor Mode Programmer’s Model SPRs*: Updated with the correct picture (was Model DCRs and PMRs). *Chapter 16: Core (z425n3) Description* Chapter title changed from “Core (z425n3) Overview” to “Core (z425n3) Description”. *Figure 126: Core (z425n3) Supervisor Mode Programmer’s Model SPRs*: Updated z425n3 picture from z420n3 picture. *Figure 127: Core (z425n3) Supervisor Mode Programmer’s Model DCRs and PMRs*, *Figure 128: Core (z425n3) User Mode Programmer’s Model SPRs*, and *Figure 129: Core (z425n3) User Mode Programmer’s Model PMRs*: Added Core (z425n3). *Chapter 17: System Integration Unit Lite2 (SIUL2)* *Section 17.1.1: Overview*: – Changed DMA inputs from ‘9’ to ‘16’ in the sentence “There are 16 external interrupts and 16 DMA inputs to the SIUL2 that map to EIRQ pins on the device.”. – Updated *Figure 156: SIUL2 block diagram* *Section 17.2.1: Memory map*: *Table 261: SIUL2 memory map*: – Removed Width, Access and Reset value columns. – Updated registers PGPFO, PGPDI, MPGPDO (n=0 to 12 instead of n=0 to 31). *Section 17.1.2: Features*: – Removed the number of independant DMA channels in the bullet “Independent DMA channels for each EIRQ pin”. – Added “Details about the electrical parameters and setting of functional pads can be found ...”. *Section 17.2.2.1: MCU ID Register #1 (SIUL2_MIDR1)*: – In “PKG” field description, removed unused package settings *Section 17.2.2.5: DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)*: Bits 16 to 31 updated to DIRSR[16:31]. *Table 272: SIUL2_SCR0 field descriptions*: – Bit 0 updated from “FEC_0_MODE” to “ETHERNET_0_MODE”. – Bit 1 updated from “FEC_1_MODE” to “ETHERNET_1_MODE”. – Description of Bit 0 updated to “Ethernet Controller mode setting”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Section 17.2.2.11: Soc Configuration Register 0 (SIUL2_SCR0)*: – Replaced FEC_0 with ETHERNET_0 in the introduction sentence. – Bit 0 updated from “FEC_0_MODE” to “ETHERNET_0_MODE”. – Bit 1 updated from “FEC_1_MODE” to “ETHERNET_1_MODE”. – New bitfields created. – Added paragraph “MASK_OPCn is used to prevent the SSWU OPC channel n to drive the pad during standby. PADn_MUX_SEL is used to maintain the Pad value at standby exit (PADn_MUX_SEL = 0)” and added note “PADn_MUX_SEL must be set to 1 to be able to change the pads value and direction after stand-by while system is in the RUN mode.”. *Section 17.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*: – Removed bitfield “HYS”. – Set to ‘0’ the “IBE” and “WPUE” field reset values – updated description of ILS *Table 274: I/O MSCR Reset State Exceptions* – Removed HYS column. – Added PA[4] line – Updated reset values *Section 17.2.2.14: GPIO Pad Data Output Registers (SIUL2_GPDOn)* and *Section 17.2.2.15: GPIO Pad Data Input Registers (SIUL2_GPDIn)*: Added Note “For the exact number... to this Reference Manual)”. *Chapter 20: Peripheral Bridge (PBRIDGE)* *Table 292: Peripheral bridge memory map*: – Added address offset reserved areas. – Added OPACRn registers. – Added footnotes “Access to this address space will terminate in an error” and “The following address spaces when programmed... these address spaces.” *Table 301: OPACRx field descriptions*: Updated fields names to OPACRa-OPACRh (was PACRAa-PACRh). *Chapter 21: System Memory Protection Unit (SMPU)* Updated RGDn registers instances from n=0 to 11. *Section 21.4.2.5: Region Descriptor n, Word 0 (RGDn_WORD0)*, *Section 21.4.2.6: Region Descriptor n, Word 1 (RGDn_WORD1)*, *Section 21.4.2.7: Region Descriptor n, Word 2 Format 0 (RGDn_WORD2_FMT0)*, and *Section 21.4.2.8: Region Descriptor n, Word 3 (RGDn_WORD3)*: Changed register occurences from 12 to 24. *Chapter 24: Interrupt Controller (INTC)* *Section 24.5.2.7: INTC Priority Select Register n (INTC_PSRn)*: Changed the implementation of the PRC_SEL bitfield to PRC_SEL*n* where *n* is the number of the processor(s). *Section 24.4.1: Software vector mode*: “HVEN_PRCn bit” updated to “HVENn bit”. *Chapter 25: Enhanced Direct Memory Access (eDMA)* Updated *Table 331: DMA memory map*

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 26: DMA channel multiplexer (DMACHMUX)* Updated register name to CHCFG (was CHCONFIG) throughout the chapter. *Table 379: DMACHMUX memory map*: Corrected register name to CHCFG (was CHCNFG). *Figure 265: DMACHMUX block diagram*: Replaced Trigger #2 by Trigger #3. Updated *Section 26.1.2: Features*. *Chapter 27: Clocking* Updated *Figure 270: Clock generation(1)(2) (part 1 of 2)*. *Table 382: MC_CGM relationship to clocks*: Removed “1s” from “Output clock” column of CGM_SC_DC0 register. Added CGM_SC_DC4 register row. Removed CGM_AC0_DC4 CGM_AC0_SC, CGM_AC10_DC0 CGM_AC10_SC, CGM_AC10_DC1 CGM_AC10_SC rows. Updated “Output clock” column of CGM_AC12_DC2 CGM_AC12_SC register *Table 383: Maximum system level clock frequencies*: – Replaced value of “180” with “200” for System clock selector. – Updated nominal programmed divider max output frequencies of Aux Clock 8 Selector and of Aux Clock 11 Selector. – Added PFBRIDGE_CLK to System clock selector. – Removed ECTU_CLK from Aux Clock 0 Selector. – Removed Aux Clock 10 Selector. Split the table “Maximum system level clock frequencies” into two tables *Table 383: Maximum system level clock frequencies* and *Table 384: Maximum auxiliary level clock frequencies* and updated them. *Table 385: JTAG frequencies*: updated frequencies for PD and ED devices *Table 387: Dual PLL Digital Interface register reset values*: Set offset 0x0034 to Reserved. Updated *Section 27.9: Progressive clock switching*. *Figure 273: Clock distribution*: – Updated the figure – r/w_data has been renamed BIU in the PIT/RTI box. – Replaced FEC_RXCLK and FEC_TXCLK with ETHERNET_RXCLK and ETHERNET_TXCLK respectively. *Section 27.3: System clock frequency limitations*: Deleted text “In order....specifications”. *Section 27.6.1: HSM clock divider* : Added sentence “The minimum possible divider after reset is 'divide by 2”. *Section 27.6.4: Ethernet clocking*: Reworked contains and added new *Figure 275: Ethernet clocking*. *Section 27.6.8: System Clock/GTM output clock*: Removed “Ethernet clock pin muxing” from the heading. Removed FEC_REF_CLK from this section. Updated *Figure 277: SYSCLK/EXTCLK/REF_CLK pin muxing*. *Table 391: Clock input sources*: Replaced “CMU_13_ECTU” with “CMU_13_PFBRIDGE” and “ECTU” with “PFBRIDGE_CLK”. *Chapter 28: Dual PLL Digital Interface (PLLDIG)* *Section 28.3: Features*: – Added “The frequency range after the prescaler is required to be 8-20Mhz”. – Removed the information about inout and output clock frequency range. Added a note to consult the Device data sheet for the same.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Table 394: Dual PLL Digital Interface memory map*: Removed “Access” and “Reset Value (hex)” columns. Reformated all end address of reserved spaces. *Figure 285: PLL1 Control Register (PLL1CR)* and *Figure 288: PLL1 Frequency Modulation Register (PLL1FM)*: added “default” to figure footnote. *Figure 283: PLL0 Status Register (PLL0SR)*. Updated reset value. *Section 28.5.2.3: PLL0 Divider Register (PLL0DV)* Updated the description of bitfields RFDPHI and MFD. *Chapter 30: Clock Generation Module (MC_CGM)* *Section 30.4.1.4.1: System clock divider synchronization*: Updated the section. Removed figure “MC_CGM auxiliary clock 10 generation overview”. *Section 30.4.2.1: Auxiliary clock dividers*: Updated the section. Removed register “Auxiliary Clock 0 Divider 4 Configuration Register (CGM_AC0_DC4)”. *Chapter 31: OSC Digital Interface (XOSC)* Updated *Table 485: XOSC configurations*. *Chapter 33: LPRC Digital Interface* *Section 33.3.1.1: Low Power RC Control register (CTL)*: Changed register reset value from 0x00000300 to 0x00000700. *Chapter 35: Platform RAM controller (PRAM)* *Section 35.3.1.2: Optional read wait-state*: Removed note. *Chapter 36: Flash memory controller* *Section 36.2: Features*: Added feature “double bit” to the exisitng featue “Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary”. *Section 36.5.15: e2eECC on data Flash accesses*: Added instance of “double bit correction”. *Table 500: PFCR1 field descriptions*: Modified APC bitfield description. *Section 36.4.1.7: PFlash calibration region descriptor n (PFCRDn)*: Renamed PFCRD registers PFCRDn.Word0-3 into PFCRDn_Word0-3. *Chapter 37: Embedded Flash Memory* Updated *Figure 399: Flash memory module structure*. Updated *Section 37.2.1.2: Data Flash*. *Table 516: UTEST block memory map*: Updated UTEST base address. Added *Section 37.2.1.4: RWR1_UTEST virtual block memory map*. *Table 518: Flash User Registers memory map*: Added registers ALTSELn, ELOCKn, PLOCKn and ADR2. *Table 518: Flash User Registers memory map*, *Figure 414: Program Address register (PAR)* and *Table 534: PAR field descriptions*: Changed register name from Parallel Address register (PADR) to Program Address regsiter (PAR).

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Table 535: ADR field descriptions*: Updated description of bitfield ADDR. Updated *Table 536: ADR update mode list* and *Table 537: ADR content: priority list*. *Table 544: UT0 field descriptions*: Updated description of bitfields CPA, CPR and CPE. *Section 37.3.2.18: User Multiple Input Signature registers*: Changed the bitfields representation of all registers in this section. *Section 37.4.5.1.2: Over-programming protection (OPP) enable*: Replaced doubleword by quad-word in the sentence “In an OPP enabled block...cannot be programmed again.” *Chapter 38: Flash Memory Programming and Configuration* In *Section 38.1: Selection of Flash memory blocks for erase*, – Removed page footnotes “The table lists the LOWLOCK register field...” and “Register bits in Power Architecture-based microcontrollers...” – Removed tables “Flash memory partition 1 memory map” and “Flash memory partition 4 memory map” – Changed value to write to SEL0 register to select for erase the blocks in *Table 510* from *0x0030_0000* to *0x0005_0000* – Changed value to write to LOCK0 register to select for erase the blocks in *Table 510* from *0x0030_0000* to *0x0005_0000* – Changed the Data[31:0] value of DCF record from *0x0030_0000* to *0x0005_0000* In *Section 38.8.2: Passcode-protected test mode disable seal*, changed value to program into the Test Mode Disable Seal location from *0x2D3C_4B5A* to *0x5A4B_3C2D* *Chapter 40: Analog-to-Digital Converters (ADC) Configuration* *Table 581: ADC implementation*: updated SAR_ADC_12bit_2 from ‘15’ to ‘13’ *Table 574: External analog input pins*: removed row ‘216 FusionQuad ED’ *Section 40.2.2.1.1: 12-bit Fast SAR ADC* and *Section 40.2.2.1.3: 10-bit Fast SAR ADC*: added “4 internal test channels...up to the external circuitry. This includes: four internal voltage...impedance” *Section 40.2.2.5: SAR ADC triggering*: added in ‘The bCTU...’ paragraph ‘or from EMIOS’. *Section 40.2.2.9.2: Internal reference*: updated ‘The SAR_ADC_12bit_B0’ by ‘All SAR_ADC’s’. *Figure 478: Analog input — discharge switch to VSS_HV_ADV*: updated ‘SAR_ADC_4’ by ‘SAR_ADC_n’. *Table 591: SAR_ADC analog test channel assignment*: from 124 to 127 added ‘SAR_ADC_12bit_0 to 3, SAR_ADC_10bit_0/1’ in column Fast SAR and Fast SAR channel numbers. *Section 40.2.2.11: SAR ADC register definitions* added. *Chapter 41: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* *Section 41.3: Features*: Added new feature “Cascaded COMB...data path”. *Section 41.6.2: Module Configuration Register (SDADC_MCR)*: Updated description of PDR field. *Section 41.6.8: FIFO Control Register (SDADC_FCR)*: Updated description of “FTHLD” field. *Figure 479: SDADC block diagram*: Added “PSI” digital interface.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 42: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface* *Section 42.4.1.1: Start of normal conversion*: Text “If the trigger mode...conversion request” updated to read “If the trigger mode....MCR[NSTART] bit”. *Chapter 43: Temperature Sensor* *Section 43.2: Functional description*: Updated the section. *Chapter 44: Body Cross Triggering Unit (BCTU)* *Section 44.5: Functional description*: Removed table “Trigger source” as it is redundant with the assignment between eMIOS outputs and BCTU trigger inputs of the device that is defined in the *Chapter 7: Device configuration*. *Chapter 47: GTM343 Integration (GTMINT) Module* replaces the Chapter GTM303 Integration *Chapter 48: Generic Timer Module (GTM343)* replaces the Chapter Generic Timer Module (GTM303) *Chapter 49: GTM Development Interface (GTMDI)* *Table 725: GTMDI_DS field descriptions*: Description of field “HLT” updated. *Section 49.5.9: Fetch trace*: “Fetch trace ties...MCS channel” updated to “Fetch trace tries...in the MCS pipeline” *Section 49.5.9.2.1: Fetch trace start state*: Added text “When an instruction...valid fetch access”. Added new *Section 49.2: Overview*. Updated *Section 49.1: Introduction*. *Chapter 52: CAN Subsystem* Removed Section “Shared Memory”. Removed Section “Time Triggered Modular CAN (M_TTCAN) core”. *Section 52.1: Introduction*: In *Table 820: IP user manual versions*, changed version from 3.0.1 to 3.2.1 for M_TTCAN IP. *Section 52.3.5.2: Register map*: – Renamed register DBTP (was FBTP) – Renamed register NBTP (was BTP) – Added Transmitter Delay Compensation Register (TDCR) at address offset 0x0048 – Added Rx Buffer / FIFO Element Size Configuration (RXESC) at address offset 0x00BC – Added Tx Buffer Element Size Configuration (TXESC) at address offset 0x00C8 *Section 52.3.5.2.3: Data Bit Timing and Prescaler Register (DBTP)*: – Renamed register DBTP (was FBTP) – Added field TDCO – Renamed register DBRP (was FBRP) – Renamed bitfields DTSEG1, DTSEG2, and DSJW (was FTSEG1, FTSEG2, and FSJW) – Increased configuration range for data bit timing

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Section 52.3.5.2.4: Test Register (TEST)*: – Removed field TDCV and moved to register PSR *Section 52.3.5.2.6: CC Control Register (CCCR)* – Added 1 bitfield NISO – Replaced field FDBS by EFBI – Replaced field FDO by PXHD – Change bitfield FDBS by new control bit EFBI – Change bitfield FDO by new control bit PXDH – Removed bitfield CMR. – Replaced bitfield CME by BRSE and FDOE bitfields *Section 52.3.5.2.7: Nominal Bit Timing and Prescaler Register (NBTP)*: – Renamed bitfield NBRP (was BRP) – Renamed bitfields NTSEG1, NTSEG2, and NSJW (was TSEG1, TSEG2, and SJW) *Section 52.3.5.2.13: Protocol Status Register (PSR)*: – Added bitfield TDCV – Added bitfield PXE – Renamed bitfield DLEC (was FLEC) Added *Section 52.3.5.2.14: Transmitter Delay compensation Register (TDCR)* *Section 52.3.5.2.15: Interrupt Register (IR)*: Replaced bitfields STE, FOE, ACKE, BE and CRCE by ARA, PED and PEA. *Section 52.3.5.2.16: Interrupt Enable Register (IE)*: Replaced bitfields STEE, FOEE, ACKEE, BEE and CRCEE by ARAE, PEDE and PEAE. *Section 52.3.5.2.17: Interrupt Line Select Register (ILS)*: Replaced bitfields STEL, FOEL, ACKEL, BEL and CRCEL by ARAL, PEDL and PEAL *Section 52.3.6: Message RAM*: added note “Because the Message RAM is equipped with ECC functionality...” just after the first paragraph. *Section 52.3.6.1: Rx Buffer and FIFO element*: – Renamed bit EDL to FDF *Section 52.3.6.2: Tx buffer element*: – Added bits ESI, FDF and BRS Updated *Section 52.3.7.3: CAN FD Operation*. Updated *Section 52.3.7.4: Transceiver Delay Compensation*. Added *Section 52.9: External Time Stamp* and *Figure 863: CAN external time base* *Section 52.3: Modular CAN (M_CAN) cores*: changed caution “Implemented CAN FD mode is...” to note “Implemented CAN nodes are...”. Added *Section 52.3.5.2.14: Transmitter Delay compensation Register (TDCR)*. *Section 52.3.6.1: Rx Buffer and FIFO element*: Renamed bit ELD to FDF. *Section 52.3.6.2: Tx buffer element*: Added bit ESI (Error State Indicator), bit FDF (FD format) and bit BRS (Bit Rate Switching). Updated text in *Section 52.3.7.3: CAN FD Operation*. Updated text in *Section 52.3.7.4: Transceiver Delay Compensation*. *Section 52.4: Time Triggered Modular CAN (M_TTCAN) core*: – Removed “with data fields of up to eight bytes length” from paragraph “In addition the M_TTCAN supports...”. Changed caution “Implemented CAN FD mode is...” to note “Implemented TTCAN nodes are...”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Section 52.3.5.2.16: Interrupt Enable Register (IE)*: – in *Figure 713: Interrupt Enable Register (IE)* updated DRXE field description *Section 52.8: CAN nodes 1 and 2 I/Os sharing*: In the second sentence, changed M_CAN_0 to M_CAN_1. Updated *Figure 861: Hardware control for M_TTCAN cycles management* *Figure 765: Calibration Configuration Register (CCFG)* and *Table 881: CCFG field descriptions*: Changed SWR field access to RW (was R only). Added values 0x00–0xFF to OPCM field description. Added values 0x04–0x19 to TQBT field description. *Section 52.11: Shared memory map*: Removed note sentence“The write access protection is only for CPU access to the message memory.”. *Table 820: IP user manual versions*: Renamed (was “References”). *Figure 706: Timestamp Counter Value Register (TSCV)*, *Figure 708: Timeout Counter Value Register (TOCV)*, *Figure 712: Interrupt Register (IR)*, *Figure 706: Timestamp Counter Value Register (TSCV)* and *Figure 708: Timeout Counter Value Register (TOCV)*: Changed register access to R/W (was w1c). *Figure 712: Interrupt Register (IR)*: Apply w1c to all register fields. Updated *Figure 861: Hardware control for M_TTCAN cycles management*. *Chapter 53: Serial Interprocessor Interface (SIPI)* *Table 969: SIPI memory map*: Set End-offset value to all reserved spaces. *Table 977: Channel data Register address offsets*: Reworked register names from SIPI_CDR2[0] -SIPI_CDR2[7] to SIPI_CDR2*i* and offset addresses to “0x005C + *i**0x4 (*i* = 0 to 7)”. *Chapter 56: Ethernet* replaces Chapter “Fast Ethernet Controller” *Chapter 58: Inter-Integrated Circuit (I2C)* *Section 58.2.4: Features*: Removed bullet “Operation at higher baud rates...”. *Chapter 59: SENT Receiver (SRX)* *Section 59.1.1: Features*: Changed the maximum supported bit rate from 36 µs to 90 µs. *Section 59.3.2.1: Global Control Register (GBL_CTRL)*: Updated TSPRSC field from value from [1 to 255] to [0 to 255]. *Section 59.3.2.16: DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*: Replaced field "DATA[11:8]" with "ID3_0_DATA11_8” in register figure and updated field description table accordingly. *Section 59.3.2.25: Channel n Serial Message Bit2 Read Register (CHn_SMSG_BIT2)*: – Replaced field "DATA[11:8]" with "ID3_0_DATA11_8” in register figure and updated field description table accordingly. – Replaced field "DATA[11:8]" with "ID3_0_DATA11_8” in register figure and updated field description table accordingly. *Figure 1426: Channel n Fast Message Data Read Register (CHn_FMSG_DATA)*: Updated the Offset address. *Figure 1408: Global Status Register (GBL_STATUS)* and *Figure 1424: Channel n Status Register (CHn_STATUS)*: Changed register access to R/W (was w1c).

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 62: Deserial Serial Peripheral Interface (DSPI)* *Figure 1578: DSPI block diagram*: Removed Slave Bus Interface and Clock/Reset arrows. *Chapter 63: LINFlexD* *Section 63.1: Introduction*: Updated with “2.2” version at the end of sentence starting with: “The LINFlexD supports LIN protocol version...”. *Chapter 64: Reset Generation Module (MC_RGM)* Updated the naming of all registers Peripheral Reset Status Register (RGM_PSTATn) by adding the word “Status”. *Table 1695: RGM_DES field descriptions*: Added Note to bitfield F_VOR_STDBY. *Table 1699: RGM_FES field descriptions*: Added Note to bitfield F_JTAG_FUNC. *Section 64.3.1.14: Peripheral Reset Register 1 (RGM_PRST1)*, *Section 64.3.1.18: Peripheral Reset Register 5 (RGM_PRST5)*, *Section 64.3.1.22: Peripheral Reset Status Register 1 (RGM_PSTAT1)*, *Section 64.3.1.26: Peripheral Reset Status Register 5 (RGM_PSTAT5)*: Updated ‘ADCSD_x’ by ‘SD_ADC_x’ to be consistent with other chapters (MC_ME PS*n* registers, Memory Map, ADC Config). *Section 64.3.1.15: Peripheral Reset Register 2 (RGM_PRST2)*: – CAN_RAM_SUB_0_CTR_RST bitfield description has been updated. – Added bitfield LINFLEXD_16_RST. *Table 1710: RGM_PRST3 register field descriptions* and *Table 1714: RGM_PRST7 register field descriptions*: Added note “This peripheral is coupled with RGM_PRST4.SAR_ADC_*_SEQ_RST therefore they have to be identically set” for register fields SAR_ADC_*. *Section 64.3.1.17: Peripheral Reset Register 4 (RGM_PRST4)*: Removed SAR_ADC_xxx_SEQ bitfields. *Section 64.3.1.18: Peripheral Reset Register 5 (RGM_PRST5)*: Removed bitfield PSI5_S_0_RST. *Section 64.3.1.19: Peripheral Reset Register 6 (RGM_PRST6)*: – CAN_RAM_SUB_1_CTR_RST bitfield description has been updated. – Added bitfield LINFLEXD_17_RST. *Section 64.3.1.20: Peripheral Reset Register 7 (RGM_PRST7)*: – Removed bitfields ECTU_0_RST and ECTU_1_RST. – Added bitfields ETHERNET_0_RST and ETHERNET_1_RST. – Removed bitfield FLEXRAY_1_RST. *Section 64.3.1.23: Peripheral Reset Status Register 2 (RGM_PSTAT2)*: Added bitfield LINFLEXD_16_STAT. *Section 64.3.1.25: Peripheral Reset Status Register 4 (RGM_PSTAT4)*: Removed SAR_ADC_xxx_SEQ bitfields. *Section 64.3.1.27: Peripheral Reset Status Register 6 (RGM_PSTAT6)*: Added bitfield LINFLEXD_17_STAT. *Section 64.3.1.28: Peripheral Reset Status Register 7 (RGM_PSTAT7)*: – Removed bitfields ECTU_0_STAT and ECTU_1_STAT. – Added bitfields ETHERNET_0_STAT and ETHERNET_1_STAT. – Removed bitfield FLEXRAY_1_STAT. *Section 64.3.1.10: ‘Functional’ Reset Escalation Threshold Register (RGM_FRET)*: Updated FRET bitfield description. *Section 64.3.1.11: ‘Destructive’ Reset Escalation Threshold Register (RGM_DRET)*: Updated DRET bitfield description.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 65: Boot Assist Flash (BAF)* Updated *Section 65.1: Introduction*. *Section 65.2: Memory map*: Replaced the sentence “The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block“ by “For the BAF location in flash, refer to the Embedded memories chapter”. *Section 65.3.6: Production disable activation protocol and implementation*: updated flag value from ‘7FFF_FFFFh’ to ‘FFFF_FFFEh’. Updated *Figure 1765: Flow of control*. *Section 65.3.8: Optionally perform a serial boot*: Added the sentence “The BAF is executed via the XOSC as clock source”. *Section 65.4: Resources accessed by BAF code execution*: – Renamed “Clocks” to “Magic Carpet (clocks)”. – Added SSCM, SIUL, PASS and short description of each to resource list. *Application code execution*: Deleted the sentence “The boot header contains flags that enable/disable individual cores and their reset vectors”. *Figure 1771: Production Disable callback function flow chart* *Chapter 66: System Status and Configuration Module (SSCM)* *Section 66.2.1.4: HSM and User Option Status Register (UOPS)*: Added register bitfields BAF_FA, FL_STDBY and FL_RUN. *Table 1753: Life Cycle Slots*: Renamed table title and added two rows. *Section 66.3.1: DCF mechanism* – *Table 1752: Life Cycle Slots in Memory* *Chapter 67: Power management controller digital interface (PMC_Dig)* *Table 1754: Power Management Controller Memory Map*: Removed columns “Access” and “Reset value”. *Table 1755: 32-bit registers LV0, LV1, HV0, HV1 arrangement table*: Updated VD9 from “MVD2407T_C” to “Reserved”. *Table 1756: VD number versus VD name table*: Removed VD9. *Table 1759: RES_LV0 field descriptions*: Added Note to bitfield RES3_SB. *Table 1763: REE_LV1 field descriptions*: In description of bit[REE6_C], “RES_LV1 bit” replaced with “RES_LV1[RES6_C]”. *Table 1764: RES_LV1 field descriptions*: In description of bit[REE6_C], “REE_VD3 bit” replaced with “REE_LV1[REE6_C]”. *Section 67.5.24: Voltage selection of IO (VSIO)*: – Description “This register controls the....input and output buffers” added. – Reset value of bits “VSIO_IM0_IM1”, “VSIO_IF” and “VSIO_IJ” changed from 0 to 1. *Table 1781: PNREG_S field descriptions*: For fields “PREG_ENB” and “NREG_ENB” description, the “0” and “1” description reversed. *Figure 1819: Miscellaneous CTRL REG (MISC_CTRL_REG)*: Bit 29, “SIRC_ENB” replaced with “RCOSC1M_ENB”. *Table 1793: BIST_CTRL field descriptions*: Description of “STATUS” bit updated. *Table 1797: BIST_DEBUG field description*: Description of “VD_MON” bit updated. *Section 67.5.25: PMOS/NMOS Regulator Status Register (PNREG_S)*: Description updated to “This register shows....external regulator mode”. *Section 67.5.39: User BIST Time3 and Time2 register (BIST_TIME32)*: Reset value of bit “TIME_2” changed from “00F9” to “03E7”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 68: Power Control Unit (MC_PCU)* Added *Section 68.3.2.3: Power Domain #2 Configuration Register (PCU_PCONF2)* and *Section 68.3.2.4: Power Domain #3 Configuration Register (PCU_PCONF3)*. *Section 68.3.2.5: Power Domain Status Register (PCU_PSTAT)*: added fields “PD2” and “PD3” *Chapter 69: Mode Entry Module (MC_ME)* *Section 69.3.2.26: Peripheral Control registers (ME_PCTLn)*: Removed bitfield DBG_F. *Section 69.3.2.27: Core Status register (ME_CS)*: Added fields - ChkINTC_Stat, ChkDMA1_Stat, ChkDMA0_Stat, S_CHK_CORE5, and S_CHK_CORE2 to bits 21, 22, 23, 26, and 29 respectively. Also added description to the fields. *Table 1803: MC_ME register description*: – Added register PCTL84 at offset 0x114 (S_LINFlexD_16 Control). – Added register PCTL212 at offset 0x194 (S_LINFlexD_17 Control). *Figure 1860: Peripheral Status register 2 (ME_PS2)*: Added field S_LINFlexD_16 *Figure 1864: Peripheral Status register 6 (ME_PS6)*: Added field S_LINFlexD_17 at bit 11. *Chapter 72: Debug and Calibration Interface (DCI)* Added JDC and SPU blocks. Clarified the text in *Section 72.1.3.6: Break control* after . : Renamed pd_evti_b to evti_b. *Chapter 75: JTAG Data Communication (JDC)* *Section 75.3.1.2: Module status register (JDC_MSR)*: Changed access type of register JDC_MSR to w1c (was RW). *Section 75.2: Overview*: removed sentence “The JTAG accessible registers...“. *Section 75.3.1.3: JTAG output IPS data register (JDC_JOUT_IPS)*: renamed field “JOUT_IPS Data“ to “DATA“. *Section 75.3.1.4: JTAG input IPS data register (JDC_JIN_IPS)*: renamed field “JIN_IPS Data“ to “DATA“. *Chapter 78: Debug Zipwire* *Figure 2042: Block diagram showing connections for Emulation Device* and *Figure 2043: Block diagram showing connections for the Emulation Device* : Replaced “FEC” with “Ethernet”. *Chapter 86: Cyclic Redundancy Check (CRC) Unit* *Table 2170: CRC unit memory map*: Changed CRC registers per context from (n=1 to 4) to (n=0 to CRC_CNTX_NUM - 1 with CRC_CNTX_NUM = 4). *Figure 2277: CRC computation flow*: Reworked picture (context values). *Chapter 88: Indirect Memory Access (IMA)* *Table 2205: IMA_READ_DATA_n field descriptions*: Changed field name to READ_n (was WRITE_n).

Table 2499. Document revision history (continued)

Date	Revision	Changes
08-Feb-2016	2 (cont.)	*Chapter 89: Fault Collection and Control Unit (FCCU)* All signal names (such as ipg_clk) are replaced by thier respectives description names (System clock) throughout the document. Changed register names from NCF/UF (Noncritical / Unrecovarable Faults) to CF/RF (Critical / Recoverable Faults). *Section 89.6.21: FCCU XTMR Register (FCCU_XTMR)*: Updated the second sentence with “loads (a value corresponding to T_min=250 us + value programmed in FCCU_DELTA_T register) ...which has EOUT signaling enabled.”. *Figure 2334: FCCU RF Status register n (FCCU_RF_Sn)*: Changed reset value from 0x0 to the note “The reset value is chip-specific; see the chapter that describes how modules are configured and connected.” *Figure 2335: FCCU RF Key register (FCCU_RFK)* and *Figure 2346: FCCU RF Fake Register (FCCU_RFF)*: Replaced access “Write” by “Write-only”. *Chapter 90: Self-Test Control Unit (STCU2)* *Figure 2408: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*: Updated offset value to “Offset: 0x0600 + n * 0x4 (n = 0 to 100)”. *Chapter 92: Password and Device Security Module (PASS)* – Renamed bitfield L_128LCK into A256KLOCK. – Renamed bitfield U_256LCK into A256KLOCK. *Table 2310: PASS memory map*: – Changed LOCK3_PG*n* reset values to 0xXFXXXXXX (was 0xXXXXXXXX). – Changed LCSTAT reset value to 0xX0000007 (was 0x000000XX). *Chapter 93: Tamper Detection Module (TDM)* *Section 93.5.3: Diary Base Address (TDM_DBA)*: – changed reset value to 0xFFFF_FFFF and added a footnote. *Chapter 94: ASC Modeling Unit, Version 2 (AMU2)* *Section 94.4.2: Single calculation using SDMA for data load, CPU for post-processing*: “5X16-byte 4-beat bursts” updated to “5X8-byte 8-beat bursts”. Added Footnote(a) in *Section 94.1.1: Overview*. *Chapter 96: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Section 96.4.2: RTC Control Register (RTCC)*: Added bitfield TRIG_EN. *Figure 2507: RTC/API block diagram*: Added rtc_clk. *Table 2402: RTC/API register map*: Removed Base Address. *Chapter 97: Emulation and Debug Device Introduction* *Section 97.2: Feature summary*: Updated on-chip SRAM size from 4 x 256 KB to 4 x 512 KB in the sentence “Implemented as 4 × 512 KB partitions where...”.

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3	*Chapter 2: Introduction* Created two sub chapters, for SPC58xEx and for SPC58xGx. *Chapter 3: Embedded memories* *Figure 7: Flash memory segmentation and read-while-write partitioning*: centered in the figure RWW Partition 4 and 5. *Section 3.3.2: Flash memory array*, update size of double word from 64 to 128-bits;added “For code Flash sectors” at the beginning of 2nd paragraph. *Section 3.3.2.1: Features*, updated ECC bullet *Chapter 5: Memory Map* *Table 8: Peripheral (PBRIDGE_0, PBRIDGE_1, PBRIDGE_2) memory map*: updated *Table 9: Flash memory map*: updated header cells. *Table 10: Emulation and debug map* added with information merged from *Table 9: Flash memory map* (Buddy Device and Overlay RAM) and *Table 10: Emulation and debug map* removed. *Table 11: RAM memory map*: Reviewed the standby RAM partitioning for PRAMC_2. (8K+120K+128K) *Table 13: UTest Flash memory map* updated. *Section 5.7: Security module memory*: Added this section *Chapter 6: Functional Safety* *Table 16: Module classification*: Replaced ‘EBI’ by ‘External memory interface *Section 6.4.1.7.1: External error indication*: Added paragraph ‘In case of functional reset, the application... during functional reset.” *Table 18: ECC RAM implementations*, ‘Ethernet’ Location: updated ‘FIFO’ by ‘FIFO RX’, ‘MIB’ by ‘FIFO TX’ and value in cell ‘React to uncorrectable error’ to‘Y’. *Table 17: FCCU failure inputs*: – put table in landscape orientation, – updated column “Failure description” for rows 63, 83, 88 to 91, 103 to 106, 114, 123 – removed rows115 to 122. – Copied content from fault 85 row and updated faults 111, 112, 113 and 114 row with the same content. *Chapter 7: Device configuration* Added *Section 7.5.2: Platform RAM Controler (PRAMC) configuration* Updated *Table 39: DMAMUX Map*

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 8: Reset and Boot* *Section 8.1: Introduction*: After reset, Core_2 is woken-up, Checker_Core_2 and HSM may be woken-up (see details in DCF Record chapter). *Figure 41: Reset Generation Module Reset Sequence* reworked. *Section 8.3.12.2: Boot CPU start-up*: replaced “BAF DCF” by “BAF configuration DCF” within this section and through the chapter. *Figure 42: Boot CPU start-up sequence*: – updated text box “Found Bypass Mode DCF?” by “Found BAF Configuration DCF?” – updated text box “Bypass Mode DCF” by “BAF_BYPASS selection” *Section 8.3.12.2.3: SW boot record search (BAF search)*: deleted in 2nd bullet “not” in sentence “the BAF configuration DCF does bypass the BAF code and no valid ...” *Section 8.1.1: TEST flash memory block*: Replaced following list bullet: “Selection between HPREG or SMPS in internal regulator mode” with this one: “Power management configuration, for the devices supporting different regulation schemes” *Chapter 9: Device Configuration Format (DCF) Records* *Section 9.1: Introduction*: Added Note “Because the Flash memory programming resolution is 128 bits then 2 DCF records must be written within 1 Flash programming operation.”. *Section 9.3: DCF records*: Updated this section. *Table 130: DCF client list*: – Removed Life Cycle (LCSTAT) to DCF client description and this row to Reserved. – Added “Write Once” and “Refer to Boot Assist Flash (BAF) chapter” to all Security Watchdog in BAF ‘Soft’ Clients subsection. – Added “Support for 7 LBIST partitions (NLBIST); 102 Memory Cuts (NMCUT); 32-bit PRPG; 64-bit MISR” to STCU subsection. – separated the DCF address [16:2] into [16:10] and [9:2] – changed all BAF ‘Soft’ Client DCF address values from hexadecimal to binary – changed the value of UTEST miscellaneous to 0x00049E01 – Marked address 0_0000_1000_ 0101_01 (0x0215) as reserved *Section 9.4: DCF client table*: Completed the phrase - DCF order dependency in flash memory: this column details whether or not there are special conditions on the location of a particular DCF record in flash memory *Table 132: UTEST Miscellaneous DCF Client field descriptions*: updated the field descriptions for XOSC_FREQ_SEL and XOSC_LOAD_CAP_SEL *Figure 50: UTEST Miscellaneous DCF Client* and *Table 132: UTEST Miscellaneous DCF Client field descriptions*: added CORE_CLK_ONLINE_SELF_TEST bit field *Table 136: PNREG_ENB field descriptions*: – inverted the descriptions for the NREG_ENB bit – inverted the descriptions for the PREG_ENB bit

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 10: Power management* *Table 140: Voltage monitors configurability*: simplified the table *Table 138: Device power management controller external signals*: removed 3.3V from VDD_HV_IO_FLEX description *Section 10.1.2: Power management supply description*: changed the Warning to a Caution *Table 139: Voltage monitors description*: removed “low range” from the description of MVD094_C *Section 10.2.1: Low power mode (HALT/STOP/STANDBY)*: Added a note with 2 cross-references. *Section 10.5.3.1: LVD and HVD implementation*: Updated the fifth bullet. *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* Extensive updates throughout the chapter. *Chapter 13: Calibration and Debug* *Section 13.4: Debug over CAN*: Replaced M_CAN_0 with CAN_SUB_0_M_CAN_1 and M_CAN_1 with CAN_SUB_0_M_CAN_2 *Chapter 15: Core (z420n3) Description* *Figure 106: L1 Cache Control and Status Register 0 (L1CSR0)*: Updated bit 12 from “reserved” to “DCWA” *Section 15.8: MPU* Created *Figure 115: MPU Read Entry Instruction (mpure)*, *Figure 116: MPU Write Entry Instruction (mpuwe)*, *Figure 117: MPU Synchronize Instruction (mpusync)* *Figure 110: L1 Flush/Invalidate Register 0 (L1FINV0)*: Updated the figure title with a missing “0” *Figure 111: L1 Flush/Invalidate Register 1 (L1FINV1)*: Updated the figure title with the register’s full name *Chapter 17: System Integration Unit Lite2 (SIUL2)* *Table 273: SIUL2_MSCR_IOn field description*: Updated ILS bitfield description with the following note“(CMOS for LP pads)” related to TTL. *Table 262: SIUL2_MIDR1 field descriptions*, updated PARTNUM description. *Table 263: SIUL2_MIDR2 field description*, updated FAMILYNUM description. *Table 273: SIUL2_MSCR_IOn field description*, updated ILS description. *Chapter 18: Crossbar switch (XBAR)* *Figure 180: XBAR Control Register (XBAR_CRSn)* and *Table 284: XBAR_CRSn field descriptions*: Changed field HPEx to 8 bitfields HPE7–HPE0 (bits 8 to 15). *Chapter 19: Crossbar Integrity Checker (XBIC)* *Table 287: XBIC_EIR field descriptions*: added footnotes for fields ‘Target Slave Port’ and ‘Target Master ID’. *Chapter 24: Interrupt Controller (INTC)* *Section 24.5.2.6: INTC Software Set/Clear Interrupt Register n (INTC_SSCIRn)* : Removed text “Unlike the SWT bit in the PSRs,” from the first paragraph.

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 26: DMA channel multiplexer (DMACHMUX)* updated *Figure 267: DMACHMUX triggered channels* *Chapter 27: Clocking* *Figure 270: Clock generation(1)(2) (part 1 of 2)*: updated. *Figure 273: Clock distribution*: updated. *Table 382: MC_CGM relationship to clocks*: Updated 'Output clock' column of CGM_SC_DC2 into 'PBRIDGE_CLK (All peripheral bridges and peripherals not connected to any other system clock divider)' *Section 27.5: Clock sources*: updated "Slow internal RC oscillator ... (SIRC)" by "Low power RC oscillator ... (LPRC)". *Table 382: MC_CGM relationship to clocks*: – CGM_SC_DC1: added SWT and STM in Output Clock, – CGM_SC_DC3: removed SWT, STM and INTC. *Table 383: Maximum system level clock frequencies*: – HPBM_CLK: updated "SYS_CLK / 2" by 90, – PBRIDGE_CLK: updated "SYS_CLK / 4" by 45. – FBRIDGE_CLK: updated "SYS_CLK" by 180, – HSM_CLK: updated "SYS_CLK / 2 or SYS_CLK / 4" by 90. *Section 27.4: Default clock configuration*: updated sentence "Under the sofware responsability...set in the Magic Carpet documentation..." by "Under the software responsibility, the value chosen for the divisors CGM_SC_DC0, CGM_SC_DC1 and CGM_SC_DC2 shall respect the ratios shown in ...." *Section 27.5.2: External oscillator (XOSC)*: updated clock range to "4 MHz - 40 MHz". *Section 27.5.2.1: XOSC Start-up*: – rewrote 1st sentence and added cross-reference to DCF Records chapter – updated UTEST Miscellaneous[x] bit numbers – updated sentence "The XOSC has the ability to be started with either... " by "The XOSC has the ability to be started with 4 MHz - 40 MHz crystal. The default value of this field is for an 35 MHz - 40 MHz:" – updated "XOSC EN_40MHz" by "XOSC_FREQ_SEL" – updated default value for "UTEST Miscellaneous[19:21] = 111b (XOSC_FREQ_SEL)" *Section 27.6.8: System Clock/GTM output clock*: updated "The two system clocks..." by "The system clock...", removed "CGM_AC7_SC" and "SYSCLK1". *Chapter 28: Dual PLL Digital Interface (PLLDIG)* *Section 28.6.2: Clock configuration*: Added text "refer to the device datasheet"; Added 2 notes. *Table 402: PLL1FD field descriptions*: Updated DTHDIS field description; Added note to FRCDIV field description. *Section 28.6.3: Frequency modulation*: – Changed feedback divider f_{ref} by $f_{pll1ref}$ – Move text "PLLFM[MODPRD] and PLLFM[INCSTP] are subject to the following restriction:" to next equation.

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 30: Clock Generation Module (MC_CGM)* *Table 411: MC_CGM memory map*: Swapped address offsets of CGM_PCS_DIVS1 and CGM_PCS_DIVE1 registers. *Figure 311: PCS Divider End Register 1 (CGM_PCS_DIVE1)*: Changed offset address to 0x0108 (was 0x010C). *Figure 312: PCS Divider Start Register 1 (CGM_PCS_DIVS1)*: Changed offset address to 0x010C (was 0x0108). *Figure 327: System Clock Divider 3 Configuration Register (CGM_SC_DC3)*: Changed title from Table to Figure. *Figure 329: Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)*, *Table 449: CGM_AC1_SC field descriptions*, *Table 454: CGM_AC3_SC field descriptions*, *Table 456: CGM_AC4_SC field descriptions*, *Table 461: CGM_AC6_SC field descriptions*, *Table 464: CGM_AC7_SC field descriptions*, *Table 467: CGM_AC8_SC field descriptions*, *Table 470: CGM_AC9_SC field descriptions*, *Table 473: CGM_AC11_SC field descriptions* and *Table 476: CGM_AC12_SC field descriptions* : Added Note “Status of respective clock source must be ensured before selection.” to field SELCTL. *Table 411: MC_CGM memory map*: Swapped address offsets of CGM_PCS_DIVS2 and CGM_PCS_DIVE2 registers. Swapped address offsets of CGM_PCS_DIVS4 and CGM_PCS_DIVE4 registers. *Figure 314: PCS Divider End Register 2 (CGM_PCS_DIVE2)*: Changed offset address to 0x0114 (was 0x0118). *Figure 315: PCS Divider Start Register 2 (CGM_PCS_DIVS2)*: Changed offset address to 0x0118 (was 0x0114). *Figure 317: PCS Divider End Register 4 (CGM_PCS_DIVE4)*: Changed offset address to 0x012C (was 0x0130). *Figure 318: PCS Divider Start Register 4 (CGM_PCS_DIVS4)*: Changed offset address to 0x0130(was 0x012C). *Figure 297: MC_CGM block diagram*: updated “SIRC” by “LPRC”. *Section 30.4.1: System clock generation*: figure “MC_CGM system clock generation overview” removed, added cross-ref to “Clock generation” figure from Clocking chapter. *Section 30.4.2: Auxiliary clock generation*: figures “MC_CGM auxiliary clock *n* *generation* overview” removed (and their cross-refs), added cross-ref to “Clock generation” figure from Clocking chapter. *Chapter 33: LPRC Digital Interface* *Section 33.2: Low Power RC Oscillator*: Renamed MISC_CTRL_REG[SIRC_ENB] into MISC_CTRL_REG[RCOSC_1M_ENB]; Changed RCOSC_1M_ENB to RCOSC1M_ENB *Chapter 36: Flash memory controller* Updated *Figure 384: Platform-centric simple block diagram with Flash memory controllers*: – removed “+” signs, – replaced “p” with “P” and “s” with “S”, – aligned port numbers with Device configuration chapter’s Crossbar switch section.

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 37: Embedded Flash Memory* *Section 37.3.2.21: HSM Alternate selector registers*: Reworked introduction sentence. Field N8KH has been replaced with N128KL in *Table 522: MCRE field descriptions* Corriged typo: “last” instead of “fast” in *Section 37.3.2.15: Program Address register (PAR)* Added*Table 542: Flash Memory EEPROM data partition 3 addresses mapping* Corrected typo in *Chapter 37.3.2.20: Test Mode Disable Password Check register (TMD)*: UTEST location for password was not correct and TMD Seal was not updated wit *Table 559: TMD field descriptions*: Added Note “PWD bitfield is byte-reversed...” *Chapter 40: Analog-to-Digital Converters (ADC) Configuration* *Section 40.2.2.11: SAR ADC register definitions* updated *Section 40.2.2.5: SAR ADC triggering*: Added (SAR_ADC parameter CTSEN = 2) for instance SAR_ADC_10bit_STDBY. *Section 40.2.2.1: SAR ADC configuration overview*: Removed sentence “This file is used as a text inset in ADC Configuration chapter”. *Figure 478: Analog input — discharge switch to VSS_HV_ADV* added the weak pullup/pulldown *Section 40.2.2.9.4: Analog input pin switch to $V_{SS_HV_ADV}$*: Updated this section. *Chapter 41: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* *Figure 479: SDADC block diagram*: updated VAREF2 by VDD_HV_ADR_D, VAGND2 by VSS_HV_ADR_D. *Table 607: Signal properties*: – appended in cell ‘VREFP’ ‘= VDD_HV_ADR_D’, in cell ‘VREFN’ ‘= VSS_HV_ADR_D’ – replaced cells named ‘VDD_HV_ADR_D’ by ‘VDD_LV’, ‘VSS_HV_ADR_D’ by ‘VSS_LV’ – Added table note “See Section: Sigma-Delta ADC integration diagram.” to column name. *Table 610: SDADC_MCR field descriptions*, ‘EN’ bitfield: removed “Channel and conversion configuration values” sentence, added “Refer to *Section 41.8: .Initialization information*...”. *Chapter 42: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface* *Table 622: CTU modes*: added table footnote to CTSEN “Refer to Section 1.2.2.5: SAR ADC triggering of Chapter 1: Analog-to-Digital Converters (ADC) Configuration for CTSEN value applicable on each SAR_ADC instance.” *Section 42.4.4.1: Conversion timings*: – “PRECHG must be greater than...” replaced with “PRECHG is the configured precharging phase duration” – Removed “In case the value of...inside SARADC” *Table 625: MCR field descriptions*, added note in the description of CTUEN

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 49: GTM Development Interface (GTMDI)* *Table 734: GTMDI_SPEB_WPC1 field descriptions*: Changed description of value '000' to "SPE1" (was "SPE0"), '001' to Reserved (was "SPE1") and '111' to "SPE0" (was Reserved). *Figure 557: GTMDI block diagram*: Added arrow "Restore" between GTM IP and Halt Control blocks. *Chapter 50: Periodic Interrupt Timer (PIT)* Extensive updates throughout the chapter. *Chapter 52: CAN Subsystem* Extensive updates throughout the chapter. *Chapter 53: Serial Interprocessor Interface (SIPI)* *Section 53.15.1.7: SIPI Channel Data Register (SIPI_CDRn)*: – Added CDR0, CDR1 and CRDR3 offsets in *Figure 900: SIPI Channel Data Register (SIPI_CDRn)* – Added *Section 53.15.1.7.1: SIPI Channel Data Register (SIPI_CDR2i)* included *Figure 901: SIPI Channel Data Register (SIPI_CDR2i)* and *Table 978: SIPI_CDR2i field descriptions* *Figure 895: Channel Status Register (CSRn)*: Changed TID field at bit 25:27 to read-only access (was w1c). *Figure 888: SIPI data stream model*: Replaced a "Bus Master DMA" box with a "Bus AMBA lite" one. *Figure 890: SIPI data stream model - Target*: Replaced a "Bus Master DMA" box with a "Bus AMBA lite" one. *Chapter 56: Ethernet* Extensive updates throughout the chapter. *Chapter 59: SENT Receiver (SRX)* *Figure 1419: DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)* and *Figure 1428: Channel n Fast Message Time Stamp Read Register (CHn_FMSG_TS)*: Changed register access from R/W to Read-only. *Chapter 60: Peripheral Sensor Interface (PSI5)* *Figure 1461: Overwrite Status Register (CH0_OWSR)*: Changed register access to User read/write (was User w1c). *Figure 1463: Set New Data Status Register (PSI5_CH0_SNDSR)*, *Figure 1464: Set Overwrite Status Register (PSI5_CH0_SOWSR)*, *Figure 1465: Set Error Status Register (PSI5_CH0_SEISR)* and *Figure 1466: Set SMC Error Status Register (PSI5_CH0_SSESR)*: Changed register access to User read/write (was User w1s). *Chapter 62: Deserial Serial Peripheral Interface (DSPI)* *Figure 1581: Hardware Configuration Register (DSPI_HCR)* and *Table 1600: DSPI_HCR field descriptions*: Updated register CMDFR bitfield lenght to 4 bits (was 5 bits); moved register bitfields MSTR_MODE, SLV_MODE, TSB_EN and ITSB_EN; updated reset value; updated description of CMDFR

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 63: LINFlexD* *Section 63.4.2.9: LIN Time-Out Control Register (LINTOCR)*: Changed the reset value of bitfield HTO from 0x1C to 0x2C. *Figure 1690: LIN Time-Out Control Register (LINTOCR)*: Deleted footnote. *Chapter 64: Reset Generation Module (MC_RGM)* *Section 64.1.3: Reset sources*: – Removed “and the memory content must be considered to be unknown except in the software ‘destructive’ reset and external power-on reset cases, which do preserve the system memory content if the chip is not configured to execute a self-test on power-on, ‘destructive’, and external resets.” – Removed “as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets”. *Table 1695: RGM_DES field descriptions*: Added a table note to bit 30’s description. description. *Figure 1741: ‘Functional’ Event Reset Disable Register (RGM_FERD)*: Set bit 25, D_FCCU_SOFT, as read only (used to be R/W) *Figure 1742: ‘Functional’ Event Alternate Request Register (RGM_FEAR)* : Set bit 25, AR_FCCU_SOFT, as read only (used to be R/W) and other minor editorial changes *Chapter 65: Boot Assist Flash (BAF)* *Table 1726: BAF image header*: Added *Table 1729: BAF DCF client list*: Set addresses 0x0212, 0x213 and 0x215 to Reserved *Section 65.3.8: Optionally perform a serial boot* Replaced “If the Life Cycle is greater” with “If the Life Cycle is less”. *Chapter 67: Power management controller digital interface (PMC_Dig)* Extensive updates throughout the chapter. *Chapter 68: Power Control Unit (MC_PCU)* *Figure 1838: Power Domain #2 Configuration Register (PCU_PCONF2)*: Updated the Standby RAM value from 20KB to 120KB in the paragraph under the figure. *Figure 1839: Power Domain #3 Configuration Register (PCU_PCONF3)*:Updated the Standby RAM value from 224KB to 128KB in the paragraph under the figure. *Chapter 69: Mode Entry Module (MC_ME)* Extensive updates throughout the chapter. *Chapter 76: Sequence Processing Unit (SPU)* *Figure 2011: Trace group configuration register format (DTMTGC, PTMTGC, OTMTGC, WTMTGC)* – Added (DTMTGC, PTMTGC, OTMTGC, WTMTGC) to figure title *Table 1957: DTMTGC, PTMTGC, OTMTGC, WTMTGC field descriptions* – Updated table title with “DTMTGC, PTMTGC, OTMTGC, WTMTGC”

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 87: Memory Error Management Unit (MEMU)* *Section 87.1: Introduction* Updated info related to correctable and uncorrectable errors. *Section 87.6.2.1: Control register (CTRL)* Added new field “FLASH_ERR_SELECT[1:0] *Table 2176: CTRL field descriptions*: Added description of new field “FLASH_ERR_SELECT” *Section 87.6.2.14: Flash memory correctable error reporting table status register (FLASH_CERR_STSn)*: ; Added Note “MEMU captures flash ecc error address on 64bit boundary”. *Table 2189: FLASH_CERR_STSn register field descriptions*: in [BAD_BIT] description, “RAM” updated to read “FLASH”. *Chapter 88: Indirect Memory Access (IMA)* *Figure 2311: IMA RAM Write Data register n (IMA_WRITE_DATA_n)* and *Table 2204: IMA_WRITE_DATA_n field descriptions*: Changed register fields WRITE_n to WRITE. *Figure 2312: IMA RAM Read Data register n (IMA_READ_DATA_n)* and *Table 2205: IMA_READ_DATA_n field descriptions*: Changed register fields READ_n (n=4 to 0) to READ. *Table 2201: IMA_SLCT field descriptions*: Removed “word” from ROW_SLCT field description. *Section 88.3.3.7: IMA RAM Write Data register n (IMA_WRITE_DATA_n)*: Changed text “IOs for the RAM selected.” by text “bits for the RAM selected.” in long description paragraph. *Section 88.3.3.8: IMA RAM Read Data register n (IMA_READ_DATA_n)*: Changed text “IOs for the RAM selected” by text “bits for the RAM selected.” in long description paragraph. *Section 88.3: Accessing memory via the IMA module*: removed bullet ‘ECC must be disabled...’, added the 2 bullets ‘When a bus master performs an IMA access...’ and ‘Before any IMA access...’. *Chapter 89: Fault Collection and Control Unit (FCCU)* *Section 89.5.7: FAULT interface*: removed “in order to generate fake faults directly in the FAULT root” in sentence “To support a fault injection mechanism ... optional signal is available.” *Section 89.5.6: NMI/WKPU interface*, removed bullet about of Wake-up indication *Chapter 90: Self-Test Control Unit (STCU2)* *Figure 2400: STCU2 Offline LBIST MISR Expected Low n Register (STCU_LB_MISRELn)*: Changed MISRE[31:0] field to MISRE31-MISRE0 fields. *Figure 2401: STCU2 LBIST MISR Expected High n Register (STCU_LB_MISREHn)*: Changed MISRE[63:32] field to MISRE63-MISRE32 fields. *Chapter 92: Password and Device Security Module (PASS)* *Figure 2424: Clock Jitter Enable (CJE)*: Moved bitfield CJE from bit 0 to bit 31.

Table 2499. Document revision history (continued)

Date	Revision	Changes
03-May-2017	3 (cont.)	*Chapter 93: Tamper Detection Module (TDM)* *Table 2341: TDM memory map*: Added TDM_ prefix to STO_KEY*n* registers. [All projects] From *Section 93.4.1: Diary Base Address (DBA) DCF client* to *Section 93.4.9: Tamper Region Assignment DCF client (TDRn_LOCK2)*: changed the Warning to a Caution *Table 2334: OTPEN1 field descriptions*: Added a reference to the Embedded memories chapter. *Chapter 95: Wakeup unit (WKPU)* *Table 2392: WKPU Memory Map*: Removed reserved space 0x000C–0x03FF). *Section 95.4: Functional Description*: Removed Note “An edge enable for a given input must be asserted before the NMI/external interrupt edge in order for a system wakeup or interrupt to be generated.”. *Section 95.3.2.9: Wakeup/Interrupt Pullup Enable Register (WIPUER)*: Added note “This register shall be left at '0' default value, as:...”. *Chapter 96: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Section 96.2: Features*, *Figure 2507: RTC/API block diagram* and *Figure 2508: Clock gating for RTC clocks*: Removed XOSC (4-40 MHz) Removed register RTC_ANLCMP_CNT and its relative description. *Figure 2507: RTC/API block diagram*: – Changed CNTEN from 10 to 32 – Changed 32 bit counter output from 12 to 32 – Removed RTC rollover wakeup block. *Table 2404: RTCC register field descriptions*: Removed wakeup related text. *Section 96.5: RTC functional description* – Rephrased the sentence starting by “When the counter value...” to change from 12 to 32 bits and to remove the example. – Removed rollover wakeup occurrences as it is not supported *Section 96.6: API functional description*: Replaced 10-bit by 32-bit in the second sentence. *Table 2408: RTC_RTCVAL register field descriptions*: added Note “Minimum supported value of RTCVAL is 4. This is due to synchronization issues.” *Chapter 97: Emulation and Debug Device Introduction* *Table 2411: BD memory map*: – Changed Extended overlay RAM allocated size to 2048KB at space address 0x0C00_0000–0x0C1F_FFFF. – Updated address 0x0C80_C000 by “Reserved” (was “DWPU”), updated address 0x0C81_0000 by “BD XBAR” (was “Reserved”). *Figure 2515: Emulation and debug device architecture*: Updated the figure to suppress the lock-step core associated to Core_1 *Chapter 101: Buddy Device—System Integration Unit Lite (BD_SIUL2)* Added registers *Section 101.4.1.5: BD_SIUL2 Multiplexed Signal Configuration Registers (BD_SIUL2_MSCR1, BD_SIUL2_MSCR2)*

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4	Following are the changes in this version of the Reference manual: *Chapter 2: Introduction*: *Section 2.1.9: Software debug and calibration*: added 32 KB overlay RAM. Canceled referenced to ED (Emulation Device) not present on Chorus devices. *Chapter 5: Memory Map* *Table 7: Overview memory map*: Updated HSM. Updated *Table 14: HSM memory map*. *Table 13: UTest Flash memory map*: Address 0x0000036F replaced by 0x0000035F and 0x00000370 replaced by 0x00000360. *Chapter 6: Functional safety* *Table 15: PMHF module categories*: Updated definition of Non-safety modules *Section 6.4.4.2: All-x words and ECC*: – Added sentence starting with “Memories that include addresses in the ECC...” – Reworked the paragraph starting with “In case of not valid codeword...” *Section 6.4.4.3: ECC failure handling*, *Section 6.4.4.4: Memory Error Management Unit (MEMU)* and *Section 6.4.4.4.1: Interface to ECC units*: Added “with same (optional) syndrome” *Table 16: Module classification*: – Moved Concentrator DMA from NoSaMos to ViMos. – Added STANDBY SAR ADC in NoSaMos Classification. *Section 6.4.1.5.1: BIST during boot (off-line)*: Updated Logic BIST bullet *Table 17: FCCU failure inputs*: – Set “Not testable” as Error reaction path for Failures LVD_ERROR and HVD_ERROR – Replaced Failure descriptions for FCCU channel 93, 99, 104 - 109 – Replaced PRAM with “FLASH controller internal RAM” in FCU channel 115 – Filled Error reaction path, Default reaction, Reference Manual reference and Recovery mechanism *Section 6.4.4.1: ECC for storage*: Changed introduction. *Chapter 8: Reset and Boot* *Section 8.3.3*, *Section 8.3.4*, *Section 8.3.5*, *Section 8.3.8* and *Section 8.3.9*: Deleted all indications of duration of each phase (“This phase is completed in...”) *Chapter 10: Power management* *Table 137: Device power management controller external signals*. Added VDD_HV_OSC and VSS_HV_OSC *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* *Section 11.3: Architecture*: Added the paragraph starting with “In STANDBY mode, only RTC is powered on....”

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Chapter 17: System Integration Unit Lite2 (SIUL2)* *Figure 166: SIUL2 MCU ID Register #1 (SIUL2_MIDR1)*, in the footnote removed the default value of PKG bitfiled. *Table 269: SIUL2_MIDR1 field descriptions*. PARTNUM for Chorus6M changed from 0x5848 to 0x5846 *Chapter 21: System Memory Protection Unit (SMPU)* *Figure 197: Control/Error Status Register 1 (CESR1)*, changed reset value of NRGD field to 0110 *Chapter 27: Clocking* *Section 27.1: Introduction*: changed divider value from 512 to 1024 *Section 27.5.1.4: PLL register write protection*: added cross ref to Device configuration chapter *Table 392: PLL register write protection*: deleted "Protection" column *Section 27.6.2: PSI5 clock dividers*: deleted "three" and replaced by "two" PSi5 modules *Section 27.6.6.2: M_CAN subsystem 1*: "/M_TTCAN" deleted from section title *Section 27.7.1.3: CMU register write protection*: – Added cross ref to Device configuration chapter – Deleted "Protection" column *Table 388: MC_CGM relationship to clocks*, Deleted "Bridge clock" from Output clock column of CGM_SC_DC1 *Chapter 28: Dual PLL Digital Interface (PLLDIG)* *Table 397: PLL0DV field descriptions* and *Table 400: PLL1DV field descriptions*: Updated division factors of RFDPHI. *Section 28.6.3: Frequency modulation*, replaced PLLnCR[MFD] with PLL1DV[MFD]. *Section 28.7: Initialization information*: added footnote linked to "procedure" *Table 395: PLL0CR field descriptions*: EXPEDIE bitfield description enhanced Changed "MC_ME_<mode>" by "<ME_mode>, "MC_ME_" or "ME" by "<ME>" and "MC_CGM_ACn" by "<CGM_ACn>" throughout all this chapter. *Section 28.4: Modes of operation*: – Changed "the operating modes" by "the operating mode" – Changed "The various modes of operation for the PLL are" by "The mode of operation for the PLL is defined below" *Chapter 29: Clock Monitor Unit (CMU)* *Table 411: CMU_CSR field descriptions* – SFM: added sentences "MDR[MD] ... CSR[SFM]=1" and "Software ... bit" – RCDIV: added sentence "Ensure ... [RCDIV]" – CME: added sentence "CMU_HFREF ... (CSR[CME=1])" *Section 29.5.2: CLKMN0_RMT supervisor*: deleted Note "f_{CLKMN0_RMT} ··· *monitoring"*

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Chapter 31: OSC digital interface (XOSC)* *Figure 382: XOSC Control register (XOSC_CTL)*: Changed I_OSC field access type to R/w1c (was RW). *Chapter 37: Embedded Flash Memory* *Table 522: UTEST block memory map*: For Customer OTP data, the size changed from 4096 bytes to 12288 bytes. *Figure 409: Flash memory module structure*: Updated to depict RWR0 and RWR1 Flash arrays *Section 37.3.2.3: Extended Module Configuration Register (MCRE)*: Bitfield "HT" replaced by Reserved bitfield *Section 37.4.4.1: Read While Read*: Removed lines "RWW P6" and "RWW P7" Updated *Table 518: Flash memory partition 5 memory map* *Section 37.3.2.24: Parallel Address register (ADR2)*: Added the sentence "For the address mapping, refer to *Section 37.3.2.16: Address register (ADR)* description." Added *Section 37.4.4.2.1: Multi-bits error management (more than 3 bits error >=4)* *Section 37.3.2.1: Module Configuration Register (MCR)*: updated description of bitfield EEE *Chapter 40: Analog-to-Digital Converters (ADC) Configuration* *Section 40.2.2.1.2: 12-bit SAR ADC B0*: Removed references to SUPERVISOR *Table 588: ADC implementation*: updated SAR_ADC_12bit_2 from '13' to '15' *Section 40.2.2.1.1: 12-bit Fast SAR ADC* Specified 124-127 as Test channels *Section 40.2.2: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*; Removed SUPERVISOR referred to 12 bit SAR ADC. *Chapter 41: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* Throughout the chapter, renamed all occurrences of – AN[x] to AIN[x] – EMDATA to BSEXT – EMCLK to CLKEXT *Figure 489: Converted Data Register (SDADC_CDR)*: Changed register access type to Read (was RW). *Chapter 42: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Table 616: SARADC digital interface register map*: Removed the "Register classification" column. *Table 617: MCR field descriptions*: removed note in CTUEN bitfield Replaced SDADC by SARADC in FRZ bitfield description (was a typo) *Section 42.4.5.1: CTU trigger mode*: Replaced JABORT by JABORTCHAIN (was a typo) *Section 42.4.6: Test channel connection with internal analog channel*: Minor changes *Section 42.5.1.16: Internal Channel Data Register n (ICDRn)*: Removed reference to REFSEL bitfield. *Section 42.5.1.41: External Channel Data Register n (ECDRn)*: Removed reference to REFSEL bitfield

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Chapter 46: Software Watchdog Timer (SWT)* *Section 46.1.1: Overview*: Added "Note: The SWT runs over all device mode except the STANDBY mode where it is not powered." *Chapter 50: Periodic Interrupt Timer (PIT)* *Section 50.2.1.6: PIT RTI Timer Control Register (RTI_TCTRL)*: Removed bitfield CHN *Chapter 53: Serial Interprocessor Interface (SIPI)* *Section 53.11.3: Maximum count reached error*: updated blank cross reference to SIPI_ACR. *Chapter 57: FlexRay communication controller (FlexRay)* *Table 1300: FlexRay memory map*: Added Strobe Port Control Register (FR_STBPCR) at 0x000A offset. *Section 57.5.2.7: Strobe Port Control Register (FR_STBPCR)*: Added this register. *Figure 1324: Stop Watch Count High Register (FR_STPWHR)* and *Figure 1325: Stop Watch Count Low Register (FR_STPWLR)*: Changed register and STPW field accesses to Read-only (was Read-write). *Chapter 59: SENT Receiver (SRX)* *Table 1464: CHNL_EN field descriptions*, *Table 1466: FMSG_RDY field descriptions*, *Table 1467: SMSG_RDY field descriptions*, *Table 1470: FDMA_CTRL field descriptions*, *Table 1471: SDMA_CTRL field descriptions* and *Table 1472: FRDY_IE field descriptions*: Changed <field>[15:0] to <field>[(CH-1):0] Changed bit position 16:31 to (32-CH):31 *Table 1473: SRDY_IE field descriptions*: Changed bit position 16:31 to (32-CH):31. *Chapter 60: Peripheral Sensor Interface (PSI5)* *Table 1494: PSI5 memory map*: Removed the "Register classification" column. *Chapter 61: Peripheral Sensor Interface-Support module (PSI5-S)* *Figure 1544: PSI5-S global control register (PS_GLCR)*: Changed field accesses of bit 21:23 to write-only and always read as 0. *Figure 1557: PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)*: Changed field access of bit 28 to write-only and always read as 0. *Figure 1560: PSI5-S channel message configuration register A (PS_MSGA_CHn)*: Changed field access of bit 28 to write-only and always read as 0. *Figure 1563: PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)*: Changed field access of bit 4 to read-write. *Table 1546: PSI5-S memory map*: Removed the "Register classification" column. *Table 1582: PS_WD_CFGR_CHn field descriptions*: Removed text "This bit is one shot. it is always read as 0." at bit 4. *Figure 1566: PSI5-S ECU to sensor control register (PS_E2SCR_CHn)*: Changed field access of bit 18 to write-only and always read as 0.

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Figure 1569: PSI5-S channel1 ECU to sensor downstream data shift register low (PS_DDSR_L_CHn)* and *Table 1588: PS_DDSR_L_CHn field descriptions*: Changed field names to DDSR_L1 for bits 0:7 and DDSR_L0 for bits 8:31. *Chapter 63: LINFlexD* *Figure 1679: Master node: DMA Tx FSM (concept scheme)* and *Figure 1683: Slave node: DMA Tx FSM (concept scheme)*: Added note "DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles." *Table 1661: LINFlexD memory map*: Removed the "Register classification" column. *Figure 1700: LIN Time-Out Control Register (LINTOCR)*: Updated HTO reset value by adding a note (1) on bits 26:27. *Figure 1704: LIN Control Register 2 (LINCR2)*: Updated IOPE reset value note (3). *Chapter 65: Boot Assist Flash (BAF)* *Section 65.3.8: Optionally perform a serial boot*: updated text. *Figure 1781: Production Disable callback function flow chart*: Replaced "PIT" by "Periodic Timer". *Chapter 66: System Status and Configuration Module (SSCM)* Updated *Table 1745: Life Cycle slots*, *Table 1746: Life Cycle Slots in Memory* and *Table 1747: Resulting Life Cycle* Removed "Glossary" section. *Chapter 67: Power management controller digital interface (PMC_Dig)* *Section 67.3: IPS bus interface*: Updated the section. *Section 67.5: Registers description*: Replaced "Access: User read/write" with "Access: User read/write, Supervisor read/write, Test read/write" in all the relevant register figures. *Figure 1804: Reset Event Enable Register (REE_LV0)*: Updated the access of all the fields as read/write. *Figure 1805: Reset Event Select Register (RES_LV0)*: Updated the access of all the fields as read/write. *Figure 1806: Interrupt Enable Register (IE_LV0)*: Updated the access of all the fields as read/write. *Figure 1825: Global Interrupt Enable Register (IE_G)*: Updated the access of all the fields as read/write. *Table 1771: GR_S field descriptions*: Updated the description of fields "TEMP_2", "TEMP_1", and "TEMP_0". *Section 67.1: Introduction*: Updated the text "The PMU digital block generates a transfer error event ....." *Section 67.3: IPS bus interface*: Updated the bullet point "The PMU digital block generates a transfer error event ....." *Chapter 69: Mode Entry Module (MC_ME)* *Figure 1874: Peripheral Status register 7 (ME_PS7)*: Added fields S_ETHERNET_0 to bit 21 and S_ETHERNET_1 to bit 22.

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Chapter 76: Sequence Processing Unit (SPU)* For each occurrence of "Calibration and Debug" in the chapter, added "(or Debug and Trace)". *Chapter 55: LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications* Removed "Line Driver digital connections" section *Table 995: PLLCR field descriptions*: Updated description of FBDIV *Chapter 86: Cyclic Redundancy Check (CRC) Unit* Fixed *Equation 95*. *Chapter 87: Memory Error Management Unit (MEMU)* *Section 87.6.2.14: Flash memory correctable error reporting table status register (FLASH_CERR_STSn)* changed boundary from 64bit to 128 bit. *Figure 2278: MEMU reporting table uniqueness check flow chart*. Added arrow from [Error dropped] *Section 87.1: Introduction*: Replaced "Peripheral System RAM" by "Peripheral RAM" in the second bullet *Table 2179: SYS_RAM_UNCERR_ADDR field descriptions*, *Table 2184: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 2189: FLASH_UNCERR_ADDR field descriptions*: Added the sentence "This register must be READ ONLY when its corresponding valid bit is not asserted." to ERR_ADD field description. *Chapter 89: Fault Collection and Control Unit (FCCU)* *Table 2212: FCCU memory map*: Removed the "Register classification" column. *Table 2215: FCCU_CFG field descriptions*: updated description of bitfield FCCU_SET_CLEAR. *Figure 2336: FCCU CTRL Key Register (FCCU_CTRLK)* and *Table 2214: FCCU_CTRLK field descriptions*: Changed CTRLK field name to CTRLK_VAL. *Figure 2341: FCCU RF Key register (FCCU_RFK)* and *Table 2341: FCCU RF Key register (FCCU_RFK)*: Changed RFK field name to RFK_VAL. *Figure 2355: FCCU XTMR Register (FCCU_XTMR)* and *Table 2239: FCCU_XTMR field descriptions*: Changed XTMR field name to XTMR_VAL. *Figure 2359: FCCU Delta T Register (FCCU_DELTA_T)* and *Table 2244: FCCU_DELTA_T field descriptions*: Changed XTMR field name to XTMR_VAL. *Table 2213: FCCU_CTRL field descriptions*: – Added field numbers – Updated description of DEBUG field – Updated description of OPR field *Section 89.6.2: FCCU CTRL Key Register (FCCU_CTRLK)*: updated Note.

Table 2499. Document revision history (continued)

Date	Revision	Changes
06-Aug-2018	4 (cont'd)	*Chapter 90: Self-Test Control Unit (STCU2)* *Table 2257: STCU_WDG field descriptions*: added table note "STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE clock frequency value." *Section 90.4.2.1: Offline reset generation*: added sentence "In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module." *Table 2251: STCU2 memory map*: Renamed table title (was register set). *Section 90.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Removed equation number. *Figure 2375: STCU2 Error FM Register (STCU_ERR_FM)*: Set reset value of bits 0:15 to all 0. Removed this "Register map" section. *Chapter 92: Password and Device Security Module (PASS)* *Table 2307: LCSTAT register field descriptions*: Updated description of LIFE bitfield with value 110 (ST production). *Figure 2431: Password Group n - Lock 0 Status register (LOCK0_PGn)*: Added ATSL field at bit 1 and set undefined reset with figure note. *Table 2312: LOCK0_PGn register field descriptions*: Added ATSL field and its description at bit 1. *Section 92.3.1.4: Challenge Input register (CINn)*; added the following sentence "Valid password criteria is that it should not be all Zeros or all Ones".: *Chapter 93: Tamper Detection Module (TDM)* *Table 2340: TDM_STO_KEYn field descriptions*, added a second note. *Figure 2454: Diary implementation*; changed Diary_TDR0 size from 256x64 to 256x128 bits. *Section 93.6.3: Diary*, replaced "is 8 bytes" with "depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector." *Section 93.6.4: Specifying the diary base address*, replaced "is 8 bytes" with "depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector." Deleted "Therefore the diary can hold a maximum of 256 × 8 byte entries." *Section 93.6.5.1: Diary management*, replaced "64-bit double word "with "record". *Chapter 94: ASC Modeling Unit version 2 (AMU2)* *Figure 2469: AMU V Pointer Channel n Register (AMU2_VPTRCHn)*: Changed register and fields accesses to Read/Write (was Read). *Figure 2458: AMU P8 Channel n Register (AMU2_P8CHn)*: Changed register and fields accesses to Read (was Read/Write).

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5	Following changes are done throughout the document: Updated the subtitle, in the cover page. *Chapter 3: Embedded memories* *Section 3.2.1: System SRAM*: Updated the text from, “The SRAM can be configured....PFCR1.....controller.” to “The SRAM can be configured... PRCR1.....controller.” *Chapter 5: Memory Map* *Table 9: Flash memory map*: – Added footnote to PFLASH Controller Assignment (RWR Partition ID) in header column. – Added footnote to reserved space with assignment to PFLASH 0 at start address 0x015C0000. *Table 13: UTest Flash memory map*: Added a footnote, “Factory could program.....find it” to the “UTest DCF records” for Start offset of 0x00000370. *Chapter 6: Functional safety* *Table 16: Module classification*: – Moved Concentrator HSM to ViMos classification (was NoSaMos) – NoSaMos: Changed SEMA4 by SEMA42. – Below Modules have been moved Vimos to NoSaMoS: – Performance Core (Core_1), – D-Cache Performance Core (Core_1), – I-Cache Performance Core (Core_1), – other local memories of Performance Core (Core_1) – Overlay RAM – PIT – Below Modules to be moved from PeMoS to ViMoS: – PBRIDGEn – Below Modules to be moved from ViMoS to SuMoS – STCU2 *Section 6.4.4.1: ECC for storage*: Updated *Table 17: FCCU failure inputs*: – Updated the table. – Added note to “COMPENSATION CELLS” in “Failure description” column. – Updated failure description and Error reaction path check for FCCU channel 17-20. – Updated failure description for FCCU channel 30 – Updated column Reference Manual related information for FCCU channel 58, 60, 63, 64 and 66 to Section: Safety considerations *Table 18: ECC RAM implementations*: – Updated column-head from memory classification to MEMU classification – Added footnote for column-headed ECC for System RAM for location Platform – Added footnote for column-headed ECC in location Core0, Core1 and Core2 for all I-Dem and D-Mem

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	– Updated MEMU Classification for Location HSM for devices – Updated column-headed ECC for Nexus for location Platform *Figure 8: Simplified view of E2E ECC*: Updated this picture. *Chapter 7: Device configuration*: Updated the chapter. *Chapter 8: Reset and Boot* *Table 119: Module status during reset phases*: Removed note from Module “System watchdog” *Section 8.3.1: Power-on and the Reset Generation Module*: Updated the text from, “The STCU is reset on any power-on.....(external reset in this case is ESR0)”. to “The STCU is reset and offline self-test (if enabled) is triggered on any power-on.....(external reset in this case is ESR0)”. *Table 121: SSCM boot record search locations*: Updated: – The location for address (0x00FC_0000) is updated from Flash 16 KB Code Block 0 to Flash 16 KB Code Block 3. – The location for address (0x00FC_8000) is updated from Flash 16 KB Code Block 2 to Flash 16 KB Code Block 4. – The location for address (0x00FC_C000) is updated from Flash 16 KB Code Block 3 to Flash 16 KB Code Block 2. *Table 124: BAF boot record search locations*: Updated: – The location for address (0x00FC_0000) is updated from Flash 16 KB Code Block 0 to Flash 16 KB Code Block 3. – The location for address (0x00FC_8000) is updated from Flash 16 KB Code Block 2 to Flash 16 KB Code Block 4. – The location for address (0x00FC_C000) is updated from Flash 16 KB Code Block 3 to Flash 16 KB Code Block 2. *Table 125: SSCM boot record search locations*: Updated: – The location for address (0x0060_C000) is updated from Flash 16 KB Code Block 0 to Flash 16 KB HSM Code Block 5. – The location for address (0x0061_0000) is updated from Flash 64 KB Code Block 0 to Flash 64 KB HSM Code Block 2. – The location for address (0x0062_0000) is updated from Flash 64 KB Code Block 1 to Flash 64 KB HSM Code Block 3. *Section 8.3.5: PHASE2[DEST] Phase: flash initial configuration*: Updated the note. *Section 8.3.8: PHASE1[FUNC] Phase: temporization and monitoring setup*: Added the latest sentence “During this phase, test modules are available.” *Figure 41: Reset Generation Module Reset Sequence*: – Updated the figure – Updated footnote, “No self-tests are executed.” – Removed a block of “no self test”

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 9: Device Configuration Format (DCF) Records*: *Figure 50: UTEST Miscellaneous DCF Client*: – Renamed bit 12 from CORE_CLK_ONLINE_LBIST to CORE_CLK_ONLINE_SELF_TEST – Refer to DCF client list for reset value. *Table 131: UTEST Miscellaneous DCF Client field descriptions*: – Renamed bit 12 from CORE_CLK_ONLINE_LBIST to CORE_CLK_ONLINE_SELF_TEST – Updated description of bit field XOSC_EXT_CLOAD *Table 134: PMC_REE_BUS field descriptions*: Updated description for each bit field. *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*: *Table 159: CTUCR field descriptions*: Updated note for bit field 24. *Section 11.6.4: OPC*: Added second and third bullets to the set of pads behavior. *Chapter 15: Core (z420n3) Description*: *Section 15.9: Local memories*: Added this section. *Section 15.9.2.3: DMEM Control Register 1 (DMEMCTL1)*: Added. *Section 15.9.2.4: IMEM Configuration Register 0 (IMEMCFG0)*: Added. *Section 15.9.2.5: IMEM Control Register 0 (IMEMCTL0)*: Added. *Section 15.9.2.6: IMEM Control Register 1 (IMEMCTL1)*: Added. *Section 15.10: End-to-End ECC support*: Added this section. *Figure 102: Core (z420n3)Supervisor Mode Programmer's Model DCRs and PMRs*: Updated. *Chapter 16: Core (z425n3) description*: *Figure 135: Core (z425n3) Supervisor Mode Programmer's Model SPRs*: Added L1CSR0 / SPR 1010 in cache registers. *Table 235: Exceptions and conditions*: Deleted TBD line. *Section 16.9.2.1: DMEM Configuration Register 0 (DMEMCFG0)*: Updated. *Figure 157: DMEM Configuration Register 0 (DMEMCFG0)*: Updated DMSIZE. *Table 260: DMEMCFG0 Field Descriptions*: Updated row-headed DMEM BASE ADDR. *Section 16.9.2.4: IMEM Configuration Register 0 (IMEMCFG0)*: Updated. *Table 263: IMEMCFG0 Field Descriptions*: Updated row-headed IMEM BASE ADDR. *Section 16.10.1.1: End-to-End ECC Control Register 0 (E2ECTL0)*: Added note. *Figure 136: Core (z425n3) Supervisor Mode Programmer's Model DCRs and PMRs*: Updated. *Chapter 17: System Integration Unit Lite2 (SIUL2)*: *Table 280: SIUL2_MSCR_IOn field description*: – ILS bitfield description changed for value 00 (Automotive for SPC58xEx, Reserved for SPC58xGx). – Changed WPDE and WPUE field descriptions.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Section 17.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*: Changed the latest sentence by referring to the device I/O_Definition document. *Chapter 18: Crossbar switch (XBAR)*: *Table 289: XBAR memory map*: Added MASTER channel n (n = 0 to 7) title and XBAR_MGPCRn registers at 0x0800 +n*0x100 address offsets. *Section 18.3.3: Master General Purpose Control Register (XBAR_MGPCRn)*: Added this section. *Table 290: XBAR_PRSn field descriptions*: Added description of bitfield M3. *Table 291: XBAR_CRSn field descriptions*: Updated the note of PARK field from “Only select master.....behavior may occur.” to “Only select master.....parking configuration.” *Chapter 19: Crossbar Integrity Checker (XBIC)*: *Table 295: XBIC_EIR field descriptions*: In the second note, replaced “SMPU logical bus master assignments” with “AHB Master ID Assignments”. *Chapter 23: Semaphores2 (SEMA42)*: *Section 23.2: Memory map/register definition* *Table 322: Memory map/register definition*: – Updated register name for 0x0040 – Deleted line for 0x0042 – Updated Address offset for Reserved line *Section 23.2.2: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: Replaced all occurrences of SEMA4_RSTGT_W by SEMA4_RSTGT – *Figure 216: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: Added RSTGSM and RSTGMS. – *Table 324: SEMA4_RSTGT field descriptions*: Added RSTGSM and RSTGMS. *Table 23.2.2: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: Deleted this section. *Chapter 25: Enhanced Direct Memory Access (eDMA)*: *Figure 233: Control Register (eDMA_CR)*: – Changed GRP3PRI and GRP2PRI field access type to RW. – Updated register reset value with a specific figure footnote. *Table 338: eDMA_CR field descriptions*: Added note to GRP3PRI and GRP2PRI field descriptions. *Chapter 27: Clocking*: *Section 27.1: Introduction*: – Deleted text “as a backup clock” – Updated text “The internal 16 MHz...chapter for details.” *Section 27.2: Clock generation*: – *Figure 280: Clock generation(1)(2) (part 1 of 2)*: – Updated the figure. – Updated dividers for FRAY_CLK (AUX2).

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Section 27.2.1: MC_CGM registers*: *Table 388: MC_CGM relationship to clocks*: SEM4 replaced by SEMA42. *Table 390: Maximum auxiliary level clock frequencies*: – Added note “DSPI_CLK frequency should always be greater than or equal to 1.25 times PBRIDGE_CLK” to DSPI_CLK. – Row “FRAY_CLK”: Updated ‘40’ by ‘80’. – Added note “80 MHz maximum frequency is at aux divider output. The maximum frequency of FRAY_CLK after the multiplexer is 40 MHz” to FRAY_CLK for Aux Clock 2 Selector. *Section 27.5.1.6: Loss of clock detection*: Deleted the last sentence “Software may enable or disable an optional backup clock in the PLL”. *Section 27.8.1: Loss of PLL/XOSC clock*: Updated this section. *Section 27.8.2: Loss of IRCOSC clock*: – Updated the section. – Deleted text “and backup.” – Removed the note. *Figure 283: Clock distribution*, MEMU block: updated “Memory Clock” by “MEMU Clock” and added Note “The frequency of the MEMU clock...”. *Chapter 28: Dual PLL digital interface (PLLDIG)*: *Figure 291: Dual PLL digital interface block diagram*: – Backup Clock Selection” block is made blue and note added “Backup Clock Selection” block in blue is not implemented”. – Updated this figure by adding a divider by 2 in PLL0 block. *Section 28.4.1: Normal mode with reference, PLL0 or both PLLs enabled*: Added in Note cross-ref to *Section 28.7: Initialization information*. *Section 28.5.2.1: PLL0 control register (PLL0CR)*, *Section 28.5.2.4: PLL1 control register (PLL1CR)*: Updated note for field LOLIE. *Chapter 29: Clock Monitor Unit (CMU)*: *Section 29.4.1.1: CMU Control Status Register (CMU_CSR)*: Updated the description of RCDIV from, “Ensure clock.....CMU_CSR[RCDIV].” to “Ensure clock.....otherwise the operation can lead to a spurious OLR event.” *Section 29.4.1.5: CMU Interrupt Status Register (CMU_ISR)*: Updated Note. *Table 411: CMU_CSR field descriptions*: Updated the descriptions of SFM and CME fields. *Chapter 31: OSC digital interface (XOSC)*: *Section 31.2.4.1: Automatic Level Control (ALC)*: Added. *Chapter 32: IRCOSC digital interface*: *Table 496: IRCOSC_NT field descriptions*: Updated description of bitfields FT_CODE and RCTRIM. *Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*: Changed chapter name to PRAMC_AHB.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 36: Flash memory controller*: *Section 36.5.14.1.1: e2eECC and Flash accesses*: Added the latest sentence. *Section 36.5.15: e2eECC on data Flash accesses*: Added the latest sentence. *Chapter 37: Embedded Flash Memory*: *Table 522: UTEST block memory map*: Added note to offset 0x140. *Table 525: MCR field descriptions*: – Improved wording of DWEE both for code and data memory. – Add sentence “Note that EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash” at EEE field description. *Table 528: MCRE field descriptions*: – Updated description of fields N64KL and N16KL. – Removed the row of field “N256KH”. *Table 539: MCR2 field descriptions*: Same done for PDWEE but only for code memory *Table 541: ADR field descriptions*: Improved wording for bit field ADDR *Table 576: ADR2 field descriptions*: Improved wording for bit field PADR *Section 37.3.2.1: Module Configuration Register (MCR)*: Updated PEEE field description. *Section 37.4.1: Reset*: Sentence has been highlighted with Warning style. *Section 37.4.4.2: Error correction code*: Add sentence “EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash” at the end of the fourth sentence. *Table 529: LOCK0 field descriptions*: Updated. *Table 530: LOCK1 field descriptions*: Updated. *Table 531: LOCK2 field descriptions*: Updated. *Table 532: LOCK3 field descriptions*: Updated. *Table 533: LOCK0A field descriptions*: Updated. *Table 534: Alternate LOCK1A field descriptions*: Updated. *Table 535: SEL0 field descriptions*: Updated. *Table 536: SEL1 field descriptions*: Updated. *Table 537: SEL2 field descriptions*: Updated. *Table 538: SEL3 field descriptions*: Updated. *Chapter 38: Flash Memory Programming and Configuration*: *Section 38.6.2: Creating the tamper detect diary*: – The maximum size of Diary updated from 2 KB to 4 KB. – Multiplied by 2 KB is updated to 4 KB. *Example 4: Overriding secure write protection*: Updated paragraph list 2. *Example 7: Creating the tamper detect diary*: Updated. *Figure 464: Sample DCF record for secure write protection*: Updated the value of the figure. *Chapter 40: Analog-to-Digital Converters (ADC) Configuration*: *Section 40.2.2.1.1: 12-bit Fast SAR ADC*: Updated “analog input channel for each SARADC instances *Section 40.2.2.1.2: 12-bit SAR ADC B0*: Minor format change. SAR ADC register definitions: Deleted the section.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 42: Successive Approximation Register Analog-to-Digital Converter (SARADC)*: *Table 616: SARADC digital interface register map*: Removed “Register classification” column. *Section 42.4.4.1: Conversion timings*: Changed SAMPSEL by CTSEL field name. *Table 617: MCR field descriptions*: – Added note to NSTART, JSTART and PWDN field descriptions. – Updated the note for NSTART. *Table 636: PDEDR field descriptions*: Added latest paragraph in PDED field description. *Section 42.4.6: Test channel connection with internal analog channel*: Removed temperature sensor and bandgap from the first sentence of the first paragraph. *Section 42.5.1.11: Watchdog Threshold Register n (WTHRHLRn)*: Replaced in 1st note MSB=0 bits numbers by LSB=0 bit numbers. User access updated for: – *Section 42.5.1.32: External Channel Interrupt Pending Register n (ECIPRn)* – *Section 42.5.1.39: External Channel Analog Watchdog Out of Range Register n (ECAWORRn)* *Chapter 50: Periodic Interrupt Timer (PIT)*: *Section 50.5: Example Configuration for the Lifetime Timer*: Updated *Equation 29:* From, “current_uptime = PIT_LTMR64H << 64” to “current_uptime = PIT_LTMR64H << 32” *Chapter 51: Enhanced Modular IO Subsystem (eMIOS)*: *Table 797: EMIOSMCR field descriptions*: Updated note in GTBE field description. *Chapter 52: CAN Subsystem*: *Table 823: TSCC field descriptions*: – TCP: Removed the note, “With CAN FD ..... (TSS = ‘10’).” – TSS: Added a note, “In case of CAN FD mode..... generation.” – TSS: Updated the value of 10 from “External timestamp counter value used” to “External timestamp counter value used” only for SPC58xEx (“Reserved” for SPC58xGx).” *Section 52.3.5.2.3: Data Bit Timing and Prescaler Register (DBTP)*: Corrected time quanta max number in the first sentence. *Table 836: XIDFC field descriptions*: Corrected max enumerated value of LSE field to 0x7F. *Table 841: RXF0C field descriptions*: Corrected max enumerated value of F0WM and FOS fields to 0x7F. *Section 52.3.5.2.8: Timestamp Counter Configuration Register (TSCC)*: Updated the description of TSS field. *Chapter 53: Serial Interprocessor Interface (SIPI)*: *Section 53.1.1: Scalability*:Updated *Figure 875: SIPI module*: Updated figure note by removing “Channel 0 has the highest priority for transmission”

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Section 53.4.1: Main features*: – Updated the eleventh feature bullet. – Removed bullet “Target node...commands” – Updated bullet starting by “Target node contains a set of nine” *Figure 881: Streaming write request format*: Updated the Note below the figure. *Figure 889: Streaming transfer with data*: Added CR2[0], CR2[1] and CR2[7]. *Section 53.5: SIPI operation from reset*: Updated. *Section 53.6.2: Frame format*: Added Note at the end of the section. *Section 53.6.2.5: Streaming write request*: Updated in *Note:* *Section 53.6.2.8: Payload field*: Updated this section. *Section 53.7.2: Register read answer transfer*: – Added “big endian” in brackets to the note. – Added *Note:* and *Table 963: Target Memory content dependent from CAR content* *Section 53.7.3.2.1: Streaming write transfer with address*: – Added first sentence “The related registers...”. – Updated the second paragraph. *Section 53.8: Transfer API and flow charts*: – Updated this section. – Updated *5.* in list Multiple Write Transfer Request generation. – Updated Multiple Write Transfer Request generation sequence and Single Read Transfer Request generation sequence. *Section 53.9: DMA handling in transfer initiator mode*: – Re-named the title. – Added definition of DMA handling of transfer initiator and of transfer target *Figure 900: SIPI data stream model - Target*: Replaced “8-bit data” by “Data”. *Figure 901: SIPI data stream with acknowledge trigger*: – Replaced ‘Bus Master DMA’ by ‘Bus Master AHB’ – Moved the arrow that was between CRC Checker and ACK Frame Generation so that it is between Bus Master AHB and ACK Frame Generation. *Figure 904: SIPI Channel Control Register (SIPI_CCRn)*: Deleted footnote “Only transfers with channel 2...” *Figure 909: SIPI Channel address Register (SIPI_CARn)*: Deleted figure footnote. *Table 961: Payload size of LFAST channel frame*: – Added footnote. – Updated this table. *Table 962: Converted coding of LFAST channel code for SIPI headers*: Updated this table. *Table 965: SIPI_CCRn field descriptions*: – Updated DEN field description. – Updated row-headed TC *Table 970: SIPI_CARn field descriptions*: – Updated row-headed CAR. – Updated CAR bit field definition.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Table 974: SIPI_MCR field descriptions*: – Updated AID and SR fields. – Updated row-headed AID. *Figure 886: Data allocation*: Added 32-bit data allocation. *Figure 893: SIPI single register write API*: Changed TC name by CPU. *Section 53.9: DMA handling in transfer initiator mode*: Updated single write transfer request generation list. *Section 53.10: Modes of operation*: Updated this section. *Section 53.10.2: Normal Mode (NM)*: Removed text “SIPI needs...Register (SIPI_MCR)).” *Section 53.11.1: Timeout error*: – Added *Note:* – Removed Note: In case of timeout...being sent now. *Section 53.15.1.1: SIPI Channel Control Register (SIPI_CCRn)*: – Added “streaming command is 9 words long”. – Updated CHEN and DEN fields. – Updated *Note:* *Section 53.15.1.6: SIPI Channel Address Register (SIPI_CARn)*: Updated this section. *Table 975: SIPI_SR field descriptions*: – Updated row-headed TE. – Updated STATE field. *Section 53.15.1.12: SIPI Address Count Register (SIPI_ACR)*: – Updated this section. – Updated *Note:* *Figure 889: Streaming transfer with data*: Updated. *Figure 895: SIPI multiple register write API*: Updated. *Figure 896: SIPI single register read API*: Updated. *Figure 897: SIPI multiple register read API*: Updated. *Figure 898: SIPI data stream model*: Updated. *Chapter 54: Zipwire*: Deleted the entire section “Zipwire performance”. *Chapter 55: LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications*: *Table 985: TMCR field descriptions*: Updated description of bitfields CLKTST and LPON *Table 990: PICR field descriptions*: Updated description of bitfield PNGREQ *Table 997: UNSTCR field descriptions*: Updated description of bitfield USNDRQ *Table 995: PLLCR field descriptions*: Updated the description of FBDIV. *Figure 920: LFAST frame structure*: Added “(bits)” to “Payload size” and “Frame size” columns headers. *Table 1003: RISR field descriptions*: Updated ICPFF.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Table 1003: RISR field descriptions*: Updated ICPFF. *Figure 959: Rx Loopback mode* to *Figure 964: Tx LVDS Loopback (external) mode with automatic frame generation*: Added note regarding CSR. *Table 994: RIIER field descriptions*: Updated ICPFIE. *Table 1018: Frames supported by LFAST interfaces*: Value changed to “1 x 8” in Tx Buffer/ ICLC frame. *Section 55.7.1.1: LFAST master interface startup procedure*: Updated bullets 1, 13, 23, 26, and 28. *Chapter 56: Ethernet*: *Figure 1025: MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK)*: Updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Figure 1026: MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)*: Updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Chapter 57: FlexRay communication controller (FlexRay)*: *Table 1300: FlexRay memory map*: Corrected not implemented and reserved spaces. *Figure 1302: Protocol Configuration Register 9 (FR_PCR9)*: Corrected minislot_exists and symbol_window_exists field names. *Figure 1303: Protocol Configuration Register 10 (FR_PCR10)*: Corrected wakeup_channel field name. *Figure 1304: Protocol Configuration Register 11 (FR_PCR11)*: Corrected key_slot_used_for_startup field name. *Figure 1315: Protocol Configuration Register 22 (FR_PCR22)*: Updated bit field ‘R’ by ‘Reserved’. *Chapter 59: SENT Receiver (SRX)*: *Figure 1436: Channel n Fast Message Data read register (CHn_FMSG_DATA)*, *Figure 1441: Channel n Slow Serial Message Time Stamp read register (CHn_SMSG_TS)*: Added the following footnote and a cross ref to it “The value of the CH is device-specific. Refer to the Device Configuration chapter for details.” *Chapter 60: Peripheral Sensor Interface (PSI5)*: *Table 1494: PSI5 memory map*: Removed “Register classification” column. *Figure 1454: PSI5 Channel Control Register (PSI5_CH0_PCCR)*: Updated the access of bit 15 from “Read only” to “RW” and added a note “This is a redundant bit and RW will not have any effect”. *Chapter 61: Peripheral Sensor Interface-Support module (PSI5-S)*: *Section 61.1.2: Features*: Removed “(big endian)” from the first bullet. *Chapter 62: Deserial Serial Peripheral Interface (DSPI)*: *Section 62.3.6: DSPI Status Register (DSPI_SR)*: changed reset value from 0xDEAD_BEEF to 0x0201_0000.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Table 1594: DSPI_MCR field descriptions*: added note to HALT field description. *Section 62.5.6.3: Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)*: Added a second note. *Chapter 63: LINFlexD*: *Section 63.2.2: UART mode features*: Updated the 3 latest bullets. *Table 1659: TCD setting: UART - Tx mode*: Removed note at DADDR[31:0]. *Table 1660: TCD setting: UART - Rx mode*: Removed note at SADDR[31:0]. *Table 1661: LINFlexD memory map*: – Removed “Register classification” column. – Removed note that refer to the Device Configuration chapter and all cross-references to this note. *Section 63.4: Memory map and register description*: added note that refer to the LinFlexD configuration of the Device Configuration chapter. *Table 1686: DMATXE field descriptions*: field editorial changes to remove the table note. *Table 1687: DMARXE field descriptions*: field editorial changes to remove the table note. *Chapter 64: Reset Generation Module (MC_RGM)*: *Section 64.4.3: External reset*: – Updated the text from, “The ESR0.....ESR0 output being asserted.....the chip.” to “The ESR0.....ESR0_B output being asserted.....the chip.” – Added content “The correct timing between PORST and ESR0..... reset release.” *Section 64.4.7: ‘Destructive’ reset escalation*: added footnote to “each ‘destructive’ reset”. *Chapter 65: Boot Assist Flash (BAF)*: *Section 65.1: Introduction*: updated the fourth paragraph. *Section 65.3.8: Optionally perform a serial boot*: Deleted text “All Tx-channels have to be disabled during this phase” *Chapter 66: System Status and Configuration Module (SSCM)*: *Table 1739: ERROR field descriptions*: Removed “This feature...application code.” for row-headed PAE and RAE *Figure 1791: HSM and User Option Status Register (UOPS)*: – Added fields FL_RUN, BAF_FA and FL_STDBY and their respective descriptions. – Changed HSB bit field length to 3 bits and updated its description. *Table 1740: UOPS field descriptions*: – Added fields FL_RUN, BAF_FA and FL_STDBY and their respective descriptions. – Changed HSB bit field length to 3 bits and updated its description. *Section 66.3.3: Boot mode functionality*: updated Standby-Boot section. *Table 1746: Life Cycle Slots in Memory*: Updated.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 67: Power management controller digital interface (PMC_Dig)*: *Section 67.5.26: HPREG SMPS SELECT STATUS (HPREG_SMPS_SEL_S)*: Changed HPRE to HPREG. *Table 1752: REE_LV0 field descriptions* and *Table 1762: REE_HV0 field descriptions*: Changed “REE” by “RES” in REE_XX field descriptions. *Table 1753: RES_LV0 field descriptions* and *Table 1763: RES_HV0 field descriptions*: Changed “RES” by “REE” in RES_XX field descriptions. *Table 1776: HPREG_SMPS_SEL_S field descriptions*: Changed “SMPS_HP_N_SEL” by “HPREG_SEL pad” in all field descriptions. *Table 1785: BIST_FLAGS_PHASE1 field descriptions*, *Table 1786: BIST_FLAGS_PHASE2 field descriptions* and *Table 1791: BIST_DEBUG field description*: Replaced “Status will be ignored” by “Status should be ignored” *Section 67.5.38: User BIST Time1 and Time0 register (BIST_TIME10)*,*Section 67.5.39: User BIST Time3 and Time2 register (BIST_TIME32)* and *Section 67.5.40: User BIST Time6 and Time5 register (BIST_TIME65)*: – Added a cross-reference to Voltage monitor BIST programming section. – Updated Size of bitfields, TIME_x are updated to 12 bits from of 13 bits. *Section 67.9: Flash interface (DCF client usage)*: Added 2 paragraphs relative to monitors reactions. *Section 67.10: Voltage monitor BIST programming*: Updated this section. *Chapter 69: Mode Entry Module (MC_ME)*: *Section 69.4.1: Mode transition request*: “Added a note, “If CMU reveals..... executed correctly”. *Table 1804: ME_<mode>_MC field descriptions (continued)*: Removed table footnote in XOSCON field description. *Chapter 72: Debug and Calibration Interface (DCI)*: *Section 72.1.3.5: System watchdog control*: Added note “Debugger should...the SWT.” *Chapter 75: JTAG Data Communication (JDC)*: *Figure 1983: Module Status Register (JDC_MSR)*: corrected register access to read/write. *Chapter 77: Buddy Device—JTAG Master (JTAGM)*: *Table 1961: JTAGM_MCR register field descriptions*: Updated row-headed IIE *Table 1963: JTAGM_DOR0 register field descriptions*: Updated. *Table 1964: JTAGM_DOR1 register field descriptions*: Updated. *Table 1965: JTAGM_DOR2 register field descriptions*: Updated. *Table 1966: JTAGM_DOR3 register field descriptions*: Updated. *Chapter 79: Debug Serial Interprocessor Interface (SIPI)* *Section 79.5: Debug SIPI operation from reset*: Updated. *Section 79.6.2: Frame format*: Added Note at the end of the section. *Section 79.6.2.7: Payload field*: Updated this section.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Figure 2066: Data allocation*: Added 32-bit data allocation *Table 1973: Payload size of LFAST channel frame*: – Added footnote. – Updated this table. *Table 1974: Converted coding of LFAST channel code for Debug SIPI headers*: Updated this table. *Section 79.7.2: Register read answer transfer*: Added “big endian” in brackets to the note. *Table 1977: SIPI_MCR field descriptions*: Updated SR field. *Section 79.7.2: Register read answer transfer*: – *Note:* Added. – *Table 1975: Target Memory content dependent from CAR content*: Added. *Chapter 80: LVDS Fast Asynchronous Serial Transmission – High Speed Debug* *Table 1979: Header payload sizes*: Added “(bits)” to “Payload size” and “Frame size” columns headers. *Table 1984: TMCR field descriptions*: Updated description of bitfields CLKTST and LPON *Table 1988: PICR field descriptions*: Updated description of bitfield PNGREQ *Table 1990: UNSTCR field descriptions*: Updated description of bitfield USNDRQ *Table 1996: RIISR field descriptions*: Updated ICPFF. *Figure 2076: LFAST frame structure*: Added “(bits)” to “Payload size” and “Frame size” columns headers. *Figure 2107: Rx Loopback mode* to *Figure 2112: Tx LVDS Loopback (external) mode with automatic frame generation*: Added note regarding CSR. *Figure 2006: Frames supported by LFAST interfaces*: Value changed to “1 x 8” in Tx Buffer/ ICLC frame. *Chapter 86: Cyclic Redundancy Check (CRC) Unit*: *Figure 2278: CRC Configuration Register n (CRC_CFGn)*: Swapped reset values versus function of n in the figure footnote of POLYG reset. *Chapter 87: Memory Error Management Unit (MEMU)*: *Table 2179: SYS_RAM_UNCERR_ADDR field descriptions*: Removed to “This register is not writable when the corresponding VLD bit is zero.” *Table 2184: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 2189: FLASH_UNCERR_ADDR field descriptions*: Deleted the sentence “This register is not writable when the corresponding VLD bit is zero.)” *Chapter 88: Indirect Memory Access (IMA)*: *Table 2193: E2EECSR0 field descriptions*: Corrected register name in title. *Figure 2307: Cache Debug Access Control register (CDACNTL)*: Updated. *Figure 2308: Cache Debug Access Data register (CDADATA)*: Updated. *Section 88.2.2.1: e2eECC Error Control/Status register 0 (E2EECSR0)*: Updated.

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 89: Fault Collection and Control Unit (FCCU)*: *Figure 2319: FCCU block diagram*: Updated. *Table 2203: FCCU submodules*: Updated row-headed “REG intf”. *Table 2212: FCCU memory map*: Removed “Register classification” column. *Table 2213: FCCU_CTRL field descriptions*: Updated row-headed OPR. *Figure 2340: FCCU RF Status register n (FCCU_RF_Sn)*: Removed “Refer to for the errors description.” from table footnote 1. *Table 2231: FCCU_STAT field descriptions*: Added a note to PhysicErrorPin field description. *Section 89.7: FCCU Output Supervision Unit*: Updated this section. *Table 2235: F2A_STATUS field descriptions*: – Changed the table title from F2AF_STATUS to F2A_STATUS – Description of value 0xFF of bitfield FAFS: replaced word “critical” by word “recoverable.” *Section 89.6.1: FCCU Control Register (FCCU_CTRL)*: Updated the bullet “configure the glitch filter present on location given by FILTER_POSITION parameter” to “configure the glitch filter present on EIN0 input (FCCU failure input #96)” and replaced text “(FCCU_RF_Sn[RFSx] where y =FILTER_POSTN)” to “FCCU failure input #96”. *Section 89.6.8: FCCU RF Enable Register n (FCCU_RF_En)*: Deleted text “for debugging purposes”. *Section 89.6.13: FCCU Status Register (FCCU_STAT)*: Deleted text “for debugging purposes”. Deleted text “This register is for test/ debug purposes” from the following sections: – *Section 89.6.14: FCCU NA Freeze Status Register (N2AF_STATUS)* – *Section 89.6.15: FCCU AF Freeze Status Register (A2FF_STATUS)* – *Section 89.6.16: FCCU NF Freeze Status Register (N2FF_STATUS)* – *Section 89.6.17: FCCU FA Freeze Status Register (F2A_STATUS)*

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 90: Self-Test Control Unit (STCU2)*: *Section 90.4.2: Reset management*: Added a third sentence. *Table 2252: STCU_RUN field descriptions*: Updated MBSPLLEN and LBSPLLEN field descriptions. *Table 2253: STCU_RUNSW field descriptions*: Uupdated MBSWPLLEN and LBSWPLLEN field descriptions. *Table 2255: STCU_CFG field descriptions*: – Updated CLK_CFG field description. – Changed note in LB_DELAY field description. *Table 2257: STCU_WDG field descriptions*: Updated description for WDGEOC. *Section 90.4.6: Interrupt interface*: Added “there are two interrupt sources:” and a bullet “One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1)”. *Section 90.4.8.1: Initialization sequence*: Updated second bullet with a second sentence. *Section 90.4.9: CRC*: – Added note at the end of the section “The CRC calculated depends on the specific sample and not only the self-test configuration programmed.” – Updated the note “The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.” *Table 2289: STCU_LB_CTRLn field descriptions*: – Updated CWS field description at enumerated value 0x0. – Updated SHS field description. *Table 2301: STCU_MB_CTRLk field descriptions*: Updated PTR field description. *Section 90.5.5: STCU2 PLL Configuration Register (STCU_PLL_CFG)*: Added a note, “f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.” *Section 90.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)*: Updated description of WDGEOC bitfield. *Section 90.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Added the note to “The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.” *Section 90.5.15: STCU2 Online LBIST End Flag Register (STCU_LBESW)*: Decreased number of fields from 16 to 8. *Section 90.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*: Decreased number of fields from 16 to 8. *Section 90.5.17: STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)*: Decreased number of fields from 16 to 8. *Section 90.6: Use cases and limitations*: added paragraph: “The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.” For all available MBIST registers: – Added note, “Refer to..... number of NMCUT available in this device.” – Added note to all fields from 31:1, “The availability of this field is based on.....Device configuration chapter”

Table 2499. Document revision history (continued)

Date	Revision	Changes
30-Jul-2020	5 (cont.)	*Chapter 92: Password and Device Security Module (PASS)*: *Table 2315: LOCK3_PGn register field descriptions*: Added note to all RLx field descriptions. *Table 2320: Debug Interface Enable Truth table*: Updated the table. *Table 2321: Flash Memory Read Protection truth table*: Removed the second table. *Section 92.5.6.2.4: **Fuse Bypass Password compare***: – Removed text “of the Flash page contain different data not related to Fuse Bypass” at the end of the first sentence. – Removed “as the most significant 32 bits” in the second sentence. *Chapter 93: Tamper Detection Module (TDM)*: *Figure 2454: Diary implementation*; Changed Diary_TDR0 size from 256x64 to 256x128 bits. *Chapter 95: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)*: *Section 95.4.6: RTC Compare Value Register (RTC_RTCVAL)*: – Added a note “If RTC counter is reset (RTCC[CTNEN] = 0), it is required to reload the RTCVAL via software to re-enable the RTCVAL match interrupt before starting the RTC counter.” – Updated Note. *Chapter 96: Wakeup unit (WKPU)*: *Section 96.1.2: Features*: – Changed “configurable pullup” by “configurable pull”. – Added a note referring to the Device Configuration chapter. *Table 2395: NSR field descriptions*: added missing fields NIF2 and NOVF2. *Table 2403: WIPUER field descriptions*: – Added a table note referring to the Device Configuration chapter on “Description” heading. – Replaced “Pullup” to “Pull” in the complete table. *Section 96.3.2.5: Wakeup Request Enable Register (WRER)*: Added Note “Any wakeup pad...” *Section 96.3.2.8: Wakeup/Interrupt Filter Enable Register (WIFER)*: Added a Note, “Glitch filter must be enabled in case the wake-up sources are used to exit from Standby.” *Section 96.3.2.9: Wakeup/Interrupt Pull Enable Register (WIPUER)* – Updated the note from “This register shall be left at '0' default value” to “WIPUER bits related to those bonded LP pads that are used to wake-up the device from STANDBY Mode, should be left at 0 default value”. – Updated the text from, “This register..... value of 1” to “This register..... SIUL2_MSCR_IO_n.WPDE-WPUE bits.” *Table 2403: WIPUER field descriptions*: – Added a table note referring to the Device Configuration chapter on “Description” heading. – Replaced “Pullup” to “Pull” in the complete table.
