Reference manual

SPC58 E/G Line - 32 bit Power Architecture automotive MCU Triple z4 cores 180 MHz, 6 MBytes Flash, HSM, ASIL-D

Overview

This document defines the functionality of the SPC58xEx/SPC58xGx microcontroller for use by software and hardware developers. The SPC58xEx/SPC58xGx is built on Power Architecture technology and integrates technologies that are important for today's and tomorrow's automotive applications.

SPC58xEx/SPC58xGx applications include

- automotive powertrain controllers for six to eight cylinder gasoline, diesel engines and advanced combustion systems as well as high-end hybrid and transmission control
- integrated chassis control, high-end steering and braking
- high-end central body controller, smart junction boxes, stand-alone and integrated gateway
- in general any safety critical application requiring a very high level of safety integrity

The information in this book is subject to change without notice, as described in the disclaimer. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the ST Web site at http://www.st.com.

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC58xEx/SPC58xGx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

Contents

1 Preface 80

1.1 Document organization 80

1.2 Register conventions 80

1.3 Acronyms and abbreviations 81

1.4 Reference documents 81

2 Introduction 82

2.1 SPC58xEx microcontroller 82

2.1.1 Target applications 82

2.1.2 Overall architecture 82

2.1.3 Core features 83

2.1.4 Core_2 83

2.1.5 Memory hierarchy 84

2.1.6 Features 85

2.1.7 Feature list 86

2.1.8 Packages 88

2.1.9 Software debug and calibration 89

2.1.10 Block diagram 89

2.2 SPC58xGx microcontroller 92

2.2.1 Target applications 92

2.2.2 Overall architecture 92

2.2.3 Core features 92

2.2.4 Core_2 93

2.2.5 Memory hierarchy 94

2.2.6 Features 94

2.2.7 Feature list 96

2.2.8 Packages 98

2.2.9 Software debug and calibration 98

2.2.10 Block diagram 98

3 Embedded memories 101

3.1 Overview 101

3.2 SRAM 101

3.2.1 System SRAM 101

3.2.2 Standby SRAM regulator . . . 101
3.2.3 Overlay SRAM . . . 101
3.2.4 Processor core local RAM . . . 102
3.3 Embedded Flash memory . . . 102
3.3.1 Flash memory controller . . . 103
3.3.2 Flash memory array . . . 103
3.4 End-to-end Error Correction Code (e2eECC) . . . 106
3.5 Security features . . . 108

4 Signal Description . . . 109
4.1 Production packages . . . 109
4.2 Emulation package . . . 109
4.3 Package pinouts and ballouts . . . 109

5 Memory Map . . . 110
5.1 Peripheral memory . . . 112
5.2 Flash memory . . . 120
5.3 Emulation and debug memory . . . 124
5.4 System memory . . . 125
5.5 Local memory . . . 125
5.6 UTest Flash memory map . . . 126
5.7 Security module memory . . . 127

6 Functional safety . . . 128
6.1 Introduction . . . 128
6.2 Safety overview . . . 128
6.3 Module categorization . . . 128
6.4 System implementation . . . 130
6.4.1 General concept . . . 130
6.4.2 Dual-core lockstep . . . 160
6.4.3 Common cause failure measures . . . 163
6.4.4 ECC . . . 163

7 Device configuration . . . 167
7.1 Introduction . . . 167

7.2 Core modules . . . 167
7.3 System modules . . . 173
7.3.1 SIUL2 configuration . . . 173
7.3.2 Semaphores2 (SEMA42) configuration . . . 173
7.3.3 Crossbar switch . . . 173
7.3.4 System Memory Protection Unit (SMPU) configuration . . . 180
7.3.5 Peripheral bridge configuration . . . 183
7.3.6 Interrupt controller (INTC) configuration . . . 184
7.3.7 DMA controller configuration . . . 221
7.3.8 DMACHMUX configuration . . . 225
7.3.9 Platform Configuration Module (PCM) configuration . . . 230
7.3.10 Wakeup unit (WKPU) configuration . . . 240
7.3.11 Crossbar integrity checker (XBIC) . . . 244
7.4 Clocking . . . 244
7.5 Memories and memory interfaces . . . 244
7.5.1 Flash memory controller (PFLASH) configuration . . . 244
7.5.2 Platform RAM Controller (PRAMC) configuration . . . 246
7.5.3 Decorated Storage Memory Controller (DSMC) . . . 246
7.6 Analog modules . . . 247
7.6.1 Temperature sensor configuration . . . 247
7.6.2 SARADC . . . 247
7.6.3 SDADC . . . 248
7.6.4 Body Cross Triggering Unit (BCTU) configuration . . . 248
7.7 Timers . . . 250
7.7.1 System Timer Module (STM) configuration . . . 250
7.7.2 Software Watchdog Timer (SWT) configuration . . . 250
7.7.3 PIT configuration . . . 252
7.7.4 GTM subsystem configuration . . . 254
7.8 Communication interfaces . . . 256
7.8.1 Ethernet configuration . . . 256
7.8.2 CAN subsystem configuration . . . 258
7.8.3 LFAST and SIPI . . . 258
7.8.4 DSPI configuration . . . 260
7.8.5 FlexRay configuration . . . 262
7.8.6 PSI5 controller configuration . . . 263
7.8.7 SENT Receiver (SRX) configuration . . . 263

7.8.8 LINFlexD . . . 267
7.9 Reset and Boot modules . . . 269
7.9.1 BAF configuration . . . 272
7.9.2 System Status and Configuration Module (SSCM) configuration . . . 273
7.10 Safety modules . . . 274
7.10.1 CRC . . . 274
7.10.2 MEMU configuration . . . 275
7.10.3 Indirect Memory Access (IMA) configuration . . . 289
7.10.4 FCCU configuration . . . 293
7.10.5 Register protection (REG_PROT) configuration . . . 295
7.10.6 STCU2 configuration . . . 305
7.11 Security modules . . . 313
7.11.1 Password and Device Security Module (PASS) configuration . . . 313
7.11.2 Tamper Detection Module (TDM) configuration . . . 318

8 Reset and Boot . . . 325
8.1 Introduction . . . 325
8.1.1 TEST flash memory block . . . 325
8.1.2 UTEST flash memory block . . . 325
8.1.3 Boot Assist Flash . . . 325
8.2 Modules used in reset sequence . . . 326
8.2.1 Power Management Controller . . . 326
8.2.2 Reset Generation Module . . . 326
8.2.3 Mode Entry module . . . 327
8.2.4 System Status and Configuration Module . . . 327
8.2.5 Self-Test Control Unit . . . 327
8.3 Reset sequence . . . 327
8.3.1 Power-on and the Reset Generation Module . . . 327
8.3.2 Power-up phase: power stabilization . . . 330
8.3.3 PHASE0 Phase: analog supply initial configuration . . . 331
8.3.4 PHASE1[DEST] Phase: temporization and monitoring setup . . . 331
8.3.5 PHASE2[DEST] Phase: flash initial configuration . . . 331
8.3.6 PHASE3[DEST] Phase: device configuration . . . 332
8.3.7 IDLE[DEST] Phase: self-test execution . . . 333
8.3.8 PHASE1[FUNC] Phase: temporization and monitoring setup . . . 334
8.3.9 PHASE2[FUNC] Phase: flash initial configuration . . . 334

8.3.10 PHASE3[FUNC] Phase: device configuration monitoring 334
8.3.11 IDLE[FUNC] Phase 335
8.3.12 System start-up 335
8.3.13 Waking-up other CPUs 343
8.3.14 BAF Bootloader 343

9 Device Configuration Format (DCF) Records 345
9.1 Introduction 345
9.2 DCF clients 346
9.3 DCF records 346
9.3.1 UTEST DCF records 350
9.4 DCF client table 350
9.4.1 DCF client list 351
9.4.2 BAF configuration DCF register 363
9.4.3 Miscellaneous DCF registers 364

10 Power management 372
10.1 Overview 372
10.1.1 Power management framework 373
10.1.2 Power management supply description 373
10.1.3 Power management controller overview 375
10.2 Low power mode support 377
10.2.1 Low power mode (HALT/STOP/STANDBY) 378
10.3 Flash power requirements 379
10.4 Device trimming 379
10.5 Supply monitoring (POR and LVDs) 379
10.5.1 Power-on reset (POR) 380
10.5.2 Behavior of device LVD / HVD 380
10.5.3 Voltage detections (MVDs, LVDs, HVDs, UVDs) 381
10.6 Power sequence 384
10.6.1 Power-up sequence 384
10.6.2 Power-down sequence 388
10.6.3 Brown-out management 388
10.6.4 Low voltage requirement during crank 389

11 Smart Stand-by Wake-up Unit (SSWU) 390

11.1 Overview . . . 390
11.2 Functional description . . . 390
11.3 Architecture . . . 391
11.4 Clocking . . . 393
11.5 Memory map and register descriptions . . . 394
11.5.1 Memory map . . . 394
11.5.2 Trigger generator subunit input selection register (TGSISR) . . . 396
11.5.3 Trigger generator subunit control register (TGSCR) . . . 396
11.5.4 Trigger compare register 0–7 (TCR0–TCR7) . . . 397
11.5.5 TGS counter compare register (TGSCCR) . . . 398
11.5.6 TGS counter reload register (TGSCRR) . . . 398
11.5.7 Commands list control register 1 (CLCR1) . . . 399
11.5.8 Commands list control register 2 (CLCR2) . . . 399
11.5.9 Trigger handler control register 1 (THCR1) . . . 400
11.5.10 Trigger handler control register 2 (THCR2) . . . 401
11.5.11 Commands list register 1–32 (CLR1–CLR32) . . . 402
11.5.12 Cross triggering unit error flag register (CTUEFR) . . . 406
11.5.13 Cross triggering unit interrupt flag register (CTUIFR) . . . 407
11.5.14 Cross triggering unit control register (CTUCR) . . . 408
11.5.15 Double buffered registers . . . 409
11.6 SSWU module descriptions . . . 410
11.6.1 Stand-by eCTU . . . 410
11.6.2 CD (Command Dispatcher) . . . 414
11.6.3 ADC . . . 417
11.6.4 OPC . . . 418
11.6.5 PDC . . . 419
11.6.6 TU . . . 420
11.7 SSWU Configuration example . . . 421
11.7.1 Description . . . 421
11.7.2 Registers configuration . . . 421

12 Security . . . 424
12.1 Basic security . . . 424
12.2 Advanced security . . . 424
12.3 Detailed security information . . . 425

13 Calibration and Debug 426
13.1 Core debug support 426
13.2 Run control and memory access 426
13.2.1 Debug and Calibration Interface (DCI) 427
13.2.2 JTAG Data Communication (JDC) 430
13.2.3 Sequence Processing Unit (SPU) 430
13.3 Calibration interface 442
13.3.1 JTAG Master (JTAGM) 443
13.3.2 Debug LFAST 443
13.3.3 Development Trigger Semaphore (DTS) 443
13.4 Debug over CAN 444
13.5 Nexus Trace Aurora interface 444
13.5.1 Nexus Aurora overview 447
13.5.2 Nexus Aurora Router (NAR) 448
13.5.3 Nexus Aurora Link (NAL) 451
13.5.4 Nexus Aurora PHY (NAP) 451
13.6 Nexus clients 452
13.6.1 e200z4 Nexus 3 452
13.6.2 GTM Development Interface (GTMDI) 453
13.6.3 Nexus Crossbar Multi-master Client (NXMC) 453
13.7 Data trace filtering 455

14 e200z4d Core Complex Overview 456
14.1 Overview of the e200z420n3, e200z419, and e200z425n3 cores 456
14.2 Features 458
14.3 Microarchitecture summary 459
14.3.1 Instruction unit features 461
14.3.2 Integer unit features 461
14.3.3 Load/Store unit features 461
14.3.4 MPU features 462
14.3.5 Cache features 462
14.3.6 Local memory features 463
14.3.7 e200z420n3 and e200z425n3 system bus features 463
14.3.8 e200z419 system features 463

15 Core (z420n3) Description 464

15.1 Overview of the Core (z420n3) 464
15.2 Register Model 464
15.3 Dual Issue Operation 468
15.4 Reservation Instructions and Cache Interactions 468
15.5 Signal Processing Extension / Embedded Floating-point Status and Control Register (SPEFSCR) 468
15.6 Cache 471
15.6.1 Cache Overview 471
15.6.2 L1 Cache Control and Status Register 0 (L1CSR0) 471
15.6.3 L1 Cache Control and Status Register 1 (L1CSR1) 474
15.6.4 L1 Cache Configuration Register 0 (L1CFG0) 476
15.6.5 L1 Cache Configuration Register 1 (L1CFG1) 477
15.6.6 Data Cache Software Coherency 478
15.6.7 Data Cache Hardware Coherency 478
15.6.8 Cache Invalidate by Set and Way 478
15.6.9 Cache EDC/ECC Protection 480
15.6.10 Cache Error Injection 481
15.7 Exceptions 481
15.7.1 Exception Syndrome Register 483
15.7.2 Machine State Register 484
15.7.3 Machine Check Syndrome Register (MCSR) 485
15.7.4 Interrupt Vector Prefix Registers (IVPR) 488
15.7.5 Interrupt Definitions 489
15.8 MPU 498
15.8.1 MPU Overview 498
15.8.2 Software Interface and MPU Instructions 498
15.8.3 MPU Read Entry Instruction (mpure) 498
15.8.4 MPU Write Entry Instruction (mpuwe) 499
15.8.5 MPU Synchronize Instruction (mpusync) 499
15.8.6 MMU/MPU Configuration Register (MMUCFG) 500
15.8.7 MPU0 Configuration Register (MPU0CFG) 500
15.8.8 MPU0 Control and Status Register 0 (MPU0CSR0) 501
15.8.9 MPU Assist Registers (MAS) 504
15.8.10 MAS Registers Summary 509
15.9 Local memories 509
15.9.1 Local instruction and data memory overview 509

15.9.2 Local memory control and configuration 509
15.10 End-to-End ECC support 522
15.10.1 e2eECC control and configuration 523

16 Core (z425n3) description 527
16.1 Overview of the Core (z425n3) 527
16.2 Register model 527
16.3 Dual issue operation 530
16.4 Reservation instructions and cache interactions 531
16.5 Signal Processing Extension / Embedded Floating-point Status and Control Register (SPEFSCR) 531
16.6 Cache 534
16.6.1 Cache overview 534
16.6.2 L1 Cache Control and Status Register 0 (L1CSR0) 534
16.6.3 L1 Cache Control and Status Register 1 (L1CSR1) 535
16.6.4 L1 Cache Configuration Register 0 (L1CFG0) 537
16.6.5 L1 Cache Configuration Register 1 (L1CFG1) 538
16.6.6 Cache Invalidate by Set and Way 539
16.6.7 Cache EDC/ECC protection 540
16.6.8 Cache error injection 541
16.7 Exceptions 541
16.7.1 Exception syndrome register 542
16.7.2 Machine State Register 543
16.7.3 Machine Check Syndrome Register (MCSR) 545
16.7.4 Interrupt Vector Prefix Registers (IVPR) 548
16.7.5 Interrupt definitions 548
16.8 MPU 558
16.8.1 MPU overview 558
16.8.2 Software interface and MPU instructions 558
16.8.3 MPU read entry instruction (mpure) 558
16.8.4 MPU Write Entry Instruction (mpuwe) 559
16.8.5 MPU Synchronize Instruction (mpusync) 559
16.8.6 MMU/MPU Configuration Register (MMUCFG) 559
16.8.7 MPU0 Configuration Register (MPU0CFG) 560
16.8.8 MPU0 Control and Status Register 0 (MPU0CSR0) 561
16.8.9 MPU Assist registers (MAS) 564

16.8.10 MAS registers summary 569
16.9 Local memories 569
16.9.1 Local instruction and data memory overview 569
16.9.2 Local memory control and configuration 569
16.10 End-to-End ECC support 582
16.10.1 e2eECC control and configuration 583

17 System Integration Unit Lite2 (SIUL2) 587
17.1 Introduction 587
17.1.1 Overview 587
17.1.2 Features 589
17.1.3 Register protection 589
17.2 Memory map and register description 590
17.2.1 Memory map 590
17.2.2 Register descriptions 591
17.2.3 Multiplexed Signal Configuration Registers 609
17.3 Functional description 610
17.3.1 General 610
17.3.2 Pad control 611
17.3.3 General purpose input or output pads (GPIO) 611
17.3.4 External interrupts/DMA requests (EIRQ pins) 612

18 Crossbar switch (XBAR) 616
18.1 Introduction 616
18.2 Features 616
18.3 Memory map and register definition 616
18.3.1 XBAR Priority Registers Slave (XBAR_PRSn) 617
18.3.2 XBAR Control Register (XBAR_CRSn) 620
18.3.3 Master General Purpose Control Register (XBAR_MGPCRn) 621
18.4 Functional description 622
18.4.1 General operation 622
18.4.2 Register coherency 623
18.4.3 Arbitration 623
18.5 Initialization/application information 624

19 Crossbar Integrity Checker (XBIC) 625

19.1 Overview . . . 625
19.2 Features . . . 625
19.3 Block diagram . . . 626

19.6 Functional description . . . 633

20 Peripheral Bridge (PBRIDGE) . . . 636
20.1 Introduction . . . 636
20.1.1 Features . . . 636
20.1.2 General operation . . . 636
20.2 Memory map and register definition . . . 636
20.2.1 Master Privilege Register A (MPRA) . . . 638
20.2.2 Master Privilege Register B (MPRB) . . . 639
20.2.3 Peripheral Access Control Register (PACRx) . . . 640
20.2.4 Off-Platform Peripheral Access Control Registers (OPACRx) . . . 642
20.3 Functional description . . . 646
20.3.1 Access support . . . 646

21 System Memory Protection Unit (SMPU) . . . 647
21.1 Overview . . . 647
21.2 Block diagram . . . 647
21.3 Features . . . 648
21.4 Memory map and register definition . . . 649
21.4.1 Memory map . . . 649
21.4.2 Register descriptions . . . 650
21.5 Functional description . . . 657
21.5.1 Access evaluation macro . . . 657
21.5.2 Putting it all together and error terminations . . . 658
21.6 Initialization information . . . 659
21.7 Application information . . . 659

22 Intelligent AHB Gasket (IAHBG) . . . 661

22.1 Introduction . . . 661
22.2 Timing modes . . . 661
22.2.1 1:1 . . . 661
22.2.2 2:1 . . . 661
22.2.3 1:2 . . . 662

23 Semaphores2 (SEMA42) . . . 663
23.1 Introduction . . . 663
23.1.1 Multi-core programming . . . 663
23.1.2 Features . . . 664
23.2 Memory map/register definition . . . 665
23.2.1 Semaphores2 Gate n Register (SEMA4_GATEn) . . . 666
23.2.2 Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT) . . . 667
23.3 Functional description . . . 668

24 Interrupt Controller (INTC) . . . 671
24.1 Introduction . . . 671
24.2 Block diagram . . . 671
24.3 Features . . . 673
24.4 Modes of operation . . . 673
24.4.1 Software vector mode . . . 673
24.4.2 Hardware vector mode . . . 674
24.5 Memory map and register definition . . . 674
24.5.1 Memory map . . . 674
24.5.2 Register descriptions . . . 675
24.6 Functional description . . . 683
24.6.1 Interrupt request sources . . . 683
24.6.2 Priority management . . . 684
24.6.3 Handshaking with processor . . . 686
24.7 Initialization/application information . . . 688
24.7.1 Initialization flow . . . 688
24.7.2 Interrupt exception handler . . . 689
24.7.3 ISR, RTOS, and task hierarchy . . . 691
24.7.4 Order of execution . . . 691
24.7.5 Priority ceiling protocol . . . 692
24.7.6 Selecting priorities according to request rates and deadlines . . . 696

24.7.7 Software-settable interrupt requests 696
24.7.8 Lowering priority within an ISR 697
24.7.9 Negating an interrupt request outside of its ISR 697
24.7.10 Examining LIFO contents 698
24.8 Interrupt sources 698

25 Enhanced Direct Memory Access (eDMA) 699
25.1 Introduction 699
25.1.1 Features 699
25.2 Modes of operation 700
25.2.1 Normal mode 700
25.2.2 Debug mode 701
25.2.3 Wait mode 701
25.3 Memory map/register definition 701
25.3.1 Control Register (eDMA_CR) 703
25.3.2 Error Status Register (eDMA_ES) 705
25.3.3 Enable Request Register High (eDMA_ERQH) 706
25.3.4 Enable Request Register Low (eDMA_ERQL) 707
25.3.5 Enable Error Interrupt Register High (eDMA_EEIH) 708
25.3.6 Enable Error Interrupt Register Low (eDMA_EEIL) 709
25.3.7 Set Enable Request Register (eDMA_SERQ) 709
25.3.8 Clear Enable Request Register (eDMA_CERQ) 710
25.3.9 Set Enable Error Interrupt Register (eDMA_SEEI) 711
25.3.10 Clear Enable Error Interrupt Register (eDMA_CEEI) 711
25.3.11 Clear Interrupt Request Register (eDMA_CINT) 712
25.3.12 Clear Error Register (eDMA_CERR) 712
25.3.13 Set START Bit Register (eDMA_SSRT) 713
25.3.14 Clear DONE Status Bit Register (eDMA_CDNE) 714
25.3.15 Interrupt Request Register High (eDMA_INTH) 714
25.3.16 Interrupt Request Register Low (eDMA_INTL) 715
25.3.17 Error Register High (eDMA_ERRH) 716
25.3.18 Error Register Low (eDMA_ERRL) 717
25.3.19 Hardware Request Status Register High (eDMA_HRSH) 718
25.3.20 Hardware Request Status Register Low (eDMA_HRSL) 719
25.3.21 Channel n Priority Register (eDMA_DCHPRIn) 719
25.3.22 Channel n Master ID Register (eDMA_DCHMIDn) 720
25.3.23 TCD Source Address (eDMA_TCDn_SADDR) 721

25.3.24 TCD Transfer Attributes (eDMA_TCDn_ATTR) 722
25.3.25 TCD Signed Source Address Offset (eDMA_TCDn_SOFF) 722
25.3.26 TCD Minor Byte Count (Minor Loop Disabled) (eDMA_TCDn_NBYTES_MLNO) 723
25.3.27 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (eDMA_TCDn_NBYTES_MLOFFNO) 724
25.3.28 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (eDMA_TCDn_NBYTES_MLOFFYES) 725
25.3.29 TCD Last Source Address Adjustment (eDMA_TCDn_SLAST) 726
25.3.30 TCD Destination Address (eDMA_TCDn_DADDR) 726
25.3.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCDn_CITER_ELINKYES) 727
25.3.32 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (eDMA_TCDn_CITER_ELINKNO) 728
25.3.33 TCD Signed Destination Address Offset (eDMA_TCDn_DOFF) 728
25.3.34 TCD Last Destination Address Adjustment/Scatter Gather Address (eDMA_TCDn_DLASTSGA) 729
25.3.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCDn_BITER_ELINKYES) 730
25.3.36 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (eDMA_TCDn_BITER_ELINKNO) 731
25.3.37 TCD Control and Status (eDMA_TCDn_CSR) 731
25.4 Functional description 734
25.4.1 eDMA microarchitecture 734
25.4.2 eDMA basic data flow 735
25.4.3 Error reporting and handling 738
25.4.4 Channel preemption 740
25.4.5 eDMA performance 740
25.5 Initialization/application information 743
25.5.1 eDMA initialization 743
25.5.2 DMA programming errors 745
25.5.3 DMA Arbitration mode considerations 746
25.5.4 DMA transfer 747
25.5.5 eDMA TCDn status monitoring 750
25.5.6 Channel linking 751
25.5.7 Dynamic programming 752

26 DMA channel multiplexer (DMACHMUX) 756

26.1 Introduction 756

26.1.1 Overview . . . 756
26.1.2 Features . . . 757
26.1.3 Modes of operation . . . 757
26.2 External signal description . . . 757
26.2.1 Overview . . . 757
26.3 Memory map and register definition . . . 757
26.3.1 Register descriptions . . . 758
26.4 Functional description . . . 759
26.4.1 DMA channels with periodic triggering capability . . . 759
26.4.2 DMA channels with no triggering capability . . . 761
26.4.3 “Always Enabled” DMA sources . . . 761
26.5 Initialization/application information . . . 762
26.5.1 Reset . . . 762
26.5.2 Enabling and configuring sources . . . 762

27 Clocking . . . 767
27.1 Introduction . . . 767
27.2 Clock generation . . . 767
27.2.1 MC_CGM registers . . . 770
27.3 System clock frequency limitations . . . 772
27.3.1 JTAG frequencies . . . 775
27.4 Default clock configuration . . . 776
27.5 Clock sources . . . 776
27.5.1 PLL . . . 777
27.5.2 External oscillator (XOSC) . . . 780
27.5.3 16 MHz internal RC oscillator (IRCOSC) . . . 782
27.6 Peripheral clocks . . . 782
27.6.1 HSM clock divider . . . 784
27.6.2 PSI5 clock dividers . . . 784
27.6.3 LFAST clocking . . . 784
27.6.4 Ethernet clocking . . . 785
27.6.5 FlexRay clocking . . . 786
27.6.6 M_TTCAN/M_CAN clocking . . . 787
27.6.7 Sigma-Delta ADC clocking . . . 787
27.6.8 System Clock/GTM output clock . . . 788
27.7 Clock monitoring . . . 789

27.7.1 CMU configuration . . . 789
27.7.2 PLL0 monitor . . . 792
27.7.3 External oscillator (XOSC) monitor . . . 792
27.7.4 Internal RC oscillator (IRCOSC) monitor . . . 792
27.7.5 System clock monitors . . . 792
27.8 Loss of system clock behavior . . . 793
27.8.1 Loss of PLL/XOSC clock . . . 793
27.8.2 Loss of IRCOSC clock . . . 793
27.9 Progressive clock switching . . . 794

28 Dual PLL digital interface (PLLDIG) . . . 795
28.1 Introduction . . . 795
28.2 Block diagram . . . 795
28.3 Features . . . 796
28.4 Modes of operation . . . 796
28.4.1 Normal mode with reference, PLL0 or both PLLs enabled . . . 796
28.5 Memory map and register definition . . . 797
28.5.1 Memory map . . . 797
28.5.2 Register descriptions . . . 797
28.5.3 Register classification for safety requirements . . . 806
28.6 Functional description . . . 806
28.6.1 Input clock frequency . . . 807
28.6.2 Clock configuration . . . 807
28.6.3 Frequency modulation . . . 808
28.7 Initialization information . . . 810

29 Clock Monitor Unit (CMU) . . . 812
29.1 Introduction . . . 812
29.1.1 Main features . . . 812
29.2 Block diagram . . . 812
29.3 Signals . . . 812
29.4 Memory map and register definition . . . 813
29.4.1 Register descriptions . . . 814
29.5 Functional description . . . 819
29.5.1 Frequency meter . . . 819
29.5.2 CLKMN0_RMT supervisor . . . 819

29.5.3 CLKMN1 supervisor 819

30 Clock Generation Module (MC_CGM) 821

30.1 Introduction 821

30.1.1 Overview 821

30.1.2 Features 823

30.2 External signal description 823

30.3 Memory map and register definition 823

30.3.1 Register descriptions 825

30.4 Functional description 873

30.4.1 System clock generation 873

30.4.2 Auxiliary clock generation 877

30.4.3 Dividers functional description 879

31 OSC digital interface (XOSC) 882

31.1 Introduction 882

31.2 Functional description 882

31.2.1 Oscillator power-down control and status 882

31.2.2 Oscillator startup delay 882

31.2.3 Oscillator clock available interrupt 883

31.2.4 Oscillator bypass mode 883

31.3 Memory map and register definition 884

31.3.1 Register descriptions 884

32 IRCOSC digital interface 886

32.1 Introduction 886

32.2 Functional description 886

32.3 Memory map and register definition 886

32.3.1 Register descriptions 887

33 LPRC digital interface 890

33.1 Introduction 890

33.2 Low Power RC oscillator 890

33.3 Memory map and register definition 890

33.3.1 Register description 891

34 OSC32K digital interface (OSC32K) 892
34.1 Introduction 892
34.2 Memory map and register definition 892
34.2.1 Register descriptions 893
34.3 Functional description 894

35 Platform RAM controller AHB (PRAMC_AHB) 895
35.1 Introduction 895
35.2 SRAM controller memory map and register definitions 896
35.2.1 Platform RAM configuration register 1 (PRCR1) 896
35.3 Functional description 898
35.3.1 Read/Write introduction 898
35.3.2 Writes 899
35.4 Initialization/application information 899
35.5 Safety considerations 900
35.5.1 Hsiao ECC algorithm 900
35.5.2 Transaction monitor 903

36 Flash memory controller 905
36.1 Introduction 905
36.2 Features 905
36.3 Block diagrams 906
36.4 Flash memory controller memory map 906
36.4.1 Overview 906
36.5 Functional description 931
36.5.1 Basic interface protocol 931
36.5.2 Access protections 931
36.5.3 Read cycles – buffer miss 932
36.5.4 Read cycles – buffer hit 932
36.5.5 Error termination 932
36.5.6 Flash error response operation 932
36.5.7 Security module exclusive control 932
36.5.8 Access pipelining 933
36.5.9 Line read buffers and prefetch operation 934
36.5.10 Instruction/Data prefetch triggering 935
36.5.11 Per-Master prefetch triggering 935

36.5.12 Buffer allocation . . . 935
36.5.13 PFlash calibration remap support . . . 935
36.5.14 Safety considerations . . . 940
36.5.15 e2eECC on data Flash accesses . . . 944
36.5.16 Array integrity considerations . . . 944

37 Embedded Flash Memory . . . 945

37.1 Introduction . . . 945
37.1.1 Overview . . . 945
37.1.2 Features . . . 948
37.1.3 Modes of operation . . . 948
37.2 Flash memory map and description . . . 949
37.2.1 Flash array memory map . . . 949
37.3 Register memory maps and descriptions . . . 953
37.3.1 Register memory maps . . . 953
37.3.2 User register descriptions . . . 955
37.4 Functional description . . . 1014
37.4.1 Reset . . . 1015
37.4.2 Power-down mode (Disable mode) . . . 1015
37.4.3 Low-power mode (Sleep mode) . . . 1016
37.4.4 Read mode . . . 1016
37.4.5 Modify mode . . . 1020
37.4.6 Alternate program and erase interface . . . 1027
37.4.7 User Test mode . . . 1029
37.4.8 Protection strategy . . . 1034

38 Flash Memory Programming and Configuration . . . 1036

38.1 Selection of Flash memory blocks for erase . . . 1037
38.2 Non-secure write protection . . . 1038
38.3 Secure write protection . . . 1038
38.3.1 Implementing secure write protection . . . 1040
38.3.2 Overriding secure write protection . . . 1042
38.4 Secure read protection . . . 1044
38.4.1 Implementing secure read protection . . . 1045
38.4.2 Overriding secure read protection . . . 1047
38.5 Debug port enable/disable . . . 1048

38.6 Tamper detection 1048
38.6.1 Implementing tamper detection 1049
38.6.2 Creating the tamper detect diary 1049
38.6.3 Assigning blocks to Tamper Detection Regions (TDRs) 1050
38.6.4 Overriding tamper detection 1051
38.7 Implementing OTP 1052
38.8 Implementing test mode disable 1052
38.8.1 Unconditional test mode disable seal 1052
38.8.2 Passcode-protected test mode disable seal 1053
38.8.3 Selecting Flash memory blocks for test mode disable seal 1053
38.9 Security configuration planning 1054
38.9.1 Hardware Security Module (HSM) 1054
38.9.2 Creating password groups 1054
38.9.3 Planning secure write protection 1055
38.9.4 Planning secure read protection 1055
38.9.5 Planning debug port enable/disable 1055
38.9.6 Planning OTP Flash memory block assignment 1055
38.9.7 Planning factory test mode disable 1055

39 Decorated Storage Memory Controller (DSMC) 1056
39.1 Introduction 1056
39.2 Decorated Stores: st[b,h,w]d{cb}x rS,rB,rA 1058
39.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container . . 1058
39.2.2 Compare-and-Store (CAST) 1060
39.2.3 Logical AND (AND) 1060
39.2.4 Logical OR (OR) 1061
39.2.5 Logical Exclusive-OR (XOR) 1061
39.3 Decorated Loads: l[b,h,w]d{cb}x rT,rB,rA 1061
39.3.1 Simple Load (SLD) 1062
39.3.2 Registers-and-Memory Exchange (SWAP) 1062
39.3.3 Load-and-Set-1(Bit) (LAS1) 1063
39.4 DSMC Instantiations 1063

40 Analog-to-Digital Converters (ADC) Configuration 1064
40.1 ADC overview 1064
40.1.1 ADC subsystem block diagram 1066

40.1.2 Analog input pin multiplexing 1066
40.2 Configuration of ADC modules 1067
40.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC) 1067
40.2.2 Successive Approximation Register Analog-to-Digital Converter (SAR ADC) 1079

41 Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface 1091
41.1 Introduction 1091
41.2 Overview 1091
41.3 Features 1093
41.4 Modes of operation 1093
41.4.1 Differential input mode 1093
41.4.2 Single-ended input mode 1093
41.4.3 External modulator mode 1094
41.5 External signal description 1094
41.5.1 Detailed signal descriptions 1094
41.6 Memory map and register descriptions 1095
41.6.1 Memory map 1095
41.6.2 Module Configuration Register (SDADC_MCR) 1096
41.6.3 Channel Selection Register (SDADC_CSR) 1100
41.6.4 Reset Key Register (SDADC_RKR) 1102
41.6.5 Status Flag Register (SDADC_SFR) 1103
41.6.6 Request Select and Enable Register (SDADC_RSER) 1105
41.6.7 Output Settling Delay Register (SDADC_OSDR) 1107
41.6.8 FIFO Control Register (SDADC_FCR) 1108
41.6.9 Software Trigger Key Register (SDADC_STKR) 1109
41.6.10 Converted Data Register (SDADC_CDR) 1110
41.6.11 WDG Threshold Register (SDADC_WTHHLR) 1111
41.7 Functional description 1111
41.7.1 Differential input mode 1112
41.7.2 Single-ended input mode 1112
41.7.3 External modulator mode 1112
41.7.4 Low consumption mode 1112
41.7.5 Analog input multiplexing and bias support 1112
41.7.6 Programmable gain and decimation rate 1113
41.7.7 High-pass filter support 1113

41.7.8 Data conversion 1113
41.7.9 Hardware triggering 1114
41.7.10 Interrupt/DMA request support 1115
41.7.11 Gain calibration support 1115
41.7.12 Offset calibration support 1116
41.8 Initialization information 1116
41.8.1 Data conversion step 1117

42 Successive Approximation Register Analog-to-Digital Converter (SARADC) 1118
42.1 Introduction 1118
42.2 Overview 1118
42.3 Feature description 1119
42.3.1 Main features 1120
42.4 Functional description 1120
42.4.1 Normal channel conversion 1121
42.4.2 Injected channel conversion 1122
42.4.3 Abort conversion 1124
42.4.4 Analog conversion timings 1124
42.4.5 Cross Triggering Unit (CTU) interface 1125
42.4.6 Test channel connection with internal analog channel 1128
42.4.7 External channel mapping to internal analog channel 1128
42.4.8 Programmable analog watchdog 1129
42.4.9 DMA functionality 1130
42.4.10 Interrupts 1130
42.4.11 External decode signals selection and delay 1131
42.4.12 Power down mode 1131
42.4.13 Stop mode 1132
42.4.14 Fast comparator mode conversion 1132
42.4.15 Smart standby wake up support 1133
42.5 Memory map and registers 1134
42.5.1 Register descriptions 1136
42.6 Start of conversion pulse delay 1180
42.7 Initialization information 1182

43 Temperature Sensor 1184

43.1 Introduction 1184
43.1.1 Signal Descriptions 1184
43.2 Functional description 1184
43.2.1 Linear temperature sensor (analog output generation) 1184
43.3 Temperature formula 1185
43.3.1 Equations for converting TSENS voltages to junction temperature . . 1185
43.3.2 Equations for converting TSENS voltages into constant reference (Digital Bandgap Voltage) 1185

44 Body Cross Triggering Unit (BCTU) 1187
44.1 Introduction 1187
44.2 Main features 1187
44.3 Block diagram 1187
44.4 Memory map and register descriptions 1187
44.4.1 Control Status Register (BCTU_CSR) 1188
44.4.2 Event Configuration Register n (BCTU_EVTCFGRn) 1189
44.5 Functional description 1190

45 System Timer Module (STM) 1191
45.1 Introduction 1191
45.1.1 Overview 1191
45.1.2 Features 1191
45.1.3 Modes of operation 1191
45.2 External signal description 1191
45.3 Memory map and register definition 1191
45.3.1 Memory map 1191
45.3.2 Register descriptions 1192
45.4 Functional description 1195

46 Software Watchdog Timer (SWT) 1196
46.1 Introduction 1196
46.1.1 Overview 1196
46.1.2 Features 1196
46.1.3 Modes of operation 1196
46.2 External signal description 1196
46.3 Memory map and register definition 1197

46.3.1 Register descriptions 1197
46.4 Functional description 1202
46.4.1 Introduction 1202
46.4.2 Configuration locking 1203
46.4.3 Unlock sequence 1203
46.4.4 Servicing operations 1203
46.4.5 Time-out 1204
46.4.6 Initialization 1205

47 GTM343 Integration (GTMINT) Module 1206
47.1 Introduction 1206
47.1.1 Features 1207
47.1.2 Modes of Operation 1208
47.1.3 Block Diagram 1209
47.2 Memory Map and Register Definition 1209
47.2.1 Module Memory Map 1210
47.2.2 Register Descriptions 1239
47.3 Functional Description 1242
47.3.1 GTM-IP Timer 1243
47.3.2 GTMDI Debug Interface 1244
47.3.3 Error Detection on GTM Memories Accesses 1244
47.3.4 Stop Mode Description 1248
47.3.5 Debug / Halt Mode Description 1249
47.3.6 GTM-IP Timer Software Reset Description 1249
47.3.7 AEI Interface Software Reset Description 1249
47.3.8 Interrupt and DMA Support Logic 1249
47.3.9 Clock Enables 1251
47.3.10 ADC Interface 1251
47.4 Initialization/Application Information 1251

48 Generic Timer Module (GTM343) 1252
48.1 About this module 1252
48.2 For more information 1252

49 GTM Development Interface (GTMDI) 1253
49.1 Introduction 1253

49.2 Overview . . . 1253
49.2.1 Features . . . 1257
49.2.2 Modes of operation . . . 1258
49.2.3 DATA port . . . 1258
49.3 External signal description . . . 1258
49.3.1 Event in (EVTI) . . . 1259
49.3.2 Event out EVTO[1:0] . . . 1259
49.3.3 Test clock input (TCK) . . . 1259
49.3.4 Test data input (TDI) . . . 1259
49.3.5 Test data output (TDO) . . . 1259
49.3.6 Test Mode Select (TMS) . . . 1260
49.4 Register definition . . . 1260
49.4.1 Register descriptions . . . 1262
49.5 Functional description . . . 1334
49.5.1 Debug enable logic . . . 1334
49.5.2 TIM-TOM-ATOM selection and control logic . . . 1335
49.5.3 GTMDI reset configuration . . . 1336
49.5.4 Message Data Bus —interface with NAR module . . . 1337
49.5.5 IEEE 1149.1 (JTAG) input port . . . 1341
49.5.6 Nexus Class 1 development support . . . 1346
49.5.7 Debug status . . . 1346
49.5.8 Data trace . . . 1346
49.5.9 Fetch trace . . . 1349
49.5.10 Watchpoint trace . . . 1351
49.6 Initialization/application information . . . 1352
49.6.1 Accessing GTMDI tool-mapped registers . . . 1352

50 Periodic Interrupt Timer (PIT) . . . 1353
50.1 Introduction . . . 1353
50.1.1 Block diagram . . . 1353
50.1.2 Features . . . 1354
50.2 Signal description . . . 1354
50.2.1 Memory map/register description . . . 1354
50.3 Functional description . . . 1362
50.3.1 General . . . 1362
50.3.2 Interrupts . . . 1363

50.3.3 Chained timers . . . 1363
50.4 Initialization and application information . . . 1364
50.5 Example Configuration for the Lifetime Timer . . . 1365

51 Enhanced Modular IO Subsystem (eMIOS) . . . 1366
51.1 Introduction . . . 1366
51.1.1 Overview of the eMIOS module . . . 1366
51.1.2 Features of the eMIOS module . . . 1366
51.1.3 Modes of operation . . . 1367
51.1.4 Channel implementation . . . 1367
51.2 External signal description . . . 1369
51.3 Memory map and register description . . . 1369
51.3.1 Memory maps . . . 1369

52.3.7 M_CAN functional description . . . 1479
52.3.8 Timestamp generation . . . 1489
52.3.9 Timeout counter . . . 1489
52.3.10 Rx handling . . . 1490

52.3.11 Dedicated Rx Buffers . . . 1496
52.3.12 Debug on CAN Support . . . 1497
52.3.13 Tx handling . . . 1499
52.3.14 FIFO acknowledge handling . . . 1503
52.3.15 Clock Calibration on CAN Unit (CCCU) . . . 1504
52.4 Time Triggered Modular CAN (M_TTCAN) core . . . 1516
52.4.1 Features . . . 1518
52.4.2 Block Diagram . . . 1519
52.4.3 Dual clock sources . . . 1520
52.4.4 Dual interrupt lines . . . 1520
52.4.5 Memory map and registers description . . . 1521
52.4.6 Message RAM . . . 1591
52.4.7 M_TTCAN functional description . . . 1601
52.4.8 FIFO acknowledge handling . . . 1623
52.4.9 M_TTCAN operations . . . 1624
52.4.10 M_TTCAN configuration . . . 1625
52.4.11 Message scheduling . . . 1627
52.4.12 M_TTCAN gap control . . . 1634
52.4.13 Stop watch . . . 1635
52.4.14 Local time, cycle time, global time, and external clock synchronization . . . 1635
52.4.15 M_TTCAN error level . . . 1638
52.4.16 M_TTCAN message handling . . . 1639
52.4.17 M_TTCAN interrupt and error handling . . . 1642
52.4.18 Level 0 . . . 1642
52.4.19 Synchronization to external time schedule . . . 1645
52.5 CAN RAM arbiter . . . 1646
52.5.1 Features . . . 1646
52.5.2 Functional overview using examples . . . 1647
52.6 SRAM interface and memory organization . . . 1647
52.6.1 ECC controller . . . 1647
52.7 Time Triggered CAN matrix and basic cycles management . . . 1648
52.8 CAN nodes 1 and 2 I/Os sharing . . . 1649
52.9 External Time Stamp . . . 1649
52.10 External signal description . . . 1650
52.11 Shared memory map . . . 1650

53 Serial Interprocessor Interface (SIPI) 1653

53.1 Introduction 1653

53.1.1 Scalability 1653

53.2 Overview 1653

53.3 SIPI block diagram 1655

53.4 Feature description 1655

53.4.1 Main features 1655

53.4.2 Standard features 1656

53.5 SIPI operation from reset 1656

53.6 Functional description 1656

53.6.1 External signals 1656

53.6.2 Frame format 1656

53.7 Transfer types 1662

53.7.1 Read transfer 1662

53.7.2 Register read answer transfer 1663

53.7.3 Register Write transfer 1665

53.7.4 Write acknowledge transfer 1667

53.7.5 ID request response 1668

53.8 Transfer API and flow charts 1669

53.9 DMA handling in transfer initiator mode 1675

53.10 Modes of operation 1676

53.10.1 Initialization mode (INIT) 1676

53.10.2 Normal Mode (NM) 1676

53.10.3 Module Disable (MD) 1677

53.11 Errors 1677

53.11.1 Timeout error 1677

53.11.2 CRC error 1677

53.11.3 Maximum count reached error 1677

53.11.4 Transaction ID error 1678

53.11.5 Acknowledge error 1678

53.12 CRC calculation 1678

53.13 Interrupt logic 1678

53.14 SIPI control and status overview 1679

53.15 Memory map and register description 1680

53.15.1 Register descriptions 1682

54 Zipwire 1696
54.1 Overview 1696
54.2 Introduction 1696
54.3 Zipwire block diagram 1696
54.4 Architecture 1697
54.5 LFAST clocking 1698
54.6 Zipwire interconnections 1698

55 LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications 1700
55.1 Introduction 1700
55.2 Block diagram 1700
55.3 External signals 1700
55.3.1 LFAST operating data rates 1701
55.4 LFAST frame structure 1701
55.5 Features 1704
55.6 Memory map and register definition 1704
55.6.1 Memory map 1704
55.6.2 Register descriptions 1706
55.6.3 Register safety classification requirements 1736
55.7 Functional description 1737
55.7.1 Startup procedure 1737
55.7.2 Line Receiver (LR) 1739
55.7.3 Transmit controller 1749
55.7.4 CTS mode support 1751
55.7.5 Frames supported 1752
55.7.6 Frame flow 1753
55.7.7 Test and debug support 1759
55.7.8 Interrupts 1766
55.8 Packet memory 1768
55.9 Resets 1769
55.10 Clocks 1770
55.10.1 Clocking strategy 1770
55.10.2 Slow speed clock 1771
55.10.3 Rx controller clocks 1773

55.10.4 Tx controller clocks 1774

56 Ethernet 1776

56.1 Overview 1776

56.1.1 Ethernet module Features 1777

56.2 Memory map and register description 1783

56.2.1 MAC Configuration Register (MAC_CONFIGURATION) 1793

56.2.2 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION) 1798

56.2.3 MAC Packet Filter Register (MAC_PACKET_FILTER) 1799

56.2.4 Watchdog Timeout Register (MAC_WATCHDOG_TIMEOUT) 1802

56.2.5 Hash Table Register 0 (MAC_HASH_TABLE_REG0) 1803

56.2.6 Hash Table Register 1 (MAC_HASH_TABLE_REG1) 1804

56.2.7 VLAN Tag Register (MAC_VLAN_TAG) 1805

56.2.8 VLAN Hash Table Register (MAC_VLAN_HASH_TABLE) 1807

56.2.9 VLAN Tag Inclusion Register (MAC_VLAN_INCL) 1808

56.2.10 Inner VLAN Tag Inclusion Register (MAC_INNER_VLAN_INCL) . . . 1809

56.2.11 MAC Q0 Flow Control Register (MAC_Q0_TX_FLOW_CTRL) 1811

56.2.12 MAC Q1 Flow Control Register (MAC_Q1_TX_FLOW_CTRL) 1812

56.2.13 MAC Receive Flow Control Register (MAC_RX_FLOW_CTRL) 1814

56.2.14 Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0) 1815

56.2.15 Receive Queue Control 0 Register (MAC_RXQ_CTRL0) 1816

56.2.16 Receive Queue Control 1 Register (MAC_RXQ_CTRL1) 1817

56.2.17 Receive Queue Control 2 Register (MAC_RXQ_CTRL2) 1818

56.2.18 Interrupt Status Register (MAC_INTERRUPT_STATUS) 1819

56.2.19 Interrupt Enable Register (MAC_INTERRUPT_ENABLE) 1821

56.2.20 Receive Transmit Status Register (MAC_RX_TX_STATUS) 1822

56.2.21 PMT Control and Status Register (MAC_PMT_CONTROL_STATUS) 1823

56.2.22 Wake-up Packet Filter Registers 1825

56.2.23 LPI Control and Status Register (MAC_LPI_CONTROL_STATUS) . 1832

56.2.24 LPI Timers Control Register (MAC_LPI_TIMERS_CONTROL) 1834

56.2.25 LPI Entry Timer Register (MAC_LPI_ENTRY_TIMER) 1835

56.2.26 1US Tic Counter Register (MAC_1US_TIC_COUNTER) 1835

56.2.27 Version Register (MAC_VERSION) 1836

56.2.28 Debug Register (MAC_DEBUG) 1837

56.2.29 Hardware Feature0 Register (MAC_HW_FEATURE0) 1837

56.2.30 Hardware Feature1 Register (MAC_HW_FEATURE1) 1839
56.2.31 Hardware Feature2 Register (MAC_HW_FEATURE2) 1841
56.2.32 MDIO Address Register (MAC_MDIO_ADDRESS) 1842
56.2.33 MDIO Data Register (MAC_MDIO_DATA) 1844
56.2.34 ARP Address Register (MAC_ARP_ADDRESS) 1845
56.2.35 Address0 High Register (MAC_ADDRESS0_HIGH) 1845
56.2.36 Address0 Low Register (MAC_ADDRESS0_LOW) 1846
56.2.37 MAC Address High register 1 to 31 (MAC_ADDRESSn_HIGH31_1) 1846
56.2.38 MAC Address Low register 1 to 31 (MAC_ADDRESSn_LOW31_1) 1848
56.2.39 MAC Address High register 32 to 63 (MAC_ADDRESSn_HIGH63_32) 1848
56.2.40 MAC Address Low register 32 to 63 (MAC_ADDRESSn_LOW63_32) 1849
56.2.41 MAC Address High register 64 to 127 (MAC_ADDRESSn_HIGH127_64) 1849
56.2.42 MAC Address Low register 64 to 127 (MAC_ADDRESSn_LOW127_64) 1850
56.2.43 MMC Control Register (MMC_CONTROL) 1851
56.2.44 MMC Receive Interrupt Register (MMC_RX_INTERRUPT) 1852
56.2.45 MMC Tx Interrupt Register (MMC_TX_INTERRUPT) 1856
56.2.46 MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK) 1861
56.2.47 MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK) 1863
56.2.48 Transmit Octet Count Good Bad Register (TX_OCTET_COUNT_GOOD_BAD) 1866
56.2.49 Transmit Packet Count Good Bad Register (TX_PACKET_COUNT_GOOD_BAD) 1867
56.2.50 Transmit Broadcast Packets Good Register (TX_BROADCAST_PACKETS_GOOD) 1868
56.2.51 Transmit Multicast Packets Good Register (TX_MULTICAST_PACKETS_GOOD) 1868
56.2.52 Transmit 64Octets Packets Good Bad Register (TX_64OCTETS_PACKETS_GOOD_BAD) 1869
56.2.53 Transmit 65to127Octets Packets Good Bad Register (TX_65TO127OCTETS_PACKETS_GOOD_BAD) 1869
56.2.54 Transmit 128To255Octets Packets Good Bad Register (TX_128TO255OCTETS_PACKETS_GOOD_BAD) 1870
56.2.55 Transmit 256To511Octets Packets Good Bad Register (TX_256TO511OCTETS_PACKETS_GOOD_BAD) 1871

56.2.56 Transmit 512To1023Octets Packets Good Bad Register (TX_512TO1023OCTETS_PACKETS_GOOD_BAD) 1871
56.2.57 Transmit 1024ToMaxOctets Packets Good Bad Register (TX_1024TOMAXOCTETS_PACKETS_GOOD_BAD) 1872
56.2.58 Transmit Unicast Packets Good Bad Register (TX_UNICAST_PACKETS_GOOD_BAD) 1872
56.2.59 Transmit Multicast Packets Good Bad Register (TX_MULTICAST_PACKETS_GOOD_BAD) 1873
56.2.60 Transmit Broadcast Packets Good Bad Register (TX_BROADCAST_PACKETS_GOOD_BAD) 1874
56.2.61 Transmit Underflow Error Packets Register (TX_UNDERFLOW_ERROR_PACKETS) 1874
56.2.62 Transmit Single Collision Good Packets Register (TX_SINGLE_COLLISION_GOOD_PACKETS) 1875
56.2.63 Transmit Multiple Collision Good Packets Register (TX_MULTIPLE_COLLISION_GOOD_PACKETS) 1875
56.2.64 Transmit Deferred Packets Register (TX_DEFERRED_PACKETS) 1876
56.2.65 Transmit Late Collision Packets Register (TX_LATE_COLLISION_PACKETS) 1877
56.2.66 Transmit Excessive Collision Packets Register (TX_EXCESSIVE_COLLISION_PACKETS) 1877
56.2.67 Transmit Carrier Error Packets Register (TX_CARRIER_ERROR_PACKETS) 1878
56.2.68 Transmit Octet Count Good Register (TX_OCTET_COUNT_GOOD) 1878
56.2.69 Transmit Packet Count Good Register (TX_PACKET_COUNT_GOOD) 1879
56.2.70 Transmit Excessive Deferral Error Register (TX_EXCESSIVE_DEFERRAL_ERROR) 1880
56.2.71 Transmit Pause Packets Register (TX_PAUSE_PACKETS) 1880
56.2.72 Transmit VLAN Packets Good Register (TX_VLAN_PACKETS_GOOD) 1881
56.2.73 Transmit OSize Packets Good Register (TX_OSIZE_PACKETS_GOOD) 1881
56.2.74 Receive Packets Count Good Bad Register (RX_PACKETS_COUNT_GOOD_BAD) 1882
56.2.75 Receive Octet Count Good Bad Register (RX_OCTET_COUNT_GOOD_BAD) 1882
56.2.76 Receive Octet Count Good Register (RX_OCTET_COUNT_GOOD) 1883
56.2.77 Receive Broadcast Packets Good Register (RX_BROADCAST_PACKETS_GOOD) 1884

56.2.78 Receive Multicast Packets Good Register (RX_MULTICAST_PACKETS_GOOD) 1884
56.2.79 Receive CRC Error Packets Register (RX_CRC_ERROR_PACKETS) 1885
56.2.80 Receive Alignment Error Packets Register (RX_ALIGNMENT_ERROR_PACKETS) 1885
56.2.81 Receive Runt Error Packets Register (RX_RUNT_ERROR_PACKETS) 1886
56.2.82 Receive Jabber Error Packets Register (RX_JABBER_ERROR_PACKETS) 1887
56.2.83 Receive Undersize Packets Good Register (RX_UNDERSIZE_PACKETS_GOOD) 1887
56.2.84 Receive Oversize Packets Good Register (RX_OVERSIZE_PACKETS_GOOD) 1888
56.2.85 Receive 64Octets Packets Good Bad Register (RX_64OCTETS_PACKETS_GOOD_BAD) 1888
56.2.86 Receive 65To127Octets Packets Good Bad Register (RX_65TO127OCTETS_PACKETS_GOOD_BAD) 1889
56.2.87 Receive 128To255Octets Packets Good Bad Register (RX_128TO255OCTETS_PACKETS_GOOD_BAD) 1890
56.2.88 Receive 256To511Octets Packets Good Bad Register (RX_256TO511OCTETS_PACKETS_GOOD_BAD) 1890
56.2.89 Receive 512To1023Octets Packets Good Bad Register (RX_512TO1023OCTETS_PACKETS_GOOD_BAD) 1891
56.2.90 Receive 1024ToMax Octets Packets Good bad Register (RX_1024TOMAXOCTETS_PACKETS_GOOD_BAD) 1891
56.2.91 Receive Unicast Packets Good Register (RX_UNICAST_PACKETS_GOOD) 1892
56.2.92 Receive Length Error Packets (RX_LENGTH_ERROR_PACKETS) 1893
56.2.93 Receive Out Of Range Type Packets (RX_OUT_OF_RANGE_TYPE_PACKETS) 1893
56.2.94 Receive Pause Packets Register (RX_PAUSE_PACKETS) 1894
56.2.95 Receive FIFO Overflow Packets Register (RX_FIFO_OVERFLOW_PACKETS) 1894
56.2.96 Receive VLAN Packets Good Bad Register (RX_VLAN_PACKETS_GOOD_BAD) 1895
56.2.97 Receive Watchdog Error Packets Register (RX_WATCHDOG_ERROR_PACKETS) 1895
56.2.98 Receive Error Packets Register (RX_RECEIVE_ERROR_PACKETS) 1896
56.2.99 Receive Control Packets Good Register (RX_CONTROL_PACKETS_GOOD) 1897

56.2.100 Transmit LPI USEC Counter (TX_LPI_USEC_CNTR) 1897
56.2.101 Transmit LPI Transaction Counter Register (TX_LPI_TRAN_CNTR) 1898
56.2.102 Receive LPI USEC Counter (RX_LPI_USEC_CNTR) 1898
56.2.103 Receive LPI Transaction Counter Register (RX_LPI_TRAN_CNTR) 1899
56.2.104 MMC IPC Receive Interrupt Mask Register (MMC_IPC_RX_INTERRUPT_MASK) 1899
56.2.105 MMC IPC Receive Interrupt Register (MMC_IPC_RX_INTERRUPT) 1902
56.2.106 Receive IPv4 Good Packets Register (RXIPV4_GOOD_PACKETS) 1906
56.2.107 Receive IPv4 Header Error Packets (RXIPV4_HEADER_ERROR_PACKETS) 1906
56.2.108 Receive IPv4 No Payload Packets Register (RXIPV4_NO_PAYLOAD_PACKETS) 1907
56.2.109 Receive IPv4 Fragmented Packets Register (RXIPV4_FRAGMENTED_PACKETS) 1908
56.2.110 Receive IPv4 UDP Checksum Disabled Packets Register (RXIPV4_UDP_CHECKSUM_DISABLED_PACKETS) 1908
56.2.111 Receive IPv6 Good Packets Register (RXIPV6_GOOD_PACKETS) 1909
56.2.112 Receive IPv6 Header Error Packets (RXIPV6_HEADER_ERROR_PACKETS) 1909
56.2.113 Receive IPv6 Payload Packets Register (RXIPV6_NO_PAYLOAD_PACKETS) 1910
56.2.114 Receive UDP Good Packets Register (RXUDP_GOOD_PACKETS) 1911
56.2.115 Receive UDP Error Packets Register (RXUDP_ERROR_PACKETS) 1911
56.2.116 Receive TCP Good Packets Register (RXTCP_GOOD_PACKETS) 1912
56.2.117 Receive TCP Error Packets Register (RXTCP_ERROR_PACKETS) 1912
56.2.118 Receive ICMP Good Packets Register (RXICMP_GOOD_PACKETS) 1913
56.2.119 Receive ICMP Error Packets Register (RXICMP_ERROR_PACKETS) 1914
56.2.120 Receive IPv4 Good Octets Register (RXIPV4_GOOD_OCTETS) . . 1914
56.2.121 Receive IPv4 Header Error Octets Register (RXIPV4_HEADER_ERROR_OCTETS) 1915
56.2.122 Receive IPv4 No Payload Octets Register (RXIPV4_NO_PAYLOAD_OCTETS) 1915

56.2.123 Receive IPv4 Fragmented Octets Register (RXIPV4_FRAGMENTED_OCTETS) 1916
56.2.124 Receive IPv4 UDP Checksum Disable Octets Register (RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS) 1917
56.2.125 Receive IPv6 Good Octets Register (RXIPV6_GOOD_OCTETS) . . 1917
56.2.126 Receive Header Error Octets Register (RXIPV6_HEADER_ERROR_OCTETS) 1918
56.2.127 Receive IPv6 No Payload Octets Register (RXIPV6_NO_PAYLOAD_OCTETS) 1918
56.2.128 Receive UDP Good Octets Register (RXUDP_GOOD_OCTETS) . . 1919
56.2.129 Receive UDP Error Octets Register (RXUDP_ERROR_OCTETS) . . 1920
56.2.130 Receive TCP Good Octets Register (RXTCP_GOOD_OCTETS) . . . 1920
56.2.131 Receive TCP Error Octets Register (RXTCP_ERROR_OCTETS) . . 1921
56.2.132 Receive ICMP Good Octets Register (RXICMP_GOOD_OCTETS) . 1921
56.2.133 Receive ICMP Error Octets Register (RXICMP_ERROR_OCTETS) 1922
56.2.134 Layer 3 and Layer 4 Control 0 Register (MAC_L3_L4_CONTROL0) 1922
56.2.135 Layer 4 Address 0 Register (MAC_LAYER4_ADDRESS0) 1925
56.2.136 Layer 3 Address 0 Register 0 Register (MAC_LAYER3_ADDRESS0_REG0) 1926
56.2.137 Layer3 Address1 Register 0 Register (MAC_LAYER3_ADDRESS1_REG0) 1927
56.2.138 Layer3 Address2 Register 0 Register (MAC_LAYER3_ADDRESS2_REG0) 1928
56.2.139 Layer3 Address3 Register 0 Register (MAC_LAYER3_ADDRESS3_REG0) 1928
56.2.140 Timestamp Control Register (MAC_TIMESTAMP_CONTROL) 1929
56.2.141 Sub Second Increment Register (MAC_SUB_SECOND_INCREMENT) 1932
56.2.142 System Time Seconds Register (MAC_SYSTEM_TIME_SECONDS) 1933
56.2.143 System Time Nanoseconds Register (MAC_SYSTEM_TIME_NANOSECONDS) 1934
56.2.144 System Time Seconds Update Register (MAC_SYSTEM_TIME_SECONDS_UPDATE) 1934
56.2.145 System Time Nanoseconds Update Register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE) 1935
56.2.146 Timestamp Addend Register (MAC_TIMESTAMP_ADDEND) 1936
56.2.147 System Time Higher Word Seconds Register (MAC_SYSTEM_TIME_HIGHER_WORD_SECONDS) 1936
56.2.148 Timestamp Status Register (MAC_TIMESTAMP_STATUS) 1937

56.2.149 Transmit Timestamp Status Nanoseconds Register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS) 1938
56.2.150 Transmit Timestamp Status Seconds Register (MAC_TX_TIMESTAMP_STATUS_SECONDS) 1939
56.2.151 Auxiliary Control Register (MAC_AUXILIARY_CONTROL) 1940
56.2.152 Auxiliary Timestamp Nanoseconds Register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS) 1941
56.2.153 Auxiliary Timestamp Seconds Register (MAC_AUXILIARY_TIMESTAMP_SECONDS) 1942
56.2.154 Timestamp Ingress Asymmetry Correction Register (MAC_TIMESTAMP_INGRESS_ASYM_CORR) 1942
56.2.155 Timestamp Egress Asymmetry Correction Register (MAC_TIMESTAMP_EGRESS_ASYM_CORR) 1943
56.2.156 Timestamp Ingress Correction Nanosecond Register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND) 1943
56.2.157 Timestamp Egress Correction Nanosecond Register (MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND) 1944
56.2.158 PPS Control Register (MAC_PPS_CONTROL) 1945
56.2.159 PPS0 Target Time Seconds Register (MAC_PPS0_TARGET_TIME_SECONDS) 1947
56.2.160 PPS0 Target Time Nanoseconds Register (MAC_PPS0_TARGET_TIME_NANOSECONDS) 1948
56.2.161 PPS0_Interval Register (MAC_PPS0_INTERVAL) 1948
56.2.162 PPS0 Width Register (MAC_PPS0_WIDTH) 1949
56.2.163 Operation Mode Register (MTL_OPERATION_MODE) 1950
56.2.164 Debug Access Control Register (MTL_DBG_CTL) 1951
56.2.165 Debug Status Register (MTL_DBG_STS) 1953
56.2.166 FIFO Debug Data register (MTL_FIFO_DEBUG_DATA) 1954
56.2.167 Interrupt Status Register (MTL_INTERRUPT_STATUS) 1955
56.2.168 Receive Queue and DMA Channel Mapping 0 Register (MTL_RXQ_DMA_MAP0) 1956
56.2.169 Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE) 1957
56.2.170 Queue 0 Underflow Counter Register (MTL_TXQ0_UNDERFLOW) 1958
56.2.171 Queue 0 Transmit Debug Register (MTL_TXQ0_DEBUG) 1959
56.2.172 Queue 0 ETS Status Register (MTL_TXQ0_ETS_STATUS) 1961
56.2.173 Queue 0 Quantum or Weights Register (MTL_TXQ0_QUANTUM_WEIGHT) 1961
56.2.174 Interrupt Control Status Register (MTL_Q0_INTERRUPT_CONTROL_STATUS) 1962

56.2.175 Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE) 1963
56.2.176 Queue 0 Missed Packet and Overflow Counter Register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT) 1966
56.2.177 Queue 0 Receive Debug Register (MTL_RXQ0_DEBUG) 1967
56.2.178 Queue Receive Control Register (MTL_RXQ0_CONTROL) 1968
56.2.179 Transmit Qn Operation Mode register (MTL_TXQn_OPERATION_MODE) 1969
56.2.180 Transmit Qn Underflow register (MTL_TXQn_UNDERFLOW) 1970
56.2.181 Transmit Qn Debug register (MTL_TXQn_DEBUG) 1971
56.2.182 Transmit Qn ETS Control register (MTL_TXQn_ETS_CONTROL) . . 1973
56.2.183 Transmit Qn ETS Status register (MTL_TXQn_ETS_STATUS) 1974
56.2.184 Transmit Qn Quantum Weight register (MTL_TXQn_QUANTUM_WEIGHT) 1975
56.2.185 Transmit Qn Send Slope Credit register (MTL_TXQn_SENDSPLOPECREDIT) 1976
56.2.186 Transmit Qn High Credit register (MTL_TXQn_HICREDIT) 1976
56.2.187 Transmit Qn Low Credit register (MTL_TXQn_LOCREDIT) 1977
56.2.188 Qn Interrupt Control Status register (MTL_Qn_INTERRUPT_CONTROL_STATUS) 1977
56.2.189 Receive Qn Operation Mode register (MTL_RXQn_OPERATION_MODE) 1979
56.2.190 Receive Qn Missed Packet and Overflow Counter register (MTL_RXQn_MISSED_PACKET_OVERFLOW_CNT) 1981
56.2.191 Receive Qn Debug register (MTL_RXQn_DEBUG) 1983
56.2.192 Receive Qn Control register (MTL_RXQn_CONTROL) 1983
56.2.193 DMA_Mode Register (DMA_MODE) 1984
56.2.194 System Bus Mode Register (DMA_SYSBUS_MODE) 1986
56.2.195 Interrupt Status Register (DMA_INTERRUPT_STATUS) 1987
56.2.196 Debug Status 0 Register (DMA_DEBUG_STATUS0) 1988
56.2.197 DMA Channel n Control register (DMA_CHn_CONTROL) 1989
56.2.198 DMA Channel n Transmit Control register (DMA_CHn_TX_CONTROL) 1990
56.2.199 DMA Channel n Receive Control register (DMA_CHn_RX_CONTROL) 1991
56.2.200 DMA Channel n Transmit Descriptor List Address register (DMA_CHn_TXDESC_LIST_ADDRESS) 1993
56.2.201 DMA Channel n Receive Descriptor List Address register (DMA_CHn_RXDESC_LIST_ADDRESS) 1994
56.2.202 DMA Channel n Transmit Descriptor Tail Pointer register (DMA_CHn_TXDESC_TAIL_POINTER) 1995

56.2.203 DMA Channel n Receive Descriptor Tail Pointer (DMA_CHn_RXDESC_TAIL_POINTER) 1996
56.2.204 DMA Channel n Transmit Descriptor Ring Length register (DMA_CHn_TXDESC_RING_LENGTH) 1996
56.2.205 DMA Channel n Receive Descriptor Ring Length register (DMA_CHn_RXDESC_RING_LENGTH) 1997
56.2.206 DMA Channel n Interrupt Enable register (DMA_CHn_INTERRUPT_ENABLE) 1998
56.2.207 DMA Channel n Receive Interrupt Watchdog Timer register (DMA_CHn_Rx_INTERRUPT_WATCHDOG_TIMER) 2000
56.2.208 DMA Channel n Slot Function Control Status register (DMA_CHn_SLOT_FUNCTION_CONTROL_STATUS) 2001
56.2.209 DMA Channel n Current Application Transmit Descriptor register (DMA_CHn_CURRENT_APP_TXDESC) 2002
56.2.210 DMA Channel n Current Application Transmit Descriptor register (DMA_CHn_CURRENT_APP_RXDESC) 2003
56.2.211 DMA Channel n Current Application Transmit Buffer register (DMA_CHn_CURRENT_APP_TXBUFFER) 2003
56.2.212 DMA Channel n Current Application Receive Buffer register (DMA_CHn_CURRENT_APP_RXBUFFER) 2004
56.2.213 DMA Channel n Status register (DMA_CHn_STATUS) 2005
56.2.214 DMA Channel n Miss Frame Counter register (DMA_CHn_MISS_FRAME_CNT) 2008
56.3 Functional Description 2009
56.3.1 AHB Master Interface 2009
56.3.2 DMA Controller 2010
56.3.3 MAC Transaction Layer (MTL) 2023
56.3.4 MAC 2028
56.3.5 Multiple Channels and Queues Support 2032
56.3.6 Double VLAN Processing 2042
56.3.7 Source Address Insertion, Replacement, or Deletion 2044
56.3.8 Packet Filtering 2044
56.3.9 IEEE 1588 Timestamps 2051
56.3.10 IPv4 ARP Offload 2069
56.3.11 Memory Access in Debug Mode 2069
56.3.12 Loopback 2073
56.3.13 MAC Flow Control 2074
56.3.14 Checksum Offload Engine 2076
56.3.15 MAC Management Counters 2081
56.3.16 Low Power Modes 2082

56.3.17 Interrupts . . . 2089
56.4 Descriptors . . . 2093
56.4.1 Overview . . . 2093
56.5 Programming Guidelines . . . 2117
56.5.1 Initializing DMA . . . 2117
56.5.2 Initializing MTL Registers . . . 2118
56.5.3 Initializing MAC . . . 2118
56.5.4 Programming Guidelines for Multi-Channel Multi-Queuing . . . 2120
56.5.5 Programming Guidelines for MII Link State Transitions . . . 2121

57.6.13 MTS generation . . . 2286
57.6.14 Key slot transmission . . . 2287
57.6.15 Sync frame filtering . . . 2287
57.6.16 Strobe signal support . . . 2288
57.6.17 Timer support . . . 2289
57.6.18 Slot status monitoring . . . 2290
57.6.19 System bus access . . . 2294
57.6.20 Interrupt support . . . 2295
57.6.21 Lower bit rate support . . . 2299
57.6.22 PE data memory (PE DRAM) . . . 2299
57.6.23 CHI lookup-table memory (CHI LRAM) . . . 2300
57.6.24 Memory content error detection . . . 2301
57.6.25 Memory error injection . . . 2305
57.6.26 StopWatch function . . . 2307
57.7 Application information . . . 2309
57.7.1 Module configuration . . . 2309
57.7.2 Initialization sequence . . . 2310
57.7.3 Memory error injection out of POC:default config . . . 2312
57.7.4 Shutdown sequence . . . 2312
57.7.5 Number of usable message buffers . . . 2312
57.7.6 Protocol control command execution . . . 2314
57.7.7 Message buffer search on simple message buffer configuration . . . 2315

58 Inter-Integrated Circuit (I2C) . . . 2318
58.1 Overview . . . 2318
58.2 Introduction to I2C . . . 2318
58.2.1 Definition: I^2C module . . . 2318
58.2.2 Advantages of the IC bus . . . 2318

58.2.3 Module block diagram . . . 2318
58.2.4 Features . . . 2320
58.2.5 Modes of operation . . . 2320
58.2.6 Definition: I2C conditions . . . 2321
58.3 External signal descriptions . . . 2322
58.3.1 Signal overview . . . 2322
58.3.2 Detailed external signal descriptions . . . 2322
58.4 Memory map and register definition . . . 2322
58.4.1 I2C memory map . . . 2322
58.4.2 Register accessibility . . . 2323
58.4.3 I2C Bus Address register (IBAD) . . . 2323
58.4.4 I2C Bus Frequency Divider register (IBFD) . . . 2324
58.4.5 I2C Bus Control Register (IBCR) . . . 2324
58.4.6 I2C Bus Status Register (IBSR) . . . 2326
58.4.7 I2C Bus Data I/O Register (IBDR) . . . 2328
58.4.8 I2C Bus Interrupt Config register (IBIC) . . . 2329
58.4.9 I2C Bus Debug register (IBDBG) . . . 2330
58.5 Functional description . . . 2331
58.5.1 Notes about module operation . . . 2331
58.5.2 Transactions . . . 2331
58.5.3 Arbitration procedure . . . 2334
58.5.4 Clock behavior . . . 2334
58.5.5 Interrupts . . . 2343
58.5.6 IPG STOP mode . . . 2344
58.5.7 IPG DEBUG mode . . . 2345
58.5.8 DMA interface . . . 2347
58.6 Initialization and application information . . . 2347
58.6.1 Recommended interrupt service flow . . . 2347
58.6.2 General programming guidelines (for both master and slave mode) . 2349
58.6.3 Programming guidelines specific to master mode . . . 2350
58.6.4 Programming guidelines specific to slave mode . . . 2353
58.6.5 DMA application information . . . 2353

59 SENT Receiver (SRX) . . . 2359

59.1 Introduction . . . 2359
59.1.1 Features . . . 2360
59.1.2 Modes of operation . . . 2361

59.1.3 Block diagram . . . 2363
59.1.4 Design overview . . . 2363
59.2 External signal description . . . 2365
59.2.1 SENT_RX [(CH-1):0] . . . 2365
59.3 Memory map and register definition . . . 2365
59.3.1 Memory map . . . 2365
59.3.2 Register descriptions . . . 2367
59.3.3 Register classification for safety . . . 2398
59.4 Functional description . . . 2399
59.4.1 Initialization sequence . . . 2399
59.4.2 DMA read logic . . . 2400
59.4.3 Message reading via interrupts . . . 2406
59.4.4 Overflow behavior . . . 2407
59.4.5 Adjustment for variation in sensor (Tx) clock . . . 2407
59.4.6 Input programmable filter . . . 2408
59.4.7 Receiver diagnostics . . . 2409
59.4.8 Time stamp logic . . . 2413
59.4.9 Bus-idle diagnostic . . . 2414
59.5 Clocks and resets . . . 2414
59.5.1 Clocking strategy . . . 2414
59.5.2 System bus clock requirements . . . 2415
59.5.3 High frequency receiver clock (protocol clock) requirements . . . 2416

60 Peripheral Sensor Interface (PSI5) . . . 2417
60.1 Introduction . . . 2417
60.1.1 Overview . . . 2417
60.1.2 Features . . . 2419
60.1.3 Modes of operation . . . 2420
60.2 External signal description . . . 2425
60.3 Memory map and register description . . . 2425
60.3.1 Memory map . . . 2425
60.3.2 Register description . . . 2434
60.4 Functional description . . . 2486
60.4.1 Sensor-to-ECU communication . . . 2487
60.4.2 Data Link Layer . . . 2488
60.4.3 ECU-to-sensor communication . . . 2509

60.4.4 Tx/Rx scenario . . . 2520
60.4.5 Interrupt handling . . . 2521
60.4.6 DMA support . . . 2523
60.4.7 Message read through interrupt generation . . . 2524
60.5 Clock and Reset . . . 2525
60.5.1 Latency and Jitter related requirements . . . 2527
60.5.2 Reset . . . 2527
60.6 Initialization information . . . 2527
60.6.1 Initialization . . . 2527
60.7 Design Assumptions and Limitations . . . 2528
60.7.1 Assumptions . . . 2528
60.7.2 Limitations . . . 2528
60.8 Miscellaneous descriptions . . . 2529
60.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels . . . 2529
60.8.2 Valid states for integrated sync pulse generator . . . 2533
60.8.3 Implementation of EI Diagnostic Register . . . 2535

61 Peripheral Sensor Interface-Support module (PSI5-S) . . . 2536
61.1 Introduction . . . 2536
61.1.1 Overview . . . 2536
61.1.2 Features . . . 2538
61.1.3 PSI5-S global modes of operation . . . 2539
61.1.4 PSI5-S system modes of operation . . . 2542
61.2 External signal description . . . 2542
61.3 Memory map and register description . . . 2543
61.3.1 Memory map . . . 2543
61.3.2 Transfer error generation . . . 2553
61.3.3 UART register configuration . . . 2554
61.3.4 PSI5-S register description . . . 2571
61.4 Functional description . . . 2612
61.4.1 PSI5-S UART message structure . . . 2613
61.4.2 PSI5 received message handling . . . 2615
61.4.3 ECU-to-sensor communication . . . 2623
61.4.4 Timestamp . . . 2630
61.4.5 PSI5-S watchdog operation . . . 2632

61.4.6 Interrupt handling 2634
61.5 PSI5-S clock and reset 2637

62 Deserial Serial Peripheral Interface (DSPI) 2639
62.1 Introduction 2639
62.1.1 Block diagram 2639
62.1.2 Features 2640
62.1.3 DSPI configurations 2641
62.1.4 Modes of operation 2643
62.2 DSPI signal description 2644
62.2.1 PCS0/SS — Peripheral Chip Select/Slave Select 2644
62.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3 2644
62.2.3 PCS4 — Peripheral Chip Select 4 2644
62.2.4 PCS5/PCSS — Peripheral Chip Select 5/Peripheral Chip Select Strobe 2644
62.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7 2645
62.2.6 SIN — Serial Input 2645
62.2.7 SOUT — Serial Output 2645
62.2.8 SCK — Serial Clock 2645
62.2.9 HT — Hardware Trigger 2645
62.3 Memory map/register definition 2645
62.3.1 DSPI Module Configuration Register (DSPI_MCR) 2648
62.3.2 Hardware Configuration Register (DSPI_HCR) 2651
62.3.3 DSPI Transfer Count Register (DSPI_TCR) 2653
62.3.4 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTARn) 2654
62.3.5 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTARn_SLAVE) 2659
62.3.6 DSPI Status Register (DSPI_SR) 2661
62.3.7 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER) 2664
62.3.8 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR) 2666
62.3.9 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE) 2668
62.3.10 DSPI POP FIFO Register (DSPI_POPR) 2669
62.3.11 DSPI Transmit FIFO Registers (DSPI_TXFRn) 2670
62.3.12 DSPI Receive FIFO Registers (DSPI_RXFRn) 2670
62.3.13 DSPI DSI Configuration Register 0 (DSPI_DSICR0) 2671
62.3.14 DSPI DSI Serialization Data Register 0 (DSPI_SDR0) 2673

62.3.15 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0) . . 2674
62.3.16 DSPI DSI Transmit Comparison Register 0 (DSPI_COMPR0) 2675
62.3.17 DSPI DSI Deserialization Data Register 0 (DSPI_DDR0) 2675
62.3.18 DSPI DSI Configuration Register 1 (DSPI_DSICR1) 2676
62.3.19 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0) 2677
62.3.20 DSPI DSI Parallel Input Select Register 0 (DSPI_PISR0) 2678
62.3.21 DSPI DSI Parallel Input Select Register 1 (DSPI_PISR1) 2680
62.3.22 DSPI DSI Parallel Input Select Register 2 (DSPI_PISR2) 2681
62.3.23 DSPI DSI Parallel Input Select Register 3 (DSPI_PISR3) 2682
62.3.24 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0) 2682
62.3.25 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0) 2683
62.3.26 DSPI DSI Serialization Data Register 1 (DSPI_SDR1) 2684
62.3.27 DSPI DSI Alternate Serialization Data Register 1 (DSPI_ASDR1) . . 2684
62.3.28 DSPI DSI Transmit Comparison Register 1 (DSPI_COMPR1) 2685
62.3.29 DSPI DSI Deserialization Data Register 1 (DSPI_DDR1) 2686
62.3.30 DSPI DSI Serialization Source Select Register 1 (DSPI_SSR1) 2686
62.3.31 DSPI DSI Parallel Input Select Register 4 (DSPI_PISR4) 2687
62.3.32 DSPI DSI Parallel Input Select Register 5 (DSPI_PISR5) 2689
62.3.33 DSPI DSI Parallel Input Select Register 6 (DSPI_PISR6) 2690
62.3.34 DSPI DSI Parallel Input Select Register 7 (DSPI_PISR7) 2691
62.3.35 DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1) 2691
62.3.36 DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1) 2692
62.3.37 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTAREn) 2693
62.3.38 DSPI Status Register Extended (DSPI_SREX) 2694
62.4 Register classification for safety 2694
62.5 Functional description 2695
62.5.1 Start and Stop of DSPI transfers 2696
62.5.2 Serial Peripheral Interface (SPI) configuration 2697
62.5.3 Deserial Serial Interface (DSI) configuration 2701
62.5.4 Combined Serial Interface (CSI) configuration 2705
62.5.5 DSPI baud rate and clock delay generation 2706
62.5.6 Transfer formats 2709
62.5.7 Continuous Serial Communications Clock 2718

62.5.8 Slave mode operation constraints 2720
62.5.9 Timed Serial Bus (TSB) 2720
62.5.10 Interleaved TSB (ITSB) Mode 2723
62.5.11 Parity generation and check 2726
62.5.12 Interrupts/DMA requests 2727
62.5.13 Power saving features 2730
62.6 Initialization/application information 2731
62.6.1 Managing DSPI queues 2731
62.6.2 Switching master and slave mode 2731
62.6.3 Initializing DSPI in Master/Slave Modes 2732
62.6.4 Baud rate settings 2732
62.6.5 Delay settings 2733
62.6.6 Calculation of FIFO pointer addresses 2734

63 LINFlexD 2737
63.1 Introduction 2737
63.2 Main features 2739
63.2.1 LIN mode features 2739
63.2.2 UART mode features 2740
63.2.3 Standard features 2740
63.3 Functional description 2740
63.3.1 LIN protocol 2740
63.3.2 LINFlexD features 2742
63.3.3 Timer 2759
63.3.4 UART mode 2759
63.3.5 DMA interface 2764
63.4 Memory map and register description 2783
63.4.1 Memory map 2783
63.4.2 Register description 2785
63.5 Programming considerations 2818
63.5.1 Master node 2818
63.5.2 Slave node 2820
63.5.3 Extended frames 2824
63.5.4 Timeout 2824
63.5.5 UART mode 2825
63.5.6 Interrupts 2825

64 Reset Generation Module (MC_RGM) 2827
64.1 Introduction 2827
64.1.1 Overview 2827
64.1.2 Features 2828
64.1.3 Reset sources 2829
64.2 External signal description 2830
64.3 Memory map and register definition 2830
64.3.1 Register descriptions 2832
64.4 Functional description 2880
64.4.1 Reset state machine 2880
64.4.2 ‘Destructive’ resets 2884
64.4.3 External reset 2885
64.4.4 ‘Functional’ resets 2886
64.4.5 Alternate event generation 2886
64.4.6 ‘Functional’ reset escalation 2887
64.4.7 ‘Destructive’ reset escalation 2887
64.4.8 Individual peripheral resets 2888

65 Boot Assist Flash (BAF) 2889
65.1 Introduction 2889
65.2 Memory map 2889
65.2.1 BAF image header 2889
65.3 Functional description 2890
65.3.1 Boot modes 2891
65.3.2 Device initialization 2891
65.3.3 Flow of control 2891
65.3.4 Optionally wait for HSM 2893
65.3.5 Initialization of BAF DCF clients 2893
65.3.6 Production disable activation protocol and implementation 2899
65.3.7 TDM Diary Operation 2902
65.3.8 Optionally perform a serial boot 2903
65.3.9 Serial boot configuration 2907
65.4 Resources accessed by BAF code execution 2910

66 System Status and Configuration Module (SSCM) 2911
66.1 Introduction 2911

66.1.1 Overview . . . 2911
66.1.2 Features . . . 2911
66.1.3 Modes of operation . . . 2911
66.2 Memory map and register definition . . . 2911
66.2.1 Register descriptions . . . 2912
66.3 Functional description . . . 2917
66.3.1 DCF mechanism . . . 2917
66.3.2 ECC error monitoring . . . 2919
66.3.3 Boot mode functionality . . . 2920
66.3.4 BAF configuration . . . 2920
66.3.5 User code boot sector search . . . 2920
66.3.6 HSM boot header search . . . 2922
66.3.7 Life Cycle . . . 2923
66.4 Initialization and application information . . . 2924
66.4.1 Reset . . . 2924
66.5 Additional safety measures . . . 2924
66.5.1 Spurious reset protection . . . 2924

67 Power management controller digital interface (PMC_Dig) . . . 2925
67.1 Introduction . . . 2925
67.2 Main features . . . 2927
67.2.1 Standard features . . . 2927
67.3 IPS bus interface . . . 2927
67.4 Memory map/register definition . . . 2927
67.5 Registers description . . . 2931
67.5.1 Event Pending Register (EPR_LV0) . . . 2931
67.5.2 Reset Event Enable Register (REE_LV0) . . . 2932
67.5.3 Reset Event Select Register (RES_LV0) . . . 2933
67.5.4 Interrupt Enable (IE_LV0) . . . 2934
67.5.5 FCCU Event Enable Register (FEE_LV0) . . . 2935
67.5.6 Event Pending Register (EPR_LV1) . . . 2936
67.5.7 Reset Event Enable Register (REE_LV1) . . . 2937
67.5.8 Reset Event Select Register (RES_LV1) . . . 2938
67.5.9 Interrupt Enable (IE_LV1) . . . 2938
67.5.10 FCCU Event Enable Register (FEE_LV1) . . . 2939
67.5.11 Event Pending Register (EPR_HV0) . . . 2940

67.5.12 Reset Event Enable Register (REE_HV0) 2942
67.5.13 Reset Event Select Register (RES_HV0) 2943
67.5.14 Interrupt Enable (IE_HV0) 2945
67.5.15 FCCU Event Enable Register (FEE_HV0) 2946
67.5.16 Event Pending Register (EPR_HV1) 2948
67.5.17 Reset Event Enable Register (REE_HV1) 2949
67.5.18 Reset Event Select Register (RES_HV1) 2951
67.5.19 Interrupt Enable Register (IE_HV1) 2953
67.5.20 FCCU Event Enable Register (FEE_HV1) 2955
67.5.21 Supply Gauge Status Register (GR_S) 2956
67.5.22 Pending Gauge Status Register (GR_P) 2960
67.5.23 Global Interrupt Enable Register (IE_G) 2962
67.5.24 Voltage selection of IO (VSIO) 2964
67.5.25 PMOS/NMOS Regulator Status Register (PNREG_S) 2964
67.5.26 HPREG SMPS SELECT STATUS (HPREG_SMPS_SEL_S) 2965
67.5.27 Miscellaneous CTRL REG (MISC_CTRL_REG) 2966
67.5.28 SSWU CTRL Register (SSWU_CTRL_REG) 2967
67.5.29 Event Pending Register (EPR_TD) 2967
67.5.30 Reset Event Enable Register (REE_TD) 2969
67.5.31 Reset Event Select Register (RES_TD) 2970
67.5.32 Temperature Sensor Configuration Register (CTL_TD) 2971
67.5.33 Temperature Sensor FCCU Event Enable Register (FEE_TD) 2973
67.5.34 BIST Mask Status register (BIST_MASK_STATUS) 2974
67.5.35 User BIST Flags Phase1 register (BIST_FLAGS_PHASE1) 2975
67.5.36 User BIST Flags Phase2 register (BIST_FLAGS_PHASE2) 2977
67.5.37 User BIST Control register (BIST_CTRL) 2978
67.5.38 User BIST Time1 and Time0 register (BIST_TIME10) 2979
67.5.39 User BIST Time3 and Time2 register (BIST_TIME32) 2980
67.5.40 User BIST Time6 and Time5 register (BIST_TIME65) 2980
67.5.41 User BIST VD Under Test Monitor register (BIST_DEBUG) 2981
67.6 Standby entry/exit 2982
67.7 Temperature Sensor Interface Logic 2982
67.8 Power On Reset (MC_RGM Phase Gates) 2983
67.9 Flash interface (DCF client usage) 2983
67.10 Voltage monitor BIST programming 2984

68 Power Control Unit (MC_PCU) 2987

68.1 Introduction . . . 2987
68.1.1 Overview . . . 2987
68.1.2 Features . . . 2988
68.2 External Signal Description . . . 2988
68.3 Memory Map and Register Definition . . . 2989
68.3.1 Memory Map . . . 2989
68.3.2 Register descriptions . . . 2989
68.4 Functional description . . . 2993
68.4.1 General . . . 2993
68.4.2 Reset / Power-On Reset . . . 2993
68.4.3 MC_PCU configuration . . . 2993
68.4.4 Mode transitions . . . 2993
68.5 Application information . . . 2995
68.5.1 STANDBY mode considerations . . . 2995

69 Mode Entry Module (MC_ME) . . . 2996
69.1 Introduction . . . 2996
69.1.1 Overview . . . 2996
69.1.2 Features . . . 2998
69.1.3 Modes of operation . . . 2998
69.2 External signal description . . . 2999
69.3 Memory map and register definition . . . 2999
69.3.1 Memory map . . . 3000
69.3.2 Register description . . . 3005
69.4 Functional description . . . 3039
69.4.1 Mode transition request . . . 3039
69.4.2 Modes details . . . 3040
69.4.3 Mode transition process . . . 3044
69.4.4 Protection of Mode Configuration Registers . . . 3053
69.4.5 Mode Transition Interrupts . . . 3053
69.4.6 Peripheral Clock Gating . . . 3055
69.4.7 Application Example . . . 3056

70 e200z425n3 Core Debug Support . . . 3058
70.1 Overview . . . 3058
70.1.1 Software debug facilities . . . 3058

70.1.2 Additional debug facilities . . . 3059
70.1.3 Hardware debug facilities . . . 3059
70.1.4 Sharing debug resources by software/hardware . . . 3060
70.2 Software debug events and exceptions . . . 3061
70.2.1 Instruction Address Compare event . . . 3062
70.2.2 Data Address Compare event . . . 3063
70.2.3 Linked Instruction Address Compare and Data Address Compare events . . . 3070
70.2.4 Trap debug event . . . 3071
70.2.5 Branch Taken debug event . . . 3071
70.2.6 Instruction Complete debug event . . . 3071
70.2.7 Interrupt Taken debug event . . . 3072
70.2.8 Critical Interrupt Taken debug event . . . 3072
70.2.9 Return debug event . . . 3072
70.2.10 Critical Return Debug Event . . . 3072
70.2.11 External debug event . . . 3072
70.2.12 Unconditional debug event . . . 3073
70.2.13 Performance Monitor Interrupt debug event . . . 3073
70.3 Debug registers . . . 3073
70.3.1 Debug Address and Value registers . . . 3073
70.3.2 Debug Control and Status registers . . . 3074
70.3.3 External Debug Resource Allocation Control (EDBRAC0) register . . 3095
70.3.4 Debug Event Select register (DEVENT) register . . . 3103
70.3.5 Debug Data Acquisition Message (DDAM) register . . . 3103
70.4 Using debug resources for stack limit checking . . . 3104
70.5 External debug support . . . 3106
70.5.1 External debug registers . . . 3107
70.5.2 OnCE introduction . . . 3112
70.5.3 JTAG/OnCE pins . . . 3115
70.5.4 OnCE internal interface signals . . . 3115
70.5.5 OnCE interface signals . . . 3116
70.5.6 OnCE controller and serial interface . . . 3118
70.5.7 Access to debug resources . . . 3125
70.5.8 Methods of entering Debug mode . . . 3127
70.5.9 CPU Status and Control Scan Chain Register (CPUSCR) . . . 3128
70.5.10 Reserved registers (Reserved) . . . 3134
70.6 Watchpoint support . . . 3134

70.7 MPU operation during debug 3137
70.8 Cache array access during debug 3138
70.9 Basic steps for enabling, using, and exiting External Debug mode . . . 3138

71 e200z420n3 Core Debug Support 3140

71.1 Overview 3140
71.1.1 Software debug facilities 3140
71.1.2 Additional debug facilities 3141
71.1.3 Hardware debug facilities 3141
71.1.4 Sharing debug resources by software/hardware 3142
71.2 Software debug events and exceptions 3143
71.2.1 Instruction Address Compare event 3144
71.2.2 Data Address Compare event 3145
71.2.3 Linked Instruction Address Compare and Data Address Compare events 3153
71.2.4 Trap debug event 3154
71.2.5 Branch Taken debug event 3154
71.2.6 Instruction Complete debug event 3154
71.2.7 Interrupt Taken debug event 3155
71.2.8 Critical Interrupt Taken debug event 3155
71.2.9 Return debug event 3155
71.2.10 Critical Return Debug Event 3155
71.2.11 External debug event 3155
71.2.12 Unconditional debug event 3156
71.2.13 Performance Monitor Interrupt debug event 3156
71.3 Debug registers 3156
71.3.1 Debug Address and Value registers 3156
71.3.2 Debug Control and Status registers 3157
71.3.3 External Debug Resource Allocation Control (EDBRAC0) register . . 3178
71.3.4 Debug Event Select register (DEVENT) register 3186
71.3.5 Debug Data Acquisition Message (DDAM) register 3186
71.4 Using debug resources for stack limit checking 3187
71.5 External debug support 3189
71.5.1 External debug registers 3190
71.5.2 OnCE introduction 3195
71.5.3 JTAG/OnCE pins 3198
71.5.4 OnCE internal interface signals 3198

71.5.5 OnCE interface signals . . . 3199
71.5.6 OnCE controller and serial interface . . . 3201
71.5.7 Access to debug resources . . . 3208
71.5.8 Methods of entering Debug mode . . . 3210
71.5.9 CPU Status and Control Scan Chain Register (CPUSCR) . . . 3211
71.5.10 Reserved registers (Reserved) . . . 3217
71.6 Watchpoint support . . . 3217
71.7 MPU operation during debug . . . 3220
71.8 Cache array access during debug . . . 3220
71.9 Basic steps for enabling, using, and exiting External Debug mode . . . 3221

72 Debug and Calibration Interface (DCI) . . . 3223
72.1 Introduction . . . 3223
72.1.1 Features . . . 3223
72.1.2 Overview . . . 3223
72.1.3 Operating modes . . . 3225
72.2 External signal description . . . 3237
72.3 Register description . . . 3237
72.3.1 DCI control register (DCI_CR) . . . 3238
72.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR) . . . 3239
72.4 Functional description . . . 3240
72.4.1 DCI mode transition . . . 3240
72.4.2 LFAST LVDS pad fault . . . 3241

73 JTAG Controller (JTAGC) . . . 3243
73.1 Introduction . . . 3243
73.1.1 Block Diagram . . . 3243
73.1.2 Features . . . 3244
73.1.3 Modes of operation . . . 3244
73.2 External signal description . . . 3245
73.2.1 TCK—Test clock input . . . 3245
73.2.2 TDI—Test data input . . . 3245
73.2.3 TDO—Test data output . . . 3245
73.2.4 TMS—Test mode select . . . 3245
73.2.5 JCOMP—JTAG compliancy . . . 3245
73.3 Register description . . . 3246

73.3.1 Instruction register . . . 3246
73.3.2 Bypass register . . . 3246
73.3.3 Device identification register . . . 3246
73.3.4 JTAG_PASSWORD register . . . 3247
73.3.5 Boundary scan register . . . 3248
73.4 Functional description . . . 3248
73.4.1 JTAGC reset configuration . . . 3248
73.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port . . . 3248
73.4.3 TAP controller state machine . . . 3249
73.4.4 JTAGC block instructions . . . 3251
73.4.5 Boundary scan . . . 3254
73.5 Initialization/Application information . . . 3254

74 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) . . . 3255
74.1 References . . . 3255
74.2 Introduction . . . 3255
74.2.1 Types of operation . . . 3255
74.2.2 Deployment by class . . . 3256
74.2.3 1149.7 TAP signals . . . 3256
74.2.4 TAP.7 architecture . . . 3257
74.2.5 Protocols . . . 3257
74.3 Operating models . . . 3259
74.4 CJTAG implementation summary . . . 3259
74.4.1 T0 Functions . . . 3259
74.4.2 T1 functions . . . 3259
74.4.3 T2 functions . . . 3259
74.4.4 T3 functions . . . 3260
74.4.5 T4 functions . . . 3260
74.5 Ancillary services . . . 3260
74.5.1 Overview . . . 3260
74.5.2 Resets . . . 3260
74.5.3 Start-up Options . . . 3263
74.5.4 RSU operation . . . 3264
74.5.5 TAPC State Machine . . . 3265
74.6 EPU (Extended Protocol Unit) Operation . . . 3266

74.6.1 EPU Operation . . . 3266
74.6.2 EPU Registers . . . 3268
74.6.3 EPU Commands . . . 3278
74.6.4 EPU operating states . . . 3285
74.6.5 System and EPU Paths . . . 3286
74.7 APU (Advanced Protocol Unit) Operation . . . 3287
74.7.1 Overview . . . 3287
74.7.2 Operation . . . 3289
74.7.3 Escape sequences . . . 3290
74.7.4 Signal behaviors . . . 3290
74.7.5 APU Functions . . . 3291
74.7.6 Configuration Change Packets (CP) . . . 3298
74.7.7 Scan Packet . . . 3298
74.7.8 SP Format . . . 3298
74.8 Functional Description . . . 3304
74.8.1 Switching from Standard Protocol to Advanced Protocol . . . 3304

75 JTAG Data Communication (JDC) . . . 3305
75.1 Introduction . . . 3305
75.2 Overview . . . 3305
75.3 Register definition . . . 3306
75.3.1 Register descriptions . . . 3306
75.3.2 Non-Memory mapped register definition . . . 3308
75.4 Functional description . . . 3309
75.4.1 IPS register access . . . 3310
75.4.2 JTAG register access . . . 3310
75.5 Use case example . . . 3310

76 Sequence Processing Unit (SPU) . . . 3312
76.1 Introduction . . . 3312
76.1.1 SPU block diagram . . . 3312
76.1.2 Overview . . . 3313
76.1.3 Features . . . 3314
76.2 SPU actions . . . 3315
76.3 Operation mode . . . 3316
76.3.1 SPU enable/disable . . . 3316

76.4 SPU module interface 3316
76.5 Register definition 3317
76.5.1 Registers description 3321
76.6 Functional description 3363
76.6.1 Input Mux unit 3363
76.6.2 Processor exception vector encoding 3365
76.6.3 State logic unit (SLU) 3366
76.6.4 Sequence formation 3367
76.6.5 Performance counters/timers unit 3370
76.6.6 Action unit 3372
76.6.7 Optional trace group 3372
76.6.8 Format for CKSRC & CKDATA Values 3372

77 Buddy Device—JTAG Master (JTAGM) 3374
77.1 Introduction 3374
77.1.1 Overview 3374
77.1.2 Feature description 3375
77.2 Functional description 3375
77.2.1 Module architecture 3375
77.2.2 JTAGM JCOMP usage in LFAST 3376
77.2.3 JTAGM data error detection 3377
77.2.4 JTAGM message tagging 3377
77.2.5 JTAGM Ready signal 3377
77.2.6 EVTO and EVTI signals 3378
77.2.7 JTAGM configuration and status monitoring 3378
77.2.8 JTAGM to DCI serial interface 3379
77.2.9 JTAGM data handling and CRC calculation in LFAST mode 3379
77.2.10 Software interface 3380
77.3 Modes of operation 3381
77.4 Memory map and register definition 3381
77.4.1 Register descriptions 3381

78 Debug Zipwire 3390
78.1 Overview 3390
78.2 Debug Zipwire Overview 3390
78.3 Debug Zipwire Block Diagram 3390

78.4 Architecture . . . 3391
78.5 Debug Zipwire implementation . . . 3392
78.6 LFAST clocking . . . 3393
78.7 LFAST switch . . . 3394
78.8 Debug SIPI module . . . 3395
78.8.1 ED power supply constraints . . . 3398
78.9 Debug Zipwire interconnections . . . 3398

79 Debug Serial Interprocessor Interface (SIPI) . . . 3400
79.1 Introduction . . . 3400
79.2 Overview . . . 3400
79.3 Debug SIPI block diagram . . . 3401
79.4 Feature description . . . 3401
79.4.1 Main features . . . 3402
79.4.2 Standard features . . . 3402
79.5 Debug SIPI operation from reset . . . 3402
79.6 Functional description . . . 3402
79.6.1 External signals . . . 3402
79.6.2 Frame format . . . 3402
79.7 Transfer types . . . 3407
79.7.1 Read transfer . . . 3407
79.7.2 Register read answer transfer . . . 3408
79.7.3 Register Write transfer . . . 3410
79.7.4 Write acknowledge transfer . . . 3411
79.7.5 ID request response . . . 3412
79.8 Transfer API and flow charts . . . 3413
79.9 CRC calculation . . . 3414
79.10 Memory map and register description . . . 3414
79.10.1 Register descriptions . . . 3414

80 LVDS Fast Asynchronous Serial Transmission – High Speed Debug . . . 3417
80.1 Introduction . . . 3417
80.2 Block diagram . . . 3417
80.3 External signals . . . 3418

80.3.1 LFAST operating data rates . . . 3418
80.4 LFAST frame structure . . . 3418
80.5 Features . . . 3421
80.6 Memory map and register definition . . . 3421
80.6.1 Memory map . . . 3421
80.6.2 Register descriptions . . . 3423
80.6.3 Register safety classification requirements . . . 3443
80.7 Functional description . . . 3443
80.7.1 Startup procedure . . . 3443
80.7.2 LFAST Interface enable signal (lfast_sysclk_en) . . . 3444
80.7.3 Line Receiver (LR) . . . 3445
80.7.4 Transmit controller . . . 3454
80.7.5 Frames supported . . . 3457
80.7.6 Frame flow . . . 3457
80.7.7 Test and debug support . . . 3460
80.8 Packet memory . . . 3468
80.9 Resets . . . 3468
80.10 Clocks . . . 3469
80.10.1 Clocking strategy . . . 3469
80.10.2 Slow speed clock . . . 3470
80.10.3 Rx controller clocks . . . 3473
80.10.4 Tx controller clocks . . . 3474

81 Development Trigger Semaphore (DTS) . . . 3476
81.1 Introduction . . . 3476
81.2 Overview . . . 3476
81.3 DTS device connections . . . 3478
81.3.1 DTS register access . . . 3479
81.4 Memory map and register definition . . . 3479
81.4.1 Register descriptions . . . 3480
81.5 Example application . . . 3483

82 Nexus Aurora Router (NAR) . . . 3485
82.1 Introduction . . . 3485
82.2 Overview . . . 3486

82.3 Features . . . 3486
82.4 Register definition . . . 3486
82.4.1 Register descriptions . . . 3487
82.4.2 Message filtering registers . . . 3490
82.4.3 Trace memory bus configuration registers . . . 3493
82.4.4 Suppress mode triggers register (NAR_STCR) . . . 3495
82.4.5 Receive queue client disable register (NAR_CDR) . . . 3497
82.4.6 Trace Memory fill level and partition configuration register (NAR_AHFPAR) . . . 3499
82.5 Functional description . . . 3499
82.5.1 Reset/Startup . . . 3499
82.5.2 Operation modes . . . 3500
82.5.3 Data reception and arbitration . . . 3502
82.5.4 Suppress mode . . . 3503
82.5.5 Stall detection . . . 3504
82.5.6 Output arbitration . . . 3505

1 Preface

1.1 Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or provide device-specific information.
- Part II includes chapters that describe the functionality of the individual modules on the device.
- Part III includes chapters that describe the functionality of the Emulation and Debug Device (ED).

1.2 Register conventions

Figure 1 and *Table 1* provide the register conventions used throughout this manual.

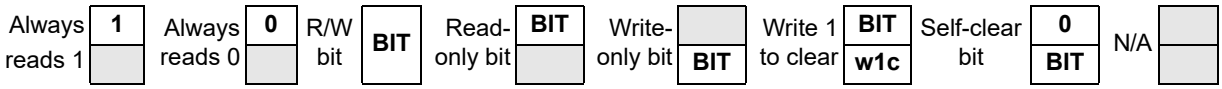

Figure 1. Key to register fields

Table 1. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset values	
0	Resets to zero
1	Resets to one
—	Undefined at reset

1.3 Acronyms and abbreviations

Appendix A: Acronyms and abbreviations lists acronyms and abbreviations used in this document.

1.4 Reference documents

In addition to this reference manual, the following documents provide additional information on the operation of the SPC58xEx/SPC58xGx:

- IEEE-ISTO 5001™-2012 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture

Information about Power ISA™ Book is available on the Power Architecture web site

2 Introduction

2.1 SPC58xEx microcontroller

The SPC58xEx microcontroller belongs to a family of devices continuing the SPC57x PWT family. SPC58xEx builds on the legacy of the SPC57x PWT family, while introducing new features coupled with higher throughput to provide substantial reduction of cost per feature and significant power and performance improvement (MIPS per mW). On the SPC58xEx microcontroller there are up to 3 e200z4d processor cores, 2 checkers and one e200z0 core embedded in the Hardware Security Module.

Table 2. Processor cores

Core	Type
Computing Shell 0	
Main Core_0	e200z420
Main Core_1	e200z420
Checker Core_0s	e200z419
Computing Shell 1	
Peripheral Core_2	e200z425
Checker Core_2s	e200z425
Hardware Security Module	
e200z0 Core	

2.1.1 Target applications

This device is targeted at automotive powertrain, chassis applications:

- Powertrain controllers for six to eight cylinder gasoline, diesel engines and advanced combustion systems as well as high end hybrid and transmission control
- Integrated chassis control, high-end steering and braking

These applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-D compliance.

For this reason, safety measures have been added which are further described in *Chapter 6: Functional safety*.

2.1.2 Overall architecture

The architecture is split into two computing shells as shown in *Table 2*. The computing shell 0 consists of one pair of CPU in lock-step for safety, one CPU without lock-step, a DMA move engine, fast local memories inside the CPUs and fast system memory. All components of the computational shell are connected through a crossbar switch (XBAR_0).

The computing shell 1 consists of two CPUs in lock-step, a DMA move engine, fast local memories inside the CPU, fast system memories, a Hardware Security Module (HSM) and all the other peripherals connected through a crossbar switch (XBAR_1).

2.1.3 Core features

The computing shell 0 consists of dual e200z4 CPUs operating up to 180 MHz, one core paired with a safety checker core in delayed lock-step mode.

The computing shell 1 includes a CPU targeted at managing the peripherals. The shell core is also an e200z4 CPU running at up to 180 MHz, paired with a safety checker core in delayed lock-step, and including enhancements to implement Digital Signal Processing (DSP) algorithms.

The sixth programmable CPU is a e200z0 running up to 90 MHz and is embedded in the HSM.

All CPUs are compatible with the Power Architecture VLE instruction set, that supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

Note: The e200z0 core is embedded in the Hardware Security Module.

2.1.4 Core_2

The Core_2 is one of six processor cores on the SPC58xEx device as shown in *Table 2*. In general, the intended use of the Core_2 is to initially configure the machine and then control various peripheral elements of the device. However, the Core_2 is not limited to any particular duty.

The data and the instruction bus structures of the Core_2, which consist of a 64-bit data bus and a 32-bit address bus, are connected to a Crossbar Switch XBAR_1 which operates at 180 MHz.

The Core_2 is automatically started during the boot-up sequence after the release of RESET. This process is fully described in *Chapter 8: Reset and Boot*. During the boot sequence the System Status and Configuration Module (SSCM) reads and interprets a set of device configuration records located in the TEST Flash Area. One of these records is the start address of the code where the Core_2 will begin program execution. This vector will always point to a location in the Boot Assist Flash. Once the System Status and Configuration Module finds and interprets this particular device configuration record, the SSCM will write the start address for the Core_2 to the appropriate location in the Mode Entry module (ME). When the internal reset signal is released, the Mode Entry module transfers the Core_2 start address to the Core_2 and code execution begins at that address.

The code for the Boot Assist Flash, the TEST Device Configuration Records and some of the UTEST Device Configuration Records are written by the device manufacturer and are programmed into the device during production testing. All SPC58xEx devices are shipped with start-up code programmed into the Boot Assist Flash. Also, the SPC58xEx is configured such that code execution by the Core_2 must begin with a start address located in the Boot Assist Flash.

If there is no user application code to execute, the Core_2, executing pre-programmed code in the Boot Assist Flash, will attempt to download user applications code through the LINFlexD port using a specific data transfer protocol. This downloaded code is installed into program memory and code execution will begin at the start address embedded in the downloaded code.

The Core_2 is placed in the SPC58xEx architecture in such a way that enables it to access many of the peripheral elements without affecting the processing speed of Core_0 and

Core_1. On the SPC58xEx device there are several A/D channels taking data which must be analyzed for various spectral components.

This specificity associated with its integrated DSP processor which has special hardware to execute multiply and accumulate functions makes of this core the most avantageous one to manage a system of analog-to-digital converters and fetch the digital data that is generated. The integrated DSP unit uses a signal processing algorithm to digest the incoming data. The results of this signal processing algorithm are used in other engine control algorithms. Using the Core_2 to manage the A/D converters and do the initial signal processing of the data allows the two other cores to focus on other compute intensive applications instead of managing relatively slow peripheral elements.

Once the Core_2 has performed its initialization duties, as determined by pre-loaded instruction code in the Boot Assist Flash and downloaded any needed applications code, the Core_2 can essentially be programmed to perform any duty or access any memory element. When executing instructions from its internal instruction cache and fetching data from peripherals connected to the Cross Bar Switch XBAR_1, the Core_2 operates autonomously from Core_0 and Core_1.

2.1.5 Memory hierarchy

The SPC58xEx computational shell has three levels of memory hierarchy. At the top level is a combination of Instruction Cache, Data Cache, Local Instruction RAM and Local Data RAM, depending on the specific CPU. The local RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time. The second level of memory is system RAM and flash. These are connected via a 180 MHz, 64-bit wide crossbar. The third level of memory system is the I/O subsystem. All the I/O peripherals are connected together via a 180 MHz 64-bit wide crossbar switch, while peripherals are connected at either 180 MHz or 45 MHz depending on their need. The reduced speed for the peripherals helps to reduce power consumption.

2.1.6 Features

On-chip modules within SPC58xEx include the following features:

- Three main CPUs, dual issue, 32-bit CPU core complexes (e200z4), two of them having a checker core in lock-step
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - Lightweight signal processing auxiliary processing unit (LSP APU) instruction support for digital signal processing (DSP) on Core_2
  - 16 KB Local instruction RAM and 64 KB local data RAM for Core_0 and Core_1, 16 KB Local instruction RAM and 32 KB local data RAM for Core_2
  - 8 KB I-Cache and 4 KB D-Cache for Core_0 and Core_1, 8kB I-Cache for Core_2
- 6582 KB on-chip Flash
  - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
  - Supports read while read between the two code Flash partitions.
- 608 KB on-chip general-purpose SRAM (+ 160 KB data RAM included in the CPUs)
- Multi channel direct memory access controllers (eDMA paired in lock-step)
  - One eDMA with 64 channels
  - One eDMA with 32 channels
- One interrupt controller (INTC) in lock-step
- Dual phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual crossbar switch architecture for concurrent access to peripherals, Flash, or RAM from multiple bus masters with end-to-end ECC
- Hardware security module (HSM) to provide robust integrity checking of Flash memory
- System integration unit lite (SIUL)
- Boot assist Flash (BAF) supports factory programming using a serial bootload through the asynchronous CAN or LIN/UART.
- GTM343 - generic timer module
  - Intelligent complex timer module
  - 144 channels (40 input and 104 output)
  - 5 programmable fine grain multi-threaded cores
  - 61 KB of dedicated RAM
  - 24-bit wide channels
  - Hardware support for engine control, motor control and safety related applications
- Enhanced analog-to-digital converter system with
  - One supervisor 12-bit SAR analog converter
  - Four separate fast 12-bit SAR analog converters
  - Three separate 10-bit SAR analog converters
  - Six separate 16-bit Sigma-Delta analog converters
- Ten deserial serial peripheral interface (DSPI) modules

- Eighteen LIN and UART communication interface (LINFlexD) modules
  - LINFlexD_0 is a Master/Slave
  - All others are Masters
- Seven modular controller area network (MCAN) modules, and one time-triggered controller area network (M-TTCAN), all supporting flexible data rate (CAN-FD)
- Dual-channel FlexRay controller
- Two ethernet controllers 10/100 Mbps, compliant IEEE 802.3-2008
  - IEEE 1588-2008 Time stamping (internal 64-bit time stamp)
  - IEEE 802.1AS and IEEE 802.1Qav (AVB-Feature)
  - IEEE 802.1Q VLAN tag detection
  - IPv4 and IPv6 checksum modules
- Flexible Power Supply options:
  - External Regulators (1.2V core, 3.3V–5V IO)
  - Single internal SMPS regulator (eLQFP176 and Bare Die)
  - Single internal Linear Regulator with external ballast (FPBGA292 and Bare Die)
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard.
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Standby power domain with smart wake-up sequence (FPBGA292 and Bare Die)

2.1.7 Feature list

Table 3 lists a summary of major features for the SPC58xEx device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on-chip module is given later in this document.

Table 3. Features list

Feature	Description
SPC58 family	40 nm
Computing Shell 0	
Number of Cores	up to 2
Number of checker cores	up to 1
Local RAM	16 KB Instruction
	64 KB Data
Single Precision Floating Point	Yes
SIMD (LSP)	No
VLE	Yes
Cache	8 KB Instruction
	4 KB Data
Computing Shell 1	

Table 3. Features list (continued)

Feature	Description
Number of Cores	up to 1
Number of checker cores	1
Local RAM	16 KB Instruction
	32 KB Data
Single Precision Floating Point	Yes
SIMD (LSP)	Yes
VLE	Yes
Cache	8 KB Instruction
Other	
Security (HSM Module)	up to 1
MPU	Core MPU: 24 per CPU
	System MPU: 24 per XBAR
Semaphores	Yes
CRC Channels	2 x 4
Software Watchdog Timer (SWT)	4
Core Nexus Class	3+
Event Processor	4 x SCU
	4 x PMC
Run control Module	Yes
System SRAM	up to 608 KB (including 256KB of standby RAM)(1)
User Flash	up to 6144 KB code / 256 KB data
Security Flash	up to 144kB code / 32kB data
Flash fetch accelerator	2 x 2 x 4 x 256-bit
Flash Overlay RAM	2 x 16 KB
Calibration Interface	64-bit IPS Slave
DMA channels	96
DMA Nexus Class	3
LINFlexD	10
M_CAN supporting CAN-FD according to ISO 11898-1 2015 (instances supporting also TTCAN)	8
DSPI	18
Microsecond channel downlink	2
SENT bus	15
I2C	1

Table 3. Features list (continued)

Feature	Description
PSI5 / PSI5-S bus	2 / 1
FlexRay	1 x Dual channel
Ethernet	2 MAC with Time stamping, AVB and VLAN support
SIPI / LFAST Interprocessor bus	High Speed
System Timers	8 PIT channels
	4 AUTOSAR® (STM)
	RTC/API
GTM Timer	40 Input Channels, 104 Output Channels
GTM RAM	61 KB
Interrupt controller	> 710 sources
ADC (SAR)	8
ADC (SD)	6
Temp. sensor	Yes
Self Test Controller	Yes
PLL	Dual PLL with FM
External Power Supplies	3.3 V - 5 V, 1.2 V
Integrated linear voltage regulator	Yes(1)
integrated switch mode voltage regulator (SMPS)	Yes(2)
Low Power Modes	Stop Mode
	Halt Mode
	Smart Standby with output controller, analog and digital inputs(1)
	Standby Mode(1)

1. Except eLQFP176.
2. Except LFBGA292.

2.1.8 Packages

The SPC58xEx is available in these production packages: eLQFP176, FPBGA292 and Bare Die.

All packages support production and emulation devices with compatibility for an emulation package in a production device footprint.

2.1.9 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development and calibration of constant data. These features include:

- Nexus code execution trace on all CPUs
- Nexus data trace on all bus masters (DMA, Interprocessor bus, CPUs, etc.)
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering
- 32 KB of overlay RAM

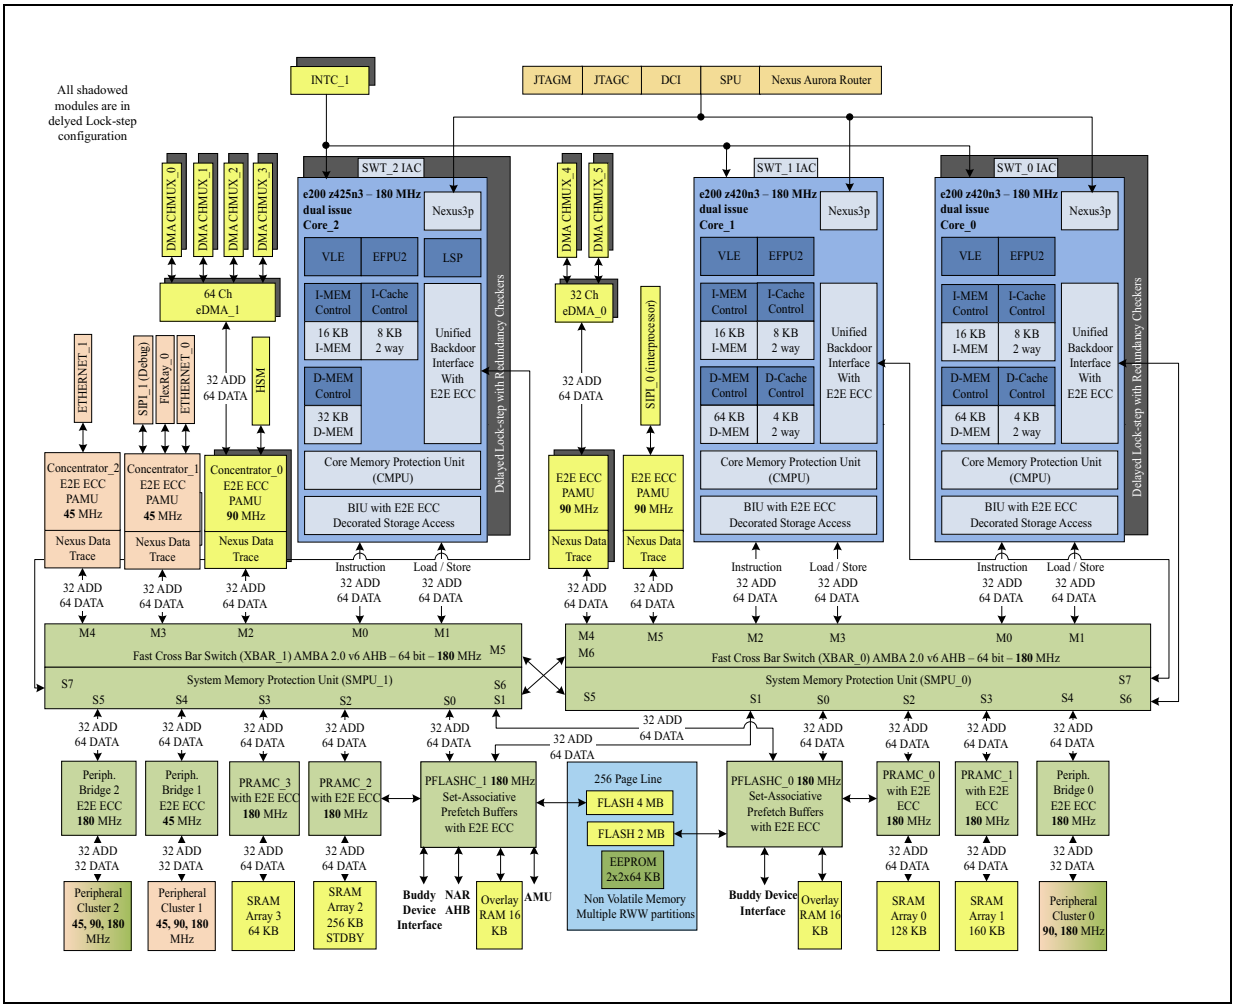
For more complex software development and calibration of constant data, a Buddy Device (BD) is packaged together with the SPC58xEx production device as a multi-die emulation and is referred to as Emulation Device (ED).

The ED provides exactly the same features as the Production Device (PD). The ED is available in the same package as the PD but has an additional overlay RAM (up to 2M bytes) and a high speed Nexus trace output port consisting of four lanes of Aurora (LVDS) operating up to 1.25 Gbit/s.

2.1.10 Block diagram

The figures below show the top-level block diagrams.

Figure 2. Block diagram



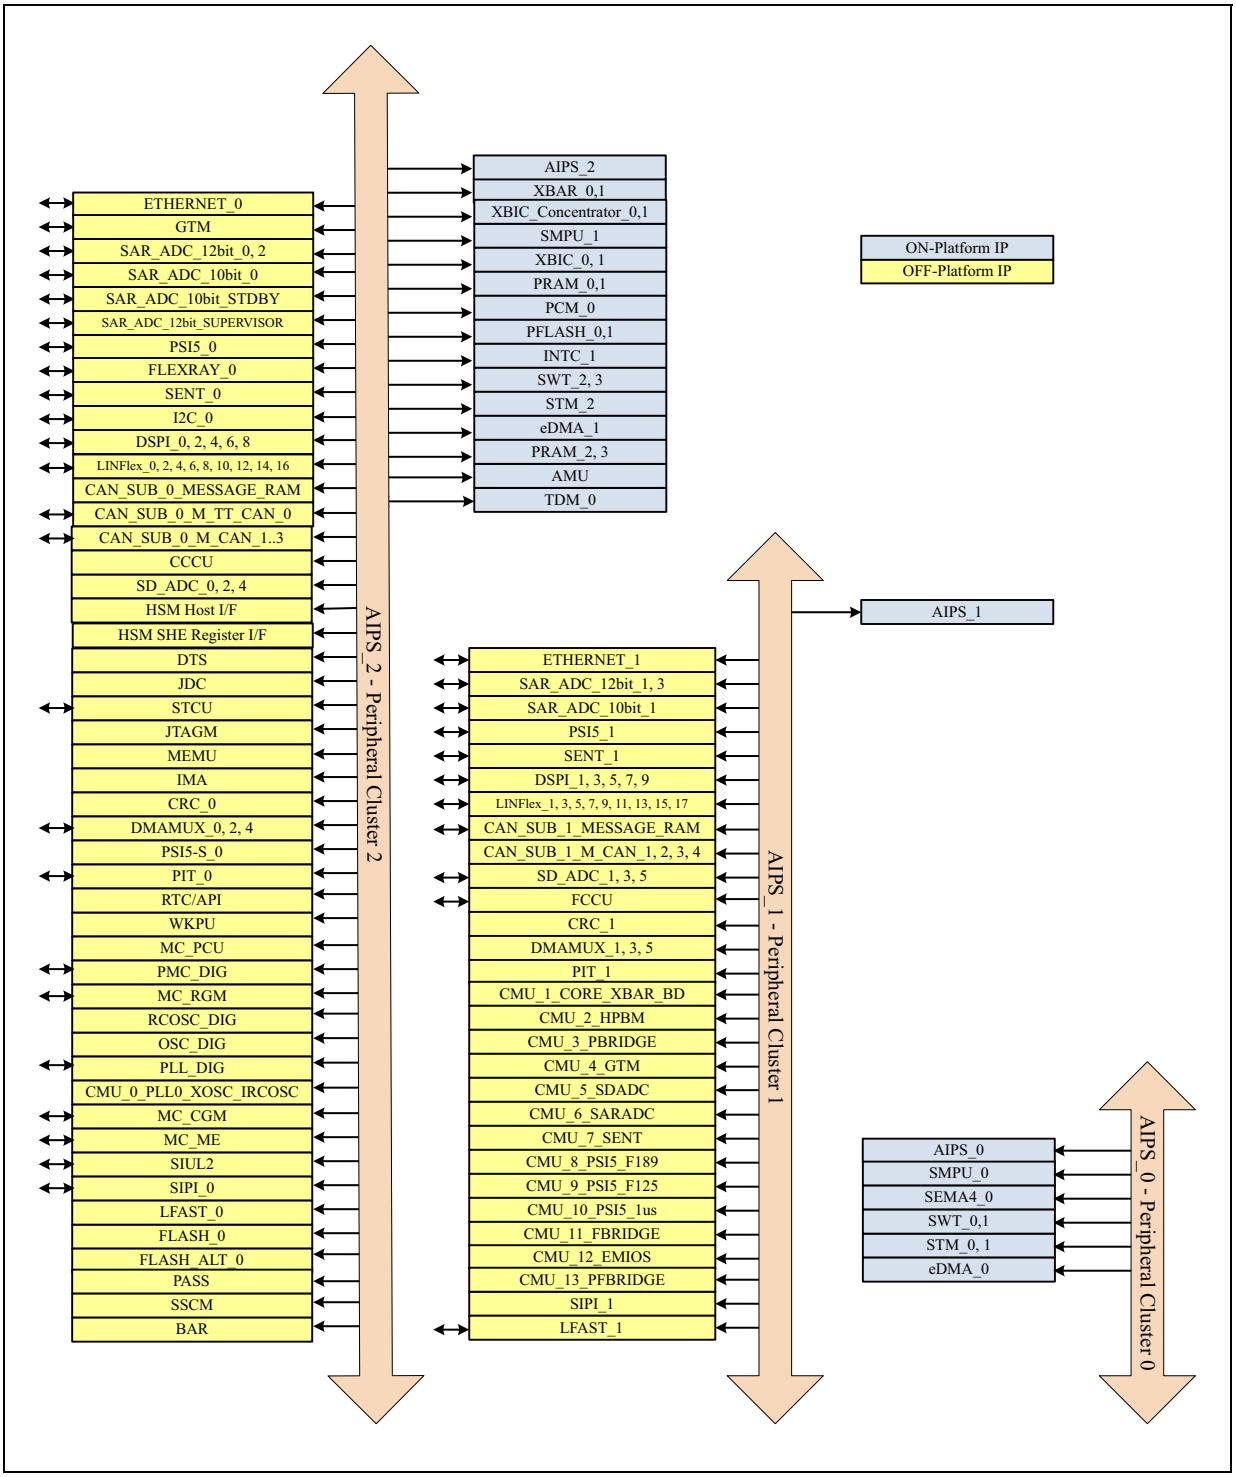


Figure 3. Periphery allocation

2.2 SPC58xGx microcontroller

The SPC58xGx microcontroller belongs to a family of devices continuing the SPC56x Body family. SPC58xGx builds on the legacy of the SPC56x Body family, while introducing new features coupled with higher throughput to provide substantial reduction of cost per feature and significant power and performance improvement (MIPS per mW). On the SPC58xGx microcontroller there are up to 3 e200z4d processor cores, 1 checker and one e200z0 core embedded in the Hardware Security Module.

Table 4. Processor cores

Core	Type
Computing Shell 0	
Main Core_0	e200z420
Main Core_1	e200z420
Checker Core_0s	e200z419
Computing Shell 1	
Peripheral Core_2	e200z425
Hardware Security Module	
e200z0 Core	

2.2.1 Target applications

This device is targeted at automotive high-end central body controller, smart junction boxes, stand-alone and connected gateway.

These applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-B up to ASIL-D compliance.

For this reason, safety measures have been added which are further described in *Chapter 6: Functional safety*.

2.2.2 Overall architecture

The architecture is split into two computing shells as shown in *Table 4*. The computing shell 0 consists of one pair of CPU in lock-step for safety, one CPU without lock-step, a DMA move engine, fast local memories inside the CPUs and fast system memory. All components of the computational shell are connected through a crossbar switch (XBAR_0).

The computing shell 1 consists of one CPU, a DMA move engine, fast local memories inside the CPU, fast system memories, a Hardware Security Module (HSM) and all the other peripherals connected through a crossbar switch (XBAR_1).

2.2.3 Core features

The computing shell 0 consists of dual e200z4 CPUs operating up to 180 MHz, one core paired with a safety checker core in delayed lock-step mode.

The computing shell 1 includes a CPU targeted at managing the peripherals. The shell core is also an e200z4 CPU running at up to 180 MHz, and including enhancements to implement Digital Signal Processing (DSP) algorithms.

The fifth programmable CPU is a e200z0 running up to 90 MHz and is embedded in the HSM.

All CPUs are compatible with the Power Architecture® VLE instruction set, that supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

Note: The e200z0 core is embedded in the Hardware Security Module.

2.2.4 Core_2

The Core_2 is one of five processor cores on the SPC58xGx device as shown in *Table 4*. In general, the intended use of the Core_2 is to initially configure the machine and then control various peripheral elements of the device. However, the Core_2 is not limited to any particular duty.

The data and the instruction bus structures of the Core_2, which consist of a 64-bit data bus and a 32-bit address bus, are connected to a Crossbar Switch XBAR_1 which operates at 180 MHz.

The Core_2 is automatically started during the boot-up sequence after the release of RESET. This process is fully described in *Chapter 8: Reset and Boot*. During the boot sequence the System Status and Configuration Module (SSCM) reads and interprets a set of device configuration records located in the TEST Flash Area. One of these records is the start address of the code where the Core_2 will begin program execution. This vector will always point to a location in the Boot Assist Flash. Once the System Status and Configuration Module finds and interprets this particular device configuration record, the SSCM will write the start address for the Core_2 to the appropriate location in the Mode Entry module (ME). When the internal reset signal is released, the Mode Entry module transfers the Core_2 start address to the Core_2 and code execution begins at that address.

The code for the Boot Assist Flash, the TEST Device Configuration Records and some of the UTEST Device Configuration Records are written by the device manufacturer and are programmed into the device during production testing. All SPC58xGx devices are shipped with start-up code programmed into the Boot Assist Flash. Also, the SPC58xGx is configured such that code execution by the Core_2 must begin with a start address located in the Boot Assist Flash.

If there is no user application code to execute, the Core_2, executing pre-programmed code in the Boot Assist Flash, will attempt to download user applications code through the LINFlexD port using a specific data transfer protocol. This downloaded code is installed into program memory and code execution will begin at the start address embedded in the downloaded code.

The Core_2 is placed in the SPC58xGx architecture in such a way that enables it to access many of the peripheral elements without affecting the processing speed of Core_0 and Core_1. On the SPC58xGx device there are several A/D channels taking data which must be analyzed for various spectral components.

This specificity associated with its integrated DSP processor which has special hardware to execute multiply and accumulate functions makes of this core the most avantageous one to manage a system of analog-to-digital converters and fetch the digital data that is generated.

The integrated DSP unit uses a signal processing algorithm to digest the incoming data. The results of this signal processing algorithm are used in other engine control algorithms. Using the Core_2 to manage the A/D converters and do the initial signal processing of the data allows the two other cores to focus on other compute intensive applications instead of managing relatively slow peripheral elements.

Once the Core_2 has performed its initialization duties, as determined by pre-loaded instruction code in the Boot Assist Flash and downloaded any needed applications code, the Core_2 can essentially be programmed to perform any duty or access any memory element. When executing instructions from its internal instruction cache and fetching data from peripherals connected to the Cross Bar Switch XBAR_1, the Core_2 operates autonomously from Core_0 and Core_1.

2.2.5 Memory hierarchy

The SPC58xGx computational shell has three levels of memory hierarchy. At the top level is a combination of Instruction Cache, Data Cache, Local Instruction RAM and Local Data RAM, depending on the specific CPU. The local RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time. The second level of memory is system RAM and flash. These are connected via a 180 MHz, 64-bit wide crossbar. The third level of memory system is the I/O subsystem. All the I/O peripherals are connected together via a 180 MHz 64-bit wide crossbar switch, while peripherals are connected at either 180 MHz or 45 MHz depending on their need. The reduced speed for the peripherals helps to reduce power consumption.

2.2.6 Features

The features described in this introduction chapter refer to the superset device, this means all features implemented on the device. To find the possible derivatives and related feature set, please refer to the "Ordering information" chapter in the device datasheet.

On-chip modules within SPC58xGx include the following features:

- Three main CPUs, dual issue, 32-bit CPU core complexes (e200z4), one of them having a checker core in lock-step
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - Lightweight signal processing auxiliary processing unit (LSP APU) instruction support for digital signal processing (DSP) on Core_2
  - 16 KB Local instruction RAM and 64 KB local data RAM for Core_0 and Core_1, 16 KB Local instruction RAM and 32 KB local data RAM for Core_2
  - 8 KB I-Cache and 4 KB D-Cache for Core_0 and Core_1, 8kB I-Cache for Core_2
- 6582 KB on-chip Flash
  - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
  - Supports read while read between the two code Flash partitions.
- 608 KB on-chip general-purpose SRAM (+ 160 KB data RAM included in the CPUs)
- Multi channel direct memory access controllers (eDMA paired in lock-step)
  - One eDMA with 64 channels
  - One eDMA with 32 channels
- One interrupt controller (INTC) in lock-step
- Dual phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual crossbar switch architecture for concurrent access to peripherals, Flash, or RAM from multiple bus masters with end-to-end ECC
- Hardware security module (HSM) to provide robust integrity checking of Flash memory
- System integration unit lite (SIUL)
- Boot assist Flash (BAF) supports factory programming using a serial bootload through the asynchronous CAN or LIN/UART.
- Hardware support for engine control, motor control and safety related applications
- Enhanced modular IO subsystem (eMIOS): up to 64 (2 x 32) timed I/O channels with 16-bit counter resolution
  - Buffered updates
  - Support for shifted PWM outputs to minimize occurrence of concurrent edges
  - Supports configurable trigger outputs for ADC conversion for synchronization to channel output waveforms
  - Shared or independent time bases
  - DMA transfer support available

- Body cross triggering unit (BCTU)
  - Triggers ADC conversions from any eMIOS channel
  - Triggers ADC conversions from up to 2 dedicated PIT_RTIs
  - One event configuration register dedicated to each timer event allows to define the corresponding ADC channel
  - Synchronization with ADC to avoid collision
- Enhanced analog-to-digital converter system with
  - Five separate 12-bit SAR analog converters
  - Three separate 10-bit SAR analog converters
- Ten deserial serial peripheral interface (DSPI) modules
- Eighteen LIN and UART communication interface (LINFlexD) modules
  - LINFlexD_0 is a Master/Slave
  - All others are Masters
- Eight modular controller area network (MCAN) modules, all supporting flexible data rate (CAN-FD)
- Dual-channel FlexRay controller
- One Ethernet controller 10/100 Mbps, compliant IEEE 802.3-2008
  - IEEE 1588-2008 Time stamping (internal 64-bit time stamp)
  - IEEE 802.1AS and IEEE 802.1Qav (AVB-Feature)
  - IEEE 802.1Q VLAN tag detection
  - IPv4 and IPv6 checksum modules
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard.
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Standby power domain with smart wake-up sequence

2.2.7 Feature list

Table 5 lists a summary of major features for the SPC58xGx device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on-chip module is given later in this document.

Table 5. Features list

Feature	Description
SPC58 family	40 nm
Computing Shell 0	
Number of Cores	up to 2
Number of checker cores	up to 1
Local RAM	16 KB Instructionω
	64 KB Data
Single Precision Floating Point	Yes
SIMD (LSP)	No

Table 5. Features list (continued)

Feature	Description
VLE	Yes

	Smart Standby with output controller, analog and digital inputs
	Standby Mode

2.2.8 Packages

The SPC58xGx is available in these production packages: eTQFP144, eLQFP176 and FBGA292.

The FPBGA292 packages support production and emulation devices with compatibility for an emulation package in a production device footprint.

2.2.9 Software debug and calibration

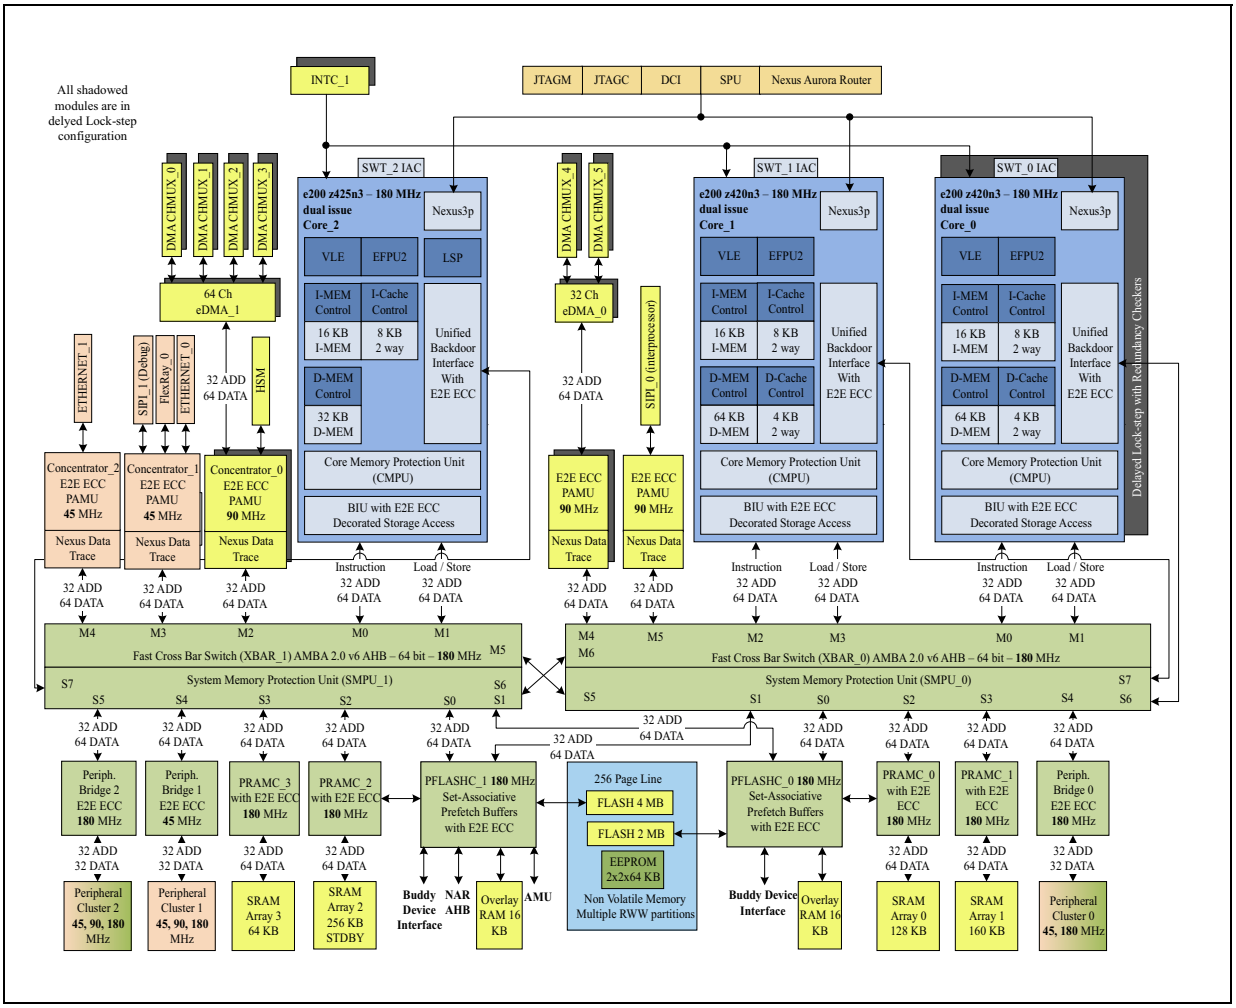
The Production Device (PD) includes many features to facilitate software development and calibration of constant data. These features include:

- Nexus code execution trace on all CPUs
- Nexus data trace on all bus masters (DMA, Interprocessor bus, CPUs, etc.)
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering
- 32 KB of overlay RAM

2.2.10 Block diagram

The figures below show the top-level block diagrams.

Figure 4. Block diagram



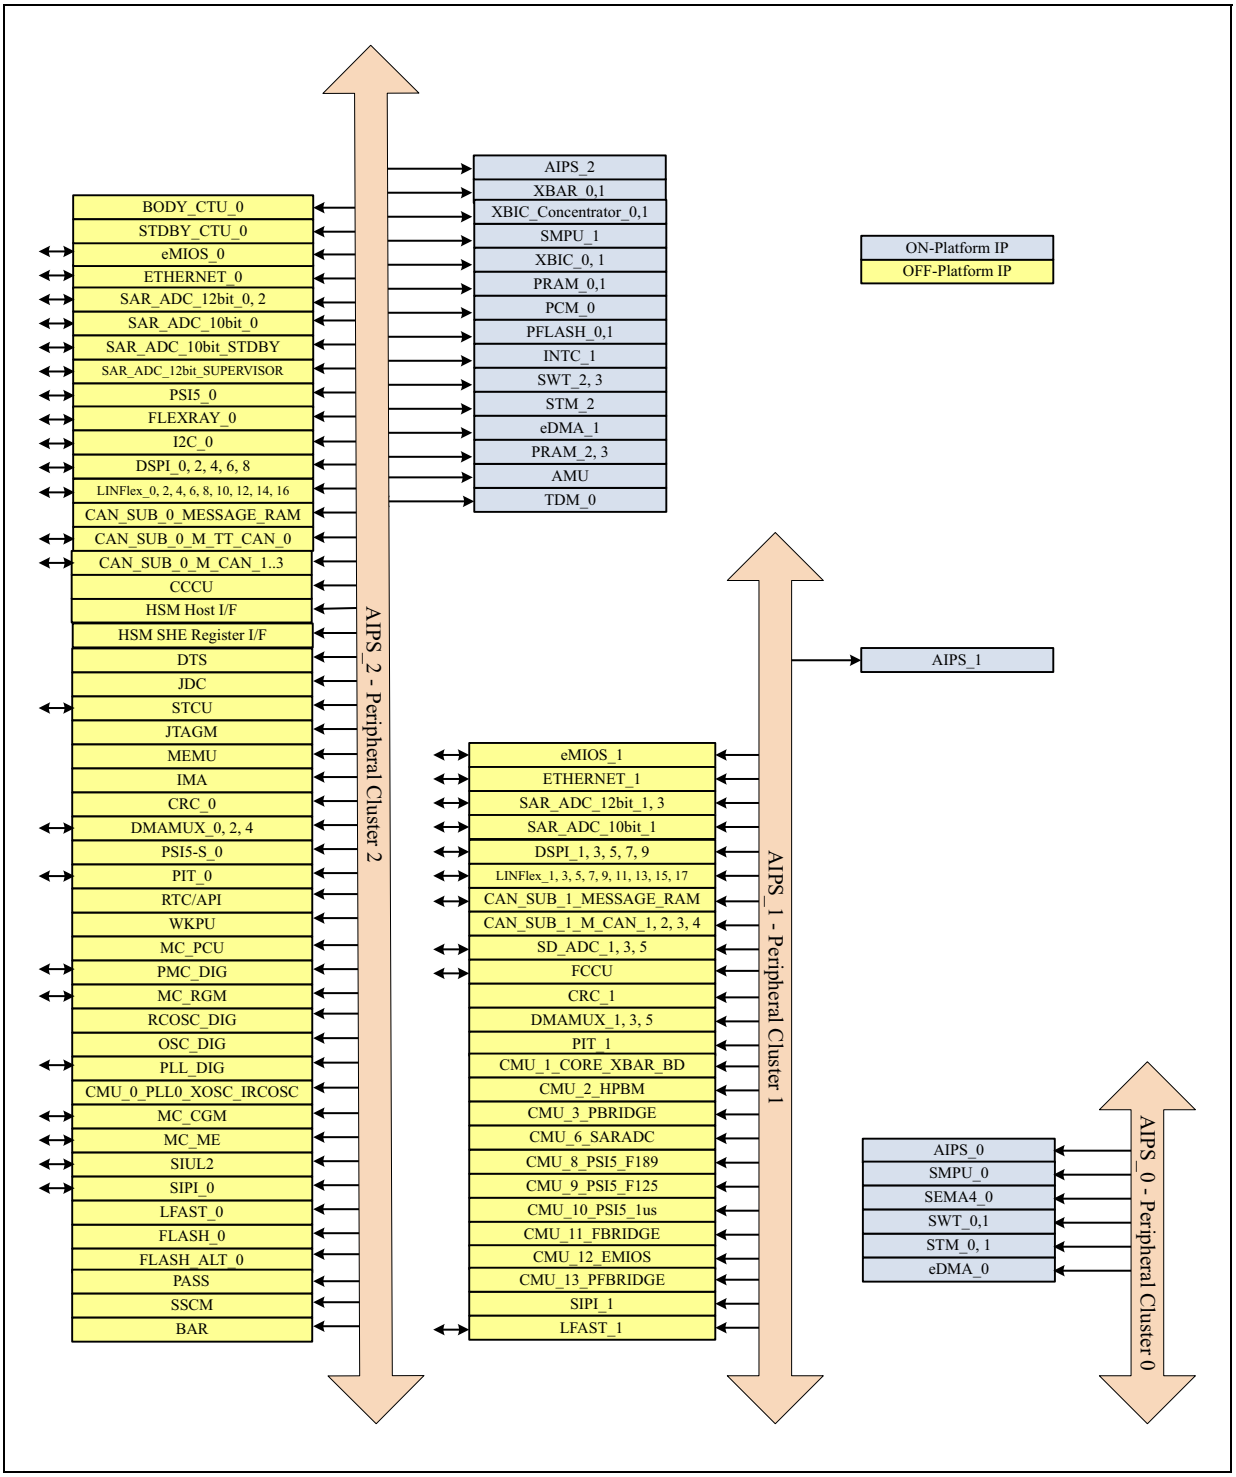


Figure 5. Periphery allocation

3 Embedded memories

3.1 Overview

Features include:

- Onboard SRAM, including system SRAM, local instruction and data memory for each processor core, and overlay SRAM
- Onboard system error correction code (ECC) Flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Built-in Flash memory security features including censorship and a programmable Hardware Security Module (HSM)
- Embedded memories in the peripherals[1]:
  - AMU
  - CAN
  - eDMA
  - Ethernet
  - FlexRay
  - GTM

3.2 SRAM

3.2.1 System SRAM

SPC58xEx/SPC58xGx device includes 608 KB of general-purpose on-chip ECC SRAM, including 256 KB standby RAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PRCR1 register in the SRAM controller.

- Refer to *Chapter 35: Platform RAM controller AHB (PRAMC_AHB)* for details on configuring the SRAM controller.
- Refer to the Memory Map chapter for the SPC58xEx/SPC58xGx SRAM map.

3.2.2 Standby SRAM regulator

A total of 256 KB of the system SRAM on the device can remain powered when the rest of the device is powered down. Refer to *Chapter 10: Power management* for details.

3.2.3 Overlay SRAM

Overlay SRAM is included in the SPC58xEx/SPC58xGx family of devices as part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip Flash memory so that any access to an overlaid Flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces.The SPC58xEx/SPC58xGx has two 16 KB banks of ECC-protected RAM, for a total of 32 KB.

1. Refer to the respective module chapter for details.

Note: Overlay SRAM is normally used for system development purposes only. Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEN]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) regardless of the PFCRCR[IRMEN] setting.

Overlay memory can also be used to hold the device debug trace stream, without requiring complex debug tool hardware and access to a high-speed trace port. Timing for calibration accesses to a particular overlay SRAM is the same as access to the underlying Flash memory if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The calibration remap function supports different types of overlay SRAM:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is available only on special emulation and debug devices.
- A portion of the system RAM can be used as the overlay RAM.

The overlay function is implemented using registers in the Flash memory controller.

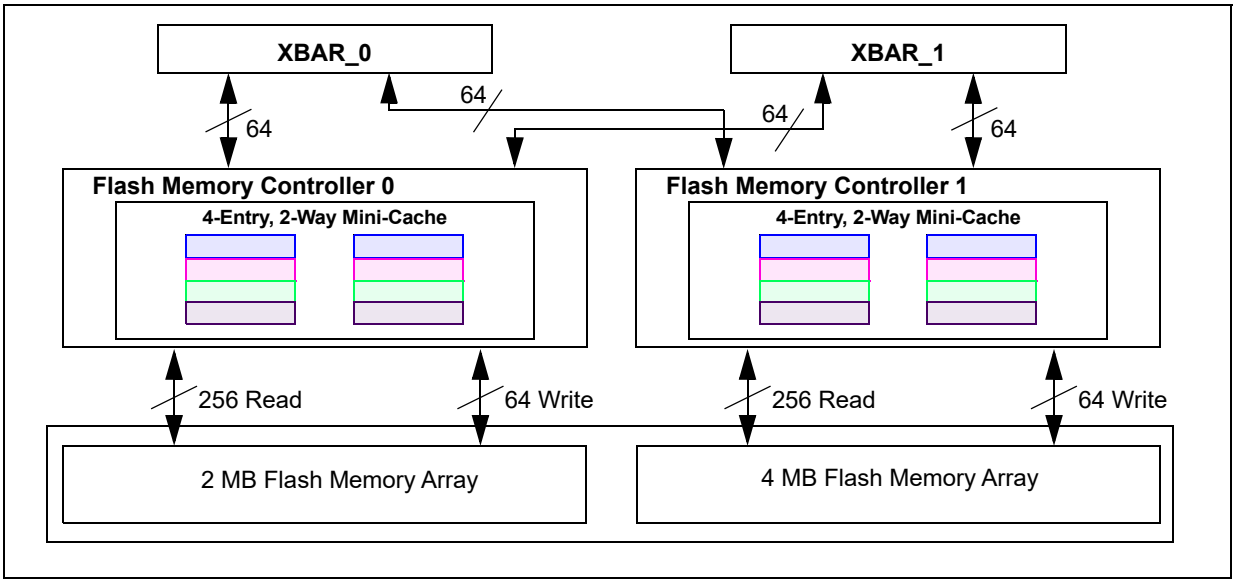
1. Using PFlash Calibration Region Descriptors (PFCRD*n*) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFlash Remap Descriptor Enable Register (PFDCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

Refer to *Section 36.5.13: PFlash calibration remap support*, for details on memory overlay (remapping).

3.2.4 Processor core local RAM

SPC58xEx/SPC58xGx devices include local instruction and data RAM (I-MEM and D-MEM) for each processor core to provide enhanced performance.

Refer to the Introduction chapter for processor cores local RAM sizes.



The core RAM supports zero wait-state, single-cycle latency on processor local accesses.

Each area of core RAM is accessible by other processor cores and bus mastering peripheral devices. Refer to the Memory Map chapter for the SPC58xEx/SPC58xGx SRAM map.

3.3 Embedded Flash memory

Flash memory on SPC58xEx/SPC58xGx device consists of two Flash memory controllers and a Flash memory array module. The Flash controller provides Flash configuration and control functions and manages the interface between the Flash memory array and the device crossbar switch. *Figure 6* shows the memory architecture.

Figure 6. SPC58xEx/SPC58xGx Flash memory block diagram

The remaining sections give the functional details of the Flash controller and Flash array, followed by the memory maps.

3.3.1 Flash memory controller

The SPC58xEx/SPC58xGx Flash memory controllers act as an interface between the system bus and the Flash memory array and serves as the interface to the on-chip overlay RAM and off-chip Buddy Device(2).

The Flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers Flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one Flash read page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed Flash memory array access.

The Flash memory controller contains configuration registers that manage Flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the Flash memory.

Refer to the *Chapter 36: Flash memory controller* for details.

3.3.2 Flash memory array

SPC58xEx/SPC58xGx device includes two Flash memory arrays, one with 4 MB and one with 2 MB, referred to as “main space,” plus an independent 16 KB block of one-time-programmable (OTP) Flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as “UTEST space.”

For code Flash sectors, reads of the embedded Flash memory return a 256-bit page of data that may be buffered in the mini-cache in the Flash memory controller. Programming of the

2. The Buddy Device is an optional companion chip with additional memory and debug features. A Buddy Device is combined with a Production Device to form an Emulation and Debug Device (ED) for use during system development. It is not used in production systems.

Flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

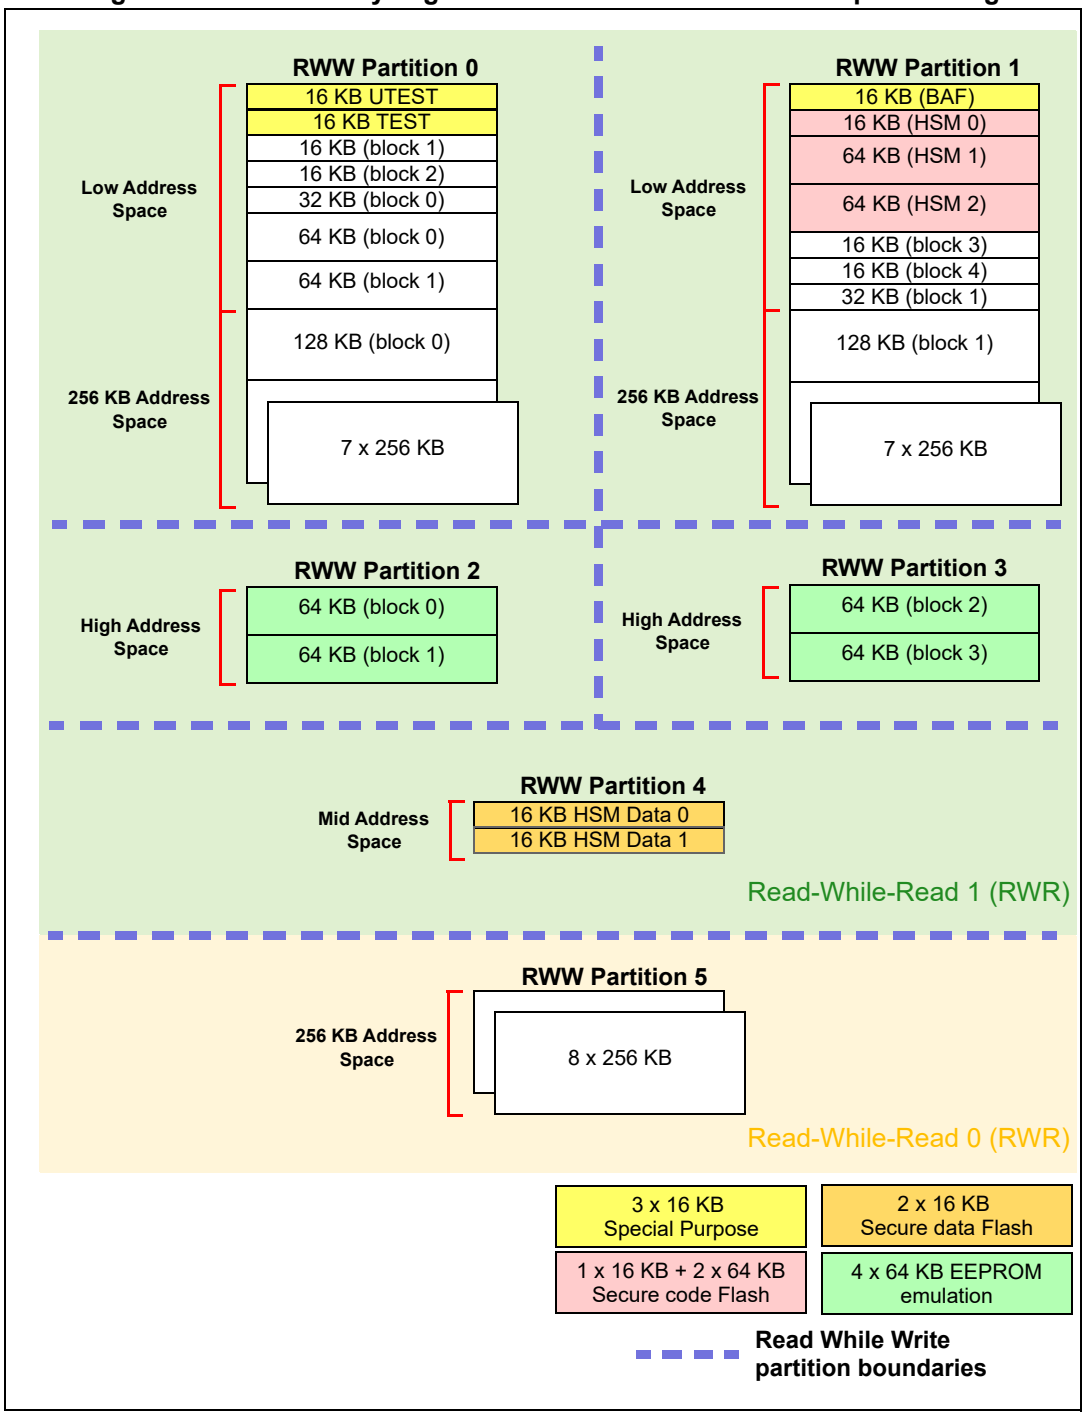
3.3.2.1 Features

- Flash segmentation
  - 16 KB, 32 KB, 64 KB, 128 KB, and 256 KB blocks provided for code or data
  - Four 64 KB blocks provided for EEPROM emulation
  - One 16 KB block and two 64 KB blocks provided for secure code
  - Two 16 KB blocks provided for secure data
  - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with triple bit detection, double and single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.3.2.2 Flash organization

The embedded Flash memory consists of six address spaces in four groupings:

- 16 KB, 32 KB and 64 KB low address spaces
- 16 KB mid address space
- 64 KB high address space
- 256 KB address space



Address space group (low-, mid- or high-address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The Flash module is further divided into four partitions that determine locations for valid Read While Write (RWW) operations. While the embedded Flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.
- For read operation two independent read accesses can be done through both PFlash controller to two Read While Read (RWR) partitions.

Figure 7 shows the Flash block segmentation and Read While Write partitioning for SPC58xEx/SPC58xGx devices.

Figure 7. Flash memory segmentation and Read While Write partitioning

Note: Refer to the Chapter 5: Memory Map for the SPC58xEx/SPC58xGx Flash memory map.

3.3.2.3 UTEST memory space

Devices in the SPC58xEx/SPC58xGx family contain a 16 KB area of one-time-programmable (OTP) Flash memory for storing test information and device configuration

data. *Refer to the Memory Map chapter* for the SPC58xEx/SPC58xGx UTEST Flash memory map.

3.3.2.4 Chip-specific C40FMC Flash register information

Refer to *Chapter 37: Embedded Flash Memory* for chip-specific layouts of the on-chip Flash memory control registers that contain bits used to lock individual Flash blocks from accidental erase or select individual Flash blocks for operations.

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional “ECC at memory” functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect or correct errors that have occurred on data stored in the memory, or both. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in *Table 6*.

Table 6. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC check-bits based on 29-bit address and 64-bit data fields
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including check-bits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC check-bits based on the data value and store data + check-bits into the memory	For a bus memory slave, store data and check-bits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC check bit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated check-bits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated check-bits, performs the ECC check bit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus check-bits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the check-bit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single or double bit error or report a non-correctable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the check bit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in

corrupted read data or check-bits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.5 Security features

The SPC58xEx/SPC58xGx architecture implements a security framework that makes it possible to protect the micro-controller resources from potential attacks.

Note: Detailed information on the SPC58xEx/SPC58xGx security architecture is published in a separate document and is available on a limited basis to customers who have a non-disclosure agreement (NDA) with STMicroelectronics.

4 Signal Description

4.1 Production packages

The following production packages are for the SPC58xEx/SPC58xGx device:

- eLQFP176 Exposed Pad
- QFP144
- BGA292

The BGA292 is a superset of the eLQFP176 pins. The LFBGA292 adds only:

- Additional GPIO
- More analog inputs
- Added muxing options for the eLQFP176 I/O

There are no I/O interfaces defined for the LFBGA292 that are not included in the eLQFP176 (external bus, etc.).

Case number and outline drawings for each package are provided in the *SPC58xEx/SPC58xGx Microcontroller Data Sheet*.

4.2 Emulation package

The eLQFP176 and LFBGA292 packages also support emulation devices for application debug and calibration support in a production device footprint.

4.3 Package pinouts and ballouts

The SPC58xEx/SPC58xGx pin package pinouts and ballouts are contained in the Microsoft Excel® workbook files attached to the IO_Definition document.

5 Memory Map

Table 7 shows the device memory map for the SPC58xEx/SPC58xGx.

All addresses on the SPC58xEx/SPC58xGx, including those that are reserved, are identified in the table. The addresses represent the physical addresses assigned to each region or module name.

Table 7 summarizes the complete 32-bit address map. A memory access, either read or write, to any region marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Table 8 lists the memory map of the peripheral region. This region is sub-divided into 16 KB byte regions or 'slots'. A peripheral occupies 1 or more slots. A memory access, either read or write, to any slot marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Within a 16 KB byte peripheral slot, it is normal for the peripheral registers to only occupy part of that 16 KB byte slot, normally from the lowest address upwards. The individual chapters for each block, define all the registers within that contiguous group of registers.

Any memory access outside the range of the defined register map will result in a transfer error. This error can generate an interrupt request in the CPU.

Table 9, *Table 10*, and *Table 11* define the embedded memory maps and the buddy memory map.

Caution: On the subset devices of the SPC58NE84 and SPC58xG84 device family several memory regions and peripheral instances listed in the global memory map have to be kept reserved. Please note the different system behavior when accessing these reserved areas:

- A memory access, either read or write, to any region marked as 'Reserved' in *Table 11.*, *Table 12.*, and *Table 13.* will result in a Transfer Error. This error can generate an interrupt request in the CPU.
- A memory access, either read or write, to any region marked as 'Used' in *Table 11.*, *Table 12.*, and *Table 13.* but not available in the subset device specification will not result in a Transfer Error. Please take care for an appropriate configuration of the System Memory Protection Unit (SMPU) to protect all these implemented but reserved address areas from being accessed unintentionally.

Table 7. Overview memory map

Start Address	End Address	Allocated Size	Used Size	Description

1. Refer to PACR registers in the Peripheral Bridge chapter
2. Refer to OPACR registers in the Peripheral Bridge chapter
3. This number indicates the assigned address range for the peripheral module on the peripheral bridge. The implemented memory size or the number of implemented peripheral registers might be smaller. Please refer to the dedicated peripheral chapter or device configuration chapter for more details.
4. For details, refer to *Chapter 47: GTM343 Integration (GTMINT) Module*.

Table 14. HSM memory map

Start offset	End offset	Allocated size	Used size
0xA0000000	0xAFFFFFFF	256 MB	Refer to the Security Reference Manual for details about how the HSM memory space is partitioned.

6 Functional safety

6.1 Introduction

The SPC58xEx/SPC58xGx offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL D of ISO 26262. This chapter gives an overview of the safety implementation for the SPC58xEx/SPC58xGx, and discusses the operation of the safety mechanisms.

6.2 Safety overview

The SPC58xEx/SPC58xGx has been designed for automotive applications executing safety-relevant tasks that require a fail-silent or fail-indicate MCU. The SPC58xEx/SPC58xGx supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms but the SPC58xEx/SPC58xGx generally supports an FTTI of 10 ms.

6.3 Module categorization

The definition of the SPC58xEx/SPC58xGx safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in *Table 15*.

Table 15. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, Flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules not used to implement any safety related functionality (for example, debug modules), modules which are functionally similar to modules in the categories above but do not provide any embedded safety provisions by default or are not used for safety in a use case scenario. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation. Notice that interference-freedom is guaranteed in both cases.
Other support modules	SuMo	These are modules that, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

Table 16 shows module classifications for the SPC58xEx/SPC58xGx.

Table 16. Module classification

Classification	Modules
ViMos	Master Safety Core, Master Safety Core D-Cache controller, Master Safety Core I-Cache controller, Local Memory Controllers Master Core, Safety Core D-Cache array, Safety Core I-Cache array, Safety Core Local D-Mem array, Safety Core Local I-Mem array, Peripheral Core (Core_2), I-Cache Peripheral Core (Core_2), Other local memories of Peripheral Core (Core_2), eDMA, DMACHMUX, Concentrator DMA, Concentrator HSM, INTC, XBAR_0 (Computational), SRAM controller, System RAM array, Flash memory controller, Flash memory array, System timer, MC_RGM, Dual PLL Digital, XOSC, MC_CGM, MC_ME, Voltage regulator, MC_PMC, SSCM, PBRIDGE*n*
PeMos	SAR ADC, PSI5, SENT, LINFlexD, DSPI, M_CAN/M_TTCAN, FlexRay, Ethernet, SIUL2, XBAR_1 (Peripheral), Concentrator Ethernet, FlexRay, LFAST, SD ADC

Table 16. Module classification (continued)

Classification	Modules
NoSaMos	Performance Core (Core_1), D-Cache Performance Core (Core_1), I-Cache Performance Core (Core_1), Other local memories of Performance Core (Core_1) External memory interface (LFAST, SIPI), GTM, HSM, Nexus, JTAG, I2C, SEMA42, WKPU, SPU, Overlay RAM, PIT, STANDBY SAR ADC
SuMos	RCCU, Checker Safety Core, System RAM/local memory controllers of Checker Safety Core (overall 4), Checker Safety Core D-Cache controller, Checker Safety Core I-Cache controller, CRC units, Temperature Sensors, IRCOSC, CMUs, HVDs, Bandgap reference, IMA, REG_PROT, SWT, FCCU, MEMUSTCU2

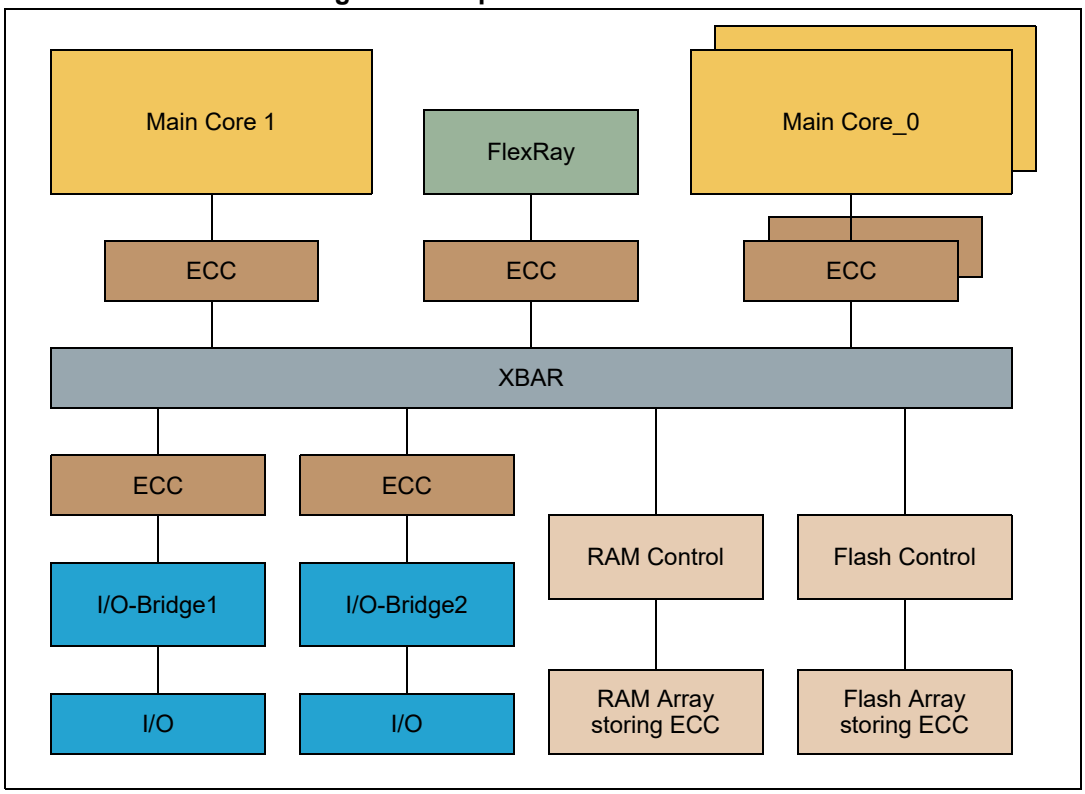
The SPC58xEx/SPC58xGx implements no specific protection of NoSaMos against Common Cause Failures between them.

6.4 System implementation

6.4.1 General concept

In general, safety integrity is achieved in the following ways:

- For the Cores, Interrupt Controllers, DMA and their closely related periphery, safety is ensured by a delayed lockstep approach (refer to *Section 6.4.2: Dual-core lockstep*).
- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for



individual modules. For the periphery, end-to-end ends at the I/O bridges (refer to *Section 6.4.1.1: End-to-End protection on data path*).

- Clock and power, generation and distribution, are supervised by dedicated monitors (refer to *Section 6.4.1.2: Clock and power monitoring*).
- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (refer to *Section 6.4.1.3: I/O peripherals*, and *Section 6.4.1.4: Communication controllers*).
- MBIST is provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms (refer to *Section 6.4.1.5: Built-In Self-Tests (BIST)*). Dedicated mechanisms are provided to check the availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection).
- The Fault Collection and Control Unit (refer to “Fault Collection and Control Unit (FCCU)” chapter for FCCU details) is responsible for collecting and reacting to failure notifications (refer to *Section 6.4.1.7: FCCU and failure monitoring*). MEMU (refer to *Section 6.4.4.4: Memory Error Management Unit (MEMU)*) is responsible for the collection and reporting (to the FCCU) of error events in system memories, and Flash memory, as well as E2E ECC errors caused by the XBAR, or RAM or Flash memory controllers. Error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (refer to *Section 6.4.3: Common cause failure measures*).

6.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected with at least 99% coverage via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a single-error correction, double-error detection (SECDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. *Figure 8* shows a general view of ECC schema.

Figure 8. Simplified view of E2E ECC

Note: Specific implementation for the SPC58xEx/SPC58xGx varies depending on the special requirements of RAM and Flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters (including, but not limited to the Safety Core) and checked on reads. The ECC correction bits are stored alongside the data in Flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, apart from memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGEs and peripherals can be used redundantly (refer to *Section 6.4.1.3: I/O peripherals*), or other mechanisms may be used to validate peripheral operation.

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) does allow the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address.
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the Flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash controllers; the target is respectively an XBAR slave port, the RAM array, or the Flash module (refer to “Crossbar Switch (XBAR)”, “Flash memory controller”, and “RAM controller (PRAM)” chapters).

6.4.1.2 Clock and power monitoring

6.4.1.2.1 Clock

Clocks in the SPC58xEx/SPC58xGx are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of lock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

6.4.1.2.2 Power

There are four types of voltage supervisors on the SPC58xEx/SPC58xGx, Low Voltage Detect (LVD), High Voltage Detect (HVD), Upper Voltage Detector (UVD) and Minimum Voltage Detector (MVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads, and so on) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion) (refer to “Power management” and “Power Control Unit (MC_PCU)” chapters for details on power monitoring).

6.4.1.3 I/O peripherals

To allow a safety application to make redundant use of all I/O peripherals, each peripheral has at least two instances (except for the GTM), and each instance is connected to a different PBRIDGE. This means, for example, that if DSPI is provided by the MCU, two DSPI modules (DSPI*n*, DSPI*m*) are included and connected externally through different pins. Internally, DSPI*n* would then be connected to PBRIDGE_0 and DSPI*m* to PBRIDGE_1 and be accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGEs, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is under the responsibility of the application software, and not the safety hardware mechanism.

6.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and therefore fall under the same safety reasoning as I/O peripherals. Yet we assume that for high bandwidth communication controllers additional software measures are employed that do not require redundant communication peripherals.

The following communication controllers do not contain special safety mechanisms (above what is included in them by their protocol specifications) nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, refer to *Section 6.4.1.3: I/O peripherals*):

- FlexRay
- Ethernet
- M_CAN
- M_TTCAN

Typically, software measures for the communication controllers (also called fault-tolerant communication layer) could contain E2E CRC data protection, sender identification, sequence numbering, and an acknowledgment mechanism.

PSI5 represents an exception to the replication of low bandwidth communications controllers. The module itself is replicated, but the two PSI5 modules share a single synchronization bit needed for staggered sync mode. This single bit is a single source of failures for both PSI5 modules if it triggers spurious synchronizations. The failure mode has to be covered by application level countermeasures, which are in any case needed to cover the single transceiver used in such a configuration.

6.4.1.4.1 Disabling of communication controllers

In the event of a dangerous failure, the MCU offers the capability of disabling transmission of individual channels of communication controllers (such as CAN modules and FlexRay). This prevents the transmission of erroneous messages while preserving the capability of communicating over the diagnostic bus. Disabling outputs is controlled by resetting the SIUL2_MSCR*n*[SMC] for the pins that are associated with communication controllers where this feature is needed (refer to the “System Integration Unit Lite2 (SIUL2)” chapter for details on disabling communication signals).

FCCU can drive a fault state on FI[0] with either one of the following two mechanisms:

- Error pin reaction due to a fault
- Software writing FCCU_CFG[FCCU_SET_CLEAR] = 01b

When the FCCU drives FI[0] to a fault state, the SIUL2 disables the output drivers of all pins whose SIUL2_MSCR*n*[SMC] = 0. This disables the possible transmission of erroneous messages. As long as the FCCU drives FI[0] to faulty state, the communication controllers’ Tx pins are disabled and internal pull-up are enabled. As soon as FI[0] is driven to non-faulty state, the communication controllers’ Tx pins are automatically enabled and state of internal pull-up/down restored.

The application should configure SIUL2_MSCR*n*[SMC] for pins that have active mapping of CAN modules (M_CAN, M_TTCAN) or FlexRay functionality and ensure that pin does not stay in undriven state.

Note: The FCCU uses an internal signal to disable the communication controller transmission, so transmission is disabled even when the FCCU cannot drive the FI[0] pin because the pin is configured as GPIO. Also, if FI[0] is used as error input, externally pulling it down will disable the communication controller transmission if this event drives FCCU to a fault state.

Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, M_TTCAN, M_CAN, FlexRay) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events.

6.4.1.5 Built-In Self-Tests (BIST)

The term BIST indicates the set of built-in hardware mechanisms that can be used (typically at startup) to avoid the accumulation of latent faults. BIST is a mechanism that permits a device to test itself. On the SPC58xEx/SPC58xGx, BIST is the principal means of meeting the requirement on latent faults as defined by the ISO 26262 standard.

Different types of BIST are implemented in the SPC58xEx/SPC58xGx:

- BIST for memories and logic: managed by the Self-Test Control Unit
- BIST for analog peripherals: requires software intervention

Refer to “Self-Test Control Unit (STCU2)” chapter for further details.

6.4.1.5.1 BIST during boot (off-line)

A device BIST is performed every time the device boots. BIST is performed transparently for the application while the device is still under reset. BIST failure will hold the device in reset, but the BIST will continue running where possible, and inform the system of the failure. Application software can start executing when the BIST finishes successfully without detecting a fault.

The boot time BIST, configured by DCF, comprises:

- Memory BIST (MBIST) for all RAMs and ROM.
- Logic BIST (LBIST) for digital logic.

6.4.1.6 Redundancy Control and Checker Units (RCCUs)

The RCCU compares a set of equivalent input signals provided by different sources and issues an alarm in case of a mismatch. For example, an RCCU compares the output of the checker core against the output of the main core and issues an alarm if they do not match. Signals are arranged in comparison groups, such as, all signals in one group are compared in one RCCU.In case of a compare mismatch the fault stays stable until clearing the FCCU channel status.

6.4.1.7 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

6.4.1.7.1 External error indication

Failure of the MCU is signaled to one or two pins, FI[0] (ERROR0) and FI[1] (ERROR1). FI[0] can also serve as an error input mechanism (refer to “Fault Collection and Control Unit (FCCU)” chapter, and “FCCU configuration” section of the “Device configuration” chapter, for details on the fault output signals). Both pins can be multiplexed with other functions with different defaults.

The error indication on pins FI[0] and FI[1] is controlled by SIUL2 and FCCU. The mapping of the FCCU output signals on the relevant pins and the associated electrical characteristics are enabled by the SIUL2_MSCR[*n*] register (refer to table “SIUL2_MSCR0 - SIUL2_MSCR511 field description” in the “System Integration Unit Lite2 (SIUL2)” chapter for signal mapping details). Once the FCCU is mapped onto the pin, the logic level is driven by the FCCU.

FI[0] is controlled by the FCCU at startup by default, but the state of FI[1] is like other I/O signals (refer to table “Pin startup and reset states” in chapter “Signal Description” for default states of FI[0] and FI[1]).

Since it is possible to reset FCCU and SIUL2 independently, the behavior of FI[0] and FI[1] is the result of the combined state of SIUL2_MSCR[*n*] and the FCCU. (refer to section “Reset interface” in chapter “Fault Collection and Control Unit (FCCU)” for FCCU reset details, and chapter “Reset and Boot” for the state of the FCCU relative to the system during different reset phases).

During functional reset, the application shall consider only the PAD PB[11] as FCCU error out. The FCCU EOUT1, that is PC[2], is not enabled during functional reset.

The FCCU_STAT[ESTAT] error status flag can be read to show whether the FCCU is in an error state. This flag can be written by software to either a 1 (fault) or 0 (operational) when the FCCU is in operational state.

FCCU_EINOUT(EINO): The value of this register depends on the state of the pad. If the IBE functionality of the SIUL is enabled, the register bit reflects the physical status of the pin as seen by the input buffer. In case the protocol selected for EOUT interface is a toggling one (Dual rail or Time switching), this may not be true due to synchronization in the safety clock domain.

The register reflects the physical status of the pin from application point of view (external status).

FCCU_STAT(PhysicalErrorPin): This register field indicates the actual status of the Error pin as driven by FCCU to the pad based on different FCCU configurations and state of the failure input channels. The value reported in the FCCU_STAT (PhysicalErrorPin) could be different from what is seen at the pad.

6.4.1.7.2 Failure handling

The FCCU is an autonomous module that is responsible for reacting to failure indicators. A different reaction can be configured for each failure source. Overall failure reaction time requires time for detecting, processing, and indicating the error. During this time, the SPC58xEx/SPC58xGx could provide wrong results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU.
- Control logic and signals monitored by the FCCU itself (refer to chapter “Fault Collection and Control Unit (FCCU)”).
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Keep in mind that software can also directly influence the state of the F*n* pins.
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERROR*n*
- Disabling the transmission capabilities of communication controllers (FlexRay, CAN, Ethernet. Note that, it is only possible in conjunction with changing the state of the failure indication pins
- No reaction

Software can read the failure source that caused a fault, either before or after a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication will stay in failure mode for a configurable minimum time. If necessary, software can also reset the MCU.

6.4.1.7.3 FCCU failure inputs from other modules

Table 17 shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset(3).

Table 17. FCCU failure inputs

FCCU channel(1)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism(2)
0	TEMP_ERROR	Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_dig_EPR_TD, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable	No reaction	*Section 67.5.29: Event Pending Register (EPR_TD)*	Correction of violating condition and power reset cycle
1	LVD_ERROR	Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable	No reaction	PMC_Dig registers EPR_LV0 EPR_LV1 *Section 67.4: Memory map/register definition*	Correction of violating condition and power reset cycle

3. All of these faults require a long functional reset.

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
2	HVD_ERROR	Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable	No reaction	PMC_Dig registers EPR_HV0 EPR_HV1 *Section 67.4: Memory map/register definition*	Correction of violating condition and power reset cycle
3	DPMC_DCF_SAFETY_ERR	Digital PMC initialization error during DCF data load. The fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status gets cleared if the fault is not persistent"	Not testable	No reaction	*Chapter 67: Power management controller digital interface (PMC_Dig)*	POR, Destructive Reset
4	DPMC_VD_BIST	Digital PMC Voltage detector BIST	Feedback loop via FCCU Fake bit.	No reaction	*Chapter 67: Power management controller digital interface (PMC_Dig)*	POR, Destructive Reset
5	SSCM_XFER_FLASH_ERR_ MEMORY_ERR	SSCM transfer error (during the SSCM and STCU DCF loading), or Flash memory initialization error, or Memory error.	Not testable (but wrong DCF configuration or spurious data from Flash can trigger other failures)	No reaction	*Table 1736: SSCM memory map*	POR, Destructive Reset
6	STCU_UF	STCU2 unrecoverable fault indication during self-test. It is simultaneously reported to the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	Destructive reset by MC_RGM directly during offline self-test	*Section 90.5.10: STCU2 Error Register (STCU_ERR_STAT)* *Section 64.3.1.2: 'Destructive' Event Reset Disable Register (RGM_DERD)*	POR, Destructive reset. During offline test, assertion of this fault will automatically cause a destructive reset request by MC_RGM.

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
7	STCU_RF	STCU2 recoverable fault indication during self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT [RFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 90.5.10: STCU2 Error Register (STCU_ERR_STAT)*	POR, Destructive Reset
8	STCU_LMBIST_USR_ERR	Activation of L/MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status will clear if the fault is not persistent.	Feedback loop via FCCU Fake bit	No reaction	—	POR, Destructive Reset
9	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG, NPC or Debug functionality moved out of reset or SSCM activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	—	Long Functional Reset
10	RCCU_Core 0_ALARM	Indication of lockstep out of sync due to a fault for Core_0 or associated DSMC. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
11	—	—	—	—	—	—
12	RCCU_Core 2_ALARM	Indication of lockstep out of sync due to a fault for Core_2 or associated DSMC. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
13	—	—	—	—	—	—
14	RCCU_INTC 1 _ALARM	INTC_1 out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
15	RCCU_DMA 0	DMA_0 out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit.	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
16	RCCU_DMA 1	DMA_1 out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit.	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
17	SWT3_ ResetReq	Reset request from SWT_3. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT3 (after a functional reset).	Test in software by enabling the SWT and failing to service it.	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	Functional Reset
18	SWT2 _ResetReq	Reset request from SWT_2. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT2 (after a functional reset).	Test in software by enabling the SWT and failing to service it.	Long Function Reset	*Chapter 46: Software Watchdog Timer (SWT)*	Functional Reset
19	SWT1 _ResetReq	Reset request from SWT_1. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT1 (after a functional reset).	Test in software by enabling the SWT and failing to service it.	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	Functional Reset
20	SWT0 _ResetReq	Reset request from SWT_0. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT0 (after a functional reset).	Test in software by enabling the SWT and failing to service it.	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	Functional Reset

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
21	MEMU_RAM_CE	Indication by MEMU of occurrence of correctable errors in system RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[SR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Injection of RAM ECC error via ECC bit access and later reading	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	
22	MEMU_RAM_UCE	Indication by MEMU of occurrence of uncorrectable errors in system RAMs. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Injection of RAM ECC error via ECC bit access and later reading	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
23	MEMU_RAM_OV	Indication of overflow of system RAM ECC buffer in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Functional test	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
24	MEMU_PER_CE	Indication by MEMU of the occurrence of correctable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Functional test	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
25	MEMU_PER_UCE	Indication by MEMU of the occurrence of uncorrectable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	Functional test	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
26	MEMU_PER_OV	Indication of overflow of peripheral RAM ECC buffer in MEMU. The fault is cleared by clearing MEMU_ERR_FLAG[PR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	Functional test	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
27	MEMU_FLS_CE	Indication by MEMU of occurrence of correctable errors in Flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Reading preprogrammed correctable ECC error from UTEST Flash memory	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
28	MEMU_FLS_UCE	Indication by MEMU of occurrence of uncorrectable errors in Flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Reading preprogrammed correctable ECC error from UTEST Flash memory	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
29	MEMU_FLS_OV	Indication of overflow of Flash memory ECC buffer in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[F_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Functional test	No reaction	*Section 87.6.2.2: Error Flag register (ERR_FLAG)*	—
30	IMA_SoC	IMA SoC Active The fault is cleared by disabling IMA (IMA.SLCT.R = 0x0), followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	IMA read/write	No reaction	*Section 88.3: Accessing memory via the IMA module*	Functional Reset

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
31	SMPU_MONITORXBAR 0	Indication of fault in SMPU_0 logic fault resulting in an incorrectly refused access, but failure to indicate the error to the requesting bus master. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Not testable	No reaction	*Chapter 21: System Memory Protection Unit (SMPU)*	POR, Destructive reset
32	SMPU_MONITOR XBAR 1	Indication of fault in SMPU_1 logic fault resulting in an incorrectly refused access, but failure to indicate the error to the requesting bus master. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Not testable	No reaction	*Chapter 21: System Memory Protection Unit (SMPU)*	POR, Destructive reset
33	SMPU ERROR XBAR 0	Indication of the SMPU_0 that it prevented an unauthorized access. The fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Willfully causing an access to an unauthorized location	No reaction	*Chapter 21: System Memory Protection Unit (SMPU)*	—
34	SMPU ERROR XBAR 1	Indication of the SMPU_1 that it prevented an unauthorized access. The fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Willfully causing an access to an unauthorized location	No reaction	*Chapter 21: System Memory Protection Unit (SMPU)*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
35	CORE 0 I-MEM address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_0 I-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
36	CORE 0 D-MEM address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_0 D-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
37	CORE 0 I-Cache address ERR	Indication of an addressing error (adddress, CS and WE feedback) inside dedicated memories of Core_0 I-Cache. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
38	CORE 0 D-Cache address ERR	Indication of an addressing error (adddress, CS and WE feedback) inside dedicated memories of Core_0 D-Cache. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
39	CORE 1 I-MEM address ERR	Indication of an addressing error (adddress, CS and WE feedback) inside dedicated memories of Core_1 I-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
40	CORE 1 D-MEM address ERR	Indication of an addressing error (adddress, CS and WE feedback) inside dedicated memories of Core_1 D-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
41	CORE 1 I-Cache address ERR	Indication of an addressing error (adddress, CS and WE feedback) inside dedicated memories of Core_1 I-Cache. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
42	CORE 1 D-Cache address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_1 D-Cache. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
43	CORE 2 I-MEM address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_2 I-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
44	CORE 2 D-MEM address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_2 D-MEM. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
45	CORE 2 I-Cache address ERR	Indication of an addressing error (address, CS and WE feedback) inside dedicated memories of Core_2 I-Cache. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	*Section 35.5.2: Transaction monitor*	—
46	—	—	—	—	—	—
47	DMA 0 TCD address ERR	Error while reading a DMA 0 TCD. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	—	—
48	DMA 1 TCD address ERR	Error while reading a DMA 1 TCD. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	Feedback loop via FCCU Fake bit	No reaction	—	—
49	FM_PLL_0	PLL0 loss of lock. In order for this fault source to be asserted in the event of loss of lock, the Loss of Lock Interrupt needs to be enabled by writing (PLLDIG_PLL0CR[LOLIE]) = 1. The fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_RF_Sn[RFSm].	Forced loss by PLL reconfiguration	No reaction	*Section 28.5.2.2: PLL0 status register (PLL0SR)*	Application integrity checks
50	FM_PLL_1	PLL1 loss of lock. In order for this fault source to be asserted in the event of loss of lock, the Loss of Lock Interrupt needs to be enabled by writing (PLLDIG_PLL0CR[LOLIE]) = 1. The fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_RF_Sn[RFSm].	Forced loss by PLL reconfiguration	No reaction	*Section 28.5.2.5: PLL1 status register (PLL1SR)*	Application integrity checks

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
51	CMU_0_OSC	Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable	No reaction	*Section 29.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional Reset
52	CMU_0_PLL	SYSCLK frequency out of range. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	Test by mis-configuration	No reaction	*Section 29.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional Reset
53	CMU_Platform	Exception from monitoring internal clocks by the CMU_Platform. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_n, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	Test by mis-configuration	No reaction	*Section 29.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional Reset
54	CMU_other	Exception from monitoring internal clocks by other CMU. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_n, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	Test by mis-configuration	No reaction	*Section 29.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional Reset
55	GASKET XBAR 2 BACKDOOR TO XBAR0	Indication of a hardware fault resulting in corrupted transaction through the peripheral XBAR or gaskets	Not testable	No reaction	*Chapter 19: Crossbar Integrity Checker (XBIC)*	POR, Destructive reset

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
56	XBAR 1 XBIC	Indication of a hardware fault resulting in corrupted transaction through the peripheral XBAR or gaskets	Not testable	No reaction	*Chapter 19: Crossbar Integrity Checker (XBIC)*	POR, Destructive reset
57	XBAR 0 XBIC	Indication of a hardware fault resulting in corrupted transaction through the computational XBAR or gaskets	Not testable	No reaction	*Chapter 19: Crossbar Integrity Checker (XBIC)*	POR, Destructive reset
58	EDC_ECC _FLASH 0	EDC after ECC for FLASH Array. Indication of a hardware fault in the ECC of the Flash memory.	Feedback loop via FCCU Fake bit or test by accessing to Flash address of the Customer Programmable Detection area in the UTEST block	No reaction	*Section 36.5.14: Safety considerations*	POR, Destructive reset
59	EDC_ECC _FLASH_C 0	EDC after ECC for FLASH Controller. Indication of hardware fault in the Flash memory controller resulting in corrupted ECC detection / correction.	Not testable	No reaction	*Section 36.5.14: Safety considerations*	POR, Destructive reset
60	ENC_ERR _FLASH 0	Flash Encoding Error. Indication of hardware fault resulting in corrupted Flash memory access.	Test by accessing to Flash address of the Customer Programmable Detection area in the UTEST block	No reaction	*Section 36.5.14: Safety considerations*	Application dependent

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
61	ADDR_FDBK_ERR_FLASH_C 0	Indication of an addressing error in the Flash memory controller resulting in corrupted Flash memory access.	Test by accessing to Flash address of the Customer Programmable Detection area in the UTEST block	No reaction	*Section 36.5.14: Safety considerations*	Application dependent
62	SAFE_CAL_ERR 0	alarm indicating the Flash controller detected a transaction monitor mismatch in the pseudo-replicated calibration evaluation hardware (PFLASHC_0).	Not testable	No reaction	—	—
63	FLASH_REF_ERR	FLASH read reference error	Test by accessing to Flash address of the Customer Programmable Detection area in the UTEST block.	No reaction	*Section 36.5.14: Safety considerations*	POR, Destructive reset
64	EDC_ECC_FLASH 1	EDC after ECC for FLASH Array. Indication of a hardware fault in the ECC of the Flash memory resulting in corrupted ECC detection/correction.	Feedback loop via FCCU Fake bit or test by accessing to Flash address of the Customer Programmable Detection area in the UTEST block.	No reaction	*Section 36.5.14: Safety considerations*	POR, Destructive reset

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
65	EDC_ECC_FLASH_C 1	EDC after ECC for FLASH Controller. Indication of hardware fault in the Flash memory controller resulting in corrupted ECC detection / correction.	Not testable	No reaction	*Section 36.5.14: Safety considerations*	POR, Destructive reset
66	ENC_ERR_FLASH 1	Flash Encoding Error. Indication of hardware fault resulting in corrupted Flash memory access.	Test by access to Flash address in Customer Programmable Detection area in the UTEST block	No reaction	*Section 36.5.14: Safety considerations*	—
67	ADDR_FDBK_ERR_FLASH_C 1	Indication of an addressing error in the Flash memory controller resulting in corrupted Flash memory access.	Test by access to Flash address in Customer Programmable Detection area in the UTEST block	No reaction	*Section 36.5.14: Safety considerations*	—
68	SAFE_CAL_ERR 1	alarm indicating the Flash controller detected a transaction monitor mismatch in the pseudo-replicated calibration evaluation hardware (PFLASHC_1).	Not testable	No reaction	—	—
69	ON_CAL_RAM_ERR	alarm indicating the Flash controller detected a transaction monitor mismatch when compared to the on-chip calibration RAM safety feedback outputs.	Not testable	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
70	ADDR_FDBK_ERR_PRAM 0 RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access or a RAM Late-Write Buffer mismatch.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
71	EDC_ERR _PRAM 0	Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
72	ADDR_FDBK_ERR_PRAM 1 RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
73	EDC_ERR _PRAM 1	Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
74	ADDR_FDBK_ERR_PRAM 2 RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
75	EDC_ERR_PRAM 2	Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
76	ADDR_FDBK_ERR_PRAM 3 RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
77	EDC_ERR_PRAM 3	Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read.	Not testable	No reaction	*Chapter 35: Platform RAM controller AHB (PRAMC_AHB)*	—
78	DFT1	Test circuitry Group 1 activation.	Not testable	No reaction	—	POR, Destructive reset
79	DFT2[3]	Test circuitry Group 2 activation.	Not testable	No reaction	—	POR, Destructive reset
80	DFT3	Test circuitry Group 3 activation.	Not testable	No reaction	—	POR, Destructive reset
81	DFT4	Test circuitry Group 4 activation.	Not testable	No reaction	—	POR, Destructive reset
82	Core 0 Exception	Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Willfully cause an appropriate exception(for example, access a non-existing address)	No reaction	*Section 16.7: Exceptions*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
83	Core 1 Exception	Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Willfully cause an appropriate exception(for example, access a non-existing address)	No reaction	*Section 16.7: Exceptions*	—
84	Core 2 Exception	Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Willfully cause an appropriate exception (for example, access a non-existing address)	No reaction	*Section 16.7: Exceptions*	—
85	Checker Core 0 disable alarm	Indication of disablement of lockstep mode	Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.2: Dual-core lockstep*	POR, Destructive reset
86	AIC_0_ALARM	Error detected by the PBRIDGE monitor during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—
87	PBRIDGE_0_e2eEDC_ERR	Error detected by the e2eEDC during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—
88	AIC_1_ALARM	Error detected by the PBRIDGE monitor during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
89	PBRIDGE_1_e2eEDC_ERR	Error detected by the e2eEDC during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—
90	AIC_2_ALARM	Error detected by the PBRIDGE monitor during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—
91	PBRIDGE_2_e2eEDC_ERR	Error detected by the e2eEDC during a read/write transaction through the PBRIDGE	Feedback loop via FCCU Fake bit	No reaction	*Chapter 20: Peripheral Bridge (PBRIDGE)*	—
92	Xbic_Concentrator_0_alarm_Alarm	XBIC Concentrator 0	Not testable	No reaction	—	—
93	Monitor_Concentrator0_edc_Alarm_Alarm	EDC after ECC error alarm for any master in concentrator 0	Feedback loop via FCCU Fake bit.	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
94	Safe Mode[4]	Indication of safe mode request assertion from MC_RGM. The event is also captured in MC_ME and available as status for crosscheck. Status should be cleared first in the MC_RGM_FES, then followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable	No reaction	*Chapter 64: Reset Generation Module (MC_RGM)*	—
95	Compensation Disable	Indication of undesired deactivation of pad compensation. Fault may affect a distorted transmissions on I/Os associated. The indication is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm][5]	Not testable	No reaction	—	—
96	EIN_ERR	Error input pin (FI[0], external of the MCU) signalling an error condition. The fault is cleared by clearing the fault driving FI[0] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	External activation of EIN. External entity has to pull the error input low.	No reaction	*Chapter 89: Fault Collection and Control Unit (FCCU)*	—
97	Reserved - Fake fault error injection should be avoided.					
98	Reserved - Fake fault error injection should be avoided.					
99	Monitor_Concentrator_0_alarm	Error in any frequency gasket in concentrator 0	Feedback loop via FCCU Fake bit	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
100	SWT3_first_timeout	First Timeout event which is also mapped to INTC	SW test by not resetting the SWT during startup	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	—
101	SWT2_first_timeout	First Timeout event which is also mapped to INTC	SW test by not resetting the SWT during startup	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	—
102	SWT1_first_timeout	First Timeout event which is also mapped to INTC	SW test by not resetting the SWT during startup	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	—
103	SWT0_first_timeout	First Timeout event which is also mapped to INTC	SW test by not resetting the SWT during startup	No reaction	*Chapter 46: Software Watchdog Timer (SWT)*	—
104	Monitor_Concentrator1_ma_Alarm	EDC after ECC error alarm for SIPI 1	Feedback loop via FCCU Fake bit	No reaction	—	—
105	Monitor_Concentrator1_mb_Alarm	EDC after ECC error alarm for Flexray 0	Feedback loop via FCCU Fake bit	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
106	Monitor_Concentrator1_mc_Alarm	EDC after ECC error alarm for Ether 0	Feedback loop via FCCU Fake bit	No reaction	—	—
107	Monitor_Concentrator2_ma_Alarm	EDC after ECC error alarm for Ether 1	Feedback loop via FCCU Fake bit	No reaction	—	—
108	Monitor_Concentrator1_Alarm	Error in the frequency gasket in the concentrator 1	Feedback loop via FCCU Fake bit	No reaction	—	—
109	Monitor_Concentrator2_Alarm	Error in the frequency gasket in the concentrator 2	Feedback loop via FCCU Fake bit.	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
110	Xbic_Concentrator_1_alarm	XBIC Concentrator 1	Not testable	No reaction	—	—

Table 17. FCCU failure inputs (continued)

FCCU channel[1]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery mechanism[2]
114	checker dma_1 disable alarm	Indication of disablement of lockstep mode	Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.2: Dual-core lockstep*	POR, Destructive Reset
115	Flash Reset Error	The pin/flag signals the following unrecoverable errors: – ECC errors on Flash internal reads during configuration loading (startup) – ECC errors on Flash internal reads during fw copy (startup) – Double ECC errors on FLASH controller internal RAM during internal self-check routine (always running)	Not testable	No reaction	—	POR, Destructive Reset

1. Refer to “Fault Collection and Control Unit (FCCU)” chapter for channel mapping details.
2. This column recommends the reaction of the application in case an FCCU channel triggers an error during the execution of the safety function. An empty cell means that the reaction is application dependent..
3. In the event of activation of RF[94] (that is safe mode request), RF[79] is also activated. If the RGM trigger of safe mode is functionally used, during servicing of the response to activation of the RF[79], software should check that the device is not in safe mode to discriminate between an unwanted activation of test circuitry and a safe mode request.
4. In the event of spurious activation of this fault source, RF[79] is activated together with RF[94]. In scenarios where safe mode trigger from RGM is a valid functional use case, the RF[94] should be disabled.
5. Compensation cell reduces the spread of some circuit parameters (slew rate of the output signal and the output impedance) in the IO buffers over temperature, process and voltage. Compensation cell might remain disabled until supplies have reached LVD290 threshold.

6.4.1.8 Operational interference protection

Being a multi-master system, SPC58xEx/SPC58xGx provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom is guaranteed via a hierarchical memory protection schema including:

- MPUs
- PBRIDGEs
- Register protection

There are two Memory Protection Unit levels included in the SPC58xEx/SPC58xGx. The Core Memory Protection Unit (CMPU) is a mechanism included in each core to protect

address ranges against access by software developed according to lower ASIL. The CMPU is typically used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. The MPUs prevent access of different bus masters to address ranges and are typically used by the safety application to prevent NoSaMos (such as the Performance Core) to access the application's safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual register to be locked against any manipulation without unlocking.

These safety mechanisms are further described in the chapters System Memory Protection Unit (SMPU), Peripheral Bridge (PBRIDGE) and Registers Protection (REG_PROT).

6.4.1.9 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, F*n*). If the FCCU does not react within a predefined interval as specified in the "FCCU configuration" section of the "Device configuration" chapter, on one of those outputs to the incoming failure indication, the FOSU assumes the FCCU has failed, and causes a destructive reset.

The FOSU does not require any configuration by software.

6.4.2 Dual-core lockstep

The SPC58xEx/SPC58xGx duplicates its safety-relevant processing elements and compares their operation in Lockstep mode (LSM).

The safety core and its strictly connected modules are replicated.

Note: As software is concerned, they behave as one core.

Each replicated processing channels contains:

- Core
- Cache control
- Local memory control
- Core MPU
- Core System Bus Interface, including e2eECC logic

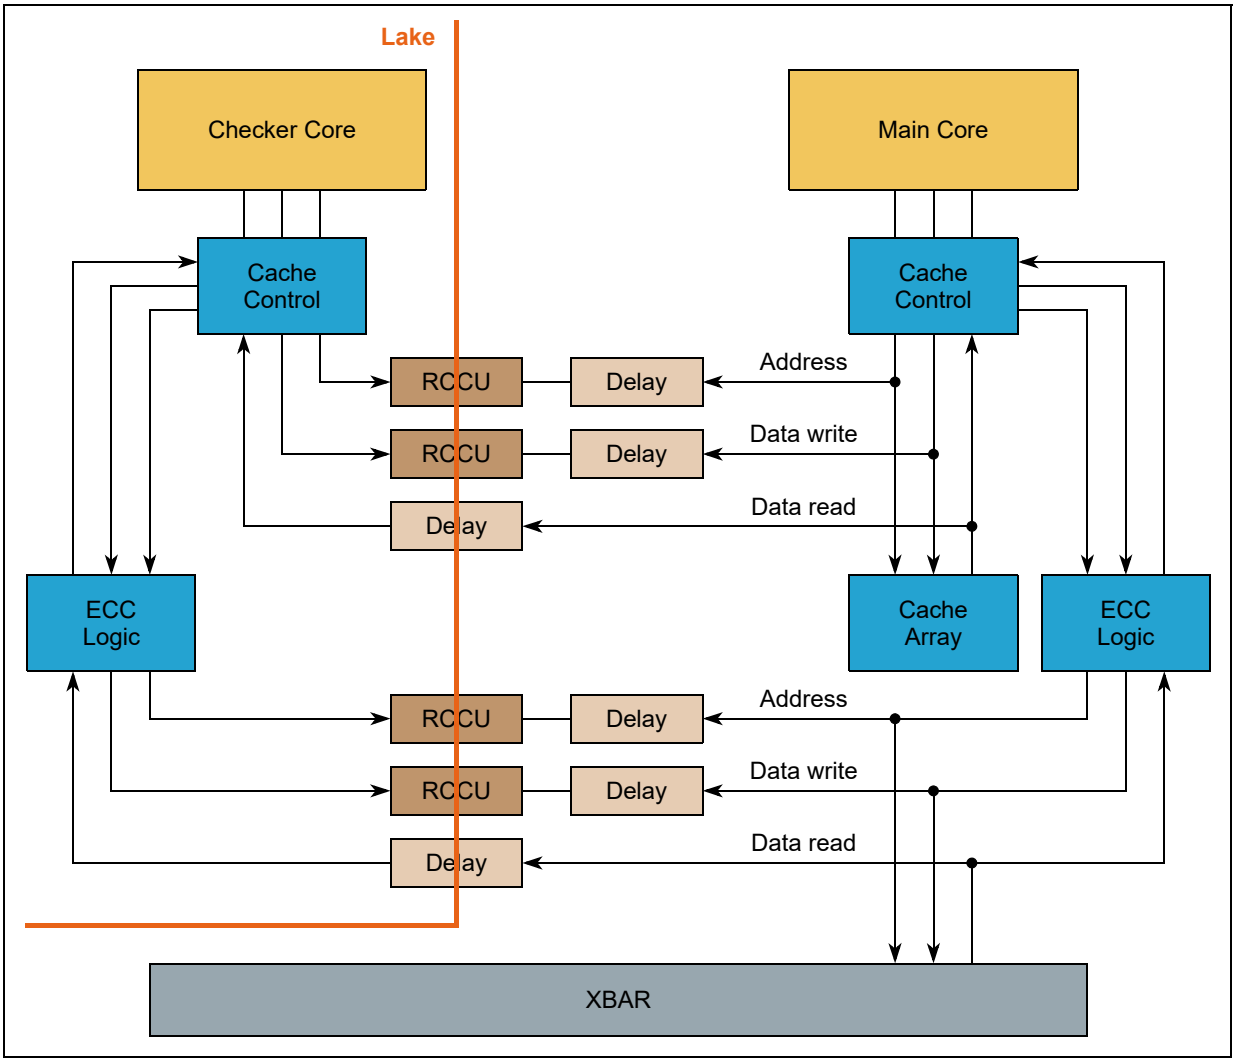
Other modules which are replicated are:

- INTC
- eDMA controller
- DMA muxes

Together each set of replicated elements forms a channel (for example, the Main channel and the Checker channel).

Elements that are not replicated are:

- Cache and local memory arrays
- Interconnect (XBAR)
- RAM controller
- Flash memory controller



Note: This is not a complete list of all non-replicated elements.

Equivalent operation of replicated resources is supervised by comparators on all functional signals leaving the channels for the rest of the MCU. Any operational deviations between the supervised signals will cause the FCCU to be notified of the discrepancy.

The Checker Core does not have a direct connection to the XBAR. All of the outputs of Checker Core that target the XBAR (as well as any other non-duplicated resource, like local memories) will end in an RCCU for verification, and all the inputs to Checker Core from the XBAR will be split off from the Main Core XBAR inputs.

An abstract view of the implementation including delays and RCCUs is shown in *Figure 9*, but does not show local memory.

Figure 9. Dual core concept

A delay of two clock cycles exists between the Main and Checker channel to reduce their susceptibility to CCFs caused by power and clock disturbances. Outputs of the Main Core (such as XBAR addresses) are registered and delayed before being forwarded to the RCCUs, while inputs signals (such as XBAR read data) are registered and delayed before being fed to the Checker channel.

LSM can be disabled during boot by reprogramming the Flash memory (UTEST Miscellaneous DCF Client). LSM is also automatically disabled when Main Core enters debug mode and automatically re-enabled when it leaves it. If LSM is disabled, the RCCUs are disabled, and a signal is sent to the FCCU. Thus no user-initiated dynamic enabling of LSM is possible. If the cores are out of lock, a destructive or functional reset is needed to reestablish LSM. Also, no Decoupled Parallel Mode (DPM) is available (Main Core and Checker Core cannot operate as two independent cores running different software). Main Core is able to operate as an independent core if Checker Core is disabled. The status of LSM for the Safety core can be verified by checking the appropriate FCCU register.

6.4.3 Common cause failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the replication of the Safety Core or of the peripherals. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

There are also configuration registers that, on change, can affect the execution of the MCU's safety function and, simultaneously, disable the respective safety mechanism. These are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing the register protection described above.

6.4.4 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

6.4.4.1 ECC for storage

All storage used in normal operation is protected by ECC with:

- SEC/DED (single bit error correction and double bit error detection) for core, local memory, peripheral RAM
- SEC/DEC/TED (single bit error correction, double bit error correction and triple error bit detection) for Flash memory

The following exceptions exist:

- The caches in the cores are protected by EDC (Error Detection Code), only detecting, but not correcting errors.
- SRAM is protected by SEC/DEC ECC in PRAM controller only during partial writes (RMW operations) otherwise it is protected by E2E-ECC mechanism
- FlexRay's schedule information RAM (lookup table RAM) is protected by EDC only.
- The HSM's AES program extension RAM are not protected by ECC.

A list showing the implementation of RAMs with ECC (including address protection) and for the SPC58xEx/SPC58xGx is shown in *Table 18*.

Table 18. ECC RAM implementations

Location	Memory	MEMU Classification	ECC	Address is ECC	Muxing Factor	Reacts to uncorrectable error
Core_0	I-MEM	System RAM	SEC/DED(1)	Y	8	Y
	D-MEM	System RAM	SEC/DED(1)	Y	16	Y

	Nexus	Peripheral	NO	—	4	N
	AMU	Peripheral	SEC/DED	Y	8	N

1. Only when accessed by its own core. During access from other cores it is protected by E2E-ECC.
2. SEC/DEC for partial write operation (RMW), refer to *Section 36.5.14: Safety considerations*.

As shown in *Table 18*, some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback). This is different for storage related to PeMos. PeMos, in general, use an ECC without address error protections and do not include additional measures to detect them. All ECC calculations for RAMs in PeMos are accomplished by logic outside of the RAM, not in the RAM block.

An exception to this is the GTM's RAMs. They include addressing failure detection measures in the ECC. In addition, the individual RAM ports of the GTM do not share common parts and connect to individual (non-interfering) RAM arrays.

6.4.4.2 All-x words and ECC

There is a special case for valid ECC values in the SPC58xEx/SPC58xGx. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not valid for memory that is checked by ECC. Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be valid. The Flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be valid.

In case of not valid codeword, All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be always uncorrectable errors. For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, a not valid All-x codeword may result in a correctable error.

Note: For Flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (refer to Chapter 37: Embedded Flash Memory, for more details on Flash memory safety mechanisms).

6.4.4.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU. The MEMU (refer to *Section 6.4.4.4: Memory Error Management Unit (MEMU)*) may filter ECC error notification for known ECC error addresses with same (optional) syndrome (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU, which filters and then forwards unfiltered notifications in an aggregated manner to the FCCU.

6.4.4.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events generated by the ECC logic used to protect system RAMs (in this context they are those RAMs with "System RAM" memory classification as shown in *Table 18*), peripheral RAM, and Flash memory. In addition to storage errors, e2eECC errors caused by XBAR, RAM or flash memory controllers and memory related faults detected during MBIST are also routed to MEMU.

When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU.

Refer to the Device Configuration chapter for MEMU connections.

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses with same (optional) syndrome in the table is ensured. For example, if an address with same (optional) syndrome is already stored in the MEMU's table, correctable errors at that address will no longer be reported to the FCCU
- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (refer to *Chapter 87: Memory Error Management Unit (MEMU)* for more information).

6.4.4.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- The (optional) ECC-syndrome or MBIST bad-bit information in case of SBE
- A configuration specifying whether the ECC unit is attached to a peripheral RAM, to a System RAM or to Flash memory

Not all ECC units provide a syndrome. If an ECC unit does not provide the syndrome, 0xFF is stored in the MEMU error table instead of the syndrome. If an error is signaled, it is compared against all errors known for that storage:

- If no entry of that address with same (optional) syndrome is already in the buffer, it is to be added into the appropriate table depending on the SBE versus UCE indicator
- If there is no free entry left in that buffer, the overflow flag is set

Note: If a previously known error has been marked invalid by software, no comparison against the address will occur.

If a valid entry of that address is in the buffer, and if the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. In case of the same error is reported by ECC which reports the syndrome and additionally by ECC which does not, the reporting order becomes important.

- If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. If ECC which provides the syndrome reports first, the second reporting without syndrome is discarded.
- If ECC which does not provide the syndrome reports first, a second entry with the syndrome is stored in the table.

7 Device configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device,
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters, and
- Links for more information.

7.2 Core modules

The SPC58xEx/SPC58xGx has cores in three distinct modules: HSM (described in the HSM chapter of the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual); GTM (described in the GTM documentation); and the main platform (described below).

The main platform has five separate cores that perform various computational and control functions:

- The main computational shell consists of 2 processing channels (Main Core_0 and Main Core_1), both of which use an e200z420n3 core. These two cores are used for general computational functions.
- Only Main Core_0 uses one e200z419 core (Checker Core_0) as lock step replica. The e200z419 is a true subset of the e200z420n3 core. When enabled, the checker core operates in lock step mode with the associated main core executing exactly the same instructions. Thus, the checker core insures that the main core is executing correctly.
- The third processing channel is implemented with a lock-step pair of 2 e200z425s and is generally used to control various I/O modules.
- Core0 and Core2 are capable of locking their respective crossbar master ports using reservation instructions for data accesses. These cores are not capable of locking their crossbar master ports for instruction accesses using reservation instructions.
- Core1 is not allowed to lock both instruction and data crossbar ports using reservation instructions.

PowerISA 2.06 and implementation-specific SPRs for the e200z420n3, e200z419, and e200z425n3 cores are listed in *Table 19*. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in *Table 19*.

Table 19. Special Purpose Registers (SPRs)

7.3 System modules

7.3.1 SIUL2 configuration

The System Integration Unit Lite 2 (SIUL2) controls the MCU pad configuration, ports, general-purpose input and output (GPIO) signals and external interrupts with trigger event configuration.

For details, refer *Chapter 17: System Integration Unit Lite2 (SIUL2)*.

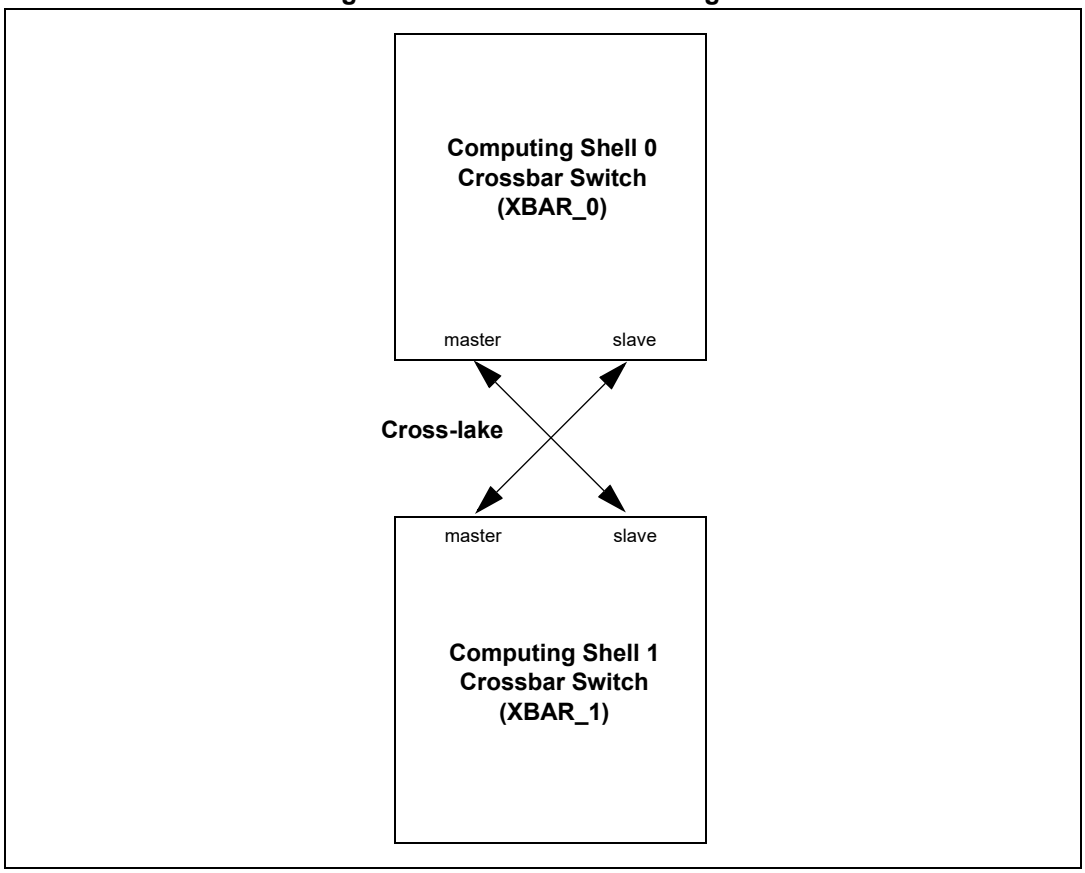
Note: All output pins, whose SIUL2_MSCRn[SMC] = 0, disable their output drivers when the device enters SAFE mode while the internal weak pull-up of GPIO is enabled automatically. Coherently, ME_SAFE_MC.PDO must be set to 1 (default value) when disabling the output buffer.
Each other configuration has no effect on output driver of pin, refer to Table 22.

Table 22. Output buffer configuration

ME_SAFE_MC [PDO]	SIUL2.MSCR_IOn[SMC]	DRUN Mode	SAFE Mode
0 (no safe gating of I/O)	0 (output buffer disabled)	Output buffer enabled	Output buffer enabled
0 (no safe gating of I/O)	1 (output buffer enabled)	Output buffer enabled	Output buffer enabled
1 (output buffer driver disabled in SAFE mode)	0 (output buffer disabled)	Output buffer enabled	Output buffer disabled, internal weak pull-up enabled
1 (output buffer driver disabled in SAFE mode)	1 (output buffer enabled)	Output buffer enabled	Output buffer enabled

7.3.2 Semaphores2 (SEMA42) configuration

The peripheral platform shell includes a memory-mapped module (SEMA42) that provides



- Robust hardware support needed in multi-core systems for implementing semaphores
- A simple mechanism to achieve "lock/unlock" operations via a single write access

The hardware semaphores module is an architecture-neutral solution that provides sixteen hardware-enforced gates for SPC58xEx/SPC58xGx as well as other useful system functions related to the gating mechanisms. The capabilities provided by the hardware semaphore module are currently utilized in dual-core AUTOSAR® implementations and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

7.3.3 Crossbar switch

This device contains two crossbar switch modules. *Figure 10* illustrates that they are connected via a cross-lake, which is comprised of intelligent bridging bus gaskets. These bus gaskets handle the traffic which crosses between the shells and do not require any interaction with the user. This dual-crossbar architecture allows all masters to access all slaves across computing shell 0 and computing shell 1.

Figure 10. Crossbar switch diagram

The following sections explain how each crossbar switch is configured on this device.

7.3.3.1 Computing shell 0 crossbar switch (XBAR_0) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, please refer to the Crossbar switch (XBAR) chapter.

Figure 11. Crossbar_0 switch integration

e2eECC Master Gasket for SIPI_0	M5
Cross-lake from computing shell 1 crossbar XBAR_1:S6	M6

7.3.3.1.2 Crossbar_0 switch slave assignments

This device contains eight slaves connected to the computing shell 0 crossbar switch.

The slave assignment is shown in *Table 25*.

Table 25. Crossbar_0 switch slave assignments

Slave module	Physical slave port number
PFLASHC_0:p0	S0
PFLASHC_1:p1	S1
PRAMC_0	S2
PRAMC_1	S3
PBRIDGE_0	S4
Cross-lake to computing shell 1 XBAR_1:M5	S5
Backdoor port to Core 0 local memory	S6
Backdoor port to Core 1 local memory	S7

7.3.3.1.3 PRS register reset values

The computing shell 0 XBAR_0 PRS*n* registers reset to 0x66301425. Note that these registers are read-only.

7.3.3.1.4 MGPCR register reset values

The streaming shell 0 XBAR_0 MGPCRn registers reset to 0x00000000.

7.3.3.2 Computing shell 1 crossbar switch (XBAR_1) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, please refer to the Crossbar switch (XBAR) chapter.

7.3.4 System Memory Protection Unit (SMPU) configuration

This chip contains three instances of the System Memory Protection Unit (SMPU):

- SMPU_HSM for the Hardware Security Module
- SMPU_0 for the Computational Shell
- SMPU_1 for the Peripheral Shell

The following sections explain how SMPU_0 and SMPU_1 are configured on this chip. See the *SPC58xEx/SPC58xGx Microcontroller Security Reference Manual* for configuration details of SMPU_HSM.

Note: SMPU_0 can only protect slaves of XBAR_0 except slave S5 (Slave port that connects to XBAR_1). Bus masters with Master IDs as mentioned in Table 27 are considered valid by SMPU_0.

SMPU_1 can only protect slaves of XBAR_1 except slave S6 (Slave port that connects to XBAR_0). Bus masters with Master IDs as mentioned in Table 28 are considered valid by SMPU_1.

7.3.4.1 SMPU0 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 13. SMPU0 configuration

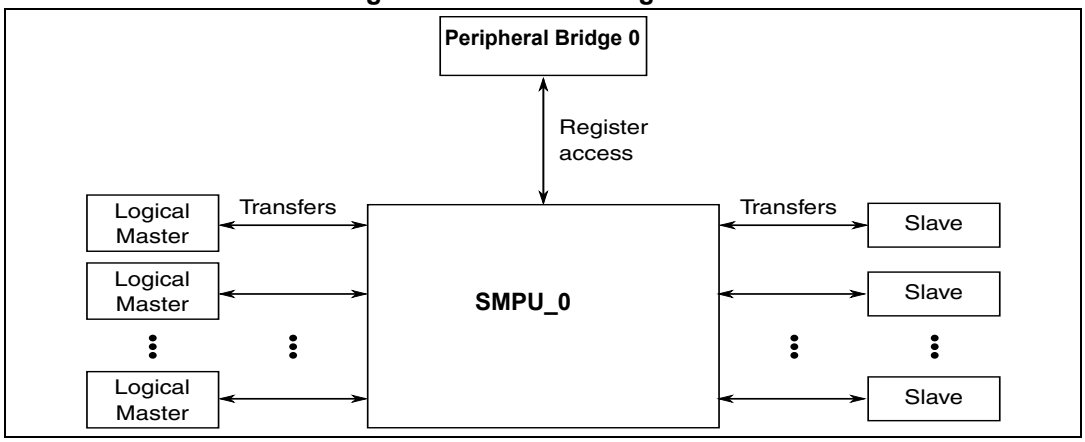

Table 31. Reference links to related information

Master Access Permissions	—	*Section 7.3.4.1.4: Master Access permissions for SMPU0*

7.3.4.1.1 SMPU0 logical bus master assignments

The logical bus master assignments for the SMPU0 are present in *Chapter 7: Device configuration*, *Section 7.3.3.3: AHB Master ID Assignments*.

7.3.4.1.2 Number of region descriptors supported by SMPU0

This instance of the SMPU module supports a maximum of twenty-four region descriptors.

7.3.4.1.3 RGD_WORD2 formats supported by SMPU0

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.1.4 Master Access permissions for SMPU0

The only masters allowed to access the SMPU0 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supervisor mode.

7.3.4.2 SMPU1 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 14. SMPU1 configuration

Master Access Permissions	—	*Section 7.3.4.2.4: Master Access permissions for SMPU1*

7.3.4.2.1 SMPU1 logical bus master assignments

The logical bus master assignments for the SMPU1 are present in *Chapter 7: Device configuration*, *Section 7.3.3.3: AHB Master ID Assignments*.

7.3.4.2.2 Number of region descriptors supported by SMPU1

This instance of the SMPU module supports a maximum of twenty-four region descriptors.

7.3.4.2.3 RGD_WORD2 formats supported by SMPU1

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.2.4 Master Access permissions for SMPU1

The only masters allowed to access the SMPU1 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supervisor mode.

7.3.5 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 15. Peripheral bridge configuration

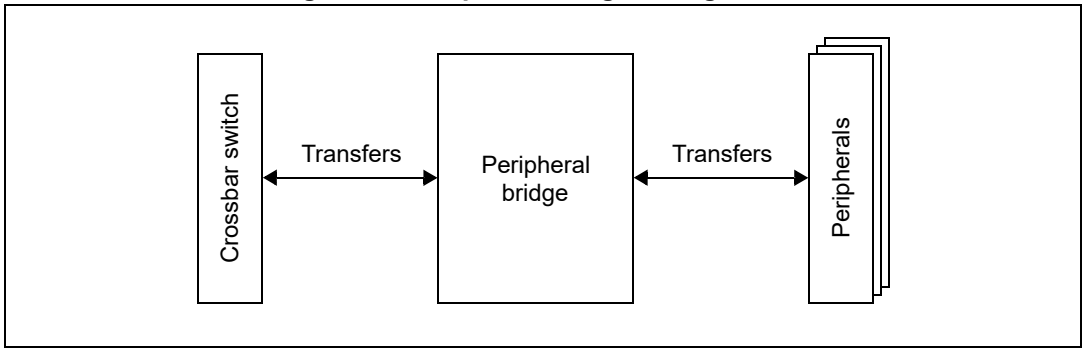

Table 33. Reference links to related information

Topic	Related module	Reference
Full description	Peripheral bridge	*Chapter 20: Peripheral Bridge (PBRIDGE)*
System memory map	—	*Chapter 5: Memory Map*
Clocking	—	*Chapter 27: Clocking*
Crossbar switch	Crossbar switch	*Section 7.3.3: Crossbar switch*

7.3.5.1 Peripheral bridge instantiation

This device contains three identical peripheral bridges.

7.3.5.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See *Chapter 5: Memory Map* for the memory slot assignment for each module.

7.3.5.3 MPR registers

Each of the three peripheral bridges supports up to sixteen crossbar switch masters, each assigned to a MPROT*n* field in the MPRA-B registers. However, fewer are supported on this device. See *Section 7.3.3: Crossbar switch* for details of the master port assignments for this device.

7.3.5.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each assigned to a PACR*n* or OPACR*n* field within the PACRA-H/OPACRA-AF registers. However, fewer peripherals are supported on this device. See *Chapter 5: Memory Map* for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

7.3.6 Interrupt controller (INTC) configuration

7.3.6.1 INTC configurable parameters

The INTC on this chip supports three processors—the safety core, the computational core and the I/O processor (IOP).

7.3.6.2 Interrupt channel map

Table 34 defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 34. Interrupt sources

Number	Description	Register bit

Table 34. Interrupt sources (continued)

Number	Description	Register bit
186 - 188	Reserved	—
189	AMU DMA interrupt for AMU channel 0	STCFG0[WDMA]
190	AMU DMA interrupt for AMU channel 1	STCFG1[WDMA]
191	AMU Error interrupt for AMU channel 0	STCFG0[EINT]
192	AMU Error interrupt for AMU channel 1	STCFG1[EINT]
193	AMU Calculation interrupt for AMU channel 0	STCFG0[VINT] :OR: STCFG0[OINT] :OR: STCFG0[NINT]
194	AMU Calculation interrupt for AMU channel 1	STCFG1[VINT] :OR: STCFG1[OINT] :OR: STCFG1[NINT]
195 - 211	Reserved	—
212	Ethernet 0 (SYNOPSYS IP)	ETHERNET_0[sbd_intr_o] combined interrupts from all EQOS sources
213		ETHERNET_0[pmt_intr_o]
214		ETHERNET_0[lpi_intr_o]
215 - 217	Reserved	—
218	Ethernet 1 (SYNOPSYS IP)	ETHERNET_1[sbd_intr_o] combined interrupts from all EQOS sources
219		ETHERNET_1[pmt_intr_o]
220		ETHERNET_1[lpi_intr_o]
221 - 223	Reserved	—
224	Real Time Counter (RTC/API)	RTC
225		API wakeup
226	Periodic Interrupt Timer 0 (PIT_0)	PIT_0_TFLG0[TIF]
227		PIT_0_TFLG1[TIF]
228		PIT_0_TFLG2[TIF]
229		PIT_0_TFLG3[TIF]
230		PIT_0_TFLG4[TIF]
231		PIT_0_TFLG5[TIF]
232		PIT_0_TFLG6[TIF]
233		PIT_0_TFLG7[TIF]
234 - 238	Reserved	—
239	Periodic Interrupt Timer 0 (PIT_0)	PIT_0_RTI_TFLG[TIF]
240	Periodic Interrupt Timer 1 (PIT_1)	PIT_1_TFLG0[TIF]
241		PIT_1_TFLG1[TIF]

Table 34. Interrupt sources (continued)

Number	Description	Register bit
242	XOSC counter	XOSC_CTL[I_OSC]
243	SIUL External Interrupt 0	SIUL2_DISR0[EIF0] (EXT_INT 0 signal)
244	SIUL External Interrupt 1	SIUL2_DISR0[EIF1] (EXT_INT 1 signal)
245 - 246	Reserved	—
247	WakeUp unit (WKPU)	WakeUp_IRQ_0
248		WakeUp_IRQ_1
249		WakeUp_IRQ_2
250		WakeUp_IRQ_3
251	Magic Carpet Module - ME 0	ME_IS[I_SAFE]
252	Magic Carpet Module - ME 1	ME_IS[I_MTC]
253	Magic Carpet Module - ME 2	ME_IS[I_IMODE]
254	Magic Carpet Module - ME 3	ME_IS[I_ICONF]
255	Magic Carpet Module - RGM 0	MC_RGM Functional and destructive reset alternate event interrupt
256 - 258	Reserved	—
259	Serial Peripheral Interface 0 (DSPI_0)	DSPI_0_SR[TFUF] :OR: DSPI_0_SR[RFOF] :OR: DSPI_0_SR[TFIWF]
260		DSPI_0_SR[EOQF]

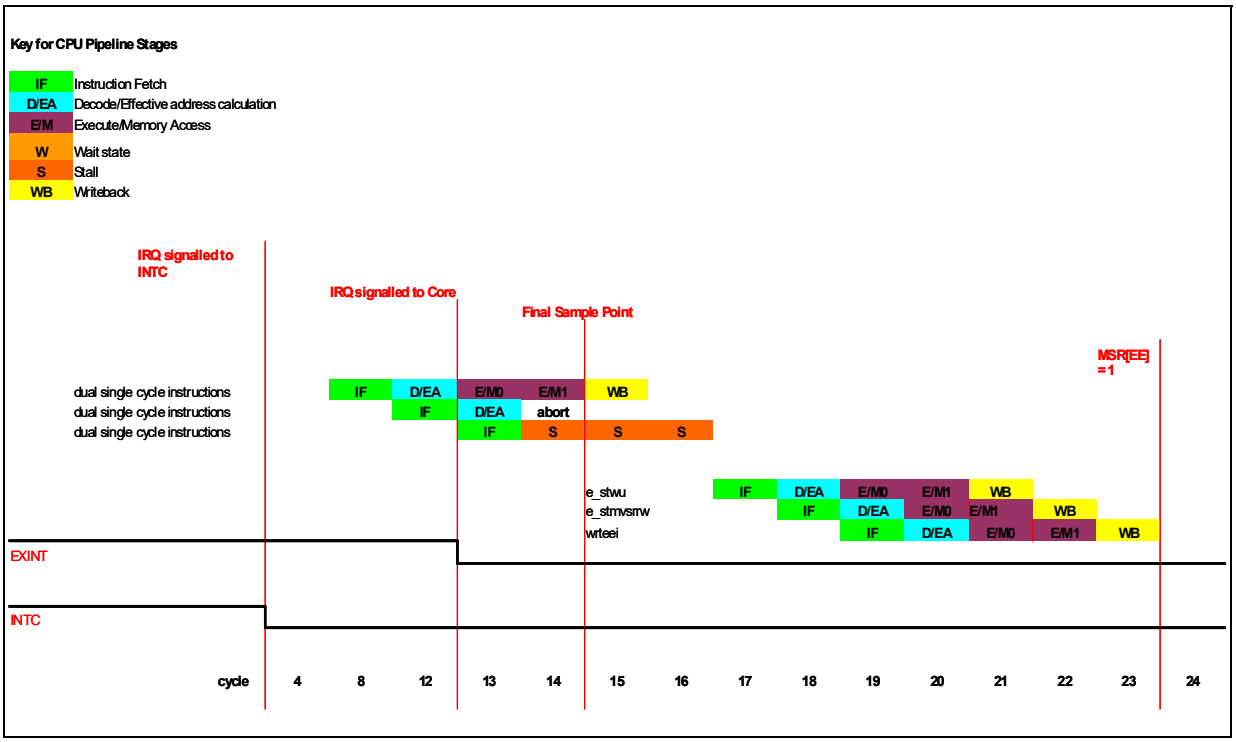
7.3.6.3 Interrupt latency



The Interrupt system is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

The latency time is difficult to define exactly because it depends on what interrupts the INTC is processing and what the CPU is doing.

In general, the latency time is divided into three subsections:

- INTC Latency
  - 3 clock cycles (INTC clock domain[4]) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency
  - 4 clock cycles (CPU clock domain[5]) from the assertion of the interrupt request from the INTC to the execution of the first instruction
- Software Latency
  - 7 clock cycles (CPU clock domain[5]) to execute the three instructions needed to save essential registers and enable interrupts

Figure 16. Interrupt timing

7.3.6.4 INTC (hsm_z0_platform) configuration

For interrupts specific to the Hardware Security Module (HSM) refer to the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual.

7.3.7 DMA controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

4. 90 MHz
5. 180 MHz

7.3.8 DMACHMUX configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.3.8.1 DMACHMUX parameters

SPC58xEx/SPC58xGx has six DMA channel multiplexers.

Each DMACHMUX includes 16 channels.

Table 37 lists the number of DMA channels, always slots and DMA triggers.

Table 37. DMACHMUX controller generics

Signal name Description	Description	DMACHMUX_0	DMACHMUX_1	DMACHMUX_2	DMACHMUX_3	DMACHMUX_4	DMACHMUX_5
NUMBER_OF_DMA_CHANNELS	Number of DMA channels	16	16	16	16	16	16
NUMBER_OF_ALWAYS_SLOTS	Module-internal slots which will always do a request	2	2	2	2	2	2
NUMBER_OF_DMA_TRIGGERS	Number of DMA channels which will be gated with a trigger pulse	3	3	3	3	3	3

7.3.8.2 DMA channel assignment

Table 38 lists which channels apply to each multiplexer.

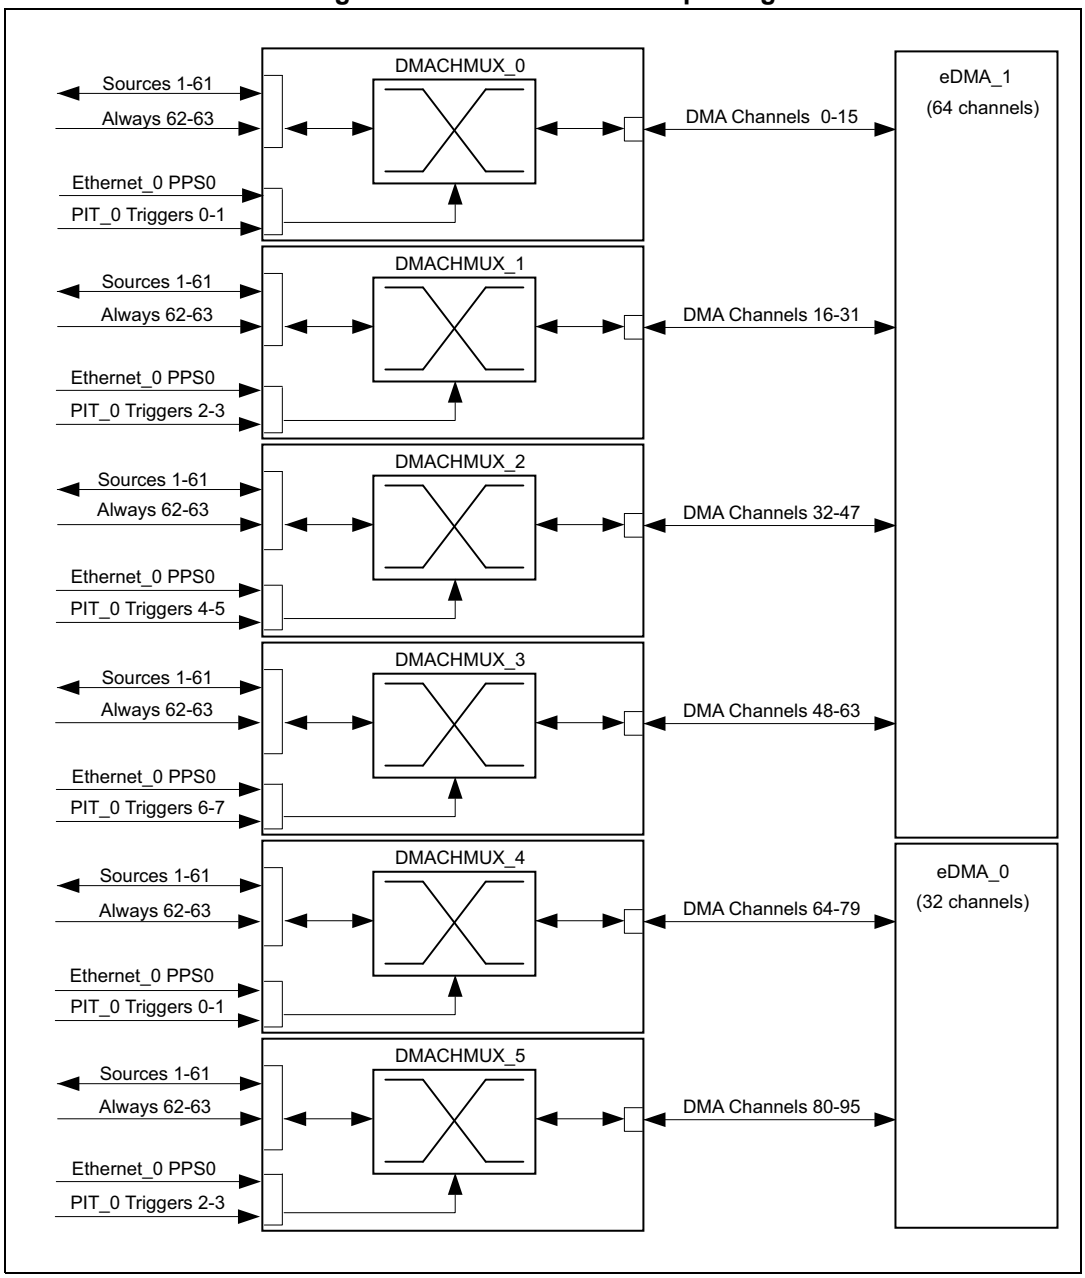

Table 38. SPC58xEx/SPC58xGx multiplexer and channel list

DMACHMUX instance	DMA channel	
	eDMA_0 channel	eDMA_1 channel
0	—	0-15
1	—	16-31
2	—	32-47
3	—	48-63
4	64-79	—
5	80-95	—

7.3.8.3 DMA channel multiplexing block diagram

The connections of the DMA channel multiplexers to the eDMA are shown in *Figure 18*. One DMACHMUX is instantiated for every sixteen DMA channels.

Figure 18. DMA channel multiplexing

7.3.8.4 DMA request mapping

The mapping of the peripheral DMA requests to the DMACHMUX input sources is shown in *Table 39*.

Table 39. DMAMUX Map(1)

1. Some sources are double mapped to increase the flexibility but only one source shall be selected at one time.

Note: Just as multiple CHCFG registers within the same instance must not select the same source value, CHCFG registers among multiple instances must not select the same source value.

The mapping of the PIT periodic triggers to the DMA channel sources is shown in *Table 40*.

Table 40. PIT_0 periodic trigger to DMA channel mapping

PIT_0 periodic trigger	DMA channel
0	0, 64
1	1, 65
2	16, 80
3	17, 81
4	32
5	33
6	48

7.3.9 Platform Configuration Module (PCM) configuration

The Platform Configuration Module (PCM) contains three registers. These PCM registers are used for controlling different aspects of the Platform functionality including the Frequency Gasket Configurations of the Intelligent Bus Bridging Gaskets.

The PCM module is mapped to PBRIDGE_2 on platform slot 10. Its base address is 0xF4028000.

Table 44. PCM0 field descriptions

Field	Description
1 PRE_CONC2	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for Concentrator 2 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
2 BRE_CONC2	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for Concentrator 2 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
3 BWE_CONC2	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for Concentrator 2 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
5 PRE_CONC1_GSKT	0 Pending reads are disabled. 1 Pending reads are enabled. **Note:** This bit has same value as bitfield PRE_CONC1.

Table 44. PCM0 field descriptions (continued)

Field	Description
6 BRE_CONC1_GSKT	0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance. **Note:** This bit has same value as bitfield BRE_CONC1.
7 BWE_CONC1_GSKT	0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. **Note:** This bit has same value as bitfield BWE_CONC1.
9 PRE_CONC0_GSKT	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
10 BRE_CONC0_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
11 BWE_CONC0_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
13 PRE_CONC1	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for Concentrator 1 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_CONC1	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for Concentrator 1 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_CONC1	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for Concentrator 1 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.

Table 44. PCM0 field descriptions (continued)

Field	Description
17 PRE_CONC0_HSM	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 HSM (HSMGasket) This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
18 BRE_CONC0_HSM	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 HSM (HSMGasket) This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
19 BWE_CONC0_HSM	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 HSM (HSMGasket) This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
21 PRE_CONC0_DMA1	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 DMA1 (DMA1Gasket) This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
22 BRE_CONC0_DMA1	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 DMA1 (DMA1Gasket) This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_CONC0_DMA1	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for Concentrator 0 DMA1 (DMA1Gasket) This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
25 PRE_XBAR1_S6_GSKT	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for XBAR1 S6 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
26 BRE_XBAR1_S6_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for XBAR1 S6 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.

Table 44. PCM0 field descriptions (continued)

Field	Description
27 BWE_XBAR1_S6_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for XBAR1 S6 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
29 PRE_XBAR1_M5_GSKT	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for XBAR1 M5 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_XBAR1_M5_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for XBAR1 M5 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_XBAR1_M5_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for XBAR1 M5 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.

22 BRE_XBAR0_S6_S7_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for XBAR0_S6_S7 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.

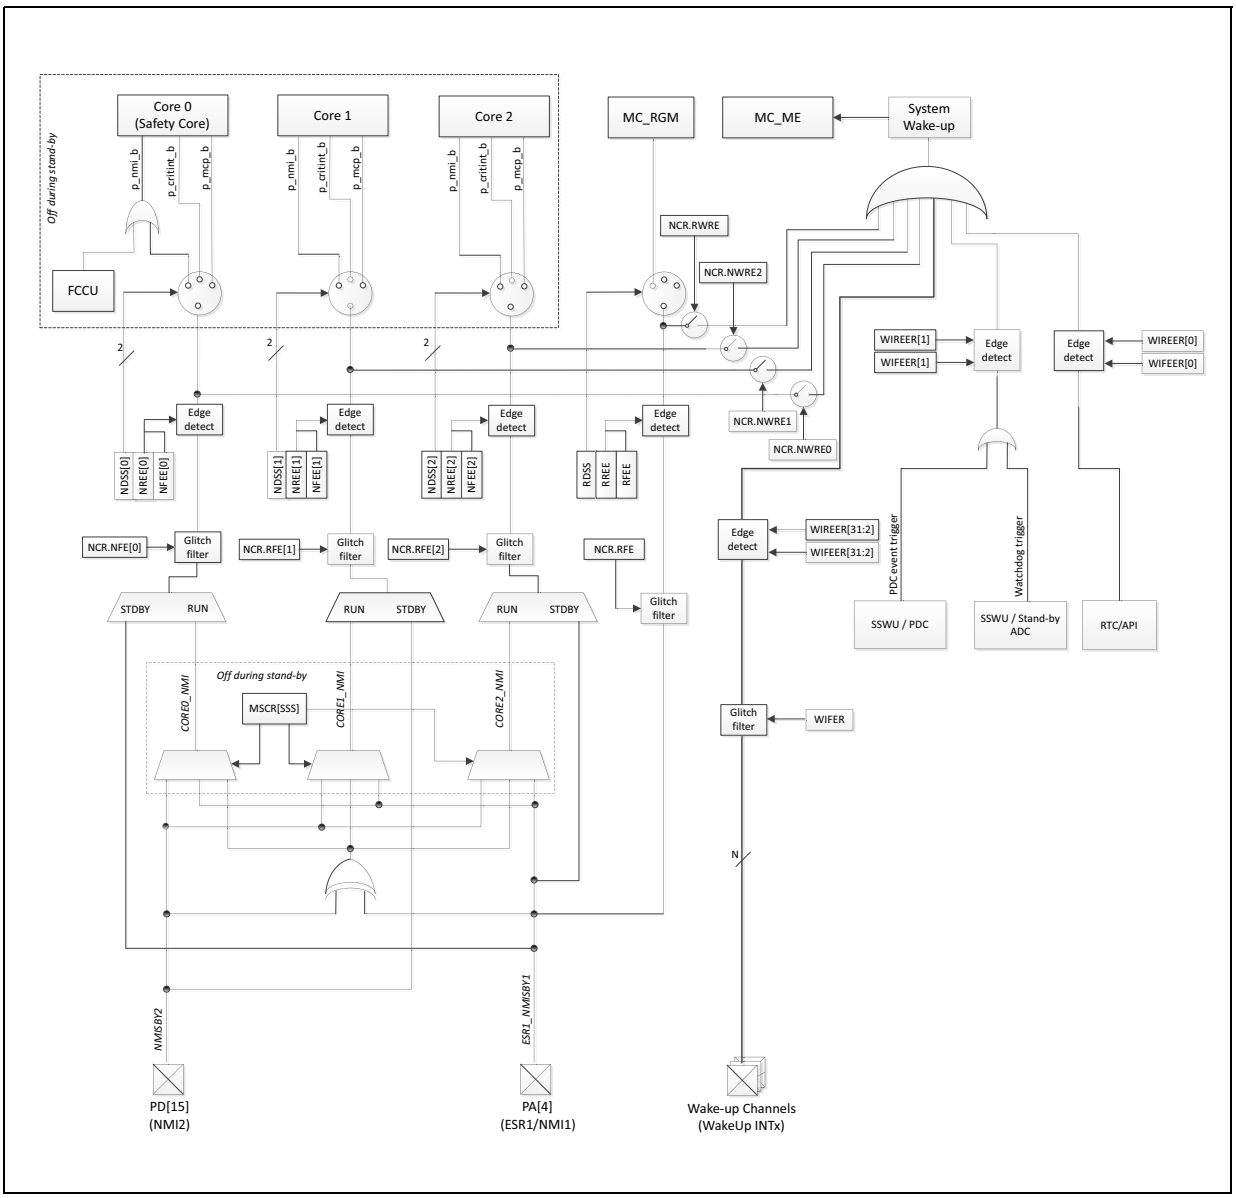
Table 46. PCM2 field descriptions (continued)

Field	Description
23 BWE_XBAR0_S6_S7_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for XBAR0_S6_S7 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
25 PRE_SIPI0_GSKT	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for SIPI0 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
26 BRE_SIPI0_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for SIPI0 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
27 BWE_SIPI0_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for SIPI0 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.
29 PRE_DMA0_GSKT	Pending read enable (PRE) used for controlling the burst parameter of frequency gasket used for DMA0 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_DMA0_GSKT	Burst read enable (BRE) used for controlling the burst parameter of frequency gasket used for DMA0 This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_DMA0_GSKT	Burst write enable (BWE) used for controlling the burst parameter of frequency gasket used for DMA0 This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance.

7.3.10 Wakeup unit (WKPU) configuration

The Wakeup unit supports 32 external sources that can generate CPU exceptions or wakeup events and 2 external sources, driven by PA[4] and PD[15], that can cause non-maskable interrupt requests or wakeup events.

The effect of the signals coming from PA[4] and PD[15] depends on the execution mode.



In any run mode, three signals (called CORE0_NMI, CORE1_NMI, and CORE2_NMI) are input to each core. Each of these signals is the output of one multiplexer, which makes it possible to select (via SIUL2 register) any of the following sources:

- PA[4]
- PD[15]
- Logical XOR'ed of PA[4] and PD[15]

In standby mode, the signals driven by PA[4] and PD[15] (called ESR1_NMISBY1 and NMISBY2 respectively) can be used to wake-up the system.

PA[4] can also be used to trigger a reset to the whole system.

Figure 22. NMI block diagram SPC58xEx/SPC58xGx

In *Figure 2509: Wakeup unit block diagram* of *Chapter 96: Wakeup unit (WKPU)*, it has to be noted that only one filter is implemented.

7.3.10.1 Features

The Wakeup unit supports these distinctive features:

- Non-maskable Interrupt support with:
  - 3 NMI source with bypassable glitch filter
  - Independent interrupt destination: non-maskable interrupt, critical interrupt, or machine check request
  - Edge detection
- External wakeup/interrupt support with:
  - 30 wakeup/interrupt sources
  - Analog glitch filter per each wakeup line
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable pull
- On-chip wakeup support
  - 2 wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status
  - Independent interrupt mask
  - Configurable system wakeup triggering from all interrupt sources

7.3.10.2 Wakeup vector mapping

1. applicable for registers WISR, IRER, WRER, WIFEER, WIFEEF, WIFER, WIPUER

7.3.11 Crossbar integrity checker (XBIC)

The device implements the following XBIC instances:

- XBIC_Concentrator_0
- XBIC_Concentrator_1
- XBIC_0
- XBIC_1

Master and slave assignments are defined as follows:

- XBIC master definition follows the AHB master (see *Section 7.3.3.1.1: Crossbar_0 switch master assignments* and *Section 7.3.3.2.1: Crossbar_1 switch master assignments*).
- XBIC slave definition follows the XBAR slave numbering (see *Section 7.3.3.1.2: Crossbar_0 switch slave assignments* and *Section 7.3.3.2.2: Crossbar_1 switch slave assignments*).

7.4 Clocking

See *Chapter 27: Clocking* for a description of the architecture for the system level clocks including clock generation, the clock sources and the peripheral clocks. The chapter also provides configuration details for the Clock Monitor Unit (CMU).

7.5 Memories and memory interfaces

See the following chapters for detailed information on memories and memory interfaces.

Table 48. Reference links to related information

Embedded flash memory	—	*Chapter 37: Embedded Flash Memory*
Decorated Storage Memory Controller	—	*Chapter 39: Decorated Storage Memory Controller (DSMC)*

7.5.1 Flash memory controller (PFLASH) configuration

Two flash controllers and arrays are implemented. The flash controllers provide flash configuration and control functions and manage the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, PFCR2, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the

flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See the crossbar switch configuration section for details. See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

Table 49. Reference links to related information

Topic	Related module	Reference
Full description	Flash Memory Controller (PFLASH)	*Chapter 36: Flash memory controller*
Flash memory architecture overview	Flash memory, Flash controller	*Section 3.3.1: Flash memory controller*
Flash memory	Flash memory	*Chapter 37: Embedded Flash Memory*
Flash port assignments	Crossbar switch	*Section 7.3.3: Crossbar switch*
System memory map	—	*Chapter 5: Memory Map*

The master assignments are shown in *Section 7.3.3.3: AHB Master ID Assignments*. Note that these are the same master assignments used elsewhere in the chip, for example, the SMPU.

7.5.1.1 Calibration remapping support

The PFLASH flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM or on-chip system RAM that can be used as overlay RAM. The relationship between flash access latency and remapped overlay RAM latency is contingent upon operating frequency and intrinsic memory access times. *Table 50* describes the intrinsic cycle latency on a random, initial access for each supported overlay RAM target.

(See *Section 36.5.13: PFlash calibration remap support* for more details on the relationship between flash access latency and overlay RAM access latency.

Note: Cycle times measured based on the PFLASH clock. See Chapter 27: Clocking for more details on clocking.

Table 50. Calibration memory access times

Calibration memory	Burst access time (cycles)
On-chip overlay RAM	5
Buddy device overlay RAM	8
System RAM	9

7.5.1.2 Wait state settings for overlay flash latency matching

A remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time for a flash access as well as the

required access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. *Table 51* describes the minimum supported flash wait state setting to guarantee a remapped access matches the response latency of a flash access.

Table 51. Minimum wait state settings for overlay flash latency match

Overlay Target	PFCR1[RWSC] Minimum Value
BD RAM	6
On-Chip Overlay RAM	3
System RAM	6

If PFCR1[RWSC] is set sufficiently high such that the remapped burst access completes before flash read data is expected to be returned, the flash controller stalls the return of overlay data the appropriate number of additional cycles to ensure the access time matches the response latency of a flash access. Once the overlay access is stored in the flash controller mini-cache, subsequent requests that hit in the mini-cache are returned with zero wait state latency.

7.5.2 Platform RAM Controller (PRAMC) configuration

7.5.2.1 Wait state management

PRAMC_CR1[FT_DIS] should be set to 1’b1 to enable 1 cycle of wait state during read operation when the controller is working @180 MHz (refer to the device datasheet to check from which frequency this wait state cycle is needed).

7.5.3 Decorated Storage Memory Controller (DSMC)

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR, and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The DSMC is instantiated multiple times within the core platform and physically resides between the CPU data AHB bus and the associated crossbar master port.

For SPC58xEx/SPC58xGx, the DSMC is instantiated six times: three times on every CPU's AHB data bus and three lock-step replicas in the sphere of replication, on for each functional DSMC instance.

Due to this architecture choice, each DSMC can access the whole addressing space.

7.6 Analog modules

This section highlights the following analog modules that are implemented on SPC58xEx/SPC58xGx:

Table 52. Reference links to related information

Module or Subsystem	Device-specific information	Block details
Temperature sensor	*Section 7.6.1: Temperature sensor configuration*	*Chapter 43: Temperature Sensor*
ADC subsystem	*Section 40.1: ADC overview*	—
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	*Section 7.6.2: SARADC*	*Section 42: Successive Approximation Register Analog-to-Digital Converter (SARADC) on page 1118*
Sigma-Delta Analog-to-Digital Converter (SDADC)	*Section 7.6.3: SDADC*	*Chapter 41: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface*

7.6.1 Temperature sensor configuration

The temperature sensor is used to measure the temperature of the SPC58xEx/SPC58xGx device. The temperature sensor has the following outputs:

- Two analog voltages
  - A voltage signal that is linearly increasing with internal junction temperature (PTAT that is proportional to absolute temperature)
  - A voltage signal that is linearly decreasing with internal junction temperature (CTAT that is complementary proportional to absolute temperature)
- Three digital outputs that signal under- or over-temperature operating conditions.

During production testing of the device, the output voltages of the temperature sensor are sampled by SARB input channel 120 and 121 of the onboard ADC module at a predefined high temperature and also at a predefined low temperature. These calibration parameters are stored during production test into UTEST Flash memory. See Section UTEST in Chapter Flash Memory.

By converting the two analog outputs of the temperature sensor through ADC, one can find out a constant reference code which does not change with temperature or the ADC reference values. It is also called 'Digital Bandgap Voltage'. See *Section 43.3.2: Equations for converting TSENS voltages into constant reference (Digital Bandgap Voltage)* in *Chapter 43: Temperature Sensor*.

For details, see *Chapter 43: Temperature Sensor*.

7.6.2 SARADC

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for an application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

SPC58xEx ncludes:

- five (5) independent 12-bit SARADCs.
- three (3) independent 10-bit SARADCs (2 + 1 standby).

SPC58xGx includes:

- five (5) independent 12-bit SARADCs.
- one independent 10-bit SARADCs (standby).

The 12-bit SARADC_B has access to all external analog input pins, access to the external multiplexed inputs, and has special safety features.

For details, refer to the section Analog-to-Digital Converters (ADC) Configuration.

7.6.3 SDADC

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides the accurate conversion data for a wide range of applications.

SPC58xEx/SPC58xGx includes six independent 16-bit SDADCs.

For details, see *Chapter 40: Analog-to-Digital Converters (ADC) Configuration*.

7.6.4 Body Cross Triggering Unit (BCTU) configuration

This section summarizes the Body Cross Triggering Unit (BCTU) configuration in the SPC58xEx/SPC58xGx device. For a comprehensive description of the BCTU, please refer to the BCTU's dedicated chapter.

Module overview

One single BCTU instance (BCTU0) is implemented. It is interconnected to:

- ADC_SAR_B (12-bit Supervisor)
- eMIOS
- PIT and GTM via IOMUX

The Body Cross Triggering Unit is used to prioritize the trigger events from eMIOS/PIT/GTM.

The BCTU synchronizes the ADC conversion with PWM signal coming from eMIOS/PIT/GTM (refer to *Table 53*). When the event is programmed to be an ADC trigger, the 7-bit channel number is provided to ADC. This channel number is used to communicate which particular channel has to be converted (refer to *Table 54*).

The BCTU is also used to route the trigger events from eMIOS as a DMA request in case the event is not programmed to be a trigger to ADC.

The supported trigger sources are the following:

- 62 eMIOS channels
- 2 PIT channels and 2 GTM channels: the trigger source selection is done via IOMUX. User selects between PIT and GTM source event by means of IOMUX selection.

Figure 23. BCTU overview

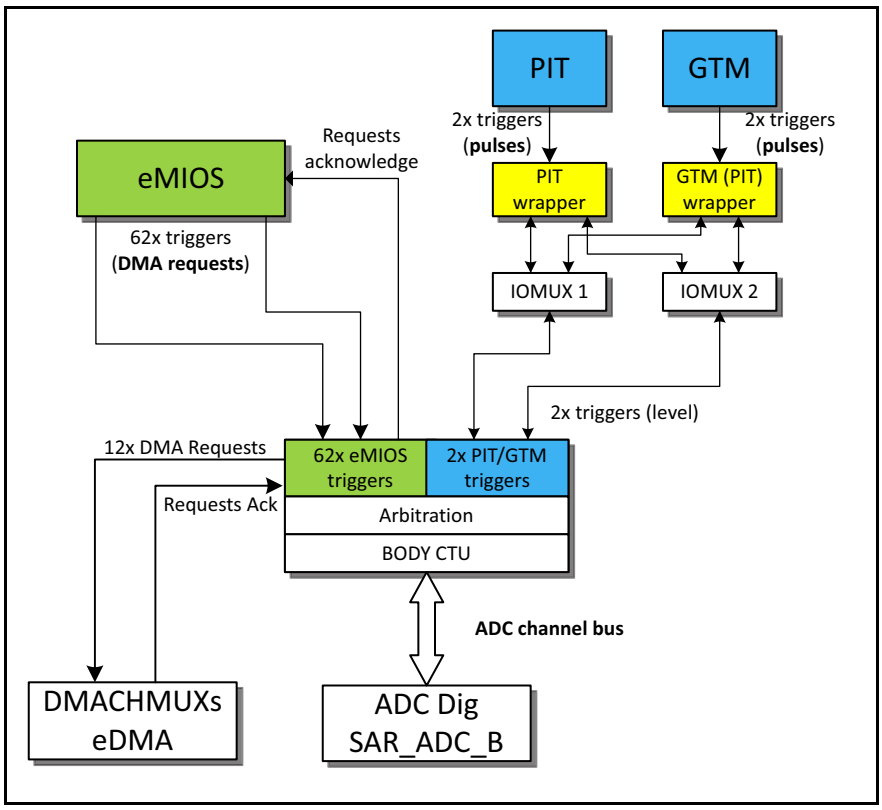

Table 53. BCTU input triggers allocation(1)

Body CTU trigger input	Trigger source	Connected signal
0–22	eMIOS_0	eMIOS_0 CH0–CH22
23	PIT_RTI_0 via IOMUX	PIT_0 CH1
	GTM via IOMUX	GTM_TOM2_IRQ7
24–31	eMIOS_0	eMIOS_0 CH24–CH31
32–54	eMIOS_1	eMIOS_1 CH0–CH22
55	PIT_RTI_0 via IOMUX	PIT_0 CH3
	GTM via IOMUX	GTM_TOM2_IRQ0

129	0x41
...	...
191	0x7F

7.7 Timers

7.7.1 System Timer Module (STM) configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the FBRIDGE_CLK divided by an 8-bit prescale value (1 to 256).

SPC58xEx/SPC58xGx includes three STMs, one for each core, with four 32-bit compare channels in each STM.

Table 55. System Timer Module (STM) instances

Instance	Description	Number of channels	Number of registers (32-bit)
STM_0	Clocked by FBRIDGE_CLK (Core_0)	4	14
STM_1	Clocked by FBRIDGE_CLK (Core_1)	4	14
STM_2	Clocked by FBRIDGE_CLK (Core_2)	4	14

7.7.2 Software Watchdog Timer (SWT) configuration

SPC58xEx/SPC58xGx includes four SWTs.

Table 56. Software Watchdog Timer (SWT) instances

Instance	Description
SWT0	Clocked by IRCOSC clock; using value of IAC8 register of Core 0 for instruction address compare feature
SWT1	Clocked by IRCOSC clock; using value of IAC8 register of Core 1 for instruction address compare feature

Table 56. Software Watchdog Timer (SWT) instances (continued)

Instance	Description
SWT2	Clocked by IRCOSC clock; using value of IAC8 register of Core 2 for instruction address compare feature
SWT3	Clocked by IRCOSC clock; not supporting the address compare feature

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Internal 16 MHz RC oscillator clock that is used for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.7.2.1 IAC (Instruction Address Compare)

The IAC feature makes it possible to serve a SWT when the CPU executes an instruction at a specific address location. The purpose is to guarantee that the application regularly executes an instruction within some fundamental section of the code. If this address location is not executed regularly, it implies that a critical error has occurred and the device should be eventually reset.

Not all the SWT embeds the IAC feature: *Table 56* shows for which watchdog the IAC feature is enabled.

If the IAC feature is enabled for a specific SWT, the address to be executed is set by the Instruction Address Compare 8 (IAC8) register, whereas the IAC feature can be activated by the register field SWT_CR[SMD] to one of the following settings:

- 2'b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this 'freezes' changes to the IAC8 register when the SWT is enabled
- 2'b11 for Incremental Address Execution; the IAC8 register can be updated

7.7.2.2 Reset assertion

The SWT can assert a reset when the watchdog timer expires. See *Chapter 8: Reset and Boot* chapter for details.

7.7.2.3 Default configuration

On SPC58xEx/SPC58xGx, the SWTs come out of reset with the default reset values summarized in *Table 57*. Minimum timeout value is 256 cycles for SWT0, SWT1, SWT2, and SWT3. For details, please refer to *Section 65.3.5: Initialization of BAF DCF clients*

Table 57. Register reset values

SWT instance	Register	Reset value
SWT0	SWT Control Register (SWT_CR)	0xFF00_010A
SWT0	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT1	SWT Control Register (SWT_CR)	0xFF00_010A
SWT1	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT2	SWT Control Register (SWT_CR)(1)	0xFF00_011B
SWT2	SWT Time-out (SWT_TO)	0x0003_FDE0
SWT3	SWT Control Register (SWT_CR)	0xFF00_010A
SWT3	SWT Time-out (SWT_TO)	0x0005_FCD0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is '1', but the DCI can override that default value by setting it to '0'. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT; it cannot enable it.) For details refer to *Section 72.1.3: Operating modes*.

7.7.3 PIT configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 24. PIT configuration

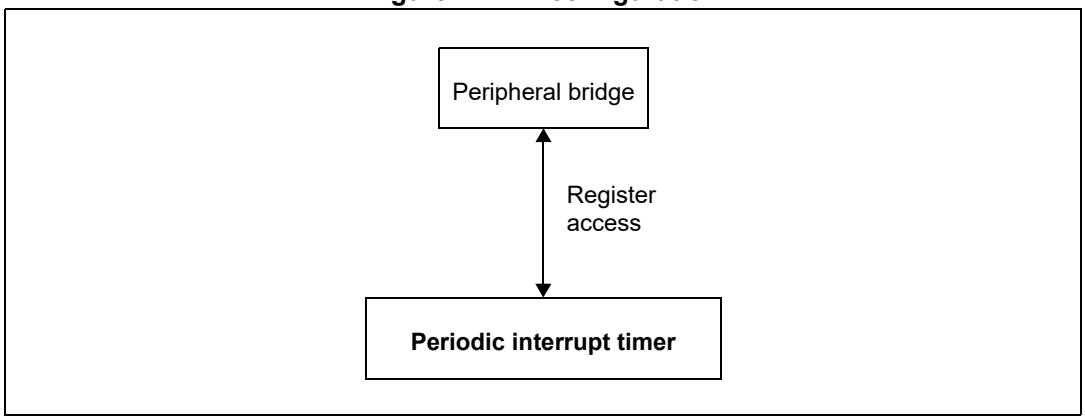

Table 58. Reference links to related information

Topic	Related module	Reference
Full description	PIT	*Chapter 50: Periodic Interrupt Timer (PIT)*
System memory map	—	*Chapter 5: Memory Map*
Clocking	—	*Chapter 27: Clocking*
Power management	—	*Chapter 10: Power management*
DMA channel assignments	Direct memory access channel multiplexer	*Chapter 26: DMA channel multiplexer (DMACHMUX)*

7.7.3.1 PIT instantiation

Table 59. PIT information

PIT module	PIT channels	Description
PIT_0	8 + RTI	The PIT has eight standard channels. All PIT registers are cleared by any reset.
PIT_1	2	PIT1 has chaining mode to implement a 64-bit timer and the timer value is unchanged by a functional reset.

7.7.3.2 PIT/DMA periodic trigger assignments

The PIT generates periodic trigger events to the DMACHMUX. To check the mapping of the PIT channel number with the corresponding DMA channel number, refer to the *Table 40: PIT_0 periodic trigger to DMA channel mapping*.

7.7.3.3 PIT Registers

The following tables show the implementation of PIT registers in this MCU.

Table 60. PIT_0 memory map

Absolute address (hex)	Register name
F7F8_4000	PIT Module Control Register (PIT0_MCR)(1)
F7F8_40E0 - F7F8_40E4	Reserved
F7F8_40F0 - F7F8_40FC	RTI Timer Channel Registers (PIT0_RTI_LDVAL, PIT0_RTI_CVAL, PIT0_RTI_TCTRL, PIT0_RTI_TFLG)
F7F8_4100 - F7F8_417C	Timer Channel [0:7] Registers (PIT0_LDVAL*n*, PIT0_CVAL*n*, PIT0_TCTRL*n*, PIT0_TFLG*n*)
F7F8_4180 - F7F8_7FFF	Reserved

1. The reset value of MCR is 0x06.

Table 61. PIT_1 memory map

Absolute address (hex)	Register name
FBF8_4000	PIT Module Control Register (PIT1_MCR)(1)
FBF8_40E0	PIT Upper Lifetime Timer Register (PIT1_LTMR64H)
FBF8_40E4	PIT Lower Lifetime Timer Register (PIT1_LTMR64L)
FBF8_40F0 - FBF8_40F8	Reserved

Table 61. PIT_1 memory map (continued)

Absolute address (hex)	Register name
FBF8_4100 - FBF8_411C	Timer Channel [0:1] Registers (PIT1_LDVAL*n*, PIT1_CVAL*n*, PIT1_TCTRL*n*, PIT1_TFLG*n*)
F7F8_4120 - F7F8_7FFF	Reserved

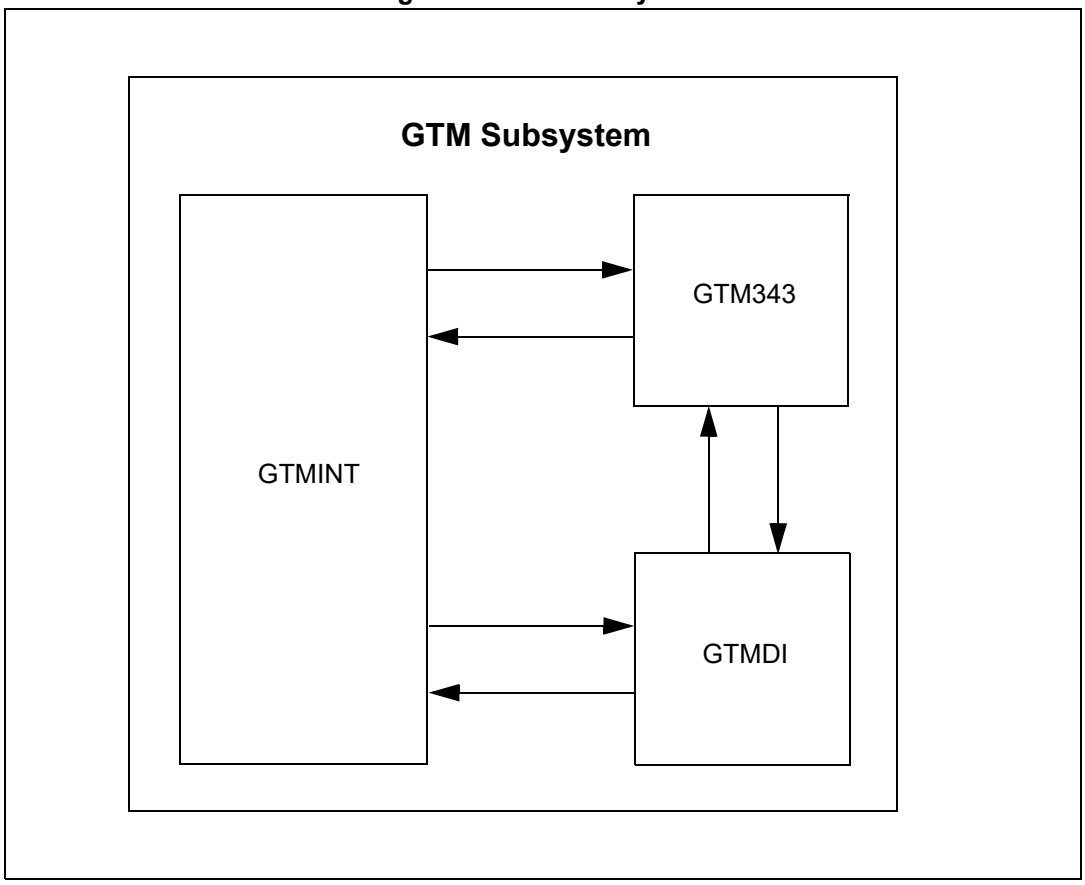
1. The reset value of MCR is 0x02.

7.7.3.4 PIT clocking

The PIT_0 standard channels are clocked with the peripheral clock (PER_CLK).

The PIT_0_RTI channel clock source is selectable between XOSC and RCOSC via the auxiliary clock selector 9.

The PIT_1 channels are clocked with the peripheral clock (PER_CLK).



7.7.4 GTM subsystem configuration

The GTM343 integration module (GTMINT) is an interface to the General Timer Module 343 (GTM343) that adds ECC functionality and a Nexus-based system debugger interface (GTMDI). It has two control registers and provides access to the GTM343's memory-mapped registers. The GTM343 is detailed separately in the GTM-IP_343_Specification. See *Chapter 47: GTM343 Integration (GTMINT) Module*, for more information.

7.7.4.1 GTM subsystem

The diagram provided in *Figure 25* illustrates the parts of the GTM subsystem.

Figure 25. GTM subsystem

7.7.4.2 Parts of the GTM subsystem

The *Table 62* describes the parts of the GTM subsystem.

Table 62. Parts of the GTM subsystem

Part	Function
GTMINT	Provides reset control, clock control, error-correcting code (ECC) functionality, interrupt and DMA control, and access to GTM343's memory mapped registers. For debug accesses from GTMDI to GTM343 registers, prevents destructive read accesses into the GTM343 registers.
GTM343	Provides programmable timer functionality.
GTMDI	Provides real-time development capabilities for the GTM subsystem.

7.7.4.3 GTM subsystem clock sources

The system clock and the peripheral clocks to the GTM subsystem are provided by the Clock Generation Module (MC_CGM).

Table 63. GTM subsystem clock sources

GTM subsystem clock	MC_CGM source	Maximum frequency
SYS_CLK	XBAR_CLK	90 MHz
GTMIP_CLK	PER_CLK	100 MHz
GTMDI_CLK		
GTMINT_CLK		

7.8 Communication interfaces

7.8.1 Ethernet configuration

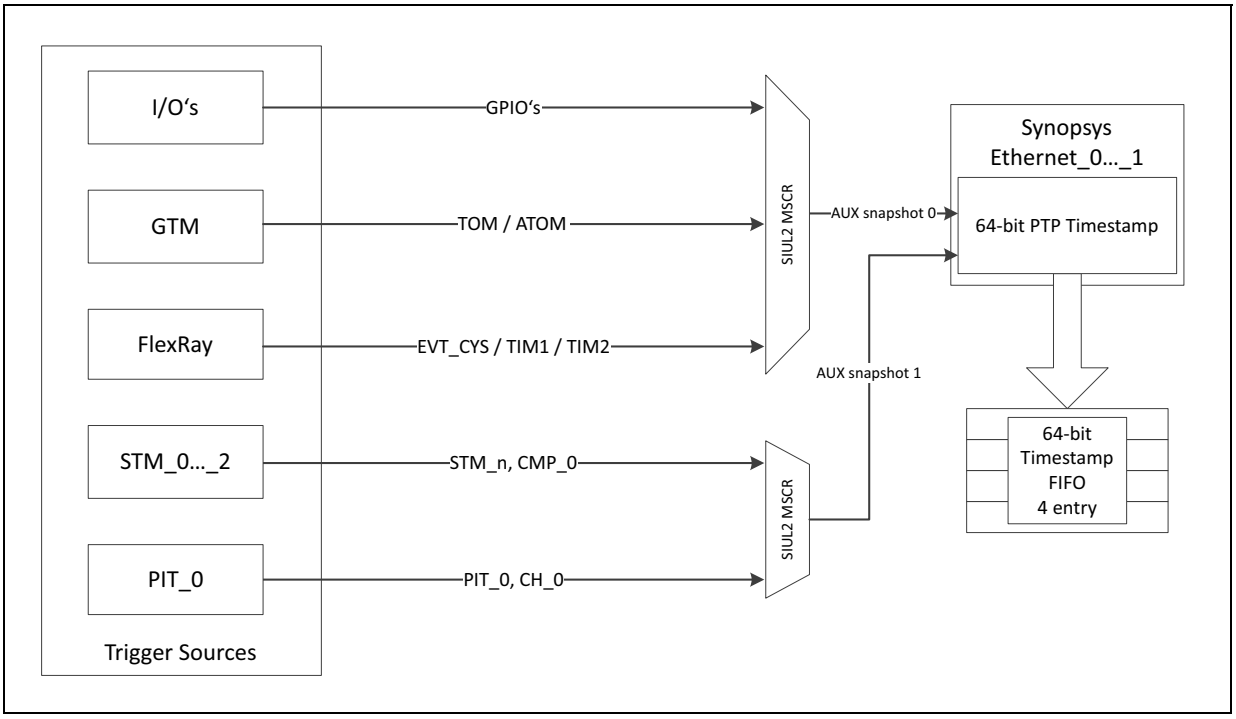
7.8.1.1 Ethernet interface selection

On this chip, the Ethernet interface depends on the SIUL2_SCR0 settings (in the SIUL2), as shown in *Table 64*.

Table 64. Ethernet interface selection

SIUL2_SCR0[Ethernet_MODE]	Interface used by the Ethernet
0	RMII
1	MII

7.8.1.2 Ethernet timestamp snapshot trigger



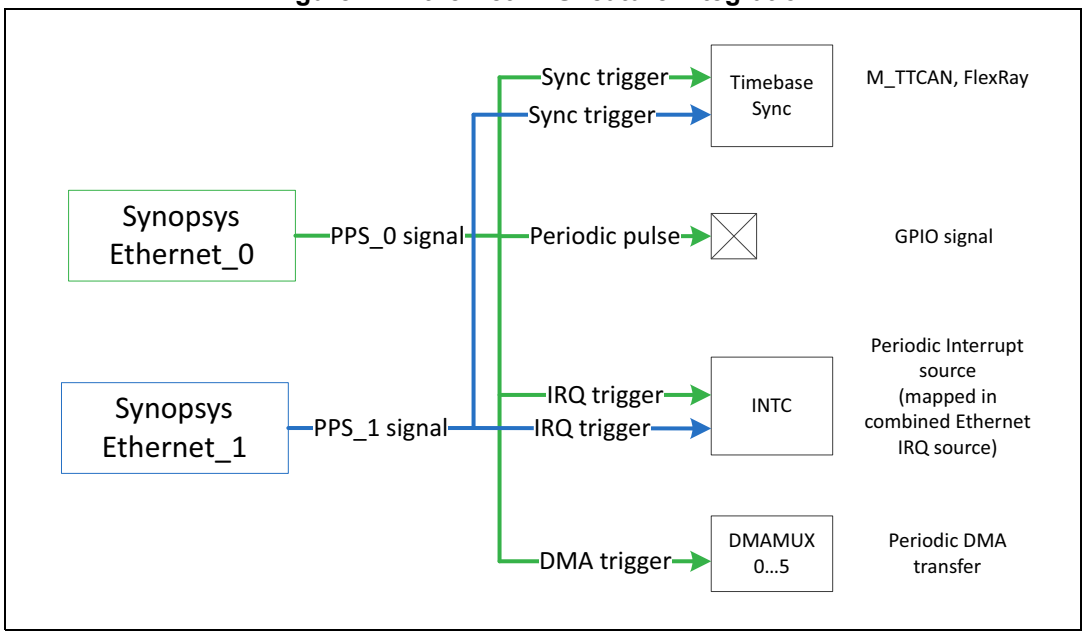
The Ethernet interface includes an internal 64-bit time base counter to support IEEE 1588 Precision Time Protocol (PTP) timestamps.

To synchronize other system events to the Ethernet PTP time base snapshot feature is available to capture the Ethernet time base on different system events into a four-entry-deep FIFO. Details about the snapshot feature is available in section “IEEE 1588 Timestaps” in Ethernet chapter.

The selection of the various trigger sources is done in the SIUL2 module by configuration of the corresponding MSCR registers. The details about the signal configuration is available in I/O Signal table.

The system implementation of the snapshot feature is shown in *Figure 26*.

Figure 26. Ethernet Snapshot feature integration



7.8.1.3 Ethernet Pulse-Per-Second output (PPS)

The Ethernet interface module includes a programmable time reference signal which can be used to trigger several system events. Details about the Pulse-Per-Second feature is available in section “Reference Timing Source” in Ethernet chapter.

The system implementation of the PPS feature is shown in *Figure 27*.

Figure 27. Ethernet PPS feature integration

7.8.2 CAN subsystem configuration

Two CAN subsystems are implemented:

- CAN subsystem_0 (M_CAN with M_TTCAN type)
- CAN subsystem_1 (M_CAN type)

Refer to *Chapter 52: CAN Subsystem* for details.

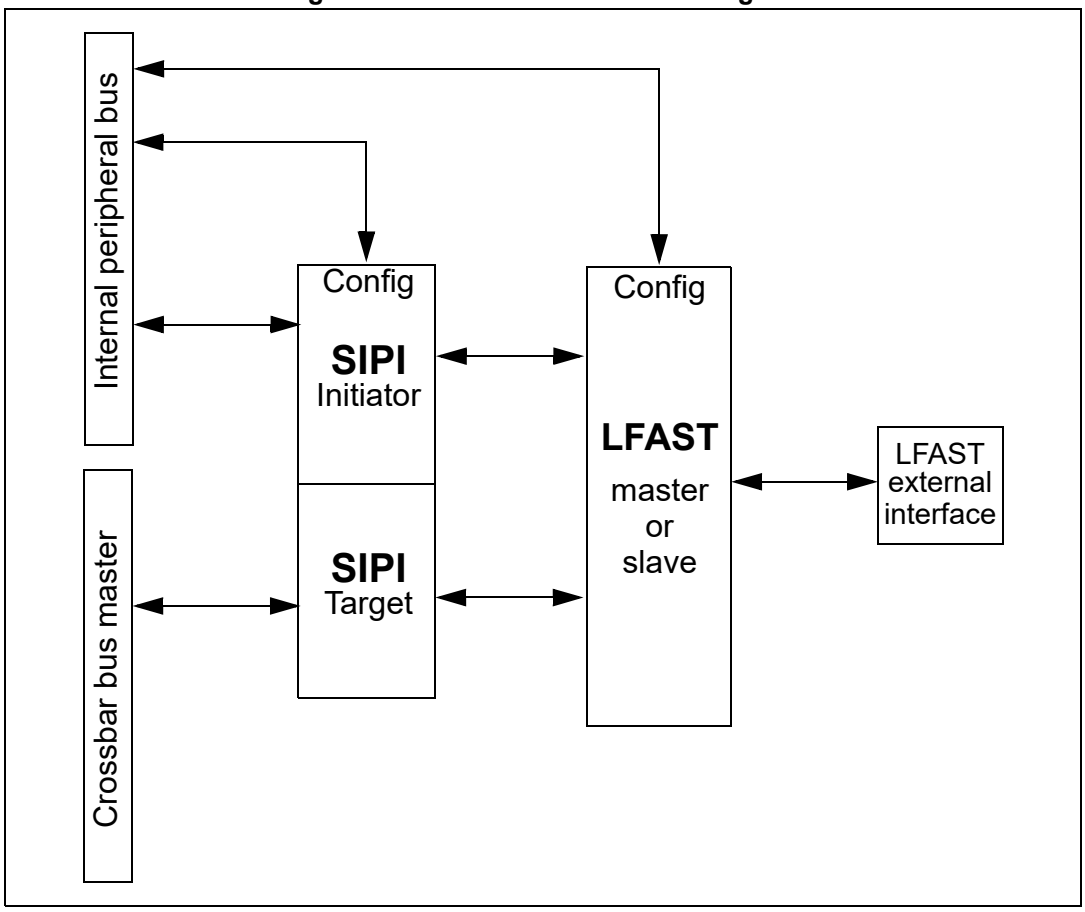
7.8.2.1 CAN nodes

Table 65 lists the different CAN nodes for both CAN subsystems.

Table 65. CAN bus controllers

Subsystem	Peripheral bridge instance	Shared message RAM size (words)	Type	Instance	CAN FD support up to 64 data byte(1)	Debug on CAN support	Clock calibration(2)
CAN subsystem_0	PBRIDGE_2	3968	M_CAN with TT_CAN	CAN_SUB_0_M_TTCAN_0	Yes	No	Yes
				CAN_SUB_0_M_CAN_1	Yes	Yes	Yes
				CAN_SUB_0_M_CAN_2	Yes	Yes	Yes
				CAN_SUB_0_M_CAN_3	Yes	No	Yes
CAN subsystem_1	PBRIDGE_1	3968	M_CAN	CAN_SUB_1_M_CAN_1	Yes	No	No
				CAN_SUB_1_M_CAN_2	Yes	No	No
				CAN_SUB_1_M_CAN_3	Yes	No	No
				CAN_SUB_1_M_CAN_4	Yes	No	No

1. M_CAN revision 3.2.1
2. Clock calibration based on M_CAN_1 messages for CAN subsystem_0.



7.8.3 LFAST and SIPI

This section summarizes the module configuration in the controller. For a comprehensive description of SIPI and LFAST, please refer to the dedicated SIPI and LFAST chapters.

7.8.3.1 Instantiation

The SIPI and LFAST are connected to one another and appear as a single unit. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules (see *Figure 28*).

Figure 28. LFAST and SIPI block diagram

7.8.3.2 Device-specific features

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality. The SIPI CHIP ID = 00110041h for SPC58xEx/SPC58xGx

DMA Channel Assignments	Direct memory access multiplexer	*Chapter 26: DMA channel multiplexer (DMACHMUX)*

7.8.4.1 DSPI instantiation

This device contains ten DSPI modules. *Table 68* shows the instantiation information for each module.

Table 68. DSPI instantiation

DSPI Module	CTARs	TX FIFO Depth	RX FIFO Depth	PCS Signals	LVDS Support	Data Serialization Support
DSPI0	8	4	4	Refer to the SPC58xEx/SPC58xGx pinout Excel file attached to the IO_Definition document	Not Available	—
DSPI1	8	4	4		Not Available	—
DSPI2	8	4	4		Available(1)	—
DSPI3	8	4	4		Not Available	—
DSPI4	8	4	4		Available(2)	64
DSPI5	8	4	4		Available(3)	64
DSPI6	8	4	4		Not Available	—
DSPI7	8	4	4		Not Available	—
DSPI8	8	4	4		Not Available	—
DSPI9	8	4	4		Not Available	—

1. Supports Differential DSPI with SCK, SIN and SOUT LVDS signal pairs.
2. Supports Microsecond Bus SCK and SOUT LVDS signal pairs.
3. Supports Microsecond Bus SCK and SOUT LVDS signal pairs; supports Differential DSPI with SCK, SIN and SOUT LVDS signal pairs

7.8.4.2 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all '1's.

7.8.4.3 Serialized timed I/O

The timer sources and injection pin inputs to be DSPI serialized downstream outputs are selected though the SIUL2 and selected through the MSCR registers. Inversion of these signals is also handled in the SIUL2. Refer to *Chapter 17: System Integration Unit Lite2 (SIUL2)*, for details.

7.8.4.4 High Speed and MicroSecond Channel (MSC) Support

The baud rate generator in the DSPI is clocked from the peripheral clock. The DSPI module can operate at a baud rate of up to half the peripheral clock.

To support microsecond channel functionality, pairs of LVDS signals are implemented for the appropriate DSPI signals. See *Table 68: DSPI instantiation* for details. In addition, SIUL2 MSCR muxing is implemented to mux the SOUT and CLK onto these LVDS signals well as standard CMOS signals. Finally, in the SIUL2 MSCR pin muxing, some input pins can be routed to 64 possible serialization inputs, each selectable for a specific DSPI.

Details of these pin assignments can be found in the SPC58xEx/SPC58xGx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to the IO_Definition document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input Multiplexing Table tab.

MSC is supported in both TSB and ITSB modes.

7.8.4.5 DSPI HT external trigger

External hardware triggers are not supported.

7.8.4.6 DSPI ITSB mode

For the ITSB trigger, the internal DSPI trigger (TRGPRD in DSICR1) is used. Use of external trigger is not supported.

7.8.4.7 DSPI registers

The absolute addresses of DSPI module registers in this MCU are provided in *Chapter 5: Memory Map*.

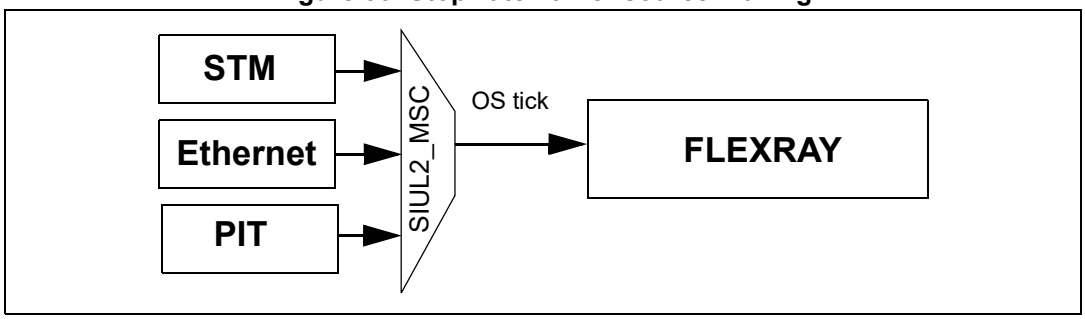
7.8.5 FlexRay configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of safety system.

7.8.5.1 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 69. Flexray pin names



Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXDA
FR_A_TX (Transmit Data Channel A)	CA_TX
$\overline{\text{FR_A_TX_EN}}$ (Transmit Enable Channel A)	CA_TR_EN
FR_B_RX (Receive Data Channel B)	RXDB
FR_B_TX (Transmit Data Channel B)	CB_TX
$\overline{\text{FR_B_TX_EN}}$ (Transmit Enable Channel B)	CB_TR_EN
FR_DBG[0] (Debug Strobe Signal 0)	DBG[0]
FR_DBG[1] (Debug Strobe Signal 1)	DBG[1]
FR_DBG[2] (Debug Strobe Signal 2)	DBG[2]
FR_DBG[3] (Debug Strobe Signal 3)	DBG[3]

7.8.5.2 Stopwatch timer input

Stopwatch timer input is routed to FlexRay module (selected by SIUL MSCR register) via:

- STM0_CMP0
- STM1_CMP0
- STM2_CMP0
- PIT1_CH0
- Ethernet_0 PTP_PPS_0

Figure 30. Stopwatch timer source muxing

7.8.6 PSI5 controller configuration

The PSI5 chapter has 2 instances. Parameters for the 2 instances are listed below:

Table 70. PSI5 controller generics

Signal name	Description	PSI5_0 value	PSI5_1 value
PSI5_NUM_CH	Number of channels	1	1
PSI5_PDIS_RST	Default State of the IP after reset	1	1

PSI5_0 and PSI5_1 have both a single channel (Channel0). PSI5_0 is a master instance here hence the PSI5_GCR register for this instance controls all the 2channels ; PSI5_0 (Channel 0) and PSI5_1 (Channel0). PSI5_1 instance does not contain the PSI5_GCR register and hence the corresponding PSI5_GCR address location for PSI5_1 is reserved. Further, with respect to the PSI5 base address the unimplemented reserved locations for PSI5_0 extend from 0x01C8 to 0xFFFF and unimplemented reserved locations for PSI5_1 extend from 0x01C8 to 0xFFFF.

7.8.7 SENT Receiver (SRX) configuration

7.8.7.1 SRX channels

Table 71 shows the SENT receiver channels for each instance configured on this chip.

Table 71. SENT channel configuration

Instance	Channels (CH)
SENT 0	8 Channels SENT_0_CH0 SENT_0_CH1 SENT_0_CH2 SENT_0_CH3 SENT_0_CH4 SENT_0_CH5 SENT_0_CH6 SENT_0_CH7
SENT 1	7 Channels SENT_1_CH0 SENT_1_CH1 SENT_1_CH2 SENT_1_CH3 SENT_1_CH4 SENT_1_CH5 SENT_1_CH6

7.8.7.2 SRX registers

Table 72 lists the address offset and memory map for both SENT receiver (SRX) instances for this chip.

Table 72. SENT receiver memory map

Offset	Register name	SENT 0	SENT 1
0x0000	GBL_CTRL— Global Control Register	X	X
0x0004	CHNL_EN—Channel Enable Register	X	X
0x0008	GBL_STATUS—Global Status Register	X	X
0x000C	FMSG_RDY—Fast Message Ready Register	X	X
0x0010	SMSG_RDY—Slow Serial Message Ready Register	X	X
0x0014	Reserved	—	—
0x0018	DATA_CTRL1— Data Control Register 1	X	X

7.8.8 LINFlexD

7.8.8.1 LINFlexD – Configurations

SPC58xEx/SPC58xGx has 18 instances of LINFlexD. *Table 73* lists the configuration for each instance.

Table 73. LINFlexD configurations

Description	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3	LINFlexD_4	LINFlexD_5	LINFlexD_6	LINFlexD_7	LINFlexD_8	LINFlexD_9	LINFlexD_10	LINFlexD_11	LINFlexD_12	LINFlexD_13	LINFlexD_14	LINFlexD_15	LINFlexD_16	LINFlexD_17
Number of filters implemented	16	0																
Number of Tx DMA channels	1 (TX_CH_NUM = 0)(1)																	
Number of Rx DMA channels	1 (RX_CH_NUM = 0)(2)																	
LIN operation mode	Master/Slave	Master (slave = 0)																
Value of auto-synchronization	1	0																

1. Number of TX DMA channels = 2**TX_CH_NUM where ** stands for exponentiation.
2. Number of RX DMA channels = 2**RX_CH_NUM where ** stands for exponentiation.

7.8.8.2 LINFlexD implemented registers

Table 74 shows the registers implemented for each LINFlexD instance on the SPC58xEx/SPC58xGx chip.

7.9 Reset and Boot modules

Table 74. LINFlexD register comparison map

Register description	Address offset (hex)																	
	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3	LINFlexD_4	LINFlexD_5	LINFlexD_6	LINFlexD_7	LINFlexD_8	LINFlexD_9	LINFlexD_10	LINFlexD_11	LINFlexD_12	LINFlexD_13	LINFlexD_14	LINFlexD_15	LINFlexD_16	LINFlexD_17
LIN Control register 1 (LINCR1)	00	00																
LIN Interrupt Enable register (LINIER)	04	04																
LIN Status register (LINSR)	08	08																
LIN Error Status register (LINESR)	0C	0C																
UART Mode Control register (UARTCR)	10	10																
UART Mode Status register (UARTSR)	14	14																
LIN Timeout Control Status register (LINTCSR)	18	18																
LIN Output Compare register (LINOCR)	1C	1C																
LIN Timeout Control register (LINTOCR)	20	20																
LIN Fractional Baud Rate register (LINFBRR)	24	24																
LIN Integer Baud Rate register (LINIBRR)	28	28																
LIN Checksum Field register (LINCFR)	2C	2C																
LIN Control register 2 (LINCR2)	30	30																
Buffer Identifier register (BIDR)	34	34																

Table 74. LINFlexD register comparison map (continued)

Register description	Address offset (hex)

DMA Rx Enable register (DMARXE)	9C	9C																

7.9.1 BAF configuration

7.9.1.1 Search boot header and boot options

Refer to *Section 8.3.12.2.3: SW boot record search (BAF search)* in the *Chapter 8: Reset and Boot*.

7.9.1.2 LINFlexD and MCAN pins configuration

Table 75 shows the device pin configurations for LINFlexD_0/2 and CAN_SUB_0_M_CAN_1/2 modules.

Table 75. LINFlexD and MCAN pin configuration

Pads	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received	Serial Boot Mode after a valid LINFlexD message received
	Function	Pad Configuration	Function	Function
PA[10]	—	(1) Output: — Push/Pull medium drive no pull-up/pull-down	MCAN_2 Tx	LINFlexD_2 Tx
PA[11]	LINFlexD_2 Rx and MCAN_2 Rx	Input: — pull-up hysteresis TTL voltage level	MCAN_2 Rx	LINFlexD_2 Rx

Table 75. LINFlexD and MCAN pin configuration (continued)

Pads	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received	Serial Boot Mode after a valid LINFlexD message received
	Function	Pad Configuration	Function	Function
PB[10]	—	(1) Output:— Push/Pull medium drive no pull-up/pull-down	MCAN_1 Tx	LINFlexD_0 Tx
PB[9]	LINFlexD_0 Rx and MCAN_1 Rx	Input: — pull-up hysteresis TTL voltage level	MCAN_1 Rx	LINFlexD_0 Rx

1. Pad is set to output configuration as described in the table. Output buffer is enabled for the whole duration of the BAF serial boot.

7.9.2 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the SPC58xEx/SPC58xGx device. For a comprehensive description of the SSCM, please refer to the SSCM's dedicated chapter.

7.9.2.1 SSCM instantiation

There is one SSCM instance in the SPC58xEx/SPC58xGx device. The SSCM is part of the reset and boot sub-system.

7.9.2.2 Device-specific features

The SSCM allows Boot Assist from Flash (BAF), and utilizes PASS security concept.

The device specific reset values for the SSCM_MEMCONFIG register are shown in *Table 76*.

Table 76. SSCM_MEMCONFIG reset values

Field	Field definition	Value
JPIN	JTAG Part ID	10'h110(1)
MREV	Minor Revision	4'h0(2)

1. This value will change for each major revision of the device.
2. This value will change for each minor revision of the device.

Table 77 shows the address locations that the SSCM uses to search for startup information.

Table 77. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET)	0x0040_0000
Location of the Boot Assist code in Flash (BAF)	0x0040_4000
Specifies the locations which are searched for a valid HSM boot header (starting from the lowest address)	0x60_C000 0x61_0000 0x62_0000

7.9.2.3 Memory map and register description

Table 78. Reference text to related information

Topic	Related module	Reference
Reset	Reset Generation Module (MC_RGM)	*Chapter 64: Reset Generation Module (MC_RGM)*
Reset/Boot	Reset and Boot	*Chapter 8: Reset and Boot*
Boot	Boot Assist from Flash (BAF)	*Chapter 65: Boot Assist Flash (BAF)*
Register Protection	Register Protection (REG_PROT)	*Chapter 91: Register Protection (REG_PROT)*
Serial Boot	LINFlexD	*Chapter 63: LINFlexD*
Security	PASS	*Chapter 92: Password and Device Security Module (PASS)*

7.10 Safety modules

7.10.1 CRC

Table 79 lists the number of contexts available for the current CRC computation of multiple data streams of CRC.

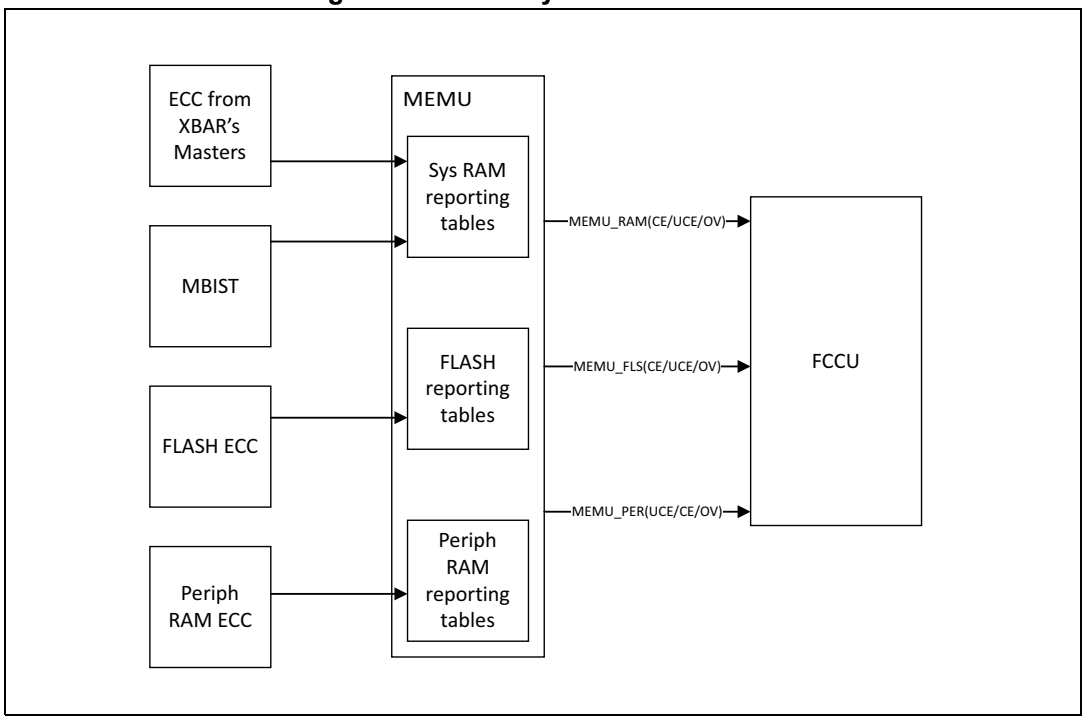

Table 79. CRC contexts

Signal name	Description	CRC_0	CRC_1
CRC_CNTX_NUM	Number of contexts available for the current CRC computation of multiple data streams.	4	4

7.10.2 MEMU configuration

7.10.2.1 MEMU system connections

Figure 31. MEMU system connections

7.10.2.2 MEMU error sources

Table 80 shows the MEMU error sources for each instance configured on this chip.

Table 80. MEMU error sources

Instance	Value
Number of system RAM unique error sources	128
Number of peripheral RAM unique error sources	36
Number of flash memory unique error sources	5

7.10.2.3 Reporting tables implementation

There are 3 categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting
- Peripheral RAM error reporting

Each category of error reporting has two tables associated with it, these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 81. Number of entries in each reporting table

Error Source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash	20	1
System RAM	10	1
Peripheral RAM	2	1

7.10.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from one of the three categories, Flash, System RAMs or Peripheral RAMs. In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Note: z4a/b/c stand for Core_0/1/2 respectively in the following tables.

Table 82. Corresponding error sources for system RAM OFLW0 register

Source number	OFLW0 bit-field position (bit)(1)	Error sources	Reporting address range (hex)
0	31	z4a Data AHB + z4A DSMC	Refer to XBAR memory map
1	30	z4a Instruction AHB	Refer to XBAR memory map
2	29	z4a Data TCM (DMEM)	0x50800000–0x5080FFFF
3	28	z4a Instruction TCM (IMEM)	0x50000000–0x5000FFFF
4	27	z4a Data Cache	0x4F010000–0x4F01FFFF
5	26	z4a Instruction Cache	0x4F000000–0x4F00FFFF
6	25	z4b Data AHB + z4b DSMC	Refer to XBAR memory map
7	24	z4b Instruction AHB	Refer to XBAR memory map

7.10.3 Indirect Memory Access (IMA) configuration

The IMA refers to the alteration of memory data values during system development and test activities. This section provides details about what memory locations can be accessed—either via processor core access or via the IMA module—and how they are configured. For details on IMA see *Chapter 88: Indirect Memory Access (IMA)*.

Note: See the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual for the HSM IMA details.

7.10.3.1 SRAM Arrays accessible by processor cores

All the SRAM arrays in *Table 92* can be accessed by all main Cores (Core_0, Core_1, Core_2).

Table 92. SRAM with processor Core access

Block	Function	SPC58xEx/SPC58xGx		
		Words	Bits	ECC Bits

7.10.4.3 FOSU parameters

The FOSU_COUNT, or FOSU timeout response time, is 1000 safe clock cycles.

7.10.5 Register protection (REG_PROT) configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software-controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the *Chapter 91: Register Protection (REG_PROT)*.

1. See the module memory map in the SIUL2 chapter for address offset.

7.10.5.2 Core Clock Monitor Unit (CMU_1) protected registers

Table 99 lists the registers that can be protected for the fast crossbar CMU (CMU_1)

Table 99. Protected CMU_1 (CORE_XBAR_BD) registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
CSR	32	0x0003	8
HFREFR	32	0x000A	16
LFREFR	32	0x000E	16
ISR	32	0x0013	8

7.10.5.3 I/O Processor Clock Monitor Unit (CMU_0) protected registers

Table 100 lists the registers that can be protected for PLL CMU (CMU_0)

Table 100. Protected CMU (PLL0_XOSC_IRCOSC) registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
CSR	32	0x0003	8
HFREFR	32	0x000A	16
LFREFR	32	0x000E	16
ISR	32	0x0013	8

7.10.5.4 PMC Digital Interface (PMC_DIG) protected registers

Table 101 lists the PMC_DIG registers that can be protected.

Table 101. Protected PMC_DIG registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
REE_LV0	32	0x0004	8
RES_LV0	32	0x0008	8
FEE_LV0	32	0x0010	8

Table 101. Protected PMC_DIG registers (continued)

Register	Register size (bits)	Offset from module base address	Protected size (bits)
REE_LV1	32	0x0025	8
RES_LV1	32	0x0029	8
FEE_LV1	32	0x0031	8
REE_HV0	32	0x0044	8

Note: HSM and FLASH online MBIST are not accessible when life cycle is customer delivered/OEM/IN FIELD (SSCM_LCSTAT[LC]=CUST_DELIV/PROD_OEM/IN_FIELD).

Refer to the Chapter 90: Self-Test Control Unit (STCU2) for a description of the registers programming and to the DCF client table for the description of the available DCF.
The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. By default, STCU2 is not bypassed.
This means that if offline self tests are not programed, the hard-coded WDG of the STCU2 will be anyway activated. As a consequence, the startup time of the device will be increased according to the WDG timeout value.

Table 114 lists the MBIST registers in STCU2 with their available fields.

1. SPC58xGx devices have only lbist_partition_0.

7.11 Security modules

7.11.1 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks on the SPC58xEx/SPC58xGx MCU. Up to four levels of password protection can be implemented for each flash block.

Note: The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See *Chapter 92: Password and Device Security Module (PASS)* for further details.

7.11.1.1 PASS_LOCK*n*_PG*n* register bit mapping

Each password group defined in the DCF records has a set of four LOCKn registers association with it: PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note: The mapping of various LOCK register bits to flash blocks in the SPC58xEx/SPC58xGx microcontroller is very similar to the LOCKx registers implemented in the FLASH, but not identical. The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

Figure 35. PASS_LOCK3_PGn registers

7.11.1.2 PASS Module DCF Records (includes lifecycle state and censorship)

The records required to configure the initial values for the PASS module password group registers are shown in *Table 116*. These values provide the following capabilities:

- Set flash memory to censored/uncensored state (censorship also depends on lifecycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part

000_0000_0000_1000	0000000	01001101	LOCK1_PG3(2)	32	1

1. See *Section 92.6.3: Censoring and uncensoring the device* for values.
2. See *Section 7.11.1.1: PASS_LOCKn_PGn register bit mapping* for values.

7.11.2 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), that is, write once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

Warning: **See the Tamper Detection Module (TDM) chapter for further details on the TDM, including the DCF clients and two additional memory-mapped registers.**

7.11.2.1 Diary Base Address (DBA) DCF client

DBA DCF client holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations. This DCF client is described in the TDM chapter.

7.11.2.2 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. This DCF client is described in the TDM chapter. The mapping is shown below.

DCF Client Address: 0x0001 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 36. Tamper Region Override (TO) DCF client

The mapping of the Tamper Region Override Enable (TOE*n*) DCF client is as follows:

Table 117. TO[TOE*n*] field mapping

Field	TDR
TOE0	0
TOE1	1
TOE2	2
TOE3	3
TOE4	4
TOE5	5

This DCF client is more fully described in the TDM chapter.

7.11.2.3 OTPEN*n* DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPEN*n* DCF clients.Each mapped bit is associated with a specific flash block. A “1” bit value indicates a block is OTP.

The mapping is shown in *Figure 37* - *Figure 40*.

Figure 40. TDR*x*_LOCK3/OTPEN3 DCF client

7.11.2.4 TDR*x*_LOCK*n* DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A "1" in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDM_LOCKn DCF client bits to flash blocks is identical to the OTPEN*n* mapping.and is shown in *Figure 37* - *Figure 40*. Any available flash block can be mapped to any tamper protection region.

7.11.2.5 DCF client details

Table 118 contains the DCF client information.

Table 118. Tamper Detection Module (TDM) DCF clients

000_0000_0001_0000	0000000	00101010	TDR5_LOCK2	32	1
000_0000_0001_0000	0000000	00101011	TDR5_LOCK3	32	1
000_0000_0001_0000	0000000	00101100 - 1111111	Reserved		

1. OTP DCF clients have the same structure and mapping as the write-protect bits of the flash and PASS module LOCK DCF clients. A value of '1' in an OTP bit indicates a block is programmable only once. Note that a block cannot be reconfigured as non-OTP after it has been configured as OTP.
2. There are no flash memory blocks mapped to the OTPEN3 DCF client.

8 Reset and Boot

8.1 Introduction

This chapter describes the reset and boot phase, from the time a power on or reset is applied, till the completion of the Boot Assist Flash (BAF) code.

After reset, Core_2 is woken-up, Checker Core_2 and HSM may be woken-up (refer to details in *Chapter 9: Device Configuration Format (DCF) Records*).

The following memory elements are involved in the boot-up process:

- UTEST flash memory
- TEST flash memory
- Boot Assist Flash (BAF)

8.1.1 TEST flash memory block

The TEST flash memory block contains Device Configuration Format (DCF) records used to hold trim values and other variables, as well as general device configuration information.

The trim values are for:

- Adjusting low-voltage and high-voltage detect circuit trip points
- Temperature sensor adjustments
- Power-on reset voltage trip point
- Analog-to-digital adjustments
- Internal RC oscillator (IRCOSC) trim values
- Power management configuration, for the devices supporting different regulation schemes

Note: The DCF records are written by the device manufacturer and programmed into TEST flash memory during production testing. Further programming of the TEST flash is disabled at the end of the factory test cycle.

8.1.2 UTEST flash memory block

The UTEST flash memory block also contains DCF records. Some UTEST DCF records are written by the factory and programmed during production testing. Others are written by the end user and programmed at the same time application code is programmed into the flash memory. UTEST DCF records are used to set up various control and configuration registers, including the Self-Test Control Unit (STCU2) and default memory configuration.

8.1.3 Boot Assist Flash

The Boot Assist Flash (BAF) contains factory code to facilitate the device boot-up procedure.

Refer to *Chapter 65: Boot Assist Flash (BAF)* for further details on this procedure.

8.2 Modules used in reset sequence

The modules involved in the SPC58xEx/SPC58xGx reset sequence are:

- Power Management Controller (PMC)
- Reset Generation Module (MC_RGM)
- Mode Entry Module (MC_ME)
- System Status and Configuration Module (SSCM)
- Self-Test Control Unit (STCU2)

8.2.1 Power Management Controller

The Power Management Controller (PMC) controls and monitors:

- Its own supply voltage
- The supply voltages to all the high- and low-voltage detect circuits
- The trip points for all the high- and low-voltage detect circuits
- The power supplies and reference voltages to the Analog-to-Digital Converter
- The major power supplies to the SPC58xEx/SPC58xGx

8.2.2 Reset Generation Module

The Reset Generation Module (MC_RGM) is a complex state machine that begins sequencing the SPC58xEx/SPC58xGx through the initial steps of the reset process. The MC_RGM does not execute program code, it is a state machine that centralizes the different reset sources and manages the reset sequence. Reset sources are organized into two categories: destructive and functional.

Refer to *Figure 41* for more information on the MC_RGM reset sequence.

8.2.2.1 Destructive resets

A destructive reset source is related to a critical error or dysfunction, usually caused by a hardware malfunction. When a destructive reset event occurs, software recovery is not possible and the contents of memory are assumed unknown. A full device reset sequence starting from PHASE0 is therefore applied to the device, ensuring a safe startup state for both digital and analog modules.

Examples of destructive resets are:

- Power-on reset
- Low voltage detection
- Reset escalation (when too many functional resets occur simultaneously)

8.2.2.2 Functional resets

A functional reset source is related to a less critical error or dysfunction usually not associated with hardware malfunction. When a functional reset event occurs, a partial reset sequence is applied to the device starting with PHASE1[FUNC]: most digital modules are reset normally and the state of analog modules, specific digital modules (for example, debug and flash memory modules) and system memory content is preserved.

Examples of functional resets are:

- External reset
- Machine check
- Software reset from mode entry
- Boundary scan instructions

8.2.3 Mode Entry module

The Mode Entry module (MC_ME) is responsible for configuring the execution mode, including the delivery of reset vectors to all the SPC58xEx/SPC58xGx cores.

8.2.4 System Status and Configuration Module

During the reset phase, the SSCM reads the DCF records in the TEST and UTEST flash memory areas in order to distribute within the device the pre-assigned configuration.

The DCF records are primarily for setting up the memory, configuring the Self-Test Control Unit (STCU2), and providing initial device configuration values.

The SSCM continues with the reset or boot-up sequence by locating boot vectors for the boot core and, if enabled for the HSM CPU. The start addresses are written into the Mode Entry Module (MC_ME) registers, which, in turns, will pass them to the proper CPU at the end of the reset phase.

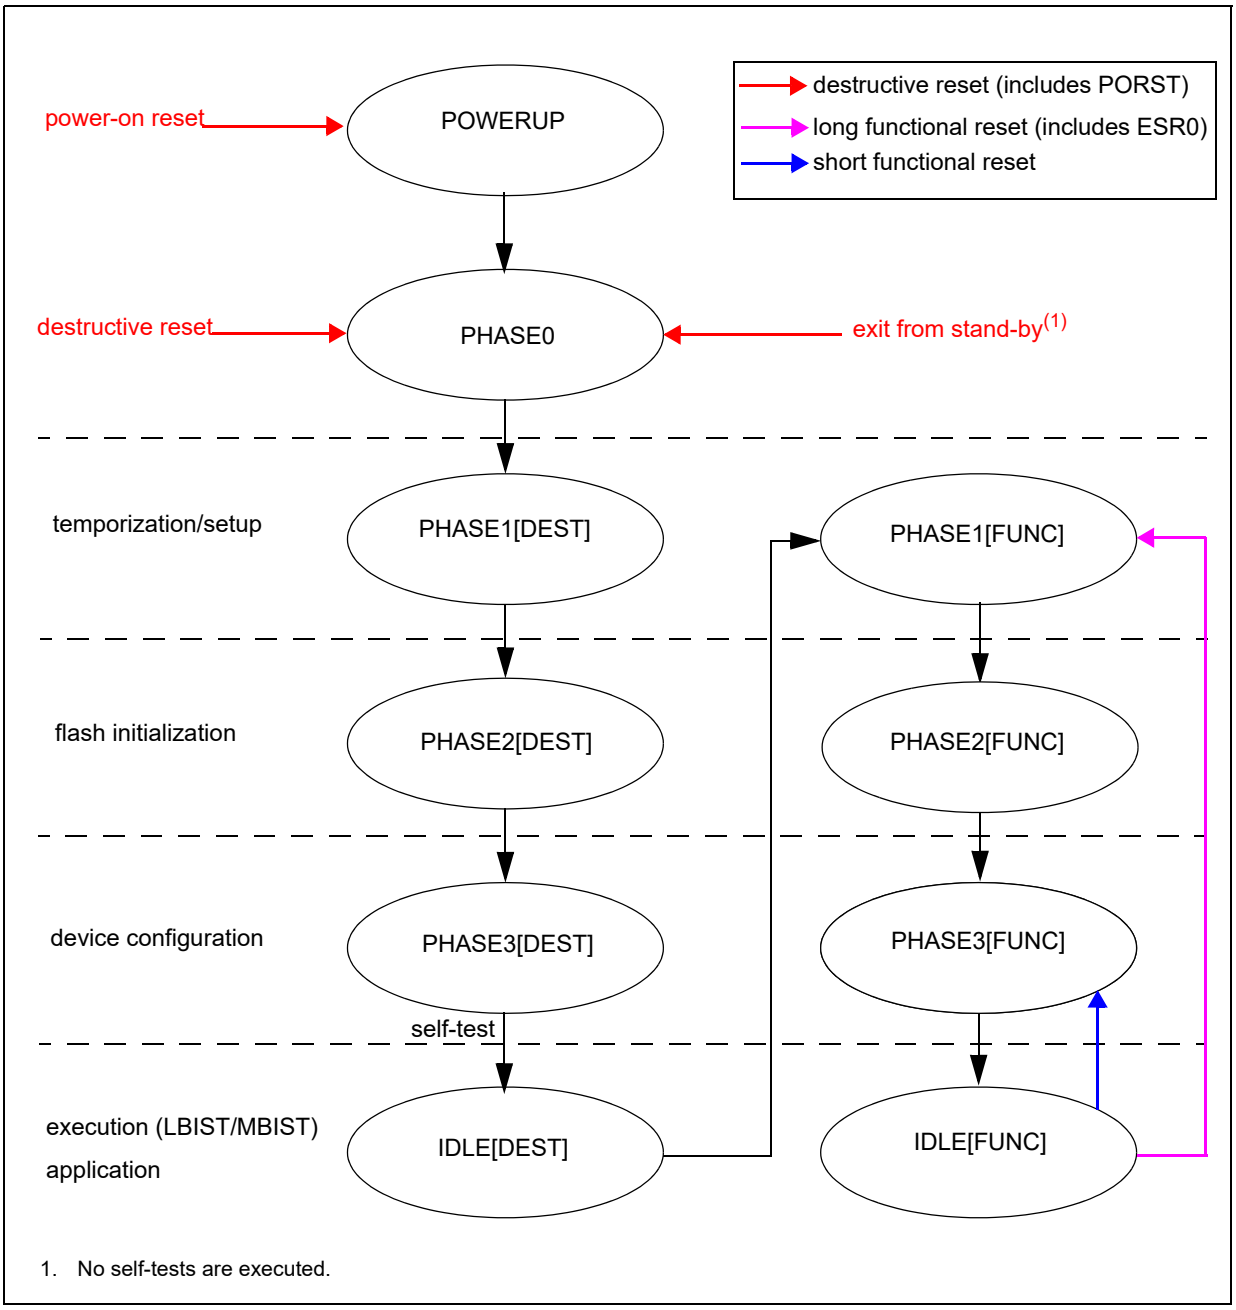
8.2.5 Self-Test Control Unit

The Self-Test Control Unit (STCU2) is a self-contained module that runs a Logic Built-In Self-Test (LBIST) and a Memory Built-In Self-Test (MBIST). The DCF record can be used to select which individual tests are run for LBIST and MBIST and disable tests for modules and memory elements that are not going to be used in user applications, thus shortening device boot-up time.

8.3 Reset sequence

The power-up reset sequence always begins with the application of power and follows different sequences depending on the condition of the SPC58xEx/SPC58xGx device and whether various modes are enabled from settings in the DCF records. For instance, the SPC58xEx/SPC58xGx device enters Serial Boot mode (the Serial Boot Loader receives startup code and begins program execution) if a valid boot header file is not found (conditioned by the Life Cycle value).

If an emulation and debug device is detected during the reset sequence, the device enters the calibration sequence. The calibration sequence is not a user mode and is only used for code development.



8.3.1 Power-on and the Reset Generation Module

When power is applied to the SPC58xEx/SPC58xGx, the Reset Generation Module (MC_RGM) advances the device through a series of steps shown in *Figure 41*.

The Reset Generation Module (MC_RGM) starts the System Status and Control Module (SSCM), which continues the boot-up process after the MC_RGM enters the IDLE state.

The STCU is reset and offline self-test (if enabled) is triggered on any power-on, destructive, or long external reset (external reset in this case is ESR0).

Figure 41. Reset Generation Module Reset Sequence

1. No self-tests are executed.

Table 119. Module status during reset phases

Module	PHASE								
	P0	P1 [DEST]	P2 [DEST]	P3 [DEST]	IDLE [DEST]	P1 [FUNC]	P2 [FUNC]	P3 [FUNC]	IDLE [FUNC]

								Short functional reset	
						functional reset			
	destructive reset								

1. RESET only during POR.
2. STCU time-out monitoring LBIST/MBIST execution.
3. Depending on flash configuration.
4. FCCU remains ON during functional reset; it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST].
5. The STCU remains idle during functional reset; it is instead reset on long external reset (external reset here is ESR0).
6. Can be triggered by SW. Please refer to *Chapter 90: Self-Test Control Unit (STCU2).*
7. MEMU is reset whenever STCU is reset.
8. LBIST is optionally triggered depending on safety execution directives.

9. LBIST is optionally triggered depending on safety execution directives after enabling from IOP. Please refer to *Chapter 65: Boot Assist Flash (BAF).*

8.3.2 Power-up phase: power stabilization

When a power-on reset event occurs (initial application of power), the reset generation module (MC_RGM) causes the device to enter the power-up phase of the reset sequence (refer to *Figure 41*). The only method to enter the power-up phase is from a power-on reset event.

The device remains in the power-up phase until the Power Management Controller module (PMC) determines that all power supplies are in their respective operational ranges.

The supplies for initial configuration are:

- VDD_HV_CORE: high voltage supply for core module, including power management unit, internal RC oscillator (IRCOSC).
- VDD_LV_CORE: low voltage supply for digital module.
- VDD_HV_FLA: high voltage supply for flash module.
- VDD_LV_FLA: low voltage supply for flash module.
- VDD_HV_IO_IM: high voltage supply associated with system pins (PORST, ESR0, TEST Mode).

Peripheral supplies such as VDD_HV_IO_JTAG, VDD_HV_IO_FLEX or VDD_HV_ADC do not gate the power-up process. The low- and high-voltage detect circuits for these and other power supplies are managed by the PMC, which provides enable and status bits for these voltage detection circuits.

The PMC sends a signal to the Reset Generation Module when power stabilization has been achieved. The Reset Generation Module then advances to the PHASE0 state (refer to *Figure 41*). During the power-up phase, the PMC does the following:

- Drives to a logic ‘0’ all VDs (voltage detectors) signals monitored by the Power Management Control (PMC) module.
- Monitors its own power supply voltage (VDD_HV_PMC) to determine that the applied voltage is within a specified range.
- Monitors the core power supply voltage (VDD_LV_CORE) to determine that the applied voltage is within a specified range.
- Monitors the low- and high-voltage detect circuit power supply voltage to determine that the applied voltage is within a specified range.
- Holds the outputs of the internal low- and high-voltage detect circuits at a ground state until the PMC determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Enables all low- and high-voltage detect circuits once all power supplies are at their functional levels.
- Begins to monitor the various power supplies using the high- and low-voltage detect circuits.
- Provides status information to the Reset Generation Module (MC_RGM) indicating whether or not power is properly applied.

To exit power-up and enter PHASE0:

- All enabled destructive resets must be processed.
- All power supplies must be at their functional voltages.
- The PMC must signal the MC_RGM that all power supplies are at the required levels.

8.3.3 PHASE0 Phase: analog supply initial configuration

This phase is entered:

- On exit from power-up phase.
- On PORST pin falling edge detection except for the initial power-up sequence.
- Immediately from PHASE2[DEST], PHASE3[DEST], IDLE[DEST], PHASE1[FUNC], PHASE2[FUNC], PHASE3[FUNC] or IDLE[FUNC], on the occurrence of a PORST falling edge event other than power-on reset.

During PHASE0:

- All digital modules are reset, including safety, security, and test modules.
- All trimming bits for analog modules are reset.
- Startup of the internal analog modules (IRCOSC, FUSE, Flash memory, and I/Os) begins:
  - PMC determines that proper voltages are applied.
  - I/O pins are ensured correctly configured: outputs are driven to known levels, inputs ignored.

To exit PHASE0 and enter PHASE1[DEST]:

- All enabled destructive resets must be processed.
- Gating PHASE0 must be released.
- All processes initiated in PHASE0 must be completed. This generally includes startup of the internal analog modules: PMC, IRCOSC, and I/Os.

Note: The core voltage must rise above LVD100 upper threshold to exit PHASE0. This ensures significant hysteresis on low voltage supply avoiding spurious low voltage detection during the power-up process.

8.3.4 PHASE1[DEST] Phase: temporization and monitoring setup

This phase is entered on exit from PHASE0.

During PHASE1[DEST]:

- Initial configuration of the watchdog to monitor the reset sequence
- Temporization for reset signal propagation in case of reset

Test modules are available during PHASE1[DEST], but their functionality is limited by the security module.

All PHASE1[DEST] tasks must be completed before entering PHASE2[DEST].

8.3.5 PHASE2[DEST] Phase: flash initial configuration

This phase is entered on exit from PHASE1[DEST].

During PHASE2[DEST]:

- Reset is released to the flash memory module by the Reset Generation Module.
- The flash memory module starts its initial configuration process.
- The flash memory initialization is performed by a state machine internal to the flash module.
- The system watchdog starts monitoring flash memory configuration execution so that a reset occurs in the event of configuration failure.

Note: System Watchdog is hardware configured to generate destructive reset in case of flash memory failure during flash boot process. In this case the software can read the cause of the reset by the MC_RGM_DES.F_FIF flag. On boot completion, the watchdog event is converted to generate an FCCU fault only.

All PHASE2[DEST] tasks must be completed before entering PHASE3[DEST].

8.3.6 PHASE3[DEST] Phase: device configuration

This phase is entered on exit from PHASE2[DEST].

During PHASE3[DEST], the System Status and Configuration Module (SSCM) starts by retrieving the Device Configuration Format (DCF) record from the TEST and UTEST flash memory areas, and uses the configuration and initialization information therein to:

- Configure the Self-Test Control Unit (STCU2) and the initial memory map of the device.
- Transfer reset vectors for the various cores to the Mode Entry Module (MC_ME). This information enables tests that the STCU runs and also provides the memory map setup information so that the STCU can test memory.
- Write trim values for analog modules including the Analog-to-Digital Converter, low- and high-voltage detect circuits, and the temperature sensor to their respective registers.

The DCF record programmed into the TEST flash memory area is written by the manufacturer. The portion of the DCF record programmed into the UTEST flash memory is usually written by the customer, although there is a default DCF record programmed into both the TEST and the UTEST flash memory areas during device production testing.

The DCF record also provides configuration information for the following:

- Trimming of the analog modules (for example, voltage regulator, voltage detectors, I/Os, and oscillator)
  - Trim values are in DCF records in the TEST flash memory area
  - Trim values are determined during production test and programmed into the TEST flash memory area
  - Security configuration
- Application configuration bits:
  - Watchdog configuration
  - Safety execution directives (self-test, LBIST/MBIST)
  - Boot Assist Flash options
  - Oscillator startup during reset sequence configuration

To exit PHASE3[DEST]: All processes that need to be completed in PHASE3[DEST] must be finished.

This phase depends on actual trim values, especially those used for safety execution directives. This device configuration is maintained until the next internal power-on reset. Each time a destructive reset event occurs, the SSCM takes values from the DCF record and writes them to the applicable registers.

During this phase, the internal STCU watchdog is started and is only cleared after completion of STCU configuration.

If self-test execution is the configuration information from the DCF record requests, the device moves to IDLE[DEST] and the STCU2 begins self-test. At the end of the test, the STCU2 asserts a functional interrupt causing the Reset Generation Module to move to PHASE1[FUNC]. If self-test execution is not requested, the device moves directly to IDLE[FUNC]. The Reset Generation Module determines whether self-test execution is enabled or not by examining an entry in the DCF record stored in the UTEST flash memory.

Note: When self-test execution is not requested, it is possible to maintain the device in PHASE3[DEST] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.

8.3.7 IDLE[DEST] Phase: self-test execution

This phase is entered upon exit from PHASE3[DEST] if the execution of self-test is enabled.

During the IDLE[DEST] phase:

- Dedicated watchdog is configured to monitor self-test execution completion within expected time. The length of this phase is variable depending on the self-test requirements.
- The Self-Test Control Unit (STCU2) executes all tests specified by the DCF information retrieved in PHASE3[DEST].
- The self-test engine updates the self-test completion flag and triggers an associated functional reset on completion of self-test.

The length of this phase is variable depending on the self-test requirements.

Note: When the SSCM is decoding the Device Configuration field, it sets and clears various flags in STCU registers and memory that can later be examined by the SSCM to determine which self-test directives must be run.

Exiting IDLE[DEST] and moving to PHASE1[FUNC]:

- The IDLE[DEST] phase is automatically exited when the self-test code generates a functional reset on completion.
- The functional reset causes the reset generation module to move to the PHASE1[FUNC] phase.

Note: In the case of unrecoverable fault detected during the execution of the offline BIST, the STCU requests a destructive reset and device re-enters PHASE0[DEST].

In the case of a permanent fault, when the reset escalation is reached, the hardware keeps the device in PHASE0[DEST] until a Power On Reset occurs.

Whereas in the case of a transient fault, the software can read the cause of the reset by reading the MC_RGM_DES.F_SUF flag.

8.3.8 PHASE1[FUNC] Phase: temporization and monitoring setup

This phase is entered either:

- On exit from IDLE[DEST].
- Immediately from PHASE2[FUNC], PHASE3[FUNC], or on IDLE[FUNC] when a non-masked external or functional reset event occurs, providing the source of the reset event has not been configured to trigger a ‘short’ reset sequence.

During PHASE1[FUNC]:

- Initial configuration of the watchdog to monitor reset process.
- Temporization for reset signal propagation in case of reset.

To exit PHASE1[FUNC] and enter PHASE2 [FUNC]:

- All enabled, non-shortened functional resets must be processed.
- All processes started in PHASE1[FUNC] must be completed.
  - Initial configuration of the watchdog to monitor reset process.
  - Temporization for reset signal propagation in case of reset.

During this phase, test modules are available.

8.3.9 PHASE2[FUNC] Phase: flash initial configuration

This phase is entered on exit from PHASE1[FUNC].

During the PHASE2[FUNC] phase:

- The reset signal is released to the flash memory.
- Flash initialization and configuration begins using a state machine that is internal to the flash memory module.
- A watchdog monitors flash initialization to ensure a reset in case of flash memory configuration failure.

The reset state machine exits PHASE2[FUNC] and enters PHASE3[FUNC] on verification that all processes started in PHASE2[FUNC] are completed.

8.3.10 PHASE3[FUNC] Phase: device configuration monitoring

PHASE3[FUNC] is entered:

- On exit from PHASE2[FUNC].
- Immediately from IDLE[FUNC] when an enabled, short functional reset event occurs.

During PHASE3[FUNC], configuration information contained within the UTEST flash memory sector is checked against information extracted during PHASE3[DEST] and written to the Self-Test Control Unit (STCU2). In case of mismatches, a dedicated boot fault is triggered within the FCCU which, if enabled, can cause a system reset. The purpose of PHASE3[FUNC] is to verify that the DCF information transferred to the STCU, MC_ME and other modules, in PHASE3[DEST], was performed correctly and has not been corrupted.

The Reset Generation Module exits PHASE3[FUNC] and enters the IDLE[FUNC] on verification of the following:

- All processes started in PHASE3[FUNC] are completed.
- PORST and ESR0 pins are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened functional reset event.

After all PHASE3[FUNC] internal actions have been completed, it is possible to maintain the device within PHASE3[FUNC] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes in order to connect through the JTAG port to the internal debugger.

8.3.11 IDLE[FUNC] Phase

This is the Reset Generation Module's final phase of the reset sequence. It is entered either on exit from PHASE3[DEST] (if self-test was not enabled) or at the completion of PHASE3[FUNC]. When the IDLE[FUNC] phase is reached, the MC_RGM releases control of the system to the System Status and Control Module. The SSCM, which started in PHASE3[FUNC], (or in PHASE3[DEST] in case no self-test was enabled) runs and waits for a signal from the MC_RGM indicating that the MC_RGM is now in the IDLE state. The MC_RGM then waits for new reset events that can trigger a reset sequence. The SSCM continues with the system boot-up sequence.

8.3.12 System start-up

At the start-up, only one processor (from now on called Boot CPU) and, if available and enabled, the Security Module CPU wake up.

8.3.12.1 Boot CPU reset vector

After the reset phase is completed, the Boot CPU starts executing at the value forced onto its reset vector. The reset vector is driven by the ME peripheral, according to the value stored into the CADDR register.

The value of the CADDR register depends on whether the reset is generated as a consequence of a wake-up reset event (restart from Stand-by) or any other event. The Flash status (powered on or off) also concurs to select the reset vector value.

In case the reset is not due to a wake-up event, the CADDR registers for the Boot CPU and, if existing, the Security Module CPU are written by the SSCM, according to the system startup configuration, which is stored in Flash and read by the SSCM from the Flash during the reset.

In case the reset is due to a wake-up event, the ME reads the CADDR reset vectors from the RGM, which had saved a copy of the CADDR registers in its internal latches, which resides in the low-power domain. The same is valid (if embedded) for the HSM Module (refer to *Section 8.3.12.4*).

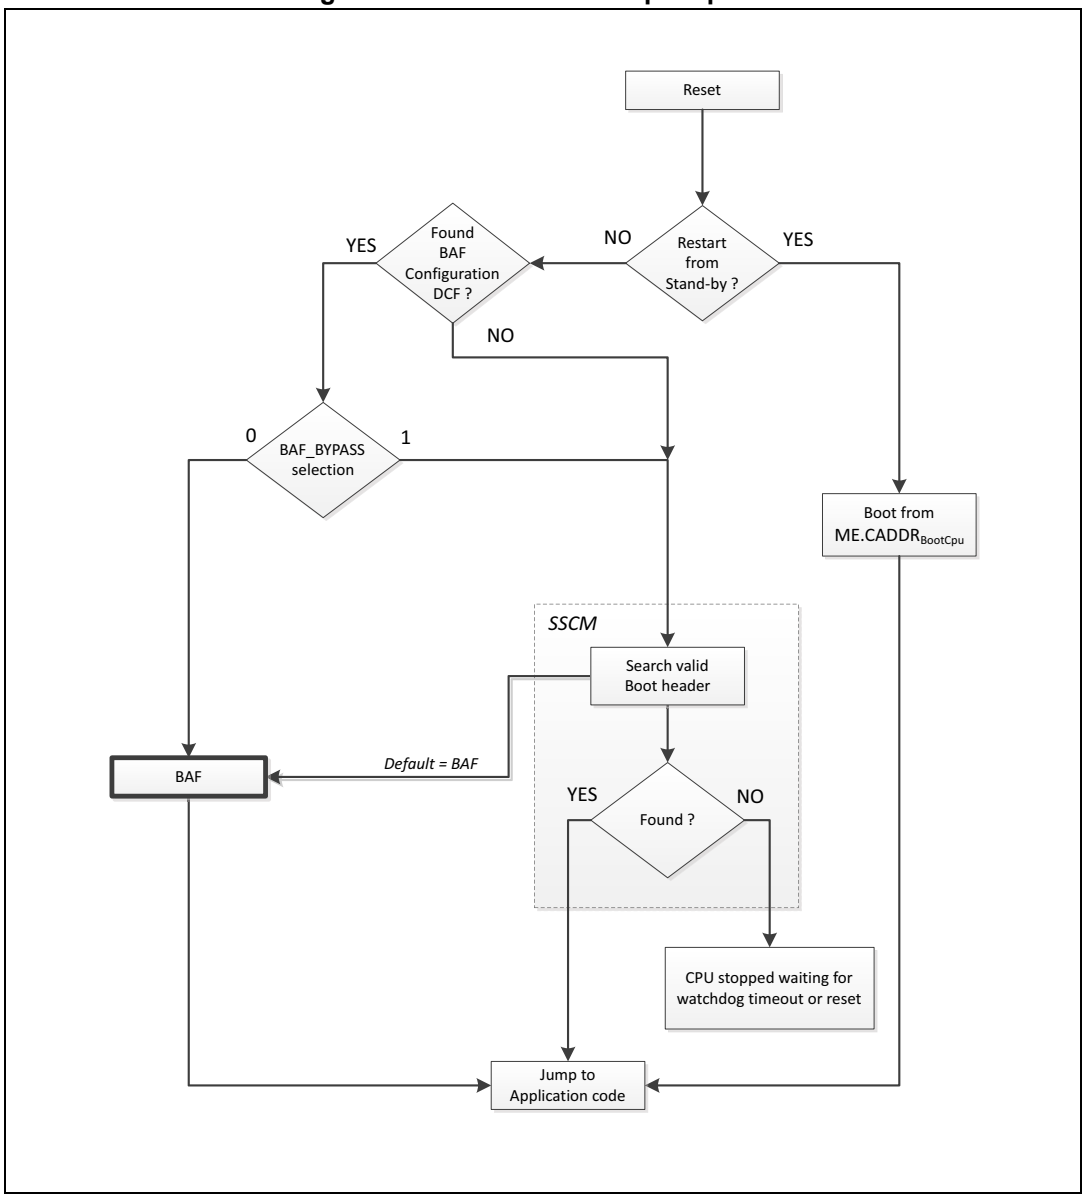
8.3.12.2 Boot CPU start-up

The Boot CPU startup configuration comprises of the following settings:

- BAF configuration DCF. It is used to decide whether the BAF code (stored by the manufacturer in the Flash BAF block) will be skipped or executed. The BAF start address is also set within the same DCF.
- Application boot records (programmed by the customer). It is used to set the customer application entry point after reset or after the BAF execution (if enabled).

The target for this device is to let the customer choose whether either the BAF code shall be started after the reset phase or directly the customer application, using the same sales part number.

The BAF configuration DCF shall be permanently written into the UTest block.



If the BAF configuration DCF is not programmed, the default value for the reset start address depends on the Life Cycle.

If the BAF configuration DCF is programmed, its value determines whether the CPU will start directly from the BAF code (programmed by ST in the Flash BAF block) or at the application entry point defined by the customer.

The application entry point can be retrieved both in HW (by the SSCM or ME, depending on the fact the system restarts from Stand-by or not (refer to *Section 8.3.12.1*)) or in SW (by the BAF). In both cases, the application entry point is retrieved by searching for a valid Boot Record, which shall be programed by the customer in one of the pre-determined Flash memory locations looked at by the SSCM or the BAF code. Next sections provide more details about the Boot Record structure and search operation.

8.3.12.2.1 Start-up flow chart

Figure 42. Boot CPU start-up sequence

8.3.12.2.2 HW boot record search (SSCM search)

If the programmed value of the BAF configuration DCF skips the BAF, then the SSCM module looks for a valid software entry point, called SSCM boot record. The SSCM boot record is organized as shown in the *Table 120*. The “Application start address” value will be passed to the CADDR register of MC_ME, which is used to set the CPU start address (reset vector) after the reset phase.

Table 120. Boot record structure searched by the SSCM

Offset	Field description	
0x4	Application start address	
0x0	SSCM Boot Record Tag (0x5A)	Reserved

The SSCM searches for a valid boot record at the addresses specified in *Table 121*. A boot record is considered valid if it contains the value 0x5A in the “Boot Record Tag” field.

The “Search Order” column specifies which location is searched first.
The SSCM stops the search as soon as a valid boot record is found.

Table 121. SSCM boot record search locations

Search order	Address	Location	SSCM configuration parameter
0 (First)	0x00FC_0000	Flash 16 KB Code Block 3	RCHW_LOC_0
1	0x00FC_4000	Flash 16 KB Code Block 1	RCHW_LOC_1
2	0x00FC_8000	Flash 16 KB Code Block 4	RCHW_LOC_2
3	0x00FC_C000	Flash 16 KB Code Block 2	RCHW_LOC_3
4	0x0100_0000	Flash 128 KB Code Block 0	RCHW_LOC_4
5	0x0102_0000	Flash 128 KB Code Block 1	RCHW_LOC_5
6 (Last)	0x0040_4000	Flash 16 KB BAF block	RCHW_LOC_6

Depending upon the fact that a valid SSCM boot record is found and the content of the SSCM boot record, three scenarios can happen:

1. If a valid Boot Record is programmed by the customer, then the application is executed after the reset from the specified entry point address.
2. If no valid Boot Record is programmed by the customer, then the default BAF Boot Record is retrieved and the BAF code is executed after the reset.
3. If no valid Boot Record is found, then the BAR code is executed after the reset. This situation happens only during ST production stage.

Note: When the device is shipped to the customer, the slot number 6 is programmed with a valid SSCM Boot Record, which points to the BAF code. This is the default start address for the SSCM Boot CPU when no other valid Boot Record are programmed or found. The content of the slot number 6 cannot be changed.

8.3.12.2.3 SW boot record search (BAF search)

The BAF is executed if:

- the BAF configuration DCF does not bypass the BAF code.
- the BAF configuration DCF does bypass the BAF code and no valid Boot Record is programmed by the customer.

The latter case happens because before the unit is delivered to the customer a valid SSCM boot record pointing to the BAF code is programmed at the location number 6. This boot record will point to the BAF entry point. Because the boot record number 6 is the last one being searched by the SSCM, this means that, if no other boot record is programmed, the

software will start from the BAF. Notice that the location of the boot record number 6 is placed within the BAF block itself, making it not erasable and not over-programmable (the BAF block is OTP).

When the BAF code is executed after the reset sequence is completed, a valid application Boot Record for the application entry point is searched. The mechanism is the same executed by the SSCM: a set of fixed locations are analyzed and, if a valid boot record is found, then, at the end of the BAF code, the CPU will start executing from the application entry point.

Note that the valid boot record is identified by a different tag: 5Ah for the SSCM; A5H for the BAF. This will make it possible to program the same boot record locations and launch the application directly after the reset or after the BAF code execution. *Table 122* shows the BAF boot record structure.*Table 124* shows the addresses of the location searched by the BAF code. *Figure 43* shows a flow chart of the whole reset sequence, including the BAF search for a valid boot header.

Table 122. Boot record structure searched by the BAF

8.3.12.2.4 HW and SW boot header search summary

The following picture summarizes the mechanism adopted to search for a valid boot header with the SCCM or the BAF code, or both.

Figure 43. Valid boot header search

Note: for sake of simplicity, the picture shows only 4 boot record positions.

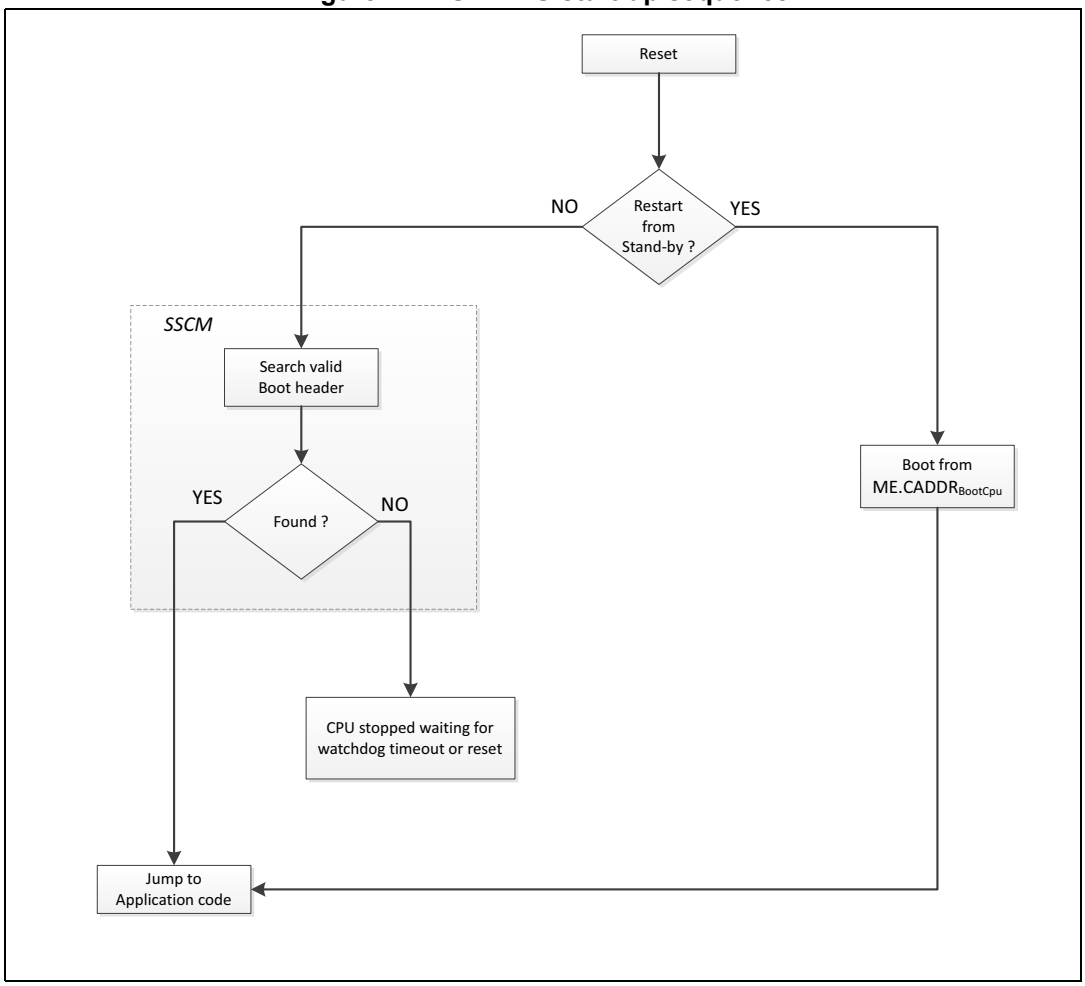
8.3.12.3 Security Module CPU start-up

The Security Module CPU is also woken up after a reset. The Security Module CPU receives the start address as described in *Section 8.3.12.2.2: HW boot record search (SSCM search)*.

The SSCM looks for a valid boot header record and then direct the Security Module CPU to the application start address specified within the record.

8.3.12.3.1 HSM restart from Stand-by

In case of restart from stand-by, then the application entry point is conditioned by the Flash status (powered on or off) and by two DCF:



1. a DCF (to be placed in UTest under the customer control) determines whether the security module should also restart after Stand-by(6).

6. If the HSM is flagged by this DCF to not restart, then also the HSM Standby RAM can be turned off during Stand-by

2. a DCF (to be placed in UTest under the customer control) is used to inhibit the possibility to let the Flash powered off after a restart from Stand-by. If the restart is from Stand-by, the Flash is powered off, and the DCF client allows this scenario, then the Boot CPU restarts from the address stored into the corresponding ME.CADDR register. Otherwise, the Boot CPU restarts following the same flow as per a non stand-by reset.

8.3.12.3.2 Start-up flow chart

Figure 44. HSM CPU start-up sequence

8.3.12.3.3 Boot vector search

The Security Module start vector is searched by the SSCM in a similar way as described in the chapter for the Boot CPU (HW SSCM search).

The SSCM stops the search as soon as a valid boot record is found within one of these locations.

Table 125. SSCM boot record search locations

Search order	Address	Location
0 (First)	0x0060_C000	Flash 16 KB HSM Code Block 5
1	0x0061_0000	Flash 64 KB HSM Code Block 2
2	0x0062_0000	Flash 64 KB HSM Code Block 3

8.3.12.4 Restart from Stand-by RAM with the Flash powered off

This feature makes it possible to wake-up the micro-controller from the Stand-By mode and let the Boot CPU and the Security Module CPU restart directly from the RAM, while the Flash is powered off.

Note: For security reason, the possibility to keep the Flash powered off in any execution modes shall be gated by a DCF.

In case of restart from stand-by with the Flash powered-off, only the Boot CPU shall be woken up. Other CPUs shall be kept under reset. The restart after Stand-by from RAM is made possible by using the Mode Entry registers:

- ME_CCTL*n* => to set up the processor status (ON/OFF) for each mode.
- ME_CADDR*n* => to set up the processor reset vector (note: the register associated to the Security Module CPU can be written by the Security Module CPU only).
- ME_<mode>_MC => to set up whether the Flash is ON or OFF.

Note: The registers related to the HSM CPU can be modified by the HSM only.

8.3.12.5 Start-up summary

Table 126. Start-up summary

Start from	Flash status	Security Module CPU (1)	Boot CPU	Other CPUs (2)
Power-on / Destructive reset	ON	It starts from the address provided by SSCM	Depending on the BAF configuration DCF setting, it starts from the BAF or from the address provided by SSCM	They can be woken-up with a ME mode change
Functional reset	ON	It starts from the address provided by SSCM	Depending on the BAF configuration DCF setting, it starts from the BAF or from the address provided by SSCM	They can be woken-up with a ME mode change

Table 126. Start-up summary (continued)

Start from	Flash status	Security Module CPU (1)	Boot CPU	Other CPUs (2)
From Stand-by	ON	It starts from the address provided by SSCM	It starts from the address saved in the ME CADDR register for the Boot CPU (which can be both in Flash or in the low power portion of the system RAM)	They can be woken-up with a ME mode change
	OFF	It starts from the address is saved in the ME CADDR register for the Security Module CPU (in case the Security Module RAM has a portion in the low-power domain, it is advisable for security reason to set the restart address within it)	It starts from the address saved in the ME CADDR register for the Boot CPU (which shall be in the low power portion of the system RAM)	They shall not be woken-up (3)

1. If existing and enabled.
2. For MCUs with multiple application processors.
3. DCFs for TCM memory repair will not be preserved during Stand-by.

8.3.13 Waking-up other CPUs

The process of waking-up the other CPU is handled by writing some registers within the ME module and triggering a Mode Change.

If the BAF code is executed, it reads form the Boot Header record the information regarding which CPU shall be woken up and at which address shall they start from, and then applied a Mode change to enable them.

If the BAF code is not executed, it is responsibility of the user code to properly write the ME module registers and trigger a mode change in order to wake up the other CPUs form the intended addresses.

8.3.14 BAF Bootloader

The BAF code includes a way to upload via CAN or UART some code into the system RAM and execute it. The possibility to execute the Bootloader is conditioned by the Life Cycle status, which regulates what can or cannot be done according to the stage of the micro-controller. If the Bootloader is allowed by the Life Cycle, then it is executed whenever the Boot CPU, executing code in the BAF, does not find a valid boot header file in flash memory. This mode uses a defined protocol to receive a program over a serial port via LINFlexD or CAN. The Boot CPU then jumps to the first instruction of the uploaded program and begins execution.

The BAF bootloader code includes the following steps:

1. Configure LINFlexD or M_CAN module and external pins
2. Wait for START WORD
3. Receive START WORD
4. Receive START ADDRESS
5. Receive DOWNLOAD SIZE
6. Receive CODE
7. Branch to START ADDRESS

Note: There is a software watchdog timer that is started by the BAF code. If a program is not received before the watchdog timer timeout, a reset occurs.

8.3.14.1 Calibration Sequence

The micro-controller detects the presence of an emulation and debug device (ED) normally used in place of a regular production SPC58xEx/SPC58xGx (PD). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The emulation and debug device (ED) consists of a regular production SPC58xEx/SPC58xGx (PD) and a special Buddy Device (BD) in a single package.

The I/O Processor (IOP) executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is detected, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC58xEx/SPC58xGx reset.

In this example, it is assumed that an emulation and debug device (ED) is not being used in place of a regular production SPC58xEx/SPC58xGx.

9 Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record is 64 bits long. It consists of a pointer to the location of a register internal to the device and the respective data.

Note: Because the Flash memory programming resolution is 128 bits then 2 DCF records must be written within 1 Flash programming operation.

There are two broad categories of DCF records: TEST DCF Records and UTEST DCF Records.

- TEST DCF records are programmed by the MCU manufacturer. They are used mainly to:
  - Program registers involved in trimming trip points for voltage comparators
  - Adjusting analog to digital voltage supplies
  - Trim oscillator frequencies
  - Enable RAM repair

Note: The TEST DCF Records are programmed into TEST Flash during production and cannot be modified. TEST Flash is not visible to the user.

- UTEST DCF records can be either:
  - Factory programmed during production testing (see “UTEST Flash memory map” table in the Memory Map chapter).
  - User programmed when application code is written into the Flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the factory UTEST DCF records. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) runs during the boot sequence, enable the HSM, assign Flash memory blocks to specific tamper detect regions, assign memory blocks as OTP and assign Flash blocks to be associated with specific password groups.

Note: DCF records are HW processed by SSCM during reset.

Soft DCF records are SW processed by BAF code execution. Refer to Section 65.3.5.1: ‘Soft’ DCF clients in Chapter 65: Boot Assist Flash (BAF).

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective Flash memories.

When power is applied to a properly programmed device:

1. The Power Management Controller (PMC) takes control of the device until the system power supplies have reached predefined levels.
2. The PMC then signals the Reset Generation Module (RGM) to begin the boot sequence.
3. During boot, the RGM enables the System Status and Control Module (SSCM) to read the device configuration records and write information to specific registers.
4. After registers are initialized, the STCU2 starts its Self-Test sequence as per its device configuration registers initialized through SSCM.

9.2 DCF clients

DCF clients are 32-bit hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written and may have special writing constraints like ‘Write Once’ or only allowing bits to be written from ‘1’ to ‘0’ or vice versa.

A list of DCF clients is shown in *Table 129*. (TEST DCF Record Only clients are not shown as these are not accessible by the user).

The DCF Records select the target DCF client via a 30-bit field in the DCF Record consisting of:

- A 15-bit Chip-Select field: each module that includes DCF clients is assigned a Chip Select during chip definition.
- A 15-bit Address field: the address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64 bits) entries programmed in a reserved area of OTP UTEST Flash memory beginning at 0x0040_0300. Take care to write 128 bits which is the ECC granularity (complete with a dummy DCF if needed). Address alignment is also on 128 bits.

Warning: Over Program Protection will generate an unrecoverable ECC error if only one DCF record (64 bits) is written.

Caution: Once a stop record is detected, the SSCM will stop scanning for further records.

The structure of a DCF Record is shown in *Figure 45*.

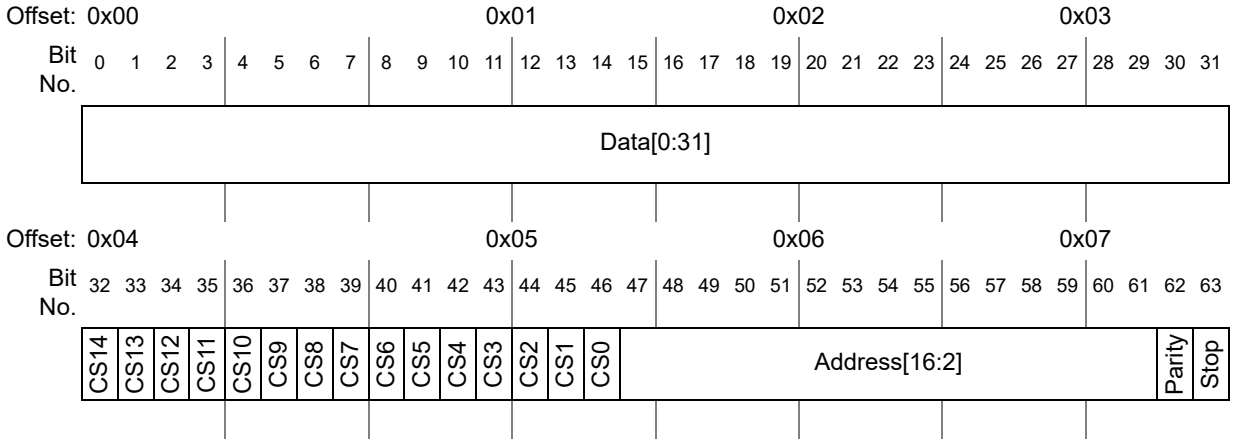


Figure 45. DCF record structure

Table 127. DCF record field description

Field	Description
0:31 Data[0:31]	32 bits of data to be written to the DCF Client.
32:46 CS*n*	Chip Select n. **Note:** Only assert one chip per DCF record to select the target module for the DCF client. All other Chip Selects should be negated. 1 Chip select is asserted. 0 Chip Select is negated.
47:61 Address[16:2]	Address of the DCF client within the selected module. **Note:** Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62 Parity	Parity Bit for the DCF Record. **Note:** This bit is NOT implemented for DCF Clients written from UTEST.
63 Stop	This bit indicates the end of the list of DCF Records. **Note:** The Erased state of Flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list. 1 End of the list. 0 NOT the end of the list.

The following structure must be present:

- The first record must be a start record.
- DCF records containing configuration data must immediately follow the start record with no blank records between an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a bit in the DCF record (stop record).

Each record is 64 bits long. *Figure 46* shows the DCF start record.

Caution: The start record must be placed at the beginning of the DCF area in UTEST Flash memory to indicate that the following data records must be processed.

Figure 46. DCF start record

0x00 0:31	0x04 32:63
0x05AA55AF	0x00000000

During system boot, while the reset signal is asserted, the SSCM reads the device configuration records and writes the data to the appropriate internal module registers. Many operational aspects of the device are therefore already configured when the reset signal is released and normal device operation begins.

Some device configuration records are calculated during production testing and programmed into the TEST Flash memory area. Other DCF records are developed by the user and programmed into the UTEST Flash area.

The stop bit designates the last device configuration record in a set of records. If it is set to ‘1’ within a DCF, then this DCF is the last one being read during the reset phase. A DCF can have the stop bit set to ‘1’ in two modes:

a) The Flash memory location of a DCF is not programmed (that is all the bits are set to ‘1’).

b) A DCF is programmed and the stop bit is set to ‘1’.

When the device is shipped from the factors, some DCF records are already programmed and the Flash memory location after the last DCF is left unprogrammed to make it possible to add additional DCF records.

Due to the Flash programming memory resolution, which is 2-times the length of a DCF record, in case an odd number of DCF shall be written but additional DCF should be programmed later on, then a dummy DCF should be written to pad the last 64 bits of the programming data.

A dummy DCF can be one of the following:

a) The same DCF record written within the 128 bits (that is the DCF record is written two times).

b) A DCF record with an invalid Chips Select (refer to the *Table 129* for a list of used Chip Selects).

The padded DCF must have the stop bit set to ‘0’ in order to be able to add new DCF records.

The general format of the stop record is shown in *Figure 47*. Only the stop bit needs to be ‘1’ in order to form a stop record, all other bits are ignored. An unprogrammed location in UTEST Flash is interpreted as a stop record.

Figure 47. DCF stop record

0:31	32:62	63
Reserved	Reserved	1

If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 128*.

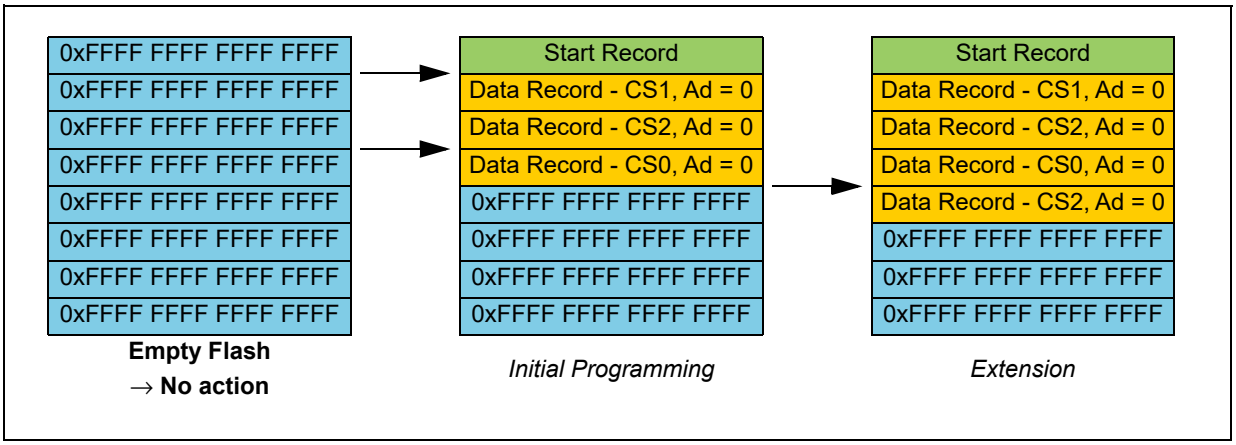

Table 128. Series of DCF records in UTEST Flash memory

ADDR offset	DATA			
0x00	0x05AA55AF			
0x04	0x00000000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8*n* + 0x0	Reserved			
8*n* + 0x4	Reserved			STOP=1
8(*n*+1) + 0x0	—			
8(*n*+1) + 0x4				

Caution: There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored.

Records programmed in several sessions is shown in *Figure 48*, appending new records to the end of the list each time.

Figure 48. Appending DCF records

It is possible for several DCF Records to write to the same DCF client. The later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST Flash memory area (refer to UTEST Flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory and the user may add USER DCF records from the first unprogrammed location following the factory programmed UTEST DCF records.

When programming UTEST DCF records, the records must start at the first address in the UTEST Flash memory area and be continuous: one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST Flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module.

9.4 DCF client table

A list of DCF clients is shown in *Table 129*. Various attributes of the DCF clients are listed in these tables:

- DCF Chip Select [14:0]: the CS field is a 15-bit field with each bit acting as a module select signal for the internal modules. Only one bit in this field should be set in a DCF record.
- DCF address [16:2]: the 15-bit ADDR field specifies an internal address for a DCF client. These addresses are only used by the SSCM when interpreting DCF records and writing data to specified modules.
- DCF Client Description: the name of the DCF clients.
- Reset value of DCF client: the reset value of DCF client before being written by the SSCM with the associated DCF record.
- IPS read: this column specifies whether or not a DCF client can be read by user software after the release of reset.
- DCF client special strategy: registers are designated as DCF clients if they need to be written with a DCF record. Other features that must be designated for DCF clients include different write strategies listed below. The following list defines the special strategies:
  - None: no special DCF strategy is used.
  - Write Once: a DCF client can only be written once. The DCF client ignores subsequent writes.
  - Triple Voted: DCF clients have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows for ‘bit-flip’ error tolerance without changing the DCF client output data.
  - Write 0 only: a bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a logic 1 is ignored.
  - Write 1 only: a bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a logic 0 is ignored.

- DCF order dependency in Flash memory
  - DCF order dependency in Flash memory: this column details whether or not there are special conditions on the location of a particular DCF record in Flash memory.

Field	Description
0:29 BAF_ADDRESS	BAF start address
31 BAF_BYPASS	BAF bypass 0 BAF is executed 1 BAF is bypassed

9.4.3 Miscellaneous DCF registers

Offset: 00000000 Access: DCF Client

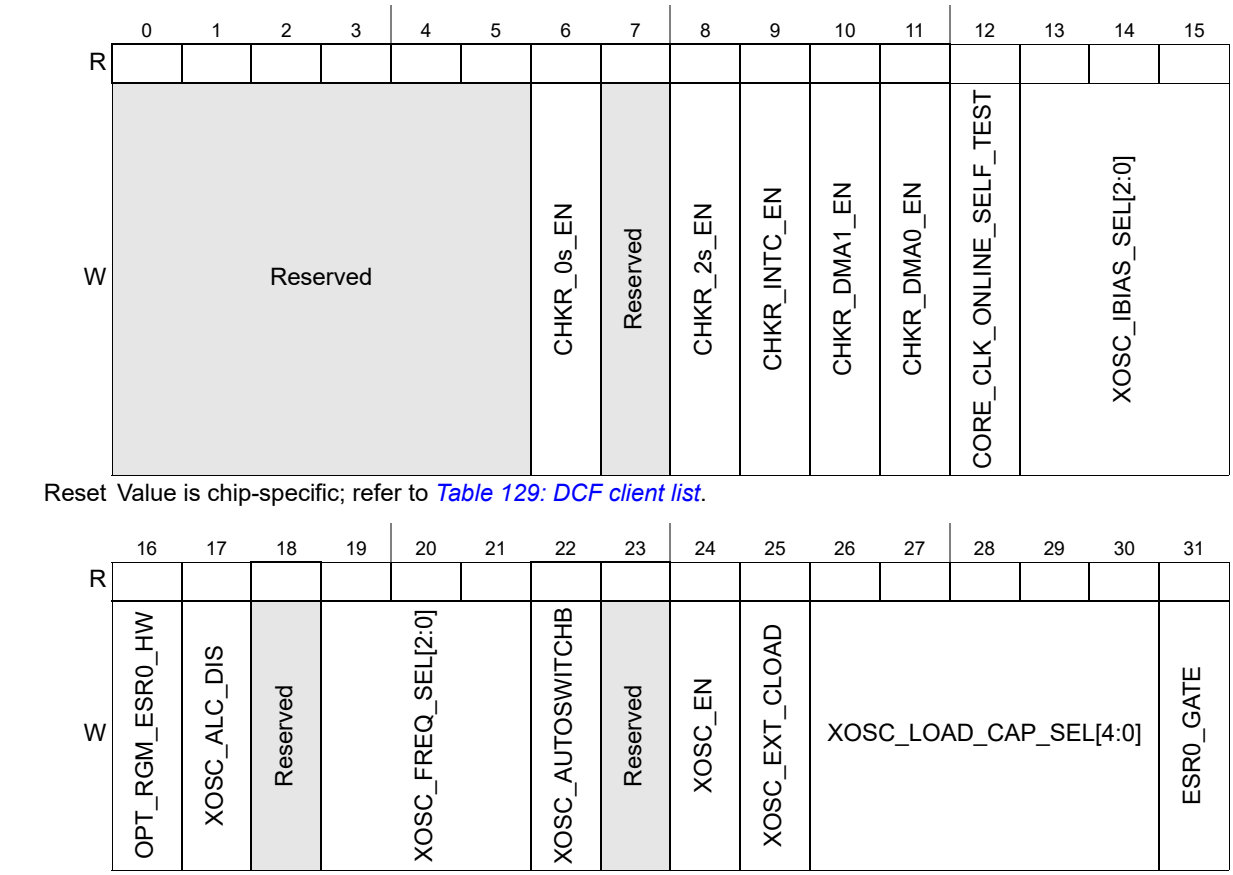

Figure 50. UTEST Miscellaneous DCF Client

Table 131. UTEST Miscellaneous DCF Client field descriptions

Field	Description
6 CHKR_0s_EN	Allows to enable/disable the checker core 0. 0 Checker disabled 1 (reset value) Checker enabled
8 CHKR_2s_EN	Allows to enable/disable the checker core 2. 0 Checker disabled 1 (reset value) Checker enabled
9 CHKR_INTC_EN	Allows to disable the checker INTC. 0 Checker disabled 1 Checker enabled **Note:** If any CHKR_x_EN is set, then CHKR_INTC_EN must be set to 1. If all CHKR_x_EN are disabled, then CHKR_INTC_EN must be set to 0.
10 CHKR_DMA1_EN	Allows to disable the checker DMA_1. 0 Checker disabled 1 Checker enabled

Table 131. UTEST Miscellaneous DCF Client field descriptions (continued)

Field	Description
11 CHKR_DMA0_EN	Allows to disable the checker DMA_0. 0 Checker disabled 1 Checker enabled
12 CORE_CLK_ONLINE_SELF_TEST	Core clock configuration during online self test. 0 Core Clock enabled. It allows to avoid RCCU alarms from checker cores during MBIST execution. 1 Core clock disabled during online LBIST.
13:15 XOSC_IBIAS_SEL[2:0]	Allows to change oscillation margin (default “100”) - User to keep default value of “100”
16 OPT_RGM_ESR0_HW	Active low to enable the SW control of release of ESR0. 0 Allows MC_RGM to continue to assert ESR0 until RGM_EROEC[EROEC] bit has been cleared by software 1 Does not allow MC_RGM to continue to assert ESR0 until RGM_EROEC[EROEC] bit has been cleared by software
17 XOSC_ALC_DIS	Active high to disable Automatic Level Controller
19:21 XOSC_FREQ_SEL[2:0]	This will select the different frequency settings of XOSC. 000 4 MHz – 8 MHz 001 5 MHz – 10 MHz 010 10 MHz – 15 MHz 011 15 MHz – 20 MHz 100 20 MHz – 25 MHz 101 25 MHz – 30 MHz 110 30 MHz – 35 MHz 111 35 MHz – 40 MHz
22 XOSC_AUTOSWITCHB	Allows to enable or disable the autoswitch 0 Reserved 1 Autoswitch mode disabled
24 XOSC_EN	Enable XOSC 0 XOSC disabled 1 XOSC enabled
25 XOSC_EXT_CLOAD	XOSC EXT CLOAD 0 Selects XOSC internal cap (recommended for 20 MHz – 40 MHz operation) 1 Selects XOSC external cap (recommended for 4 MHz – 20 MHz operation) **Note:** It is always recommended to verify the required size of the capacitances with the crystal supplier.

10 Power management

10.1 Overview

SPC58xEx/SPC58xGx microcontrollers include a robust power management infrastructure that enables applications to select among various operational and low-power modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave reset. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Clock Generation Module (MC_CGM)
- Mode Entry Module (MC_ME)
- Power Management Controller (PMC)
- Power Management Controller Digital Interface (PMC_DIG)
- Smart Standby Wake-up Unit (SSWU)

This chapter describes these modules in brief. For complete details, refer to the respective module chapters.

The MC_PCU provides a status register and a submodule, the PMC_dig (Power Management Control Digital Interface), provides an interface to configure and control internal voltages.

The MC_CGM generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement low power modes.

The MC_ME module controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application.

The PMC module contains all the internal voltage regulator and monitors of the device : refer to *Section 10.1.3: Power management controller overview*.

The PMC_DIG module is the digital interface of the PMC, and contains all the registers to control the PMC during reset and power mode changes.

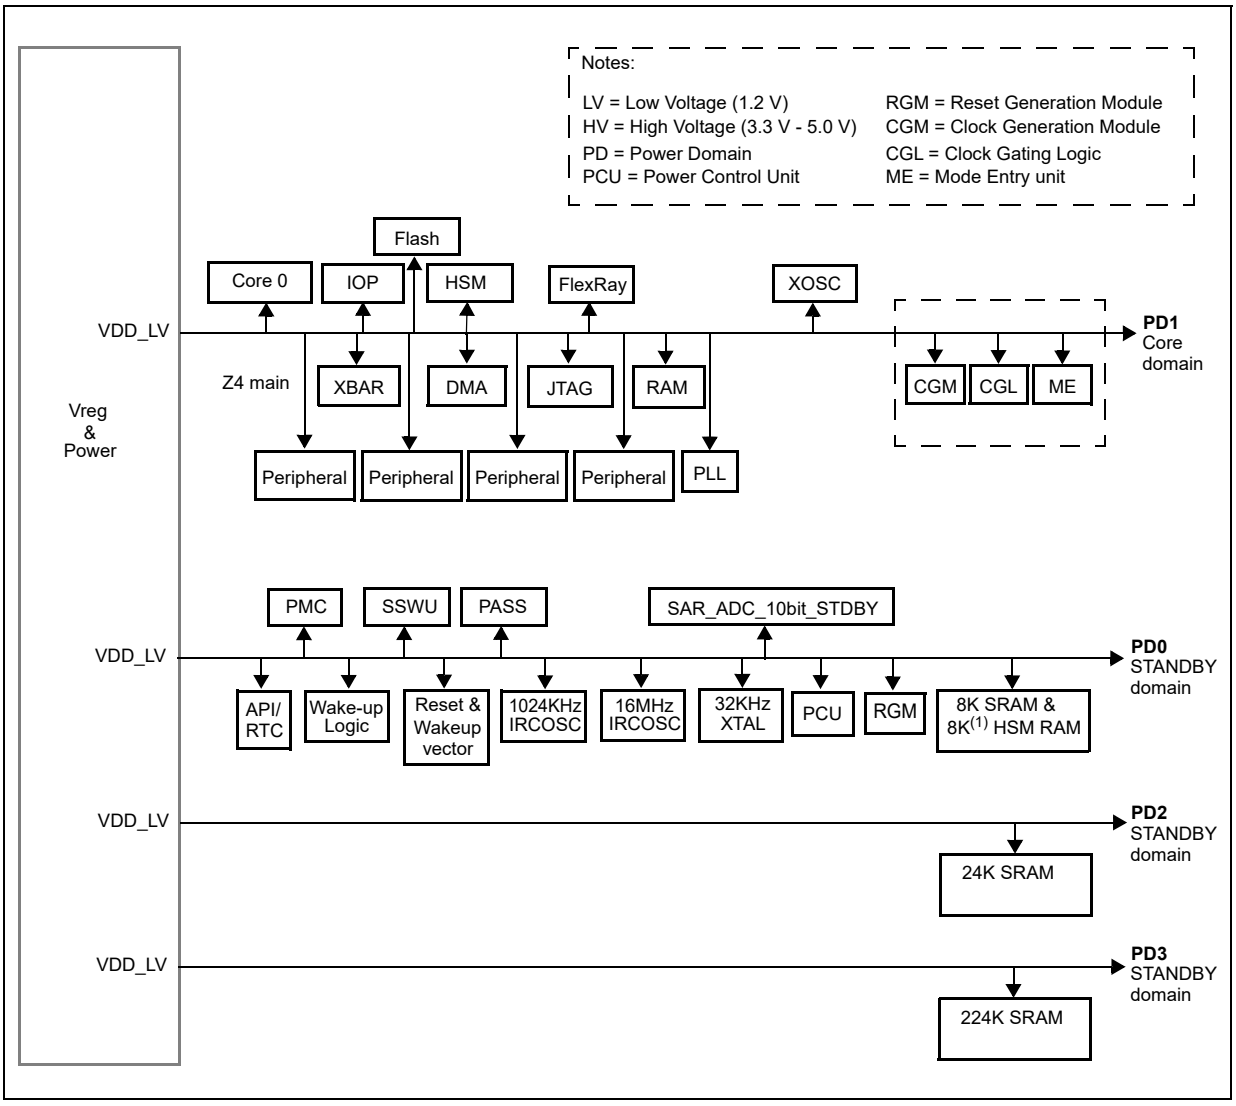
The SSWU Unit provides services to schedule sequence of tasks executed without CPU intervention. This is aimed to reduce further power consumption during standby.

The SPC58xEx/SPC58xGx has two types of modes, SYSTEM modes and USER modes.

SYSTEM modes:

- SYSTEM modes are entered automatically on system events or on application request.
- The SYSTEM modes are: RESET, SAFE, TEST and DRUN.

USER modes:



- USER modes control performance and consumption during normal application operation. The modes are organized according to the performance provided
- The USER modes are RUN0-3, HALT, STOP and STANDBY.
- Each mode is entered by writing a dedicated register protected by a key, to avoid unwanted transition

Please refer to the Magic Carpet Mode Entry Module chapter for modes details.

10.1.1 Power management framework

The power management framework supports a variety of configuration options. Refer to *Figure 56* for more details. SPC58xEx/SPC58xGx implements a unique core voltage power domain. There are no separate functional power domains.

Figure 56. Device power management framework

1. Enabled during stand-by depending on a DCF bit

10.1.2 Power management supply description

Table 137 provides an overview of the PMC supply signals.

Table 137. Device power management controller external signals

Name	Type	Description
VDD_HV_ADR_D	Reference	Voltage reference of ADC Σ/Δ module
VDD_HV_ADR_S	Reference	Voltage reference of ADC SAR module
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_FLA	Supply	Supply pin for Flash
VDD_HV_IO_MAIN	Supply	High voltage power supply for I/O
VDD_HV_IO_BD	Supply	High voltage power supply for buddy die I/O
VDD_HV_IO_FLEX	Supply	FlexRay/Ethernet I/O supply
VDD_HV_IO_JTAG	Supply	JTAG pin voltage supply
VDD_HV_OSC	Supply	Oscillator Voltage Supply
VDD_LV	Supply	External low voltage power supply for the core area
VDD_LV	Supply	Low voltage power supply for the core area generated by internal regulator
VDD_LV_BD	Supply	Low voltage power supply for the buddy device
VSS	Ground	Ground supply for the device / I/O. This is covering both VSS_LV and VSS_HV in case of exposed pad device.
VSS_HV_ADR_D	Reference	Ground reference of ADC Σ/Δ module
VSS_HV_ADR_S	Reference	Ground reference of ADC SAR module
VSS_HV_ADV	Supply	Ground supply for the ADC modules
VSS_HV_OSC	Ground	Oscillator Ground Supply

Caution: There are constraints on some input voltages relative to other input voltages. Refer to the device data sheet for detailed information.

10.1.3 Power management controller overview

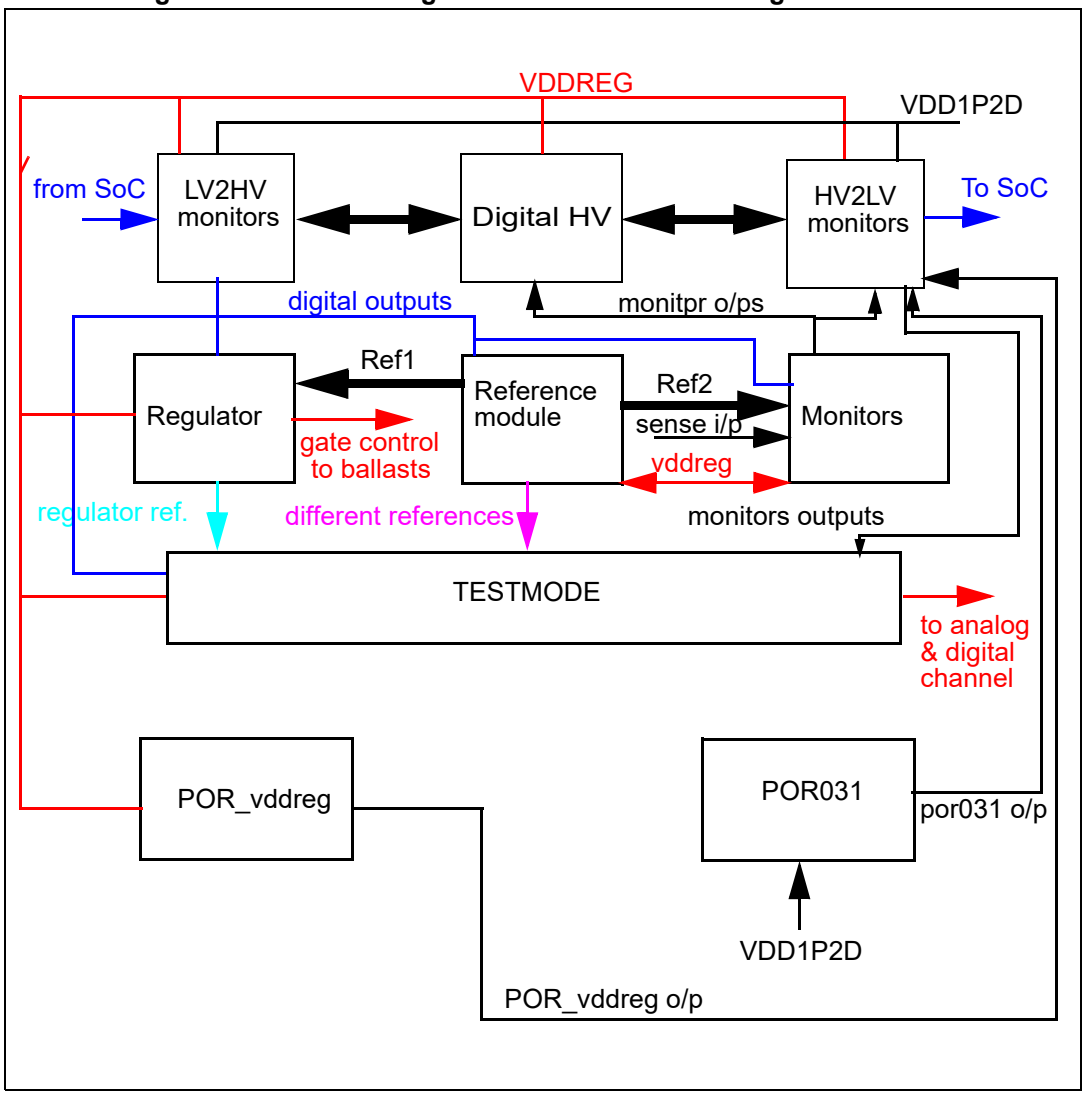
The power management controller unit (PMC) contains all the device internal voltage regulators and all the voltage monitors. The supported regulators are:

- External regulator
  - External VDD_LV supply is provided from outside and no internal regulator is required.
- Internal regulator
  - An internal high power regulator (HPREG) using an external NPN bipolar as the ballast device (Refer to the SPC58xEx/SPC58xGx datasheet for the bipolar part number).
  - An internal Switching Mode Power Supply (SMPS) regulator, using external PMOS, NMOS and inductance.
- Low-power regulator
  - When the device is in STANDBY, the supply is provided by the internal LPREG and the HPREG is off, with a reduced maximum driving capability.
  - STANDBY mode is not supported in conjunction with External regulator mode.
- Auxiliary and clamp regulators
  - For fast current transients, auxiliary and clamp regulators can be enabled through DCF records (refer to the dedicated chapter) to improve the load regulation by compensating voltage overshoots and under-shoots. Auxiliary and clamp regulators cannot be enabled in SMPS regulator mode.

Please refer to the data sheet for the electrical characteristics of the regulators and the monitors and the list of external components required. The list and functionality of the monitors is described further in this chapter.

Figure 57 describes the top level block diagram of power management unit.

Figure 57. Power management controller block diagram overview



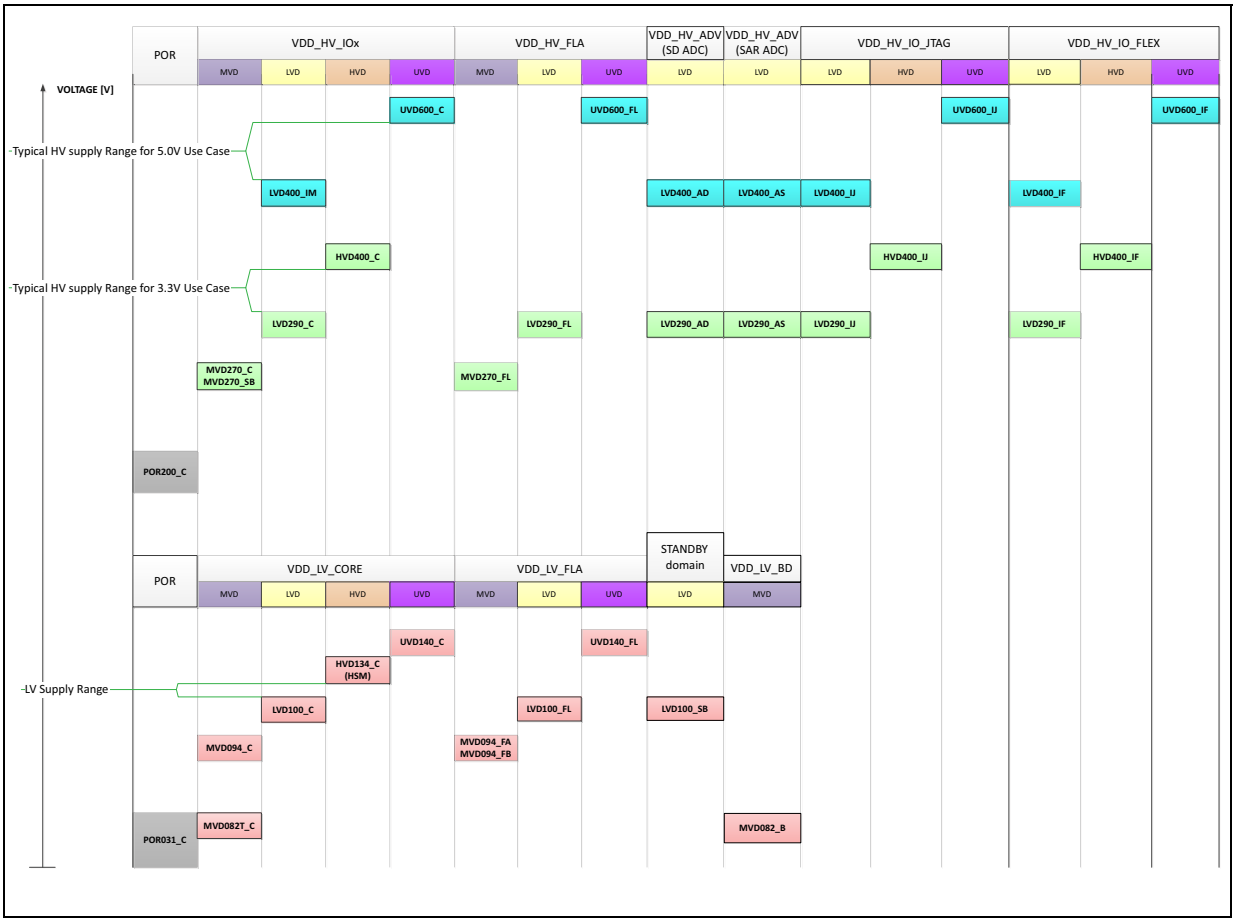


Figure 58. Voltage Monitor Coverage(1)(2)

1. Refer to *Table 138* for VDs descriptions
2. Voltage levels for all VDs are given in the data sheet

VDD_HV_IO is redundant, ensuring that single pin failure does not prevent device from functioning correctly. Full specification may not be guaranteed.

VDD_LV is redundant, ensuring that single pin failure does not prevent the device from functioning correctly.

10.1.3.1 1.2 V safety/spike regulator specification

SPC58xEx/SPC58xGx implements a 1.2 V safety/spike regulator. This regulator can be used to handle fast application current variation that cannot be fully handled by external regulator.

10.2 Low power mode support

The SPC58xEx/SPC58xGx microcontroller supports low power modes.

Dedicated logic prevents uncontrolled activation of low-power mode. This is implemented using protected sequence from ME.

Inadvertent entry into low power mode is prevented by triple voting of the control flops, both SW readable and otherwise.

10.2.1 Low power mode (HALT/STOP/STANDBY)

Low power mode may be used to control the ECU during the IDLE phase, as in a partial networking system or when the key has been turned off and periodic tasks, like contact monitoring, must be maintained.

Note: STANDBY mode behaves very differently from HALT/STOP modes. For more details, refer to Section 68.4.4.1: STANDBY Mode transition and Section 69.4.2.8: STANDBY0 Mode.

The device implements the equivalent of an idle or power-down mode through STANDBY, STOP and HALT mode configuration.

The entry into a low power mode is requested by the application code while the exit is triggered by a hardware event (internal, for instance RTC/API, or external, for instance Wake-up signal) or by the SSWU which detected a wake-up condition.

A combination of mode control and clock control (clock source selection but also peripheral clock gating) allows the user to configure the low power modes according to his application needs.

In STOP/HALT mode, peripheral modules can be enabled/disabled using the control described in the ME section. For example, it is possible to keep two CAN modules, eMIOS module and a few requested pins active. For alternate configurations, other modules can be enabled/disabled using the control described in the ME section. External interrupt request channels and external wake-up channels can be made active to wake-up the device in alternative to peripherals interrupts.

All pins associated to the active modules are functional.

Control of the pins is defined by user during run time. A wake-up line is associated to each selectable module.

One of the available modules can be configured to perform the wake-up task. For example, with all but one CAN modules on the chip set completely to power down mode and only one is configured for wake-up message receive (any of the modules can be configured to perform this task).

All CAN modules can be independently configured to receive messages and respond to wake-up messages.

Basically the low power modes allow to control the clock and the state of all peripherals (analog and digital) but also select the mode of the flash module as well as select and enable/disable clock sources like PLL or oscillator.

10.2.1.1 After-run implementation

After-run mode is implemented mainly making use of clock gating, module disabling, reduced frequency, mode switching.

Assuming that the selected CAN is kept enabled (clocked and active) then it can maintain its synchronization with the CAN network. Assuming also that the supplied CAN module can buffer the received (first) message, the CAN is then able to interrupt the IOP. The IOP would execute from TCM (such as, Flash is disabled) and use the internal RC oscillator (IRCOSC) or the external oscillator (XOSC). To support this would keep the PMC, LVD, temperature sensor, internal FIRC, XOSC and pads active. The PLL, Flash, and ADC would be disabled, with rest of part static and clock gated off.

10.2.1.2 Checker core disabling

The checker core is always in lock step with the main core: hence if the main core is clocked, the checker core is clocked (unless user intentionally disables checker clock, such as afterrun mode). Also if the main core is gated off, then the checker core is also gated off.

It is possible to disable the safety checker core to reduce current consumption.

The checker core can be placed in idle mode throughout the afterrun mode. By default the checker core mimics the main core, but it can be clock gated off during afterrun mode whilst continuing to clock the main core.

The checker core is implemented in such a way that its entire clock tree can be gated off while the core logic remains supplied.

The checker core (part of the Checker Logic) and the corresponding ‘checked main’ core share the same cache SRAM arrays and local SRAM arrays. Once the checker logic is disabled (such as,its clock is gated) the SRAM array of the cache and the local memory of the main core are still usable by the main core.

10.3 Flash power requirements

During start-up operation, the flash module operates from an untrimmed regulator, which has a slightly larger variation than the ideal case. During this start-up phase, the flash can still be read, but it must be read at a slower rate. While operating in this slower read mode, the flash can operate at a much reduced voltage.

Following completion of the start-up phase the regulator is in its trimmed condition, and subsequently the flash module reference current has also been trimmed. Therefore when entering normal operation the flash can be read in the normal access manner and support the full flash specification.

10.4 Device trimming

During the initialization phase the device defaults to a pre-determined state for each of the LVDs, HVDs and the internal regulators. As the flash becomes available the differential read process allows the trimmed data to be available for trimming the internal LVDs, HVDs and regulators.

Please refer to *Section 10.6* for further details.

10.5 Supply monitoring (POR and LVDs)

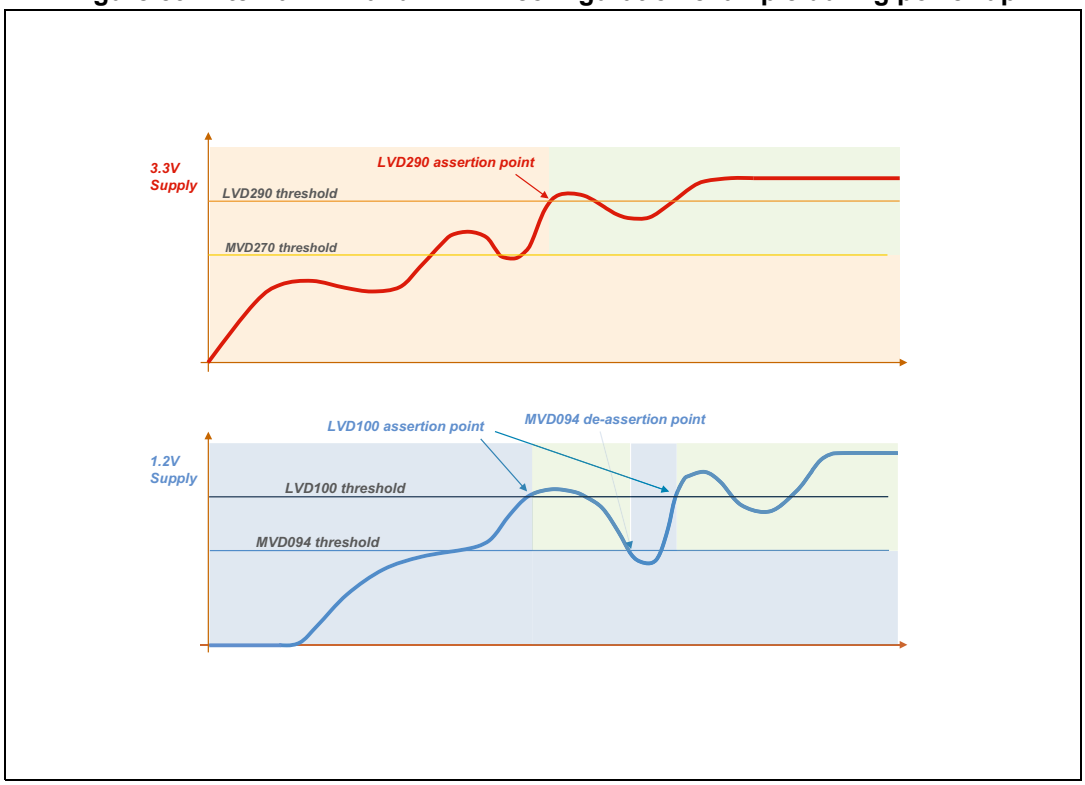
The function of the POR and LVD circuits is to hold the device in reset regardless of how slow the supply voltage rise is, until the point at which the POR and LVDs are released.

The POR and LVD circuits function correctly even if the input voltage is non monotonic.

10.5.1 Power-on reset (POR)

The PMC implements two internal power-on reset circuits:

- POR031_C monitors the voltage on the 1.2 V input supply. It is monitoring the VDD_LV_CORE pin. The POR031_C asserts a reset when the input supply is below defined values.
- POR200_C monitors the voltage on the 5.0 V - 3.3 V input supply. It is monitoring the VDD_HV_IO_MAIN pin. The POR trip point is high enough to make sure all the LVD circuits are functional.



Refer to *Chapter 8: Reset and Boot* for PORST/ESR0 pin functionality.

10.5.2 Behavior of device LVD / HVD

Although there is an option to disable the LVD and HVD following reset (refer to *Section 10.5.3*), they are capable of being used in a 'monitor' only mode and also capable of generating a safe / interrupt event. *Figure 59* illustrates the behavior of these internal LVD / HVD circuits during the power on phase, through device initialization and subsequently in 'normal' run / operating mode.

The LVDs/HVDs can also be configured after device initialization preventing reset to happen when supply crosses the LVD threshold, effectively providing a higher voltage operating range. It is the responsibility of the application to ensure that the device remains in the functional range.

Figure 59. Internal LVD and HVD in configuration example during power-up

10.5.3 Voltage detections (MVDs, LVDs, HVDs, UVDs)

The internal LVD circuits, monitor when the voltage on the corresponding supply is below the defined values and either assert a reset or an interrupt. The LVDs also support hysteresis in the falling and rising trip points.

10.5.3.1 LVD and HVD implementation

- All LVDs and HVDs are capable of generating either an RGM and/or FCCU event and/or interrupt event.
- All LVDs and HVD configured for reset generation can cause functional or destructive reset. MC_RGM PHASE0 is not exited until all destructive reset conditions are cleared.
- The appropriate bits in the PMC registers are set by LVD and HVD events. Please refer to Power management controler digital interface chapter (PMC_Dig).
- The LVDs and HVDs control is protected by the register protection scheme. Therefore it is configurable as long as the scheme is followed. Refer to *Chapter 91: Register Protection (REG_PROT)*.
- SPC58xEx/SPC58xGx implements REE (Reset event enable) DCF records to allow to associate “configurable” LVDs/HVDs to a RESET event. This is a write mechanism managed by SSCM during device initialization. When RESET event is selected through REE DCF record, it cannot be disabled by software programming of PMC REE register. When RESET event is not selected through REE DCF record, LVDs/HVDs trigger event reaction depends on the programming of the PMC REE/RES/IE/FEE registers. Refer to *Chapter 9: Device Configuration Format (DCF) Records*.
- When the LVD or the HVD is enabled for destructive reset generation and a subsequent trigger event is detected, the external PORST pin is driven low.

Note: The full list of voltage monitors is provided in Table 138. The functionality and configurability are reported in Figure 60.

Note: MVDs/UVDs are not configurable.

HVDs	Yes	Yes	Yes	Yes	Yes	Yes
UVDs	No	No	No	No	No	No

1. Refer to the Power management controller digital interface (PMC_Dig) chapter.

When using an external regulator for low voltage generation, the voltage regulator system shall have an internal LVD to satisfy the safety requirement.

10.6 Power sequence

The following sections describe the power sequence and the relation between the different supplies during power-up and power-down.

The device is considered to be in a power sequence (or POWERUP state) when it is either not supplied or partially supplied. An internal power-on signal is used to identify POWERUP state. This signal is released high on exit of power sequence. The power-on signal is a combination of the LVDs monitoring the following supplies:

- VDD_LV
- VDD_HV_IO
- VDD_HV_FLA

The actual threshold use for each LVD is dependent on the configuration of the device. This is configurable by hardware (flash option bits content) or by software (LVD event configuration through register interface). Once power-on signal has been asserted, device configuration is reset to default power-up configuration.

10.6.1 Power-up sequence

In this section it is assumed that all supplies are low when entering the power-up sequence. Brown-out and power down sequences are managed in specific sections.

10.6.1.1 POWERUP state

At the beginning of power-up, the internal power-on signal remains low due to internal parasitics diodes. As soon as minimum threshold is reached on VDD_LV and VDD_HV supply, the internal power-on signal is forced low until power-up LVDs reach upper not trimmed threshold (refer to SPC58xEx/SPC58xGx datasheet).

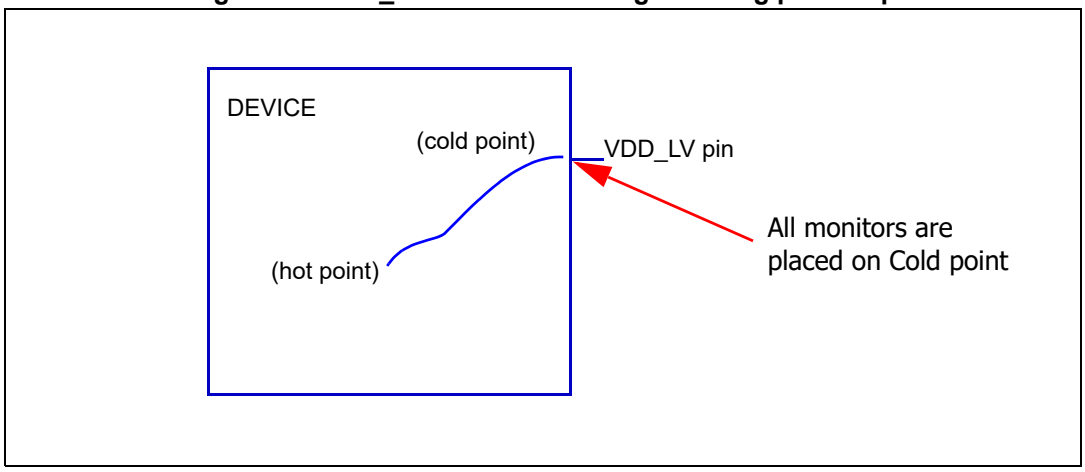
The different supplies can rise independently as long as the constraints described in the SPC58xEx/SPC58xGx datasheet are met.

During power-up, all functional terminals are maintained into a known state as described in the SPC58xEx/SPC58xGx datasheet.

10.6.1.2 POWERUP exit

The POWERUP state can be exited when both VDD_LV and VDD_HV are above the internal LVD thresholds.

10.6.1.2.1 VDD_LV conditions and LVD trimming/enabling sequence



During POWERUP, only the following low voltage VDs are enabled:

- MVD082T_C , MVD094_C , MVD094_FA, MVD094_FB , UVD140_C , UDV140_FL

The VDD_LV conditions to exit POWERUP are the following:

- MVD094_C, MVD094_FA, MVD094_FB upper threshold is crossed

Figure 61. VDD_LV monitored voltages during power-up

After the POWERUP exit conditions (low voltage, high voltage conditions) have been verified, the internal power-on signal is released to all analog modules.

The internal RC oscillator module (IRCOSC) starts initialization and provides clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and LVD100_C is masked. Only MVD094_C remains active.

MVD094_C and LVD100_C share the same reference. This difference provides margin with respect to maximum internal resistive drop and hysteresis addressing external supply.

The device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST] and PHASE3[DEST].

Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST]. Trimming of LVDs/HVDs are stored as internal DCF records. They are read by SSCM at low voltage, using the differential flash read accesses and applied to each LVDs/HVDs module. After analog delay ($t_{LVDTRIM}$) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold, the SSCM proceeds with the reset sequence, eventually running full speed accesses to the flash to read the option bits required to complete device configuration.

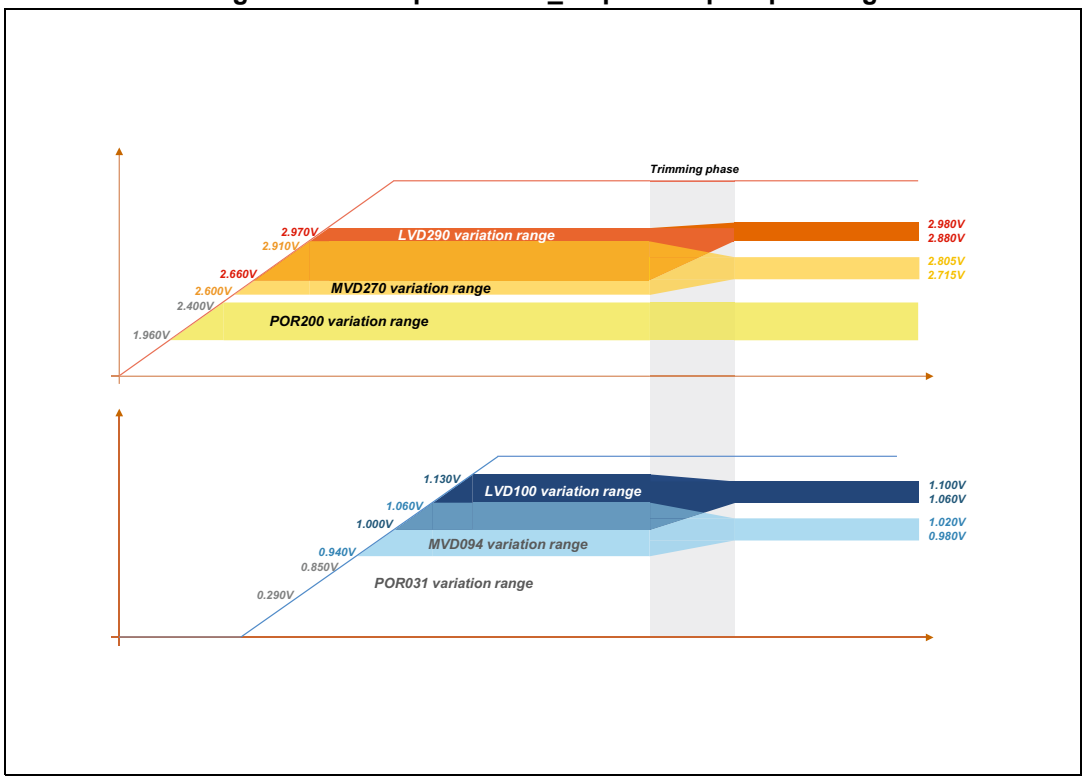
The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

When LVD100_C and LVD290_C are masked by the application using the flash user option bits, the device should rely on PORST signal to detect a voltage failure during power-up. The device must wait for PORST to be released high before proceeding with the power-up sequence.This may increase the amount of time necessary to complete the reset sequence.

Figure 62 provides an example of VDD_LV and VDD_HV power-up sequence before and after the monitor trimming.

Figure 63 provides an example of VDD_LV power-up sequence before and after the monitor trimming including UVD and HVD monitors.

Figure 62. Example of VDD_LV power-up sequencing



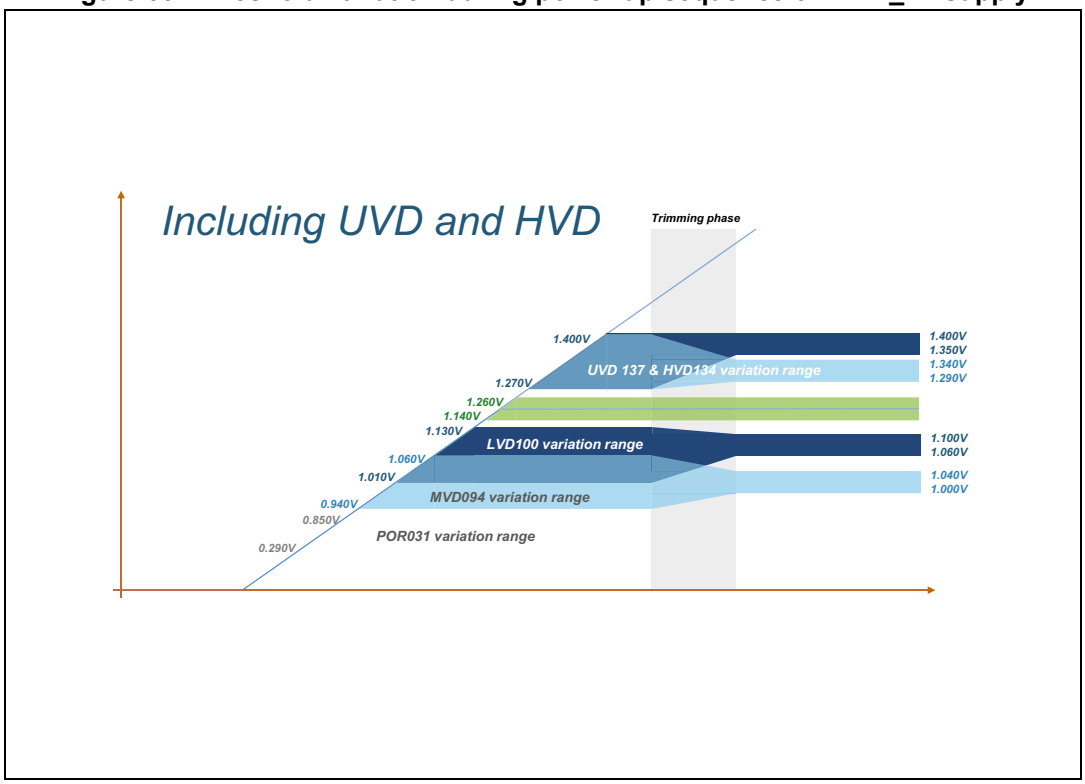


Figure 63. Threshold variation during power-up sequence on VDD_LV supply

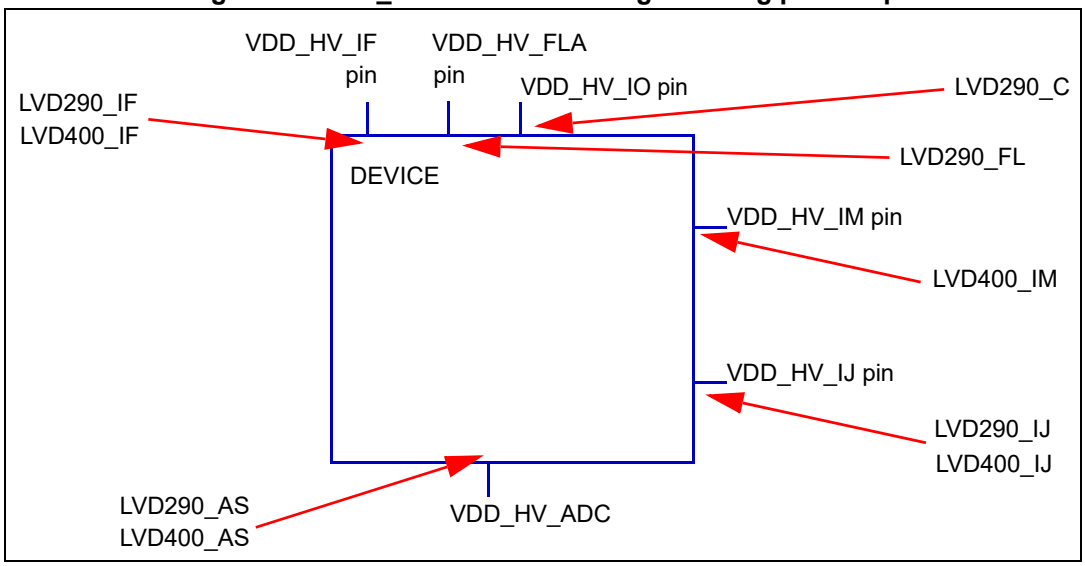
10.6.1.2.2 VDD_HV conditions and LVD trimming/enabling sequence



During POWERUP, the following high voltage MVDs are enabled:

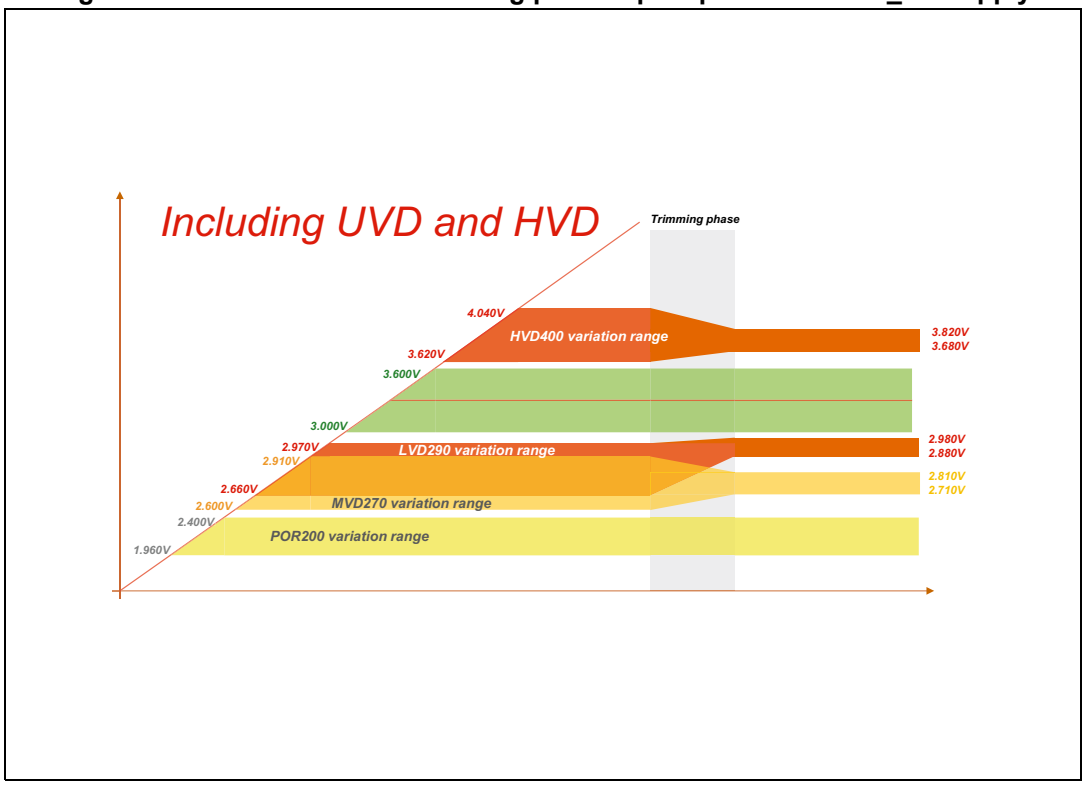
- MVD270_C
- MVD270_FL

The VDD_HV conditions to exit POWERUP are the following:

- LVD290_C
- LVD290_FL

Figure 64. VDD_HV monitored voltages during power-up

The IRCOSC module starts initialization and provides the clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles.



Device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST], PHASE3[DEST].

LVD/HVD modules are trimmed at the beginning of PHASE3[DEST]. Trimming is done by SSCM at low voltage, using the differential flash read accesses. After trimming is completed, SSCM waits for PMC acknowledgement before proceeding with reset sequence.

Configurable LVD/HVD modules are optionally enabled at the end of PHASE3[DEST].

Figure 65 provides the threshold variation of VDD_HV LVDs monitor during power-up sequence from POWERUP before and after trimming.

Figure 65. Threshold variation during power-up sequence on VDD_HV supply

The device needs to fulfill all conditions described in this section to recover.

10.6.2 Power-down sequence

In case LVDs/HVDs are configured to generate destructive reset , either LVD is below threshold or HVD is above threshold, the device enters PHASE0 phase.

Power-down sequence is actually entered as soon as the threshold of MVD094 and MVD270 is crossed. The device enters the POWERUP state. The internal power-on signal is asserted.

On power-on signal assertion, all modules reach their safe state.

Device supplies may then proceed to drop down to ground either through device leakage or external pull-down. During power-down, all supplies should comply with supply constraints.

10.6.3 Brown-out management

During brown-out, the device re-enters the POWERUP phase as soon as the threshold of either MVD094 or MVD270 is crossed. The internal power-on signal is asserted.

Note: The device will correctly start independently from any residual voltage. Below MVD270 *threshold the device is under POWERUP state. Above the* MVD270 *threshold, the device is into a RESET state as defined by Voltage monitor or external PORST pin or active state when all have been released.*

On internal power-on signal assertion, all analog modules reach their safe state.

10.6.4 Low voltage requirement during crank

The device can continue operation to the minimum input voltage during crank.

In order to proceed with execution during cranking and prevent device reset, it is important to correctly configure the high voltage LVDs.

During device switch-off the external LVDs monitoring may not be activated quickly enough (external assertion of the PORST pin) and hence the −10% level is crossed before POR is asserted. Malfunction is possible in this case, but reliability is not impacted. In particular the flash is not corrupted.

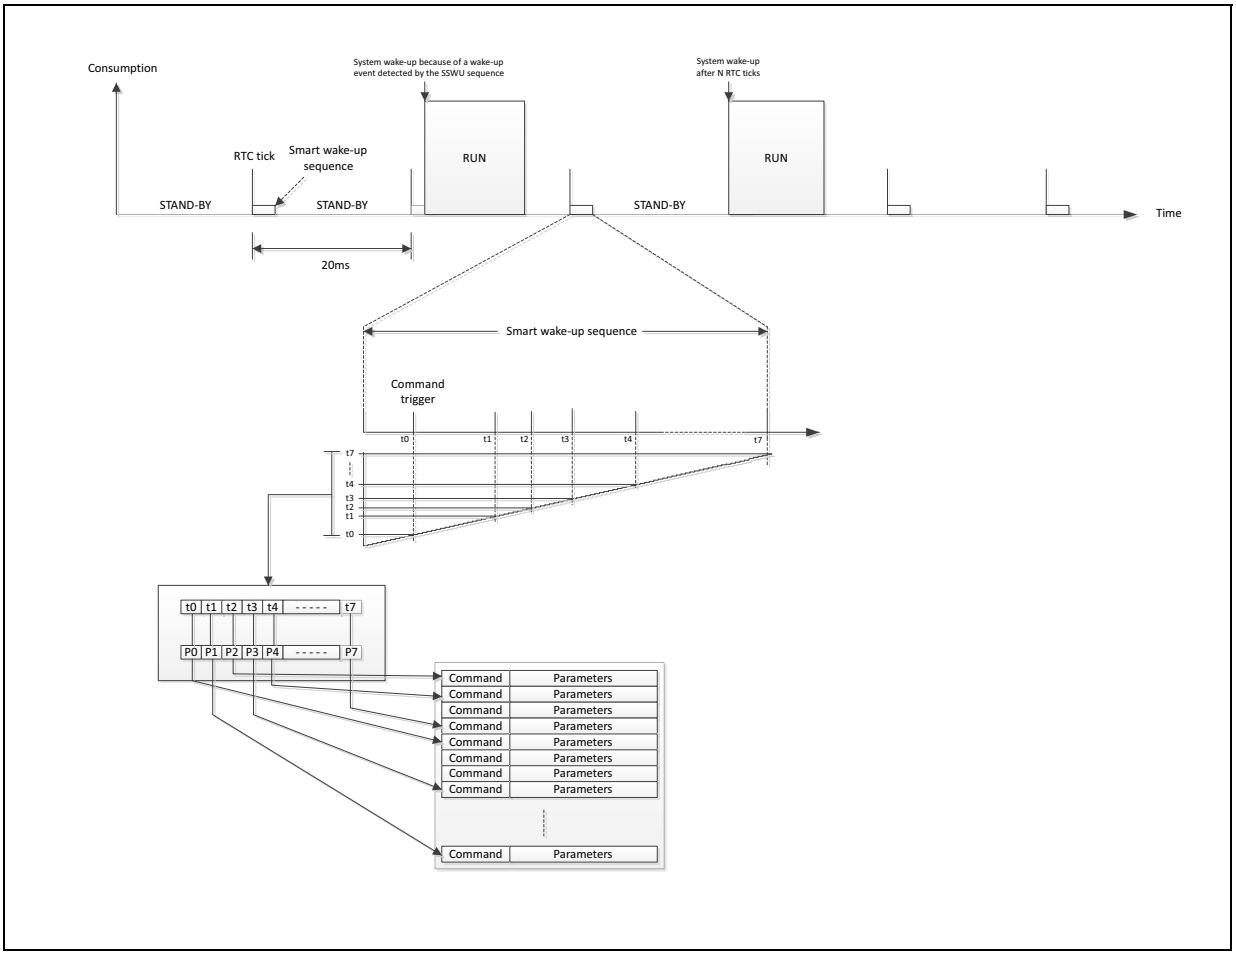
Internal LVDs that monitor the supply ensure that the flash content is protected.

11 Smart Stand-by Wake-up Unit (SSWU)

11.1 Overview

The Smart Standby Wake-Up Unit (SSWU) is aimed at further reducing the device power consumption by scheduling, on an RTC time basis, a sequence of user-programmable tasks, which are executed in STANDBY Mode without the CPU intervention.

These tasks are programmed in order to allow the following operations in STANDBY:



- Control output level
- Analog comparator versus voltage threshold or range
- Digital input state detector: In addition, it is possible to schedule a system wake-up based on a user-defined time interval.

The next sections explain the whole concept in details.

11.2 Functional description

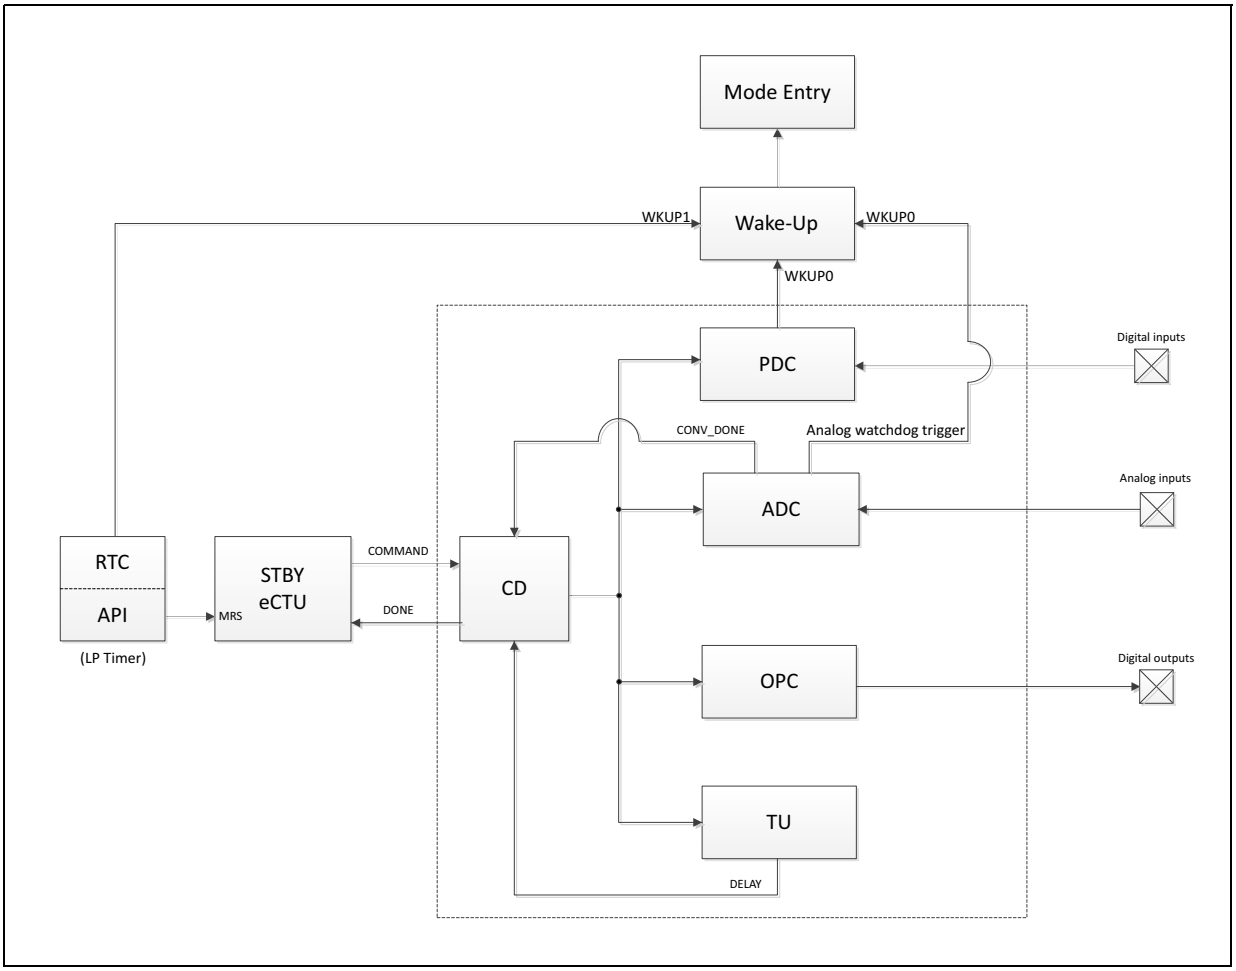
Figure 66 shows the SSWU functionality.

Figure 66. Smart Wake-Up Sequence Functionality

The module is able to maintain the system is mostly in stand-by and eventually woken up based on the acknowledge of predifined wake-up event, which basically can be of two types:

- a time based wake-up event (WKUP1 line event)
- an asynchronous wake-up event (WKUP0 line event) detected during the SSWU sequence, which is periodically started based on the RTC tick (programming API period)

The time based wake-up event type is generated by the API/RTC IP, which can be programmed to generate it after a certain number of timer ticks.
The second asynchronous wake-up event type is generated by the SSWU block itself, as explained in the next sections.



The SSWU sequence is a series of "commands" (plus some command-dependent parameters) generated by the Stand-by eCTU block based on a certain pre-programmed time schedule (t0, t1, etc. in the figure). For each scheduled time event, it is possible to assign a command to be executed. As explained later on, it is possible to assign a sub-sequence of commands, which can be displaced with a programmable time delay. Each command is then interpreted by a command decoder, which is dispatching them to the target client.

11.3 Architecture

Once the device is in STANDBY Mode, a minimum set of IPs will be periodically woken-up. This allows a pre-programmed sequence of measurements to run, limiting the power consumption to the minimum requested for a body application.

Figure 67 shows the block diagram of the SSWU architecture.

Figure 67. Smart Wake-up Architecture

Hereafter is a list of the blocks in the picture.

- RTC = Real Time Clock
- STBY eCTU = Stand-by Enhanced Cross Triggering Unit
- CD = Command Decoder
- ADC = Analog Digital Converter (client)
- PDC = Port Digital Comparator (client)
- OPC = Output Pin Control block (client)
- TU = Timer Unit (client)

Hereafter is a brief description of each block, which is explained in details in the following chapters.

The RTC/API timers block is always powered-on in STANDBY and generates a time tick based on the low power clock source (LPRC or OSC32K) selected.

The RTC timer (mapped on the WKUP1 line) allows to periodically exit from STANDBY. The API timer (mapped on the WKUP0 line), instead, drives the starting of SSWU mechanism (refer to *Section 11.4*).

The Stand-by eCTU (Enhanced Cross Triggering Unit) is used to schedule the execution of a set of pre-programmed commands: it is the "engine" of the SSWU sequence.

The CD (Command Decoder) is used to decode the command generated by the Stand-by eCTU and dispatch them to the following client blocks:

- The ADC (Analog Digital Converter) is a dedicated, low-power analog to digital converter, used to generate an API wake-up event (WKUP0) in case the converted value is above or below a certain threshold.
- The OPC (Output Pin Control block) block is used to set the output level of a digital port pin, in order to let the customer open/close some external switches.
- The PDC is used to trigger an API wake-up event (WKUP0) when the level of a pin is a certain value for a specific time.
- The TU is used to generate a programmable delay between different Stand-by eCTU command executed within the same command sequence.

The Wake-up unit collects the wake-up triggers (eventually provided by the ADC or PDC client) and generates a wake-up event (WKUP0) for the Mode Entry block.

The Mode Entry block is then responsible to change the system execution mode (from STANDBY to Run).

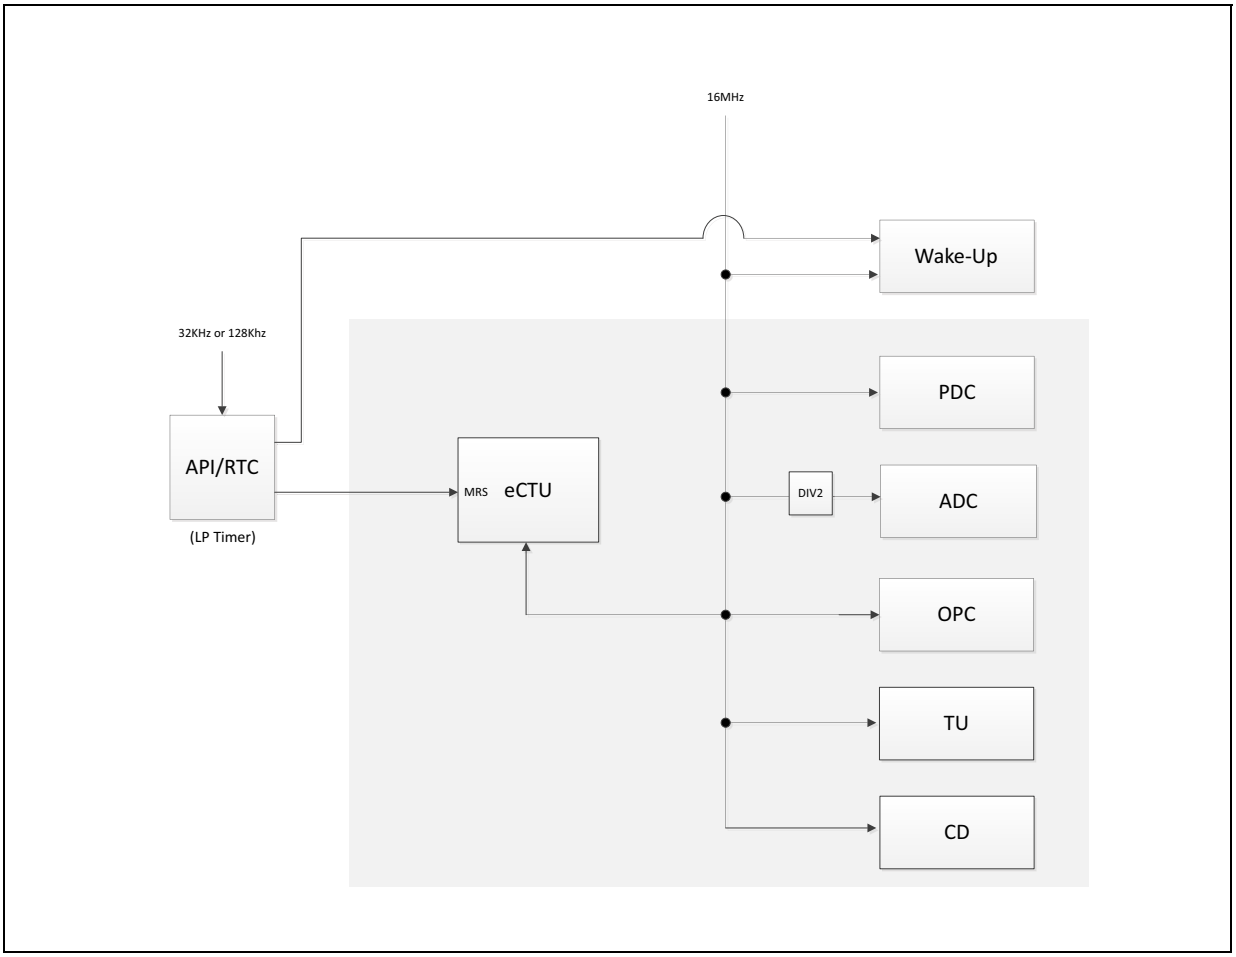
In STANDBY mode, only RTC is powered on, while all other blocks are off. At the RTC tick, the hardware switches on the 16 MHz IRCOSC and wakes up the other blocks.

11.4 Clocking

Figure 68 shows the SSWU clocking architecture.

The RTC evolves with the low power clock, which can be selectable between 32 kHz or 128 kHz.

Note: The 1024 kHz clock signal from slow internal RC oscillator (LPRC) is divided by 8 before applied as 128 kHz clock to RTC.



The SSWU IPs evolves with the internal 16 MHz IRCOSC.

A prescaler is embedded in the TU block in order to let the customer program the delay resolution (refer to *Section 11.6.6: TU*).

Note: Even if IRCOSC is configured off in STANDBY through the ME_STANDBY0_MC register, it will be automatically turned-on once SSWU is activated. The IRCOSC will be automatically turned off after SSWU Stop command is executed.

The ADC IP runs at 8MHz (IRCOSC clock divided by 2).

Figure 68. SSWU clock architecture

11.5 Memory map and register descriptions

11.5.1 Memory map

This section provides the memory map of the SSWU. For double buffering and synchronization refer to *Section 11.5.15: Double buffered registers*.

Field	Description
24 CTU_FSM_RESET	CTU state machine reset when written '1'. Writing a one has effect on the module, but it always reads as zero. **Note:** It is possible that CTU state machine is waiting for end of SSWU command, and due to any fault, it does not arrive. Therefore, this bit should be used to reset the CTU state machine before each standby entry.
27 CGRE	Clear GRE (1)
28 FGRE	Flag GRE (1)
30 GRE	General Reload Enable (1) 0 disabled 1 enabled
31 TGSISR_RE	TGS Input Selection Register Reload Enable. Is set by the user and reset automatically when its reloaded.

1. Refer to *Section 11.5.15* for details.

11.5.15 Double buffered registers

Some registers of the SSWU are double buffered. When MRS is set, the data programmed in a register on register interface clock domain is transferred to the SSWU kernel clock domain. To avoid error condition due to a MRS signal that arrives when a write operation is not fully completed, the following 2 bits are used:

1. GRE (General Reload Enable)
2. FGRE (Flag General Reload disable)

The reload of all double-buffered registers is enabled by setting the GRE bit in the CTU Control Register in order to guarantee the consistency of all double-buffered registers. The user must ensure that the trigger command list is updated before MRS occurs. If the update is not performed, the previous values of all double-buffered registers remain active.

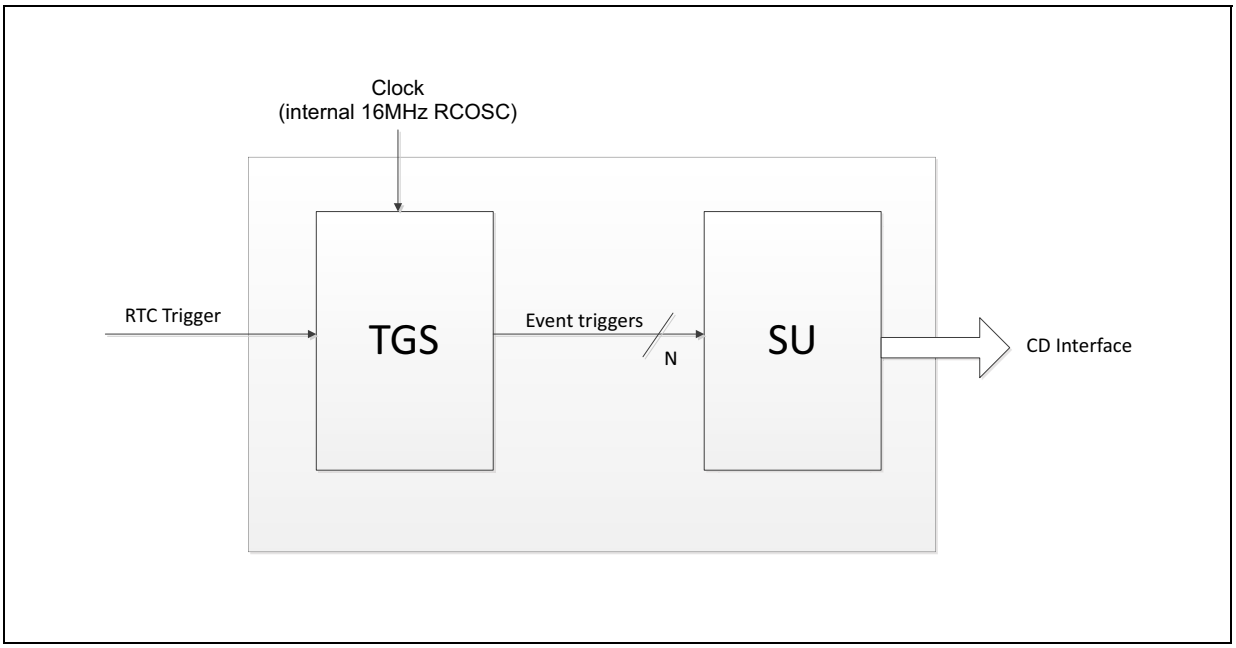
All the double-buffered registers use the same bit (GRE) to enable the reload when the MRS occurs. This bit is used to signal that the user has updated the registers and so a reload can be performed without any problem. The MRS bit is R/S (Read/Set). If the bit is 1 the reload can be performed, while if this bit is 0, the reload is not performed. A correct reload resets this bit. It is also possible to reset this bit by software setting CGRE (Clear GRE) bit. This bit can be reset in a software way but, anyway, it is reset when GRE bit is at zero.

In order to verify if a reload error occurs, FGRE (Flag GRE bit in the CTU Control Register) bit is used. When one of the double-buffered registers is written, FGRE flag is set to 1 and it is reset by a correct reload. When the MRS occurs while FGRE = 1 and GRE = 1, a correct

reload is performed (because all intended registers have been updated before the MRS occurs).

- If FGRE = 1 and GRE = 0, a reload is not performed, the error flag (MRS_RE) is set (in this case at least one register was written but the update has not been ended before the MRS occurrence).
- If FGRE = 0, it is not necessary to perform a reload because all the double-buffered registers are unchanged.
- If GRE = 1 with FGRE = 0, a MRS_RE is generated on the next master reload.

TGSISR_RE bit is used to synchronize TGSISR register. When the user set TGSISR_RE, the value written in the TGSISR register is used.



11.6 SSWU module descriptions

11.6.1 Stand-by eCTU

Figure 86 shows the Stand-by eCTU block diagram. Basically it is composed of two blocks:

- TGS (Trigger Generator Sub-unit), which is responsible to generate a set of triggers based on some pre-programmed time schedules
- SU (Scheduler Unit), which receives the trigger and starts the associated command sequence

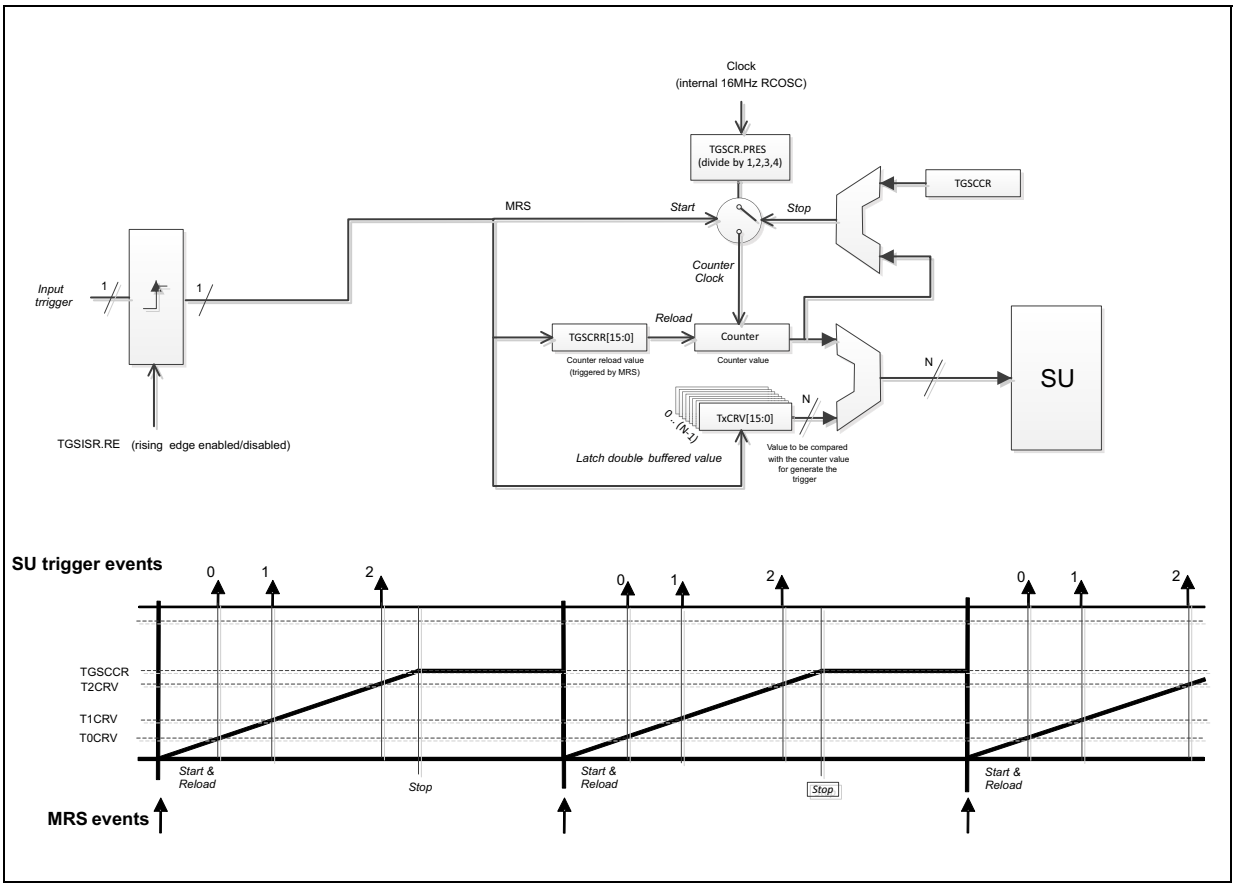
Figure 86. Stand-by eCTU Block Diagram

The figure shows that the output of the Stand-by eCTU is directed to the CD interface. The CD block of the SSWU decodes the CTU command and dispatches it to the various clients (OPC, PDC, ADC, TU).

11.6.1.1 TGS block

Figure 87 shows the Stand-by eCTU architecture and functionality.

As shown in the figure, the TGS contains a 16-bit counter unit (evolving with the internal slow clock) and a set of comparators (TxCRV) [7]. Each comparator determines one time event point (tx in *Figure 66*).



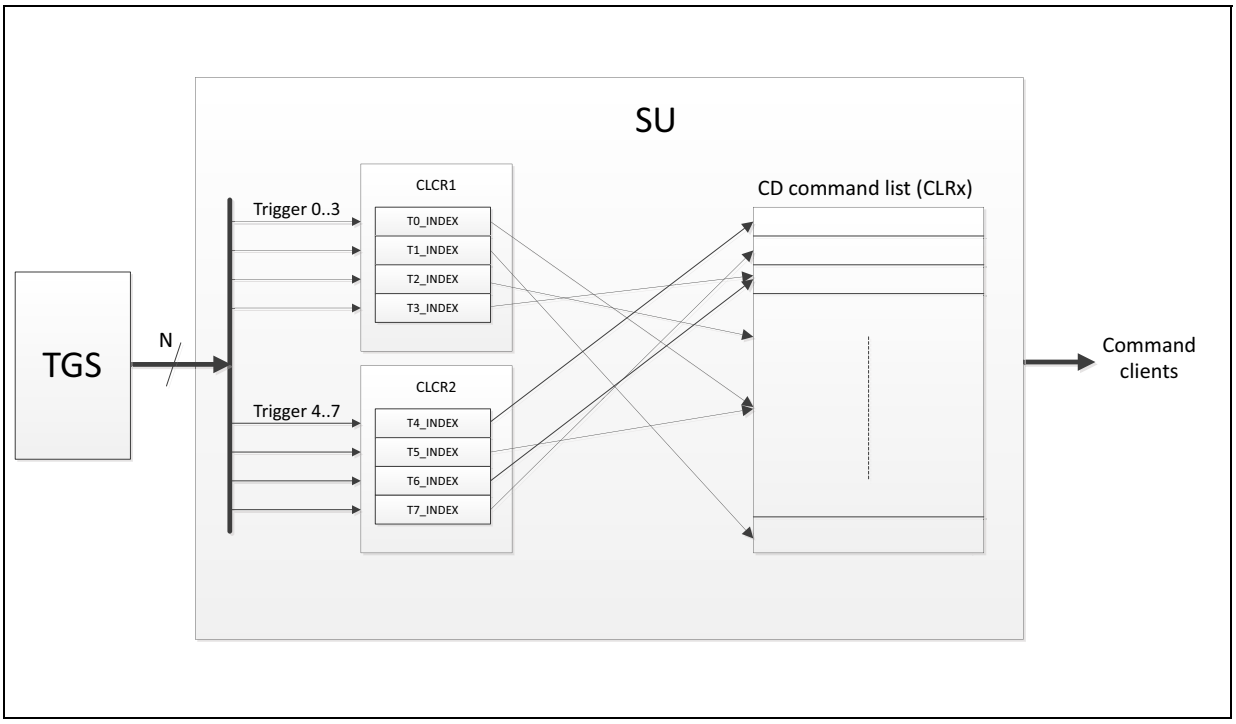
The MSR (Master Reload Signal) is used to reset and start the counter. The reset value is stored in the TGSCRR register. The MRS is generated via HW trigger (RTC tick).

When the counter reaches one of the values programed in the TxCRV comparators, an internal trigger is generated to the SU block. Note that is it possible to program TGSCCR register so that the counter will be stopped as soon as it reaches a certain value.

The waveform in *Figure 87* shows an example of three SU trigger generations, based on T0CRV, T1CRV, and T2CRV comparators. Note that, the TGS internal counter is started by a MRS event and reloaded with the '0' value. Also the TGSCCR register is used to stop the counter when it reaches the value programmed in this register.

Caution: When the SSWU sequence is generated with several SU triggers, the user must insure the SSWU command is finished before triggering a new one.

Figure 87. TGS Architecture and Functionality (triggered mode)



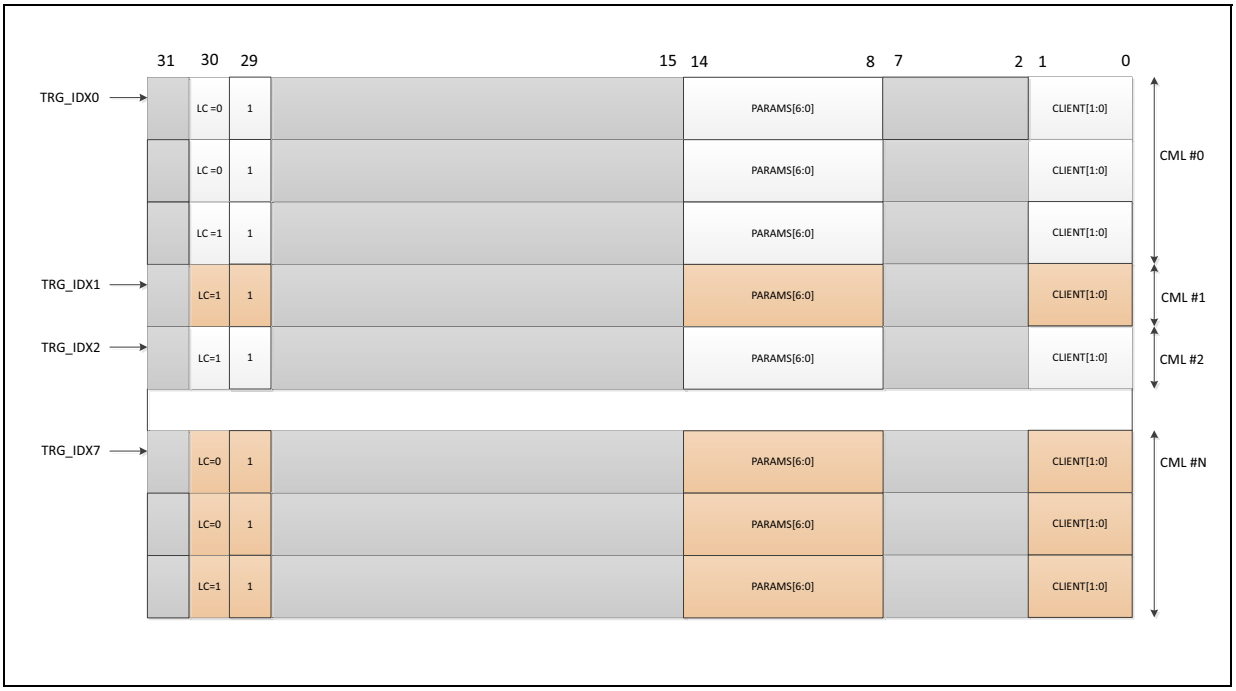
7. The number of comparators is 8

11.6.1.2 SU block

Figure 88 shows the SU block functionality. Its function is to receive the internal SU trigger and activate a sequence of commands, pre-programmed in a command table [8].

In fact, each trigger from the TGS block is associated to a programmable pointer, which determines, within the SU command table, the begin of the sequence of commands.

Figure 88. SU Functionality



11.6.1.3 Stand-by eCTU command structure

The command structure is specified in *Figure 89*.

8. The command table length is 32

Figure 89. SU Command Structure

Hereafter is a description of the command fields.

- LC (last Command): this flag is used to specify whether the command being executed is the last of the sequence started by a SU trigger. *Figure 89* shows several examples: the command sequence triggered by TRG_IDX0 is composed of 3 commands, while the sequence triggered by TRG_IDX1 is actually one single command.
- EC (bit 29): always set to 1
- PARAMS: specify the command parameters
- CLIENT: specify the client ID

Starting from the first command to be executed, as programmed in the pointer associated to a specific SU trigger, each command is executed after the previous one is completed. The "LC" command flag determines whether the current command is the last one to be executed for the sequence of commands being executed.

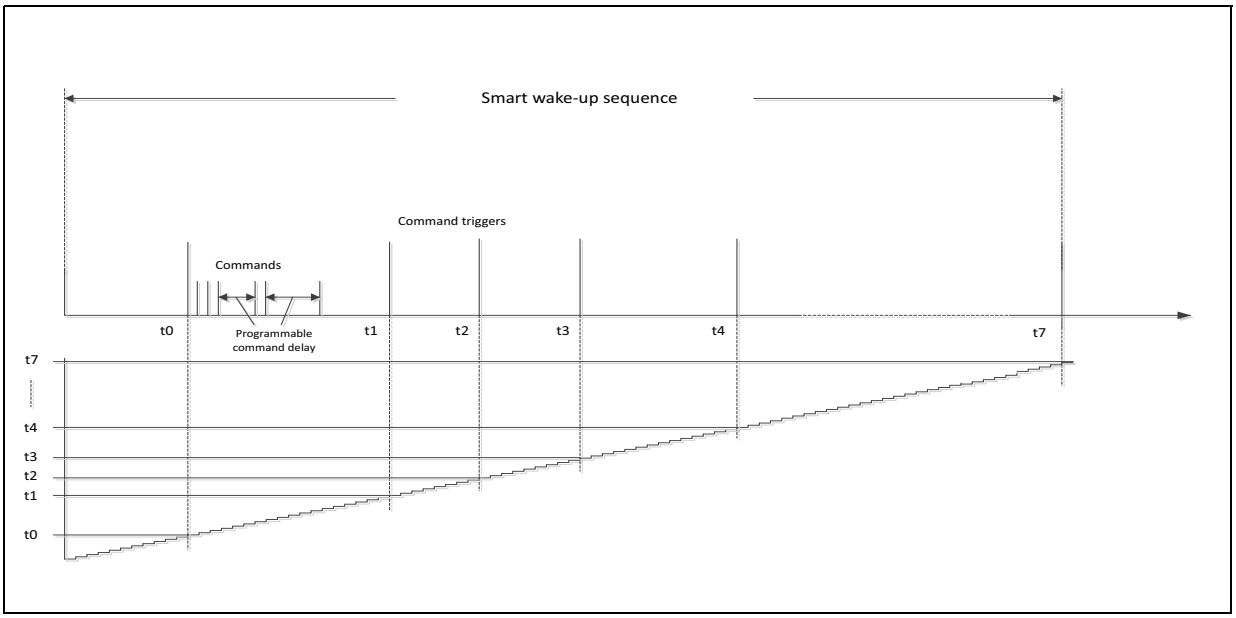
11.6.1.4 Stand-by eCTU command sequence summary

As a summary, the command sequence is driven by:

- the TGS sequence of triggers, where each SU trigger is generated on a programmable time-basis,
- the SU command sequence, activated by a SU trigger.

The Stand-by eCTU commands are executed in a row till the one marked as "LC = 1". The Stand-by eCTU executes the next command as soon as it is acknowledged that the previous command was completed. This is represented in *Figure 67* by the DONE feedback signal from the CD block to the Stand-by eCTU block.

The execution time between each command depends on the command itself.



A command associated with an ADC conversion lasts till the ADC has acknowledged the Stand-by eCTU that the conversion was completed. This is represented in *Figure 67* by the CONV_DONE feedback signal from the ADC block to the CD block.

Other commands (for example, the one used to set a digital port pin level) have no "intrinsic" duration. Because of this, the "TU" block has been introduced, in order to be able to set a programmable delay between "immediate" commands. This is represented in *Figure 67* by the DELAY feedback signal from the TU block to the CD block.

As a result, shown in *Figure 90*, the time when a command shall be executed can be controlled in two ways:

- the value of the TxCVR comparators (t0, t1, etc. in *Figure 90*)
- the TU delay times (“programmable command delay” in *Figure 90*)

Figure 90. Programmable Command Delay

11.6.2 CD (Command Dispatcher)

The Stand-by eCTU commands contain two main fields:

- CLIENT
- PARAMS

The information in these two fields is decoded by the CD block and dispatched to the target clients (refer to *Table 160*).

The PARAMS field of the command is interpreted according to the type of client being activated.

Table 160. Smart Wake-up Sequence command

11.6.2.1 OPC channel handling

The SSWU is able to drive up to 8 OPC channels.

The channels are divided into 2 groups of 4 channels each. The “GROUP” command parameter is used to select the group of channels to be operated (refer to *Table 162*). The 4 channels belonging to the selected group are driven in parallel: the 4 channels will be set according to the value specified in the “PATTERN” command parameter. The connection between each OPC channel and the corresponding pad is hard-wired.

Figure 91. SSWU OPC connections

11.6.3 ADC

The ADC block is a reduced, low-power version of the Successive Approximation Register Analog-to-Digital Converter called 10-bit SARADC_STDBY. Its main functionality is to compare the converted value towards a watchdog, and trigger a wake-up event in case the value is out of the intended range.

The watchdog thresholds (low and upper limits) are linked (that is pre-programmed during the RUN mode) to each ADC channel, so that a specific channel has its own threshold limit.

The ADC configuration comprises:

- 8 internal channels
- 4 different watchdog threshold values
- 8 external channels

More details about the ADC configuration are given in the *Chapter 40: Analog-to-Digital Converters (ADC) Configuration*.

11.6.3.1 ADC Channel Selection

The selection of internal or external channel group is done through the PARAMS[6] bit.

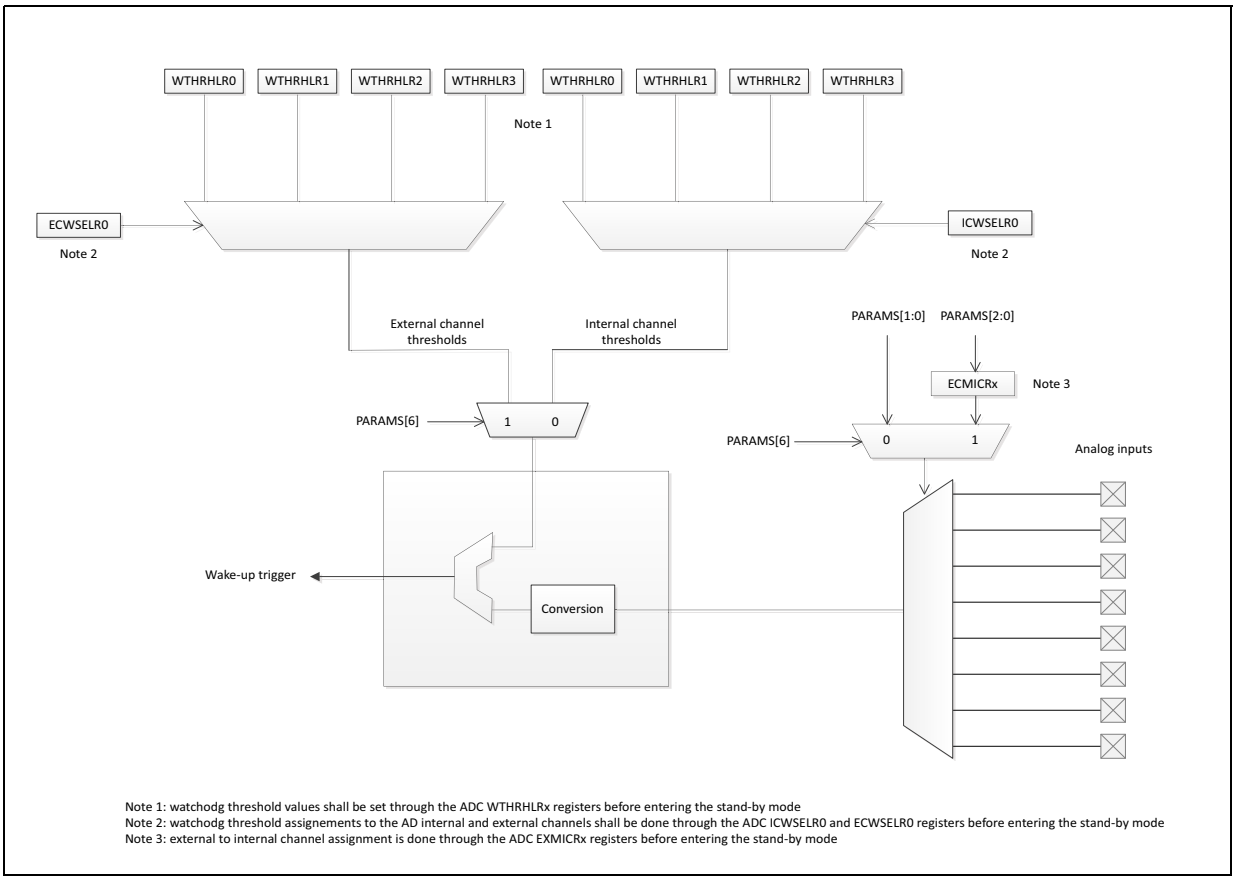
In case the internal channel group is selected (PARAMS[6] = 0), the internal channel number depends on the value specified by the PARAMS[2:0] bits. Because the internal channels are statically connected to a specific analog input pin, the channel selection is also a selection vs. which analog input pins will be used.

In case the external channel group is selected (PARAMS[6] = 1), the value of PARAM[2:0] represents the external channel number. The selected external channel number is then re-mapped on an internal channel through the ECMICR registers, which contains a set of fields, one for each external channel, where the linked internal channel can be specified. This association has to be done before entering into the stand-by mode. This way it is possible to link different external channels to the same internal channel.

11.6.3.2 ADC Watchdog Threshold Selection

A voltage measurement threshold (upper and lower limit) can be selected for each channel. The WTHRHRLx registers define a pool of watchdog threshold values, which can be referenced for each channel through the ICWSELx and ECWselx registers for the internal or external channel respectively.

In case the same analog input pin is used to measure the same voltage range with the same voltage threshold, then an internal channel is used (PARAMS[6] = 0).In this scenario, the configuration is:



- The internal channel value is fixed by the PARAMS[2:0] value
- The threshold is chosen by setting the ICWSEL register before entering the stand-by mode

In case the same analog input pin is used to measure the different voltage range with the same voltage threshold, then an external channel is used (PARAMS[6] = 1). In this scenario, the configuration is:

- The external channel value is fixed by the PARAMS[2:0] value
- The threshold is chosen by setting the ECWSEL register before entering the stand-by mode
- The internal channel (the pin to be used) linked to the chosen external channel is defined by the ECMICR register

Figure 92 represents in graphical form the above description.

Figure 92. ADC channel selection

11.6.4 OPC

The OPC block is used to drive the 8 digital output pins to a desired level.

The intended functionality is to open/close external switches.

The Stand-by eCTU command parameter contains the OPC channel and level.

The OPC channels are controlled in groups of 4 channels, but, it is possible to mask any one of these channels, in order to retain the value set in RUN mode on any pad not intended to be used for the SSWU.

The mechanism to achieve this is to use the SIUL SCR bits to mask the OPC channel driving to the pad (refer to *Section 17.2.2.11: Soc Configuration Register 0 (SIUL2_SCR0)*). In order to drive an OPC channel, the SW shall configure the associated SCR bit before entering in stand-by mode.

The set of pads used to control external logic during the Stand-by have the following behavior:

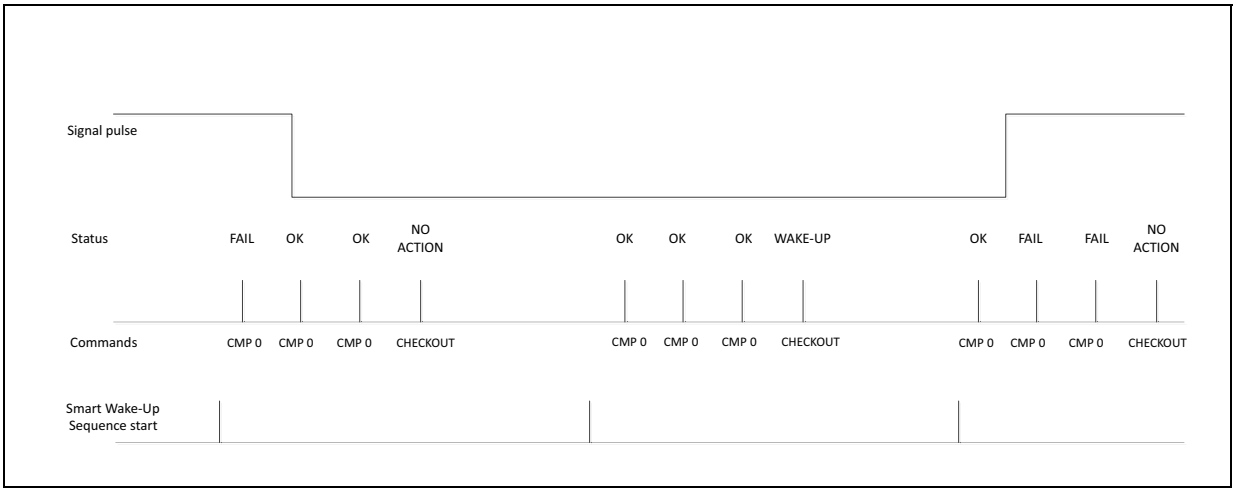
- Upon entering the stand-by mode, the pad values corresponding to OPC channels are maintained.
- That means if the pad is used for OPC functionality during STANDBY mode, then on the subsequent STANDBY mode entry, the PAD value is restored to the value during the previous STANDBY mode exit.
- However, if the PAD is not used for OPC functionality during STANDBY, then the same value as in RUN mode is maintained upon entering STANDBY mode.
- SIUL_SCR0.OPC_MASK configuration for any OPC channel should remain same during the application. Otherwise, the value on OPC channel on STANDBY entry may have some undesired transitions.
- During stand-by mode, it is possible to change the value of those pads thanks to OPC programming.
- Upon exiting from stand-by, the value of the pads connected to OPC channels can also be maintained. This avoids glitches during the transition between stand-by and run mode. For this purpose, the SIUL2_SCR0 register must be programmed before entering stand-by.

Note: Note that the pads value and direction can still be changed during the RUN mode, but this requests to write a bit within the SIUL_SCR0 register to “1”. Before entering the standby mode the SIUL_SCR0 bit shall be programmed to "0".

11.6.5 PDC

The PDC block is targeted to measure the level of a set of 4 pins and to generate a system wake-up event when the level is acknowledged at a specified level and, optionally, for a certain time.

Two commands are need for the PDC:



- CMP 0/CMP 1: to compare a pin level versus a 0 or 1
- CHECKOUT: to trigger a wake-up in case the result of the CMP commands for that specific pin executed from the beginning of the Smart Wake-up Sequence is always OK

For each pin, the PDC will latch the comparison results, which will report whether the target value was always matched (whenever a PDC, CMP0/1 command is launched) or not.

When checkout command is launched for a specific pin, it will trigger a wake-up event only if the target level was steadily acknowledged along all the comparisons done for that pin.

Figure 93 summarizes the above description.

Figure 93. Smart Wake-up Sequence PDC

11.6.6 TU

The TU block is used to create a programmable delay between the command execution. It needs only one command with the delay value programmed as a parameter.

The delay parameter is intended as number of IRCOSC periods (so that when TU = 1, then the delay is 1 clock cycle; TU = 2, then the delay is 2 clock cycles; and so on). The clock cycle can be adjusted with a linear prescaler, which is programmed though SSWU_CTRL_REG register of PMC_Dig module during the RUN mode, and whose value is preserved through the stand-by mode. The prescaler has a division factor from 1 to 128 (7 bits). Combining the TU parameter and the prescaler, the delay ranges from 62.5 ns (Clock period = 62.5 ns, PARAMS[6:0] = 1, prescaler = 1) up to 1.016 ms (Clock period = 62.5 ns, DELAY = 127, TU_{PRESC} = 128).

Note: TU_{PRESC} is defined in the SSWU_CTRL_REG. Please refer to Chapter 67: Power management controller digital interface (PMC_Dig).

Caution: The two commands which can cause wakeup (ADC-ADC or ADC-PDC or PDC-PDC) shall not be executed one after another without inserting a TU delay command.

11.6.6.1 SSWU STOP Command

In case the TU parameter (delay time) is set to 0, this is decoded as a command request to stop the whole SSWU sequence.

11.7 SSWU Configuration example

11.7.1 Description

In this scenario, the device stays in STANDBY and, every 32 msec, starts following SSWU operations sequence:

- Suddenly set OPC1 pin to '1'
- After 200 µsec, set OPC1 pin to '0'
- Perform an ADC conversion (configuring an ADC threshold to wakeup the device)
- Set a TU command for stopping the SSWU sequence

Device wakes-up from STANDBY only in case of ADC threshold overcoming.

11.7.2 Registers configuration

Following a pseudo-code that explains how to configure all the SSWU registers and all others IPs that are interconnected with it in order to get the overall STANDBY scenario

11.7.2.1 SSWU registers Configuration

```
//First command list
SSTDBY_CTU_0.CLR[0].R = 0x60001001; //set OPC1(PB9) pins to '1'

//Second command list
STDBY_CTU_0.CLR[2].R = 0x20000001;   //set OPC1(PB9) pins to '0'

STDBY_CTU_0.CLR[3].R = 0x20000C00; //convert internal channel  (AN82/PB10)

STDBY_CTU_0.CLR[4].R = 0x60000003; //add a delay of 0usec to stop the
sequence

STDBY_CTU_0.CLCR1.B.T0_INDEX = 0;   // trigger0 points to CLRN[0]
STDBY_CTU_0.CLCR1.B.T1_INDEX = 2;   // trigger0 points to CLRN[2]

STDBY_CTU_0.THCR1.R = 0x00001111;   // trigger0-1 enable
STDBY_CTU_0.TCRN[0].R = 0x00000001; // trigger0 generated quite immediately
STDBY_CTU_0.TCRN[1].R = 0x00000C80; // trigger1 generated 200us after the
API event

STDBY_CTU_0.TGSISR.R = 1;  // ctu_trg_in[0] (API) Rising edge Enable

STDBY_CTU_0.CTUCR.B.TGSISR_RE = 1;   // TGS Input Selection Register Reload
Enable

STDBY_CTU_0.CTUCR.B.GRE = 1;     // General Reload Enable
STDBY_CTU_0.CTUCR.B.CTU_FSM_reset = 1; // reset CTU FSM before
                                       // next stand-by entry
```

11.7.2.2 Other IP registers configuration

Following IPs should also be configured in order to complete the entire STANDBY scenario:

```
-----------------------------------------------
Clock and Mode Entry configuration
-----------------------------------------------

MC_ME.ME.R = 0x0000FFFF;          // Enable all modes

// Set RUN Configuration Registers
MC_ME.RUN_PCN[1].R=0x000000FE;       // Peripheral ON in every running mode
MC_ME.LP_PCN[1].R=0x00002500;

MC_ME.PCTL15.B.RUN_CFG=1;         // SIUL2
MC_ME.PCTL114.B.RUN_CFG=1;        // ADC_STDBY
MC_ME.PCTL242.B.RUN_CFG=1;        // STDBY_CTU_0

MC_CGM.AC0_DC2.R = 0x80000000;    // enable ADC_CLK
MC_CGM.AC0_DC4.R = 0x80000000;    // enable ECTU_CLK

//Enter DRUN to act the previous configurations
MC_ME.MCTL.R = 0x30005AF0;        // DRUN Mode & Key
MC_ME.MCTL.R = 0x3000A50F;        // DRUN Mode & Key

while(MC_ME.GS.B.S_MTRANS);       // Waiting for end of transaction
while(MC_ME.GS.B.S_CURRENT_MODE != 0x3);   // ME_GS Check DRUN mode has
successfully been entered

----------------------------
WKPU configuration
----------------------------

//Configure wakeup line 0 (SSWU wakeup event)
WKPU.WRER.R = 1;                  // Wakeup Request Enabled
WKPU.WIREER.R = 1;                // Rising Edge Event Enabled

-----------------------------------------------
SAR_ADC_10bit_STDBY configuration
-----------------------------------------------

SAR_ADC_10BIT_STDBY.MCR.B.OWREN = 1; // SAR ADC 0 overwrite enable set
SAR_ADC_10BIT_STDBY.MCR.B.MODE = 0; // Normal Mode
SAR_ADC_10BIT_STDBY.ICNCMR2.B.NCE_CH82 = 1; //sets channels 82 to be
converted in SARADC_10bit_standby (see table in ADC Config)
SAR_ADC_10BIT_STDBY.MCR.B.CTU_MODE = 1; // Trigger mode is selected
SAR_ADC_10BIT_STDBY.MCR.B.CTUEN = 1;    // CTU enabled
```

```
SAR_ADC_10BIT_STDBY.MCR.B.PWDN = 1; // SAR ADC 0 automatic power
                                    // up by SSWU during stand-by

//ADC_STANDBY_CH0 = Internal Channel 82:
SAR_ADC_10BIT_STDBY.WTHRHLRN[0].B.THRH = 0x333; // select high THRHLR0
treshold = 4V
SAR_ADC_10BIT_STDBY.ICWSELR11.B.WSEL_CH82 = 0;  // select THRHLR0 treshold
for CH88
SAR_ADC_10BIT_STDBY.ICWENR2.B.WEN_CH82 = 1;  // enable watchdog for CH82
SAR_ADC_10BIT_STDBY.WTIMR.B.MSKWDG0H = 1;   // enable high THRHLR0 treshold
interrupt

----------------------------
STANDBY configuration
----------------------------

PMCDIG.MISC_CTRL_REG.B.LPRCREG_ENB = 0;    // Enable LPRC in running modes

----------------------------
API/RTC configuration
----------------------------

RTC_API.RTCC.R = 0x80009001;    // Counter Enabled, API Enabled, LPRC
prescaled by 8 @128KHz used, Trigger enabled
RTC_API.APIVAL.R = 0x00001000;  // API period =32.25msec
```

Caution: For SSWU, ADCSAR must be used in CTU_TRIGGER mode.

11.7.2.3 Activate SSWU sequence

Once all previous registers configuration have been configured, it needs just to perform STANDBY Mode entering in oder to get the desired scenario.

```
//Mode Entry Module (MC_ME): Enter STANDBY Mode
MC_ME.ME_STANDBY0_MC.IRCON.B = 0; /* Switch off IRCOSC during standby */
MC_ME.MCTL.R = 0xD0005AF0;       /*! Write Mode and Key | MC_ME.MCTL */
MC_ME.MCTL.R = 0xD000A50F;  /*! Write Mode and Key inverted | MC_ME.MCTL */
```

12 Security

All SPC58 family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations while other more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off; they require significant involvement for implementation. Consequently, they provide an important opportunity to define the security level of the device.

12.1 Basic security

All SPC58xEx/SPC58xGx devices have the following basic set of security features.

- Device security feature based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
  - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection
  - SRAM and caches initialized to a constant value after reset (power-on reset, when in a test mode, when not booting from internal flash memory); MBIST functionality used in case of power-on and destructive resets to initialize RAMs selected via configuration in UTEST flash; BAF software routines to initialize RAMs when not booting from internal flash memory
- Monitoring of operating conditions
- Unique ID for each device: each SPC58xEx/SPC58xGx device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device
- Secure watchdog timer
- Debugger access control

12.2 Advanced security

Depending on the device configuration, the following features are available:

- Customer programmable Hardware Security Module (HSM): a dedicated security subsystem that includes a processor core, dedicated SRAM, an encryption module, and exclusive access to secure areas of device flash memory; HSM runs code independently from the main device processor cores and can be used to implement advanced security and monitoring functions
- Advanced debugger access control
- Boot modes:
  - Trusted/secure boot support
  - Handshake with BAF supported

12.3 Detailed security information

Details of most of the SPC58xEx/SPC58xGx security features are published in a separate *SPC58xEx/SPC58xGx Microcontroller Security Reference Manual*, which is only available to qualified customers.

13 Calibration and Debug

This chapter discusses the device-specific information for the debug and calibration modules. This device implements a high-speed serial Nexus trace auxiliary port. The Aurora interface allows the Nexus protocol information to be transmitted serially at high speed over four Aurora lanes. The Aurora protocol handles the encoding of the data and striping the information across the four Aurora lanes available on the device. In addition, the LFAST module, a high speed calibration interface, is supported for run control and memory access. The LFAST signals are alternate functions on the device's JTAG pins. The device starts up in JTAG mode and the tool can request that the JTAG interface be converted to the LFAST high-speed interface. All standards used have freely available specifications for tool developers.

The debug and calibration features for this device are provided in two separate dies: the Production die and the Buddy die, or Buddy Device (BD). The Production die is packaged alone in the Production Device (PD) package. The PD is also assembled into an Emulation and Debug Device (ED) package that consists of the Production die along with the Buddy die. The Buddy device supports additional debug capability. The Nexus Aurora interface is only available on the ED. The PD only supports trace to the internal trace/calibration memory.

The Event Out ($\overline{\text{EVTO}}$[0,1]) signals are connected to the external TGOUT[0,1] device pins and the Event In ($\overline{\text{EVTI}}$) signals are connected to the external TGIN[0,1] device pins.

13.1 Core debug support

Internal debug support in the e200z420n3 and e200z425n3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug mode, such that no code runs. This allows debuggers to perform operations such as configuration of calibration remap or edit of overlay memory prior to user code execution.

For details, see *Chapter 71: e200z420n3 Core Debug Support* and *Chapter 70: e200z425n3 Core Debug Support*.

13.2 Run control and memory access

Run control is any operation required to control device operation. Run control includes starting and stopping the processor's execution of code, as well as accessing memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both Boundary Scan and Debug modes. It is based on the IEEE 1149.1 and IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can either be fed directly from the JTAG pins or the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross-triggering of events from the device. The SPU can access some of the DCU run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the $\overline{\text{EVTI}}$ pins. Furthermore, the SPU can use system triggers to cause

many different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

13.2.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug and calibration features. The DCI module includes the device JTAG Controller and the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tools or software
- Port-sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Simultaneous operation for debug and calibration features

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. *Table 166* summarizes the sources and destinations of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the PD and the BD. For example, for the PD, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU, and inputs to the Cores, HSM, GTM, and NXMC.

Table 166. PD DCI signals

Signal	Cores	HSM	GTM	NXMC	NAR	JTAGM	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	I	I	—	O	I/O	—
$\overline{\text{EVTI}}$[1]	—	—	—	—	—	O	I/O	—
$\overline{\text{EVTO}}$[0]	O	O	O	O	—	I	I/O	—
$\overline{\text{EVTO}}$[1]	—	—	—	—	—	I	I/O	O
Core debug event	I	—	—	—	—	—	—	—
DCI cross triggering	O	—	O	—	—	—	—	—

Table 167. BD DCI signals

Signal	RWA	NAR	NAL	JTAGM
$\overline{\text{EVTI}}$[0]	—	I	—	O
$\overline{\text{EVTI}}$[1]	—	—	—	O
$\overline{\text{EVTO}}$[0]	—	—	—	I
$\overline{\text{EVTO}}$[1]	—	—	—	I

The DCI sends the system debug signal, ipg_debug, to the following modules. For details regarding module functionality during system debug, refer to the individual module chapter.

- AMU
- CAN
- LFAST (Interprocessor Communications instance only)
- DSPI
- eDMA
- FCCU
- GTMINT
- I2C
- NXMC
- PIT
- PSI5
- SARADC
- SDADC
- SRX
- SSCM
- STM
- SWT

13.2.1.1 DCI $\overline{\text{EVTx}}$ Pin Multiplexing Control Register (DCI_PINCR)

The DCI $\overline{\text{EVTx}}$ pin multiplexing control register (DCI_PINCR) is described below. The $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ functions share the same set of possible pins. If this register is written to enable both $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ on the same pin, the $\overline{\text{EVTI}}$ function is selected, although this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}$[0] or $\overline{\text{EVTI}}$[1] inputs to come from more than one pin is considered a programming error and no pin is enabled.

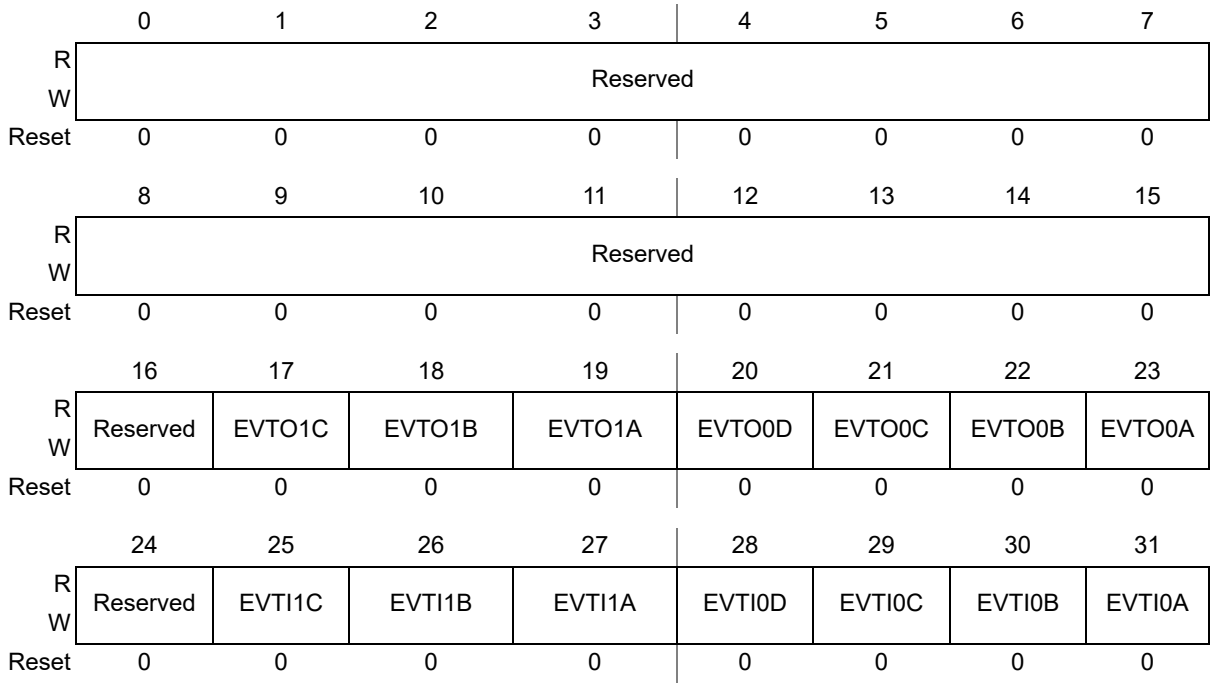

Figure 94. DCI EVTx pin multiplexing control register (DCI_PINCR)

26 EVTI1B	Enables $\overline{\text{EVTI}}$[1] function on pin PK[14]
27 EVTI1A	Enables $\overline{\text{EVTI}}$[1] function on pin PH[11]

Table 168. DCI_PINCR register field descriptions (continued)

Field	Description
28 EVTI0D	Enables $\overline{\text{EVTI}}$[0] function on pin PM[5]
29 EVTI0C	Enables $\overline{\text{EVTI}}$[0] function on pin PM[4]
30 EVTI0B	Enables $\overline{\text{EVTI}}$[0] function on pin PF[15]
31 EVTI0A	Enables $\overline{\text{EVTI}}$[0] function on pin PF[14]

13.2.1.2 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG Controller.

13.2.1.3 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

13.2.2 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows both JTAG and software access to two registers. These two registers are the challenge/response password authorization registers used by the Hardware Security Module (HSM).

13.2.3 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

13.2.3.1 SPU Level1 Input Mux Configuration registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0 to 7) are described in the following tables.

The L1SEL0 register fields are described in the following table.

Table 169. L1SEL0 register field descriptions

13.3 Calibration interface

This device includes an alternate calibration interface for high-speed run control and advanced software control. This calibration interface is based on the LFAST interface. The LFAST based calibration has the ability to perform all of the functions that JTAG supports, only at a faster speed. The MCU implements the slave module, and the pins for the LFAST interface are multiplexed onto the same pins as the JTAG pins. Initially, the device powers up with the JTAG module in control of the pins. Under tool commands, the LFAST interface

can be enabled and the pins become LFAST signals. Once the LFAST interface has been activated, all run control and other JTAG operations are converted in the MCU from LFAST messages into JTAG control operations of the JTAG Controller. The interface is supported entirely in hardware for both LFAST and JTAG modes, with no software or system overhead required to support interface traffic.

Table 177. Reference links to related information

Related module	Reference
JTAG Master (JTAGM)	*Chapter 77: Buddy Device—JTAG Master (JTAGM)*
LFAST Module (LFAST)	*Chapter 80: LVDS Fast Asynchronous Serial Transmission – High Speed Debug*
Development Tool Semaphore (DTS)	*Chapter 81: Development Trigger Semaphore (DTS)*

13.3.1 JTAG Master (JTAGM)

The JTAG Master (JTAGM) acts as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or through software.

The data transferred to this module is transformed to produce TCK, TMS, TDI, and TRST outputs and to accept TDO inputs. The module allows these five signals to connect to the JTAGC as if the JTAG data were coming from an external tool. The JTAGM generates all required JTAG scan chains to allow software and high-speed serial communication access to all JTAG-mapped resources.

13.3.2 Debug LFAST

The high-speed calibration interface provides up to a 320 Mbit/s interface between a calibration tool and the device. The calibration interface uses the LFAST as the physical layer between the tool and the JTAGM for access to debug resources. In addition, an LFAST switch allows direct access to read and write memory. The calibration debug LFAST module is one of two instantiations of the LFAST module on the device. The calibration LFAST is configured for slave-only operation and is meant to be used as a calibration interface to provide higher (than JTAG) speed debug and calibration operations.The calibration LFAST interface supports full duplex operation, where the available bandwidths for upstream and downstream traffic are independent.

13.3.3 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways that this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data-acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus auxiliary port.

13.4 Debug over CAN

As well as supporting debug via JTAG and LFAST interfaces, the device supports the use of a CAN interface for debug. This allows debug of application hardware where access to the dedicated JTAG/LFAST interface signals is not easily available. The debug over CAN mechanism is intended to provide basic debug functionality with some reduction in bandwidth and features compared to use of the dedicated JTAG or LFAST interfaces.

Use of the CAN interface for debug purposes requires the use of some M_CAN, eDMA and JTAGM resources. Some initialization of these resources via software is required, but once this initialization has completed, debug over CAN is possible without any further software overhead.

As the debug over CAN scheme generates internal JTAG messages based on received CAN data, all JTAG clients and included debug resources are accessible. Basic device trace capability is also possible by configuring the device trace hardware to stream to a device overlay/trace RAM, which can be read later using debug over CAN.

The debug over CAN scheme supports the following features:

- Supports operation through CAN_SUB_0_M_CAN_1 or CAN_SUB_0_M_CAN_2 interfaces
  - Makes use of M_CAN debug enhancements
  - Debug message selected by filter configuration SFEC/EFEC=111
- Allows debug of hardware where JTAG access is not available
- Debug traffic carried over application CAN bus
- Debug traffic on CAN coexists with application traffic
- No software overhead after initialization
- flexible selection of CAN identifiers for debug use
- Access to all JTAG debug facilities, includes CPU run control

13.5 Nexus Trace Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at high speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and the striping of information across the lanes. The Aurora interface is only available on the Emulation and Debug Device. Trace information is transferred to the Buddy Device for transmission via the Aurora interface.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the MCU.Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client; generally, it can be individually enabled (both the type of message and the client). *Table 178* shows a few examples of Nexus messages. All messages can be enabled to include a timestamp.

Table 178. Nexus message types

Message Type	Description
Program trace	Nexus program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership trace	Ownership trace provides information on process identification changes.
Watchpoint trace	Watchpoint messages are generated any time a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device identification	The device identification message allows information about the MCU to be transmitted upon startup to allow tools to identify the target system MCU type.
Debug status	Debug status messages provide additional information that may be needed to reconstruct software execution, such as whether the device has entered Debug or Low-power mode.
Data acquisition	Data acquisition messages are an optional feature that allows software control of information to be transmitted.
Error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory, or the parallel information can be serialized for transmission over a serial interface through the Nexus Aurora interface. Nexus trace information can also be routed through the Data Write Processing Unit (DWPU) as described in *Section 13.7: Data trace filtering*.

The Nexus blocks do not have memory-mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 179. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Production Die		
Cores	CORE_ENABLE	0x7C (10 bits)
NXMC	NEXUS_ENABLE	0x0 (4 bits)

RWA	CORE_ENABLE	0x7C (10 bits)

Table 179. Nexus client JTAG enable instructions (continued)

Module	Enable instruction	Opcode
NAR	NEXUS_ENABLE	0x0 (4 bits)
NAL		
DWPU		

All of the internal JTAG modules are accessed through a single JTAG connection to the device. In the case of the ED, all JTAG communication is performed through the JTAG interface located in the BD. In the production package configuration, access is performed through the JTAG interface located in the PD.

With the hierarchical JTAG configuration, the BD JTAGC is considered the master JTAG TAP controller. The PD JTAGC TAP controller is selected via an AUX_ACCESS instruction. Other TAP controllers residing on the BD are also selected via AUX_ACCESS instructions (NAR, RWA, BD_DCI). Once control is transferred from the BD JTAGC to the PD JTAGC via the AUX_ACCESS instruction, all other PD TAP controllers are then selected via AUX_ACCESS instructions executed by the PD JTAGC. This is also referenced as TAP-sharing and is shown in the following figure.

Note: On the Emulation device, when the PAUSE-DR/UPDATE-DR state is executed to pass control of the JTAG TAP controller, control is always passed to the top level JTAG TAP controller, in other words, the DCI of the BD. For this reason, it is recommended that all JTAG operations, except when the BD clients need to be accessed, that all PD JTAG access be preceded with ACCESS_PD_JTAGC command. If the device is not an ED, the access is ignored.

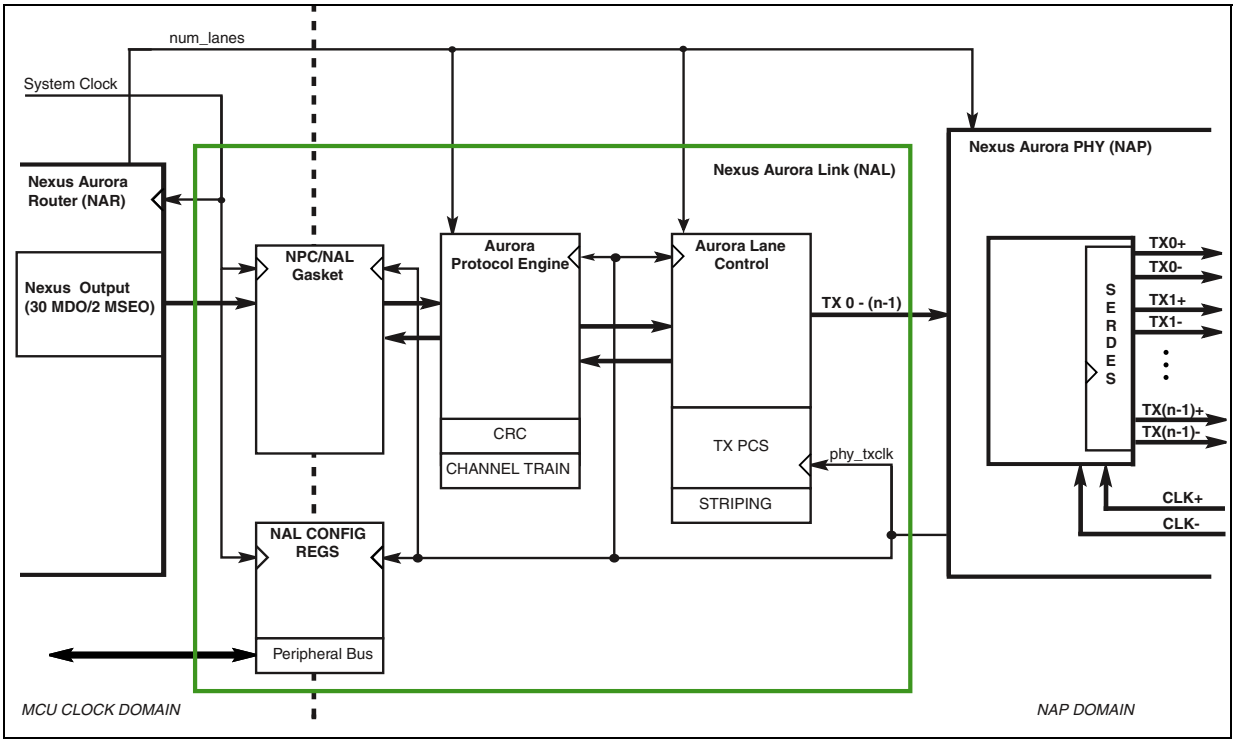
13.5.1 Nexus Aurora overview



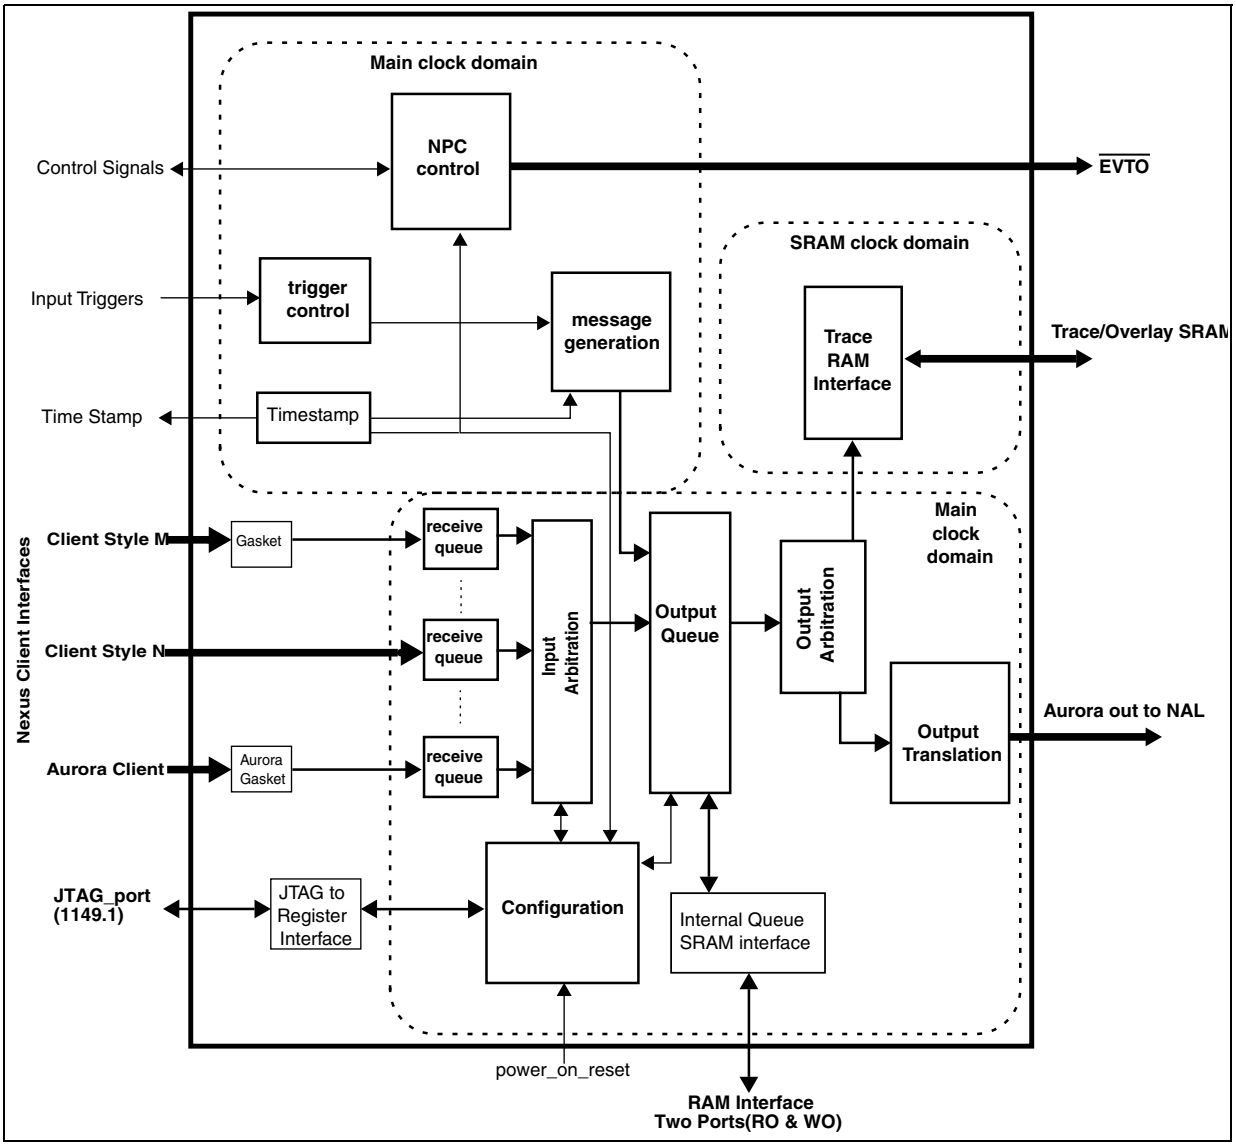
The IEEE-ISTO 5001-2011 standard adds a new type of auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8b/10b encoded LVDS driver. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on the XAUI (10 Gigabit Attachment Unit Interface) standard used in communication protocols, which covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation uses a simplex output-only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC), and the Nexus Aurora Physical interface (NAP). *Figure 96* shows the Aurora interface block diagram, where the number of lanes, *n*, is 4.

Figure 96. Aurora interface block diagram



13.5.2 Nexus Aurora Router (NAR)

The Nexus Aurora Router (NAR) manages the Nexus trace information from each of the Nexus clients. The NAR takes the parallel trace information from each of the clients, buffers it to avoid overruns, and routes it to either the internal overlay RAM or the Buddy Device, where it is stored in on-chip SRAM or transmitted out of the device through the Aurora interface.

16 KB of trace SRAM is available on the PD (located in the flash module), and 2 MB of trace SRAM is available in the ED. (Some of this SRAM may be used for calibration overlay content as well as trace content.) Similarly, a smaller NAR output queue is located on the PD (2 KB), and a much larger NAR output queue is located in the ED (8 KB). The physical Aurora pins are only available on the ED. *Figure 97* shows the NAR block diagram.

Figure 97. NAR block diagram

The PD NAR module has ten clients, with client index 1–10. Clients 11–16 are not connected. The client connections and the corresponding NAR client index are shown in *Table 181*. The NAR client index is used in the NAR_STCR, NAR_CSSR, and NAR_CDR registers. The source trace ID is used in the NAR_SFR.

Table 181. PD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
—	NAR	0b1111 (0xF)	—
1	GTM	0b0111 (0x7)	3
2	HSM	0b0011 (0x3)	1
3	Core 0	0b0000 (0x0)	1

Table 181. PD NAR clients (continued)

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)

10	NXMC Client 4	0b1010 (0xA)	1
11	—	—	—
12	—	—	—
13	—	—	—
14	—	—	—
15	—	—	—
16	—	—	—

The BD NAR module has one client and the client connections and the corresponding NAR client index are shown in *Table 182*.

Table 182. BD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
1	PD NAR	0b1110 (0xE)	2

The NAR is limited writing trace information to the overlay RAM. The PD NAR only has access to the 16 KB internal overlay RAM. Therefore, the PD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0D000000–0x0D003FFF. The BD NAR also has access to 2 MB of extended overlay RAM. Therefore, the BD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0C000000–0x0C1FFFFF.

The NUM_LANE field of the NAR_NAPCR is described in *Table 183*.

Table 183. NAR_NAPCR field descriptions

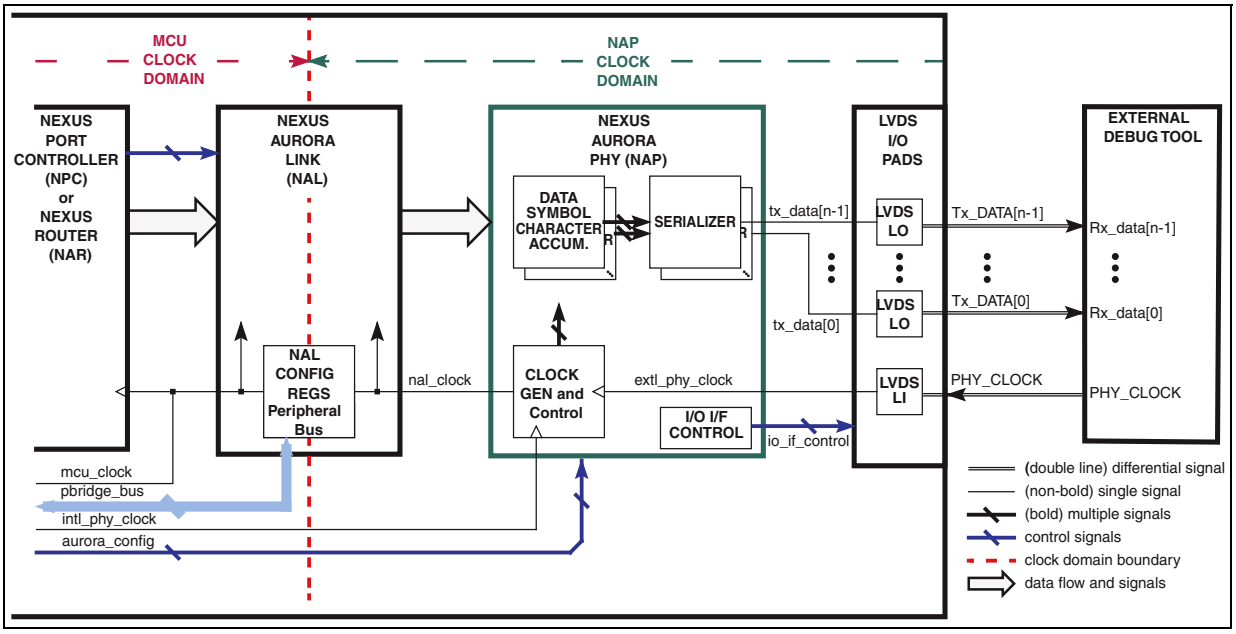
Field	Description
19:16 NUM_LANE	TX Lane Configuration – Number of enabled TX lanes 0000 Disable NAP and NAL 0001 Reserved 0010 Enable 2 lanes (Lane 0–1) 0011 Reserved 0100 Enable 4 lanes (Lanes 0–3) 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved ... 1111 Reserved

13.5.3 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) is only included in the Emulation and Debug Device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into a 32-bit format by the clients and then collected by the NAR. The NAL encodes the message data (8b/10b), stripes it across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters, and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

13.5.4 Nexus Aurora PHY (NAP)



The Nexus Aurora PHY (NAP) is only included in the Emulation and Debug Device. The NAP, in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY lane's LVDS pads. The NAL performs lane striping with settings in the NAL and NAR specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator that registers the 10-bit character for that lane from the ALC on the rising edge of the NAL clock. A serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called “lane alignment” in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

Figure 98 shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, n, is 4.

Figure 98. NAP block diagram

13.6 Nexus clients

Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the device.

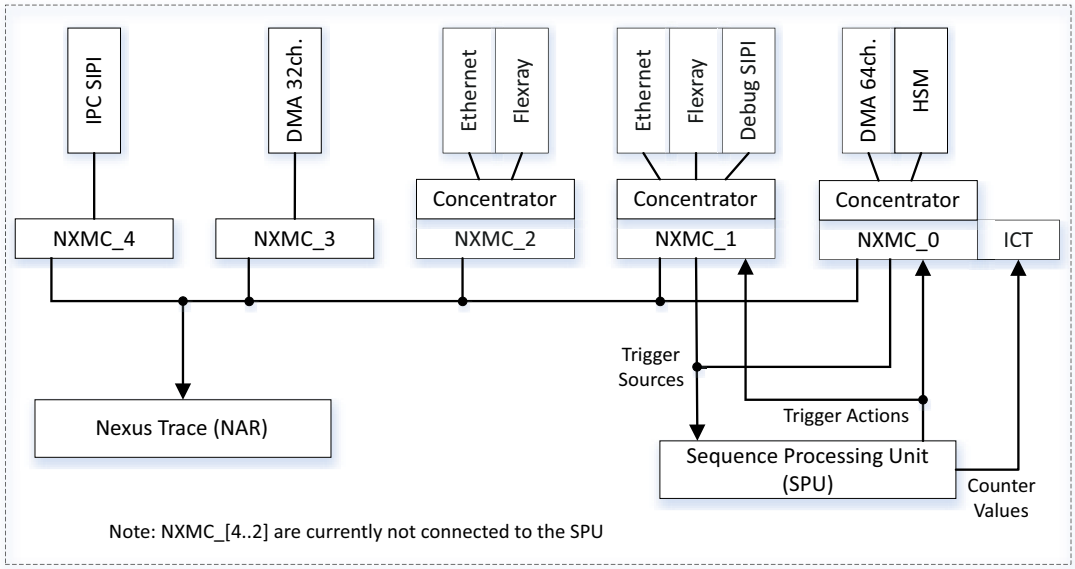
13.6.1 e200z4 Nexus 3

The e200z420n3 and e200z425n3 Nexus 3 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

13.6.2 GTM Development Interface (GTMDI)

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, Input Channel Filters trace, Output Timer channels, DPLL and Sensor Pattern Evaluation (SPE) module submodules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global timestamp that allows real-time trace for several GTM submodule events. The GTMDI implements a Nexus client standard interface and a JTAG standard port controller to provide communication capability via the JTAG port and the on-chip NAR.



13.6.3 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Five NXMCs are implemented, out of which only two interact with the SPU. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four in total—two from each NXMC) for events from the SPU.

The following figure shows a block diagram illustrating the NXMC integration.

Figure 99. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 185. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
XBAR Client 0 Concentrator	Hardware Security Module (HSM) data trace	0b1100	0b0000
	eDMA_1 Controller		0b0001
XBAR Client 1 Concentrator	Debug SIPI	0b1101	0b1000
	FlexRay_0		0b1001
	Ethernet_0		0b1010
XBAR Client 2 Concentrator	FlexRay_1	0b1000	0b0100
	Ethernet_1		0b0101
direct master	eDMA_0 controller	0b1001	ob1100
direct master	IPC SIPI	ob1010	ob1110
Data Write Processor Unit (DWPU)	e200zx core	—(1)	0b1111

1. The Nexus trace Source ID is the same as the original core SRC.

13.7 Data trace filtering

The Data Write Processing Unit (DWPU) supports data trace filtering as well as out of range parameter identification.

Table 186. Reference links to related information

Related module	Reference
Data Write Processing Unit (DWPU)	*Chapter 98: Buddy Device—Data Write Processing Unit (DWPU)*

DWPU operates in conjunction with the BD NAR and a small RAM array. DWPU receives its input trace stream from the BD NAR Nexus Out Link. The trace stream is initially decompressed (which includes conversion of relative address and data values to absolute values) to ease subsequent filtering and comparison operations. The decompression process tracks multiple contexts, with individual context tracking required for each supported Nexus client.

The processed stream then passes through an address compare block, that generates tag RAM addresses corresponding to a portion of each data write address within the trace stream. Another portion of the data write addresses is used to select a particular bit from the data word returned by the tag RAM, so that each tag RAM bit corresponds to a unique 64-bit data write address. The value of the selected bit determines whether the data write trace occurrence is passed out of the DWPU back to the BD NAR, or is removed from the trace stream. DWPU returns the data trace filtered and re-formatted stream back to a secondary Nexus client input port on the BD NAR.

14 e200z4d Core Complex Overview

The SPC58xEx/SPC58xGx has five separate cores that perform various computational and control functions. They are organized in three processing channels, two of which with a functional core and a lock step replica.

- The main computational shell consists of 2 processing channels (Main Core_0 and Main Core_1), both of which use an e200z420n3 core. These two cores are used for general computational functions.
- Only Main Core_0 uses an e200z419 core (Checker Core_0) as lock step replica. The e200z419 is a true subset of the e200z420n3 core. When enabled, the checker core operates in lock step mode with the associated main core executing exactly the same instructions. Thus, the checker core insures that the main core is executing correctly.
- The third processing channel is implemented with a lock-step pair of e200z425s and is generally used to control various I/O modules.

This chapter provides overviews of the e200z420n3, the e200z419, and the e200z425n3 cores.

The e200z420n3, e200z419, and e200z425n3 cores are very similar. The register set for all these three cores is identical. The e200z425n3 core differs in hardware from the e200z420n3 core in several ways. The e200z425n3 core and e200z420n3 core have different amount of Instruction Cache. The e200z425n3 has no Data Cache. Also, the e200z425n3 incorporates a Lightweight Signal Processing Extension (LSP) APU to provide support for real time SIMD fixed point embedded numeric operations. The e200z419 core differs in hardware from the e200z420n3 in that no Instruction Cache, Data Cache, I-memory or D-memory are implemented.

14.1 Overview of the e200z420n3, e200z419, and e200z425n3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

The e200z420n3, e200z419, and e200z425n3 are dual-issue, 32-bit Power VLE compliant designs with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

The e200z420n3, e200z419, and e200z425n3 cores implement the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document. The base *PowerISA 2.06* fixed-length 32-bit instruction set is not directly supported.

The e200z420n3, e200z419, and e200z425n3 processor cores integrate a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

A Nexus Class 3+ module is integrated into each e200z420n3, and e200z425n3 processor core.

A Memory Protection Unit is integrated in each e200z420n3, e200z419, and e200z425n3 processor core.

14.2 Features

The following is a list of some of the key features of the e200z420n3, e200z419, and e200z425n3 processor cores:

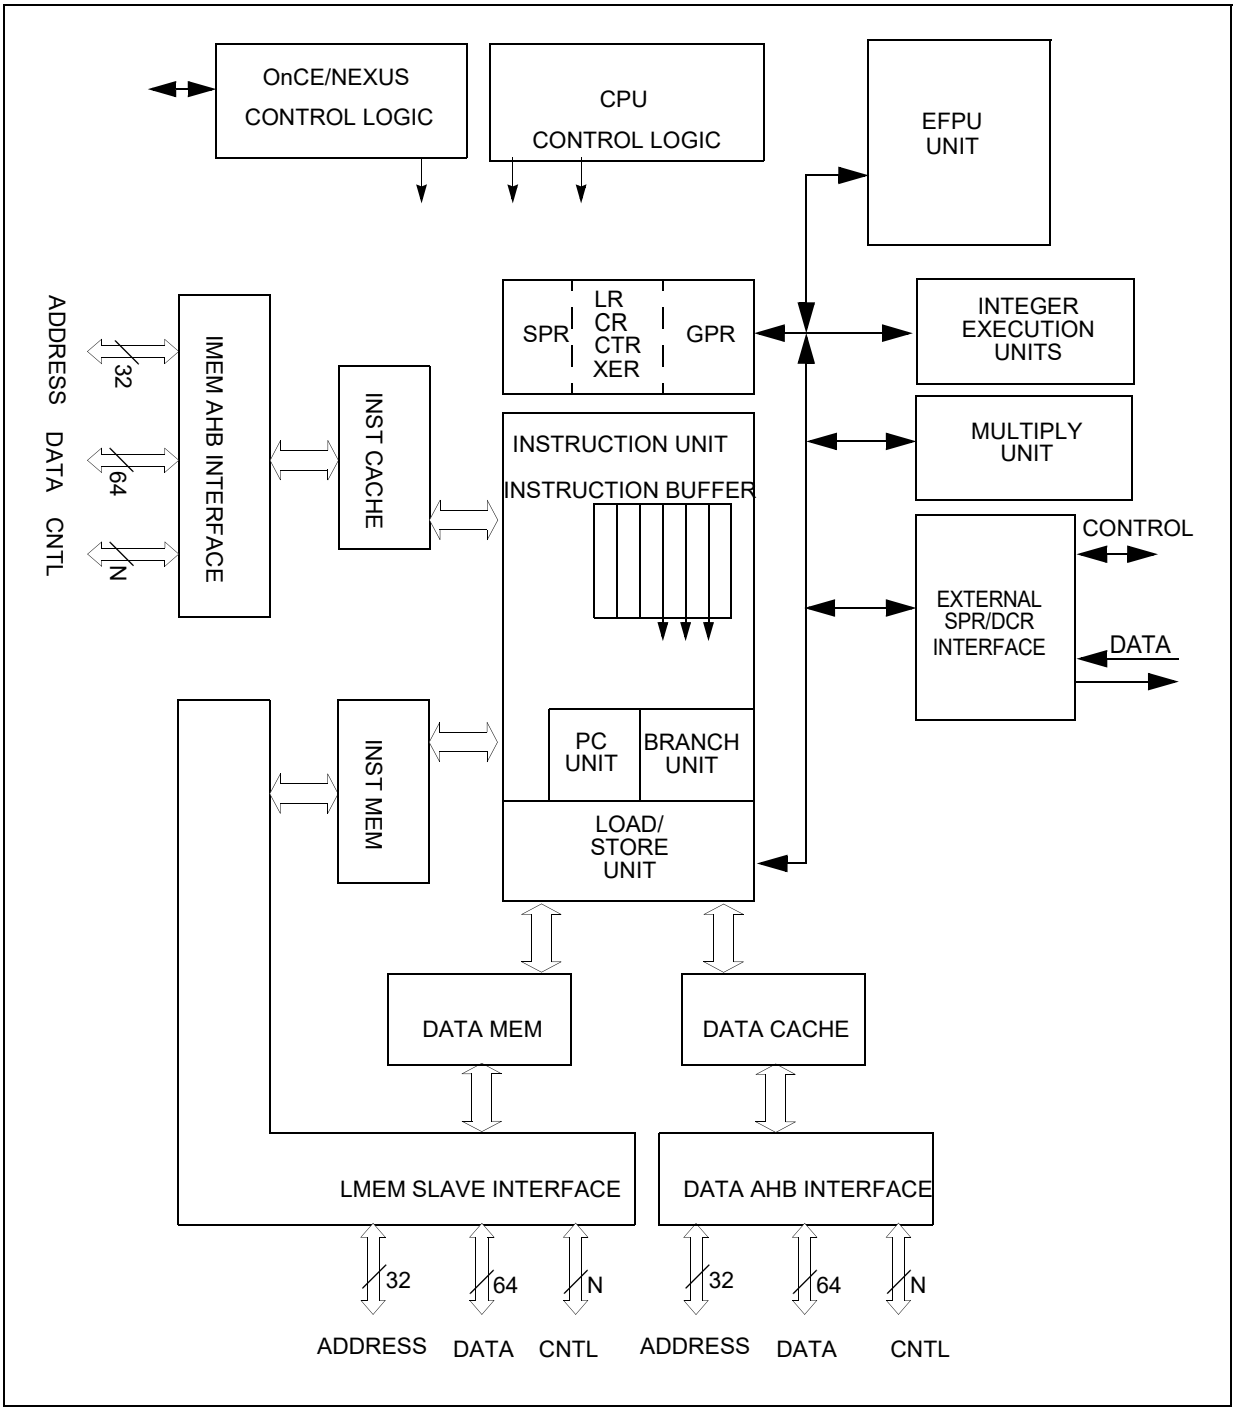
- Dual issue, 32-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
  - Return Address Stack
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit System buses
- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z420n3 core—16 KB IMEM, 64 KB DMEM
  - e200z425n3 core—16 KB IMEM, 32 KB DMEM
  - e200z419 core does not contain either Instruction or Data MEM
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
  - e200z420n3 core—8 KB ICache, 4 KB DCache
  - e200z425n3 core—8 KB ICache, no DCache
  - e200z419 core does not contain either Instruction or Data Cache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Lightweight Signal Processing (LSP) APU (e200z425n3 core only) supporting fixed-point multiply/accumulate and integer/fixed point operations using the 32-bit General Purpose Register file.
- Performance Monitor APU supporting execution profiling
- Nexus Class 3-plus Real-time Development Unit
- Power management
  - Low power design with extensive clock gating
  - Power saving modes: doze, nap, sleep, wait
  - Dynamic power management of execution units, caches and Local memories
- Testability
  - Synthesizeable, MuxD scan design
  - ABIST/MBIST for arrays
  - Built-in LBIST unit

14.3 Microarchitecture summary

The e200z420n3, e200z419, and e200z425n3 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/ EA Calc, Execute 0/ Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. *Figure 100* shows a block diagram of the e200z architecture.

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. The integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.



The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Figure 100. e200z block diagram

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The LSP APU (included only on the e200z425n3 core) supports vector instructions operating on 16-bit and 32-bit fixed-point data types. The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats and operates in a pipelined fashion. The 32-bit

general purpose register file is used for source and destination operands. There is a unified storage model for scalar single-precision floating-point data types of 32-bits and the normal integer type. Low latency floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided. Most operations can be pipelined.

14.3.1 Instruction unit features

The features of the e200z420n3, e200z419, and e200z425n3 Instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to 8 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

14.3.2 Integer unit features

The e200z420n3, e200z419, and e200z425n3 integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero’s function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

14.3.3 Load/Store unit features

The e200z420n3, e200z419, and e200z425n3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

14.3.4 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier
- Programmable Memory Attributes
- Entry Invalidation Protection
- Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

14.3.5 Cache features

The features of the Caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
  - e200z420—8 KB ICache, 4 KB DCache
  - e200z425—8 KB ICache, No DCache
  - e200z419—No ICache, No DCache
- Writethrough Support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Supports Way locking
- Supports Write allocation policies
- Supports multi-bit EDC with Correction/Auto-invalidation capability for the I and D caches
- Hardware Debug Cache Invalidate Support for the Data Cache
- Software and Hardware Debug access to cache tag, status and data storage via dedicated control registers

14.3.6 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z420n3—16 KB IMEM, 64 KB DMEM
  - e200z425n3—16 KB IMEM, 32 KB DMEM
  - e200z419—No IMEM, No DMEM
- Instruction and data memories (IMEM, DMEM) are not duplicated on e200z419 core.
- Supports zero wait-state access relative to cache hit timings
- Supports multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate unidirectional 64-bit read data bus and (for DMEM only) 64-bit write data bus

14.3.7 e200z420n3 and e200z425n3 system bus features

The features of the e200z420n3 and e200z425n3 System Bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

14.3.8 e200z419 system features

Checker Core_0 is implemented using an e200z419 core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z419 core can only be enabled or disabled by the user. For the SPC58xEx/SPC58xGx device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z419 core is identical to the e200z420n3 with five exceptions:

- IMEM memory array is not present
- ICACHE memory array is not present
- DMEM memory array is not present
- DCACHE memory array is not present
- The e200z419 has a pair of system bus interfaces, which are driven/sampled by the delayed lockstep logic

15 Core (z420n3) Description

15.1 Overview of the Core (z420n3)

Core (z420n3) is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general purpose registers (GPRs). The Core (z420n3) core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The Core (z420n3) processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

Core (z420n3) contains an 8 Kbyte Instruction Cache, and a 4 Kbyte Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit is also included which supports protections of various instruction and data memory areas.

15.2 Register Model

This section describes the registers implemented in the Core (z420n3) core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

Core (z420n3) extends usage of the General Purpose Registers to support EFPU APU operations operating on the 32-bit GPR registers.

Figure 101 and *Figure 102* show the complete Core (z420n3) register set, all of which are accessible in supervisor mode. *Figure 103* and *Figure 104* show the subset of registers which are accessible while in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 101. Core (z420n3) Supervisor Mode Programmer's Model SPRs

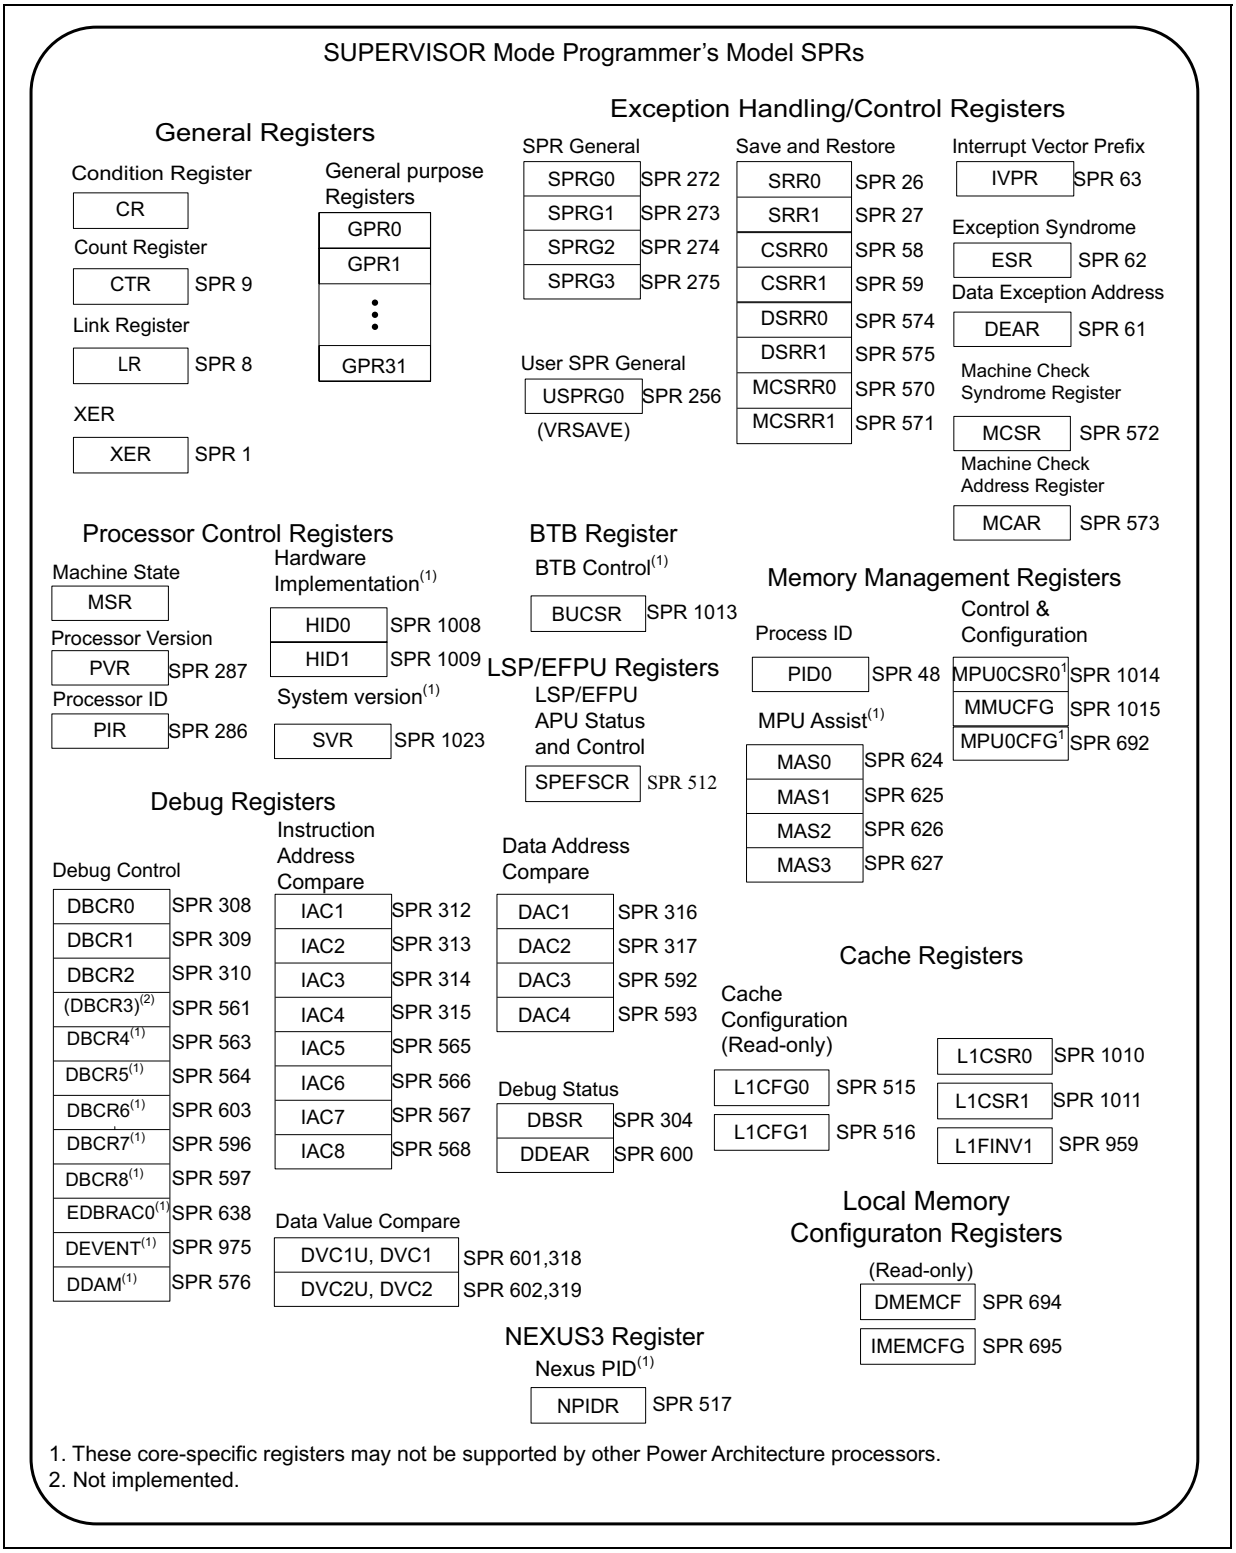


Figure 102. Core (z420n3)Supervisor Mode Programmer's Model DCRs and PMRs

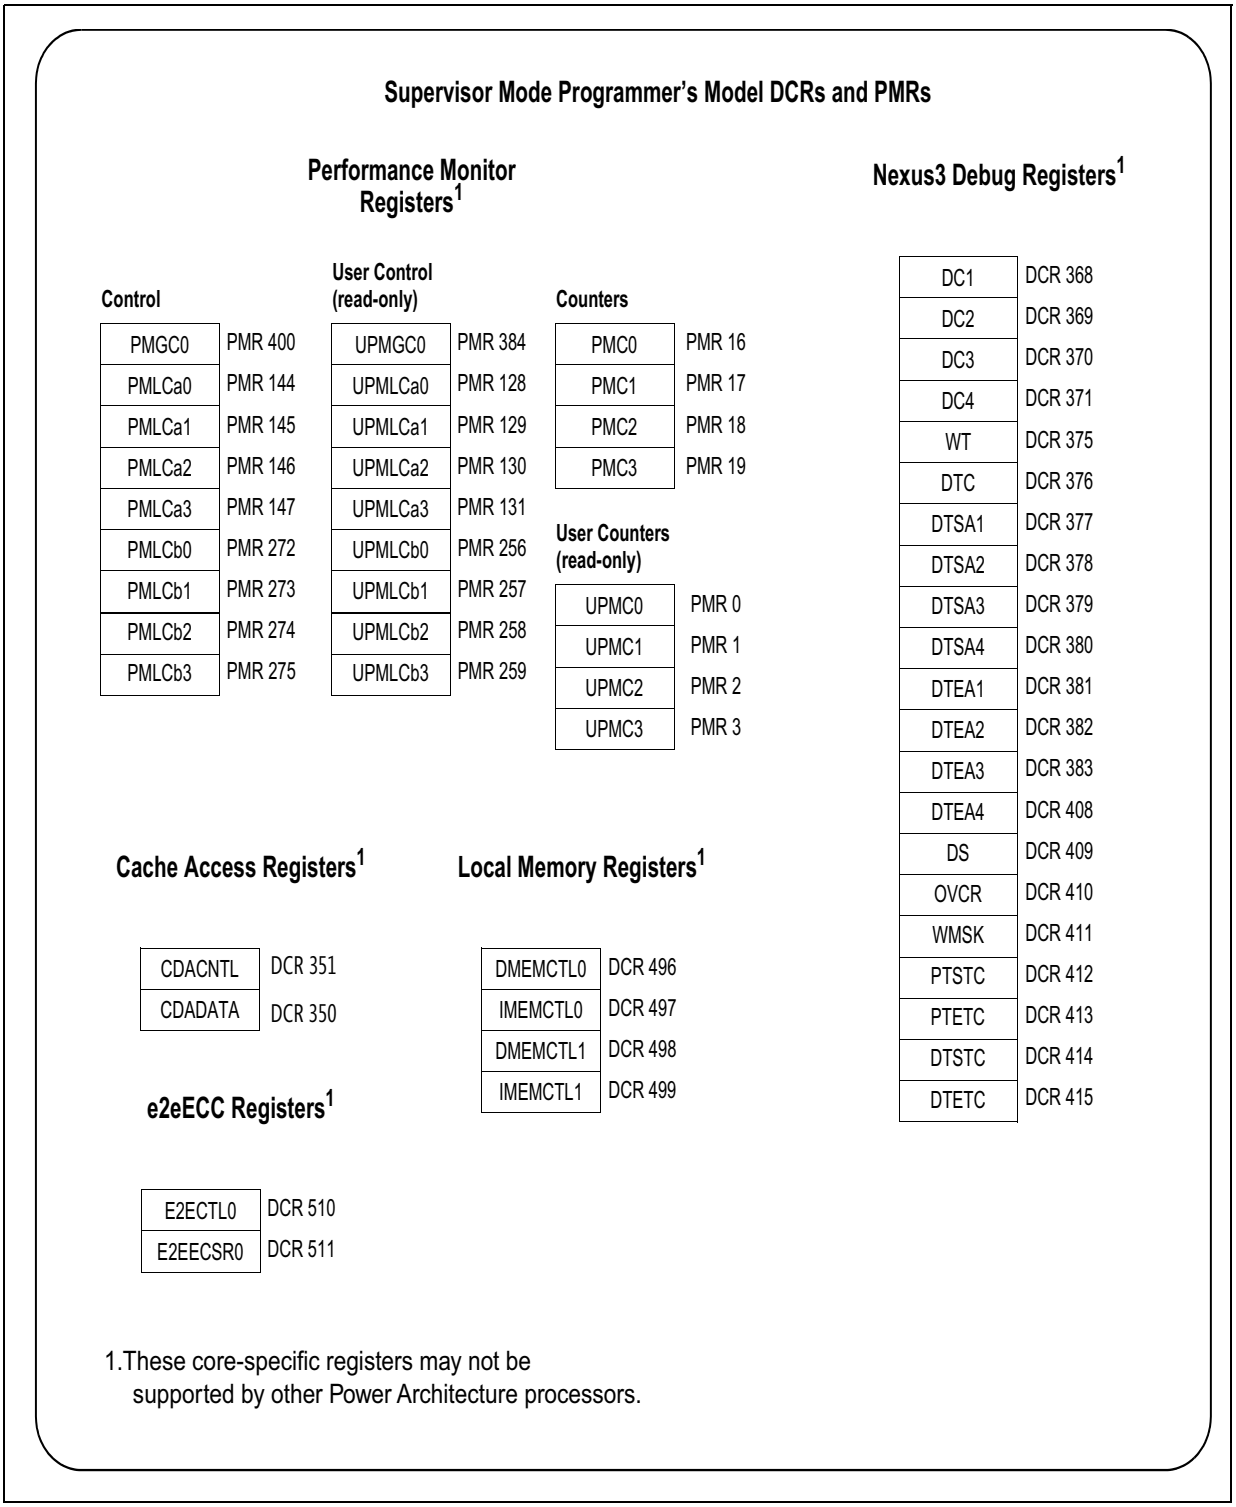

Figure 103. Core (z420n3) User Mode Programmer's Model SPRs

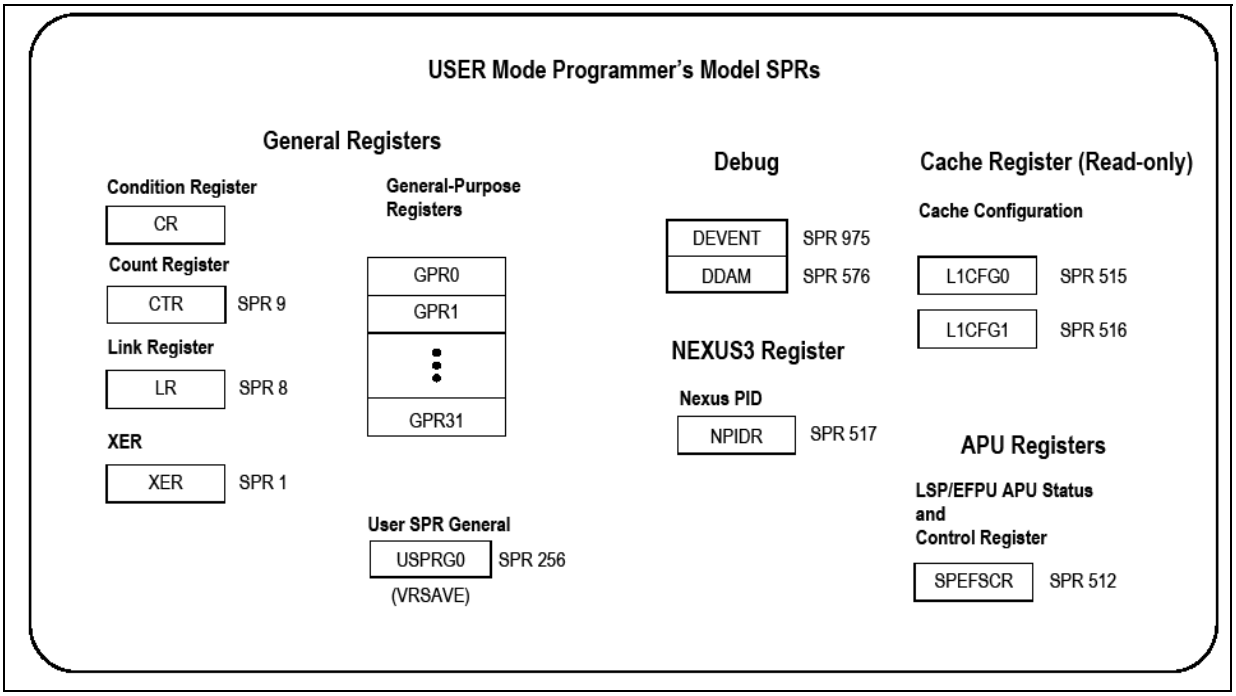

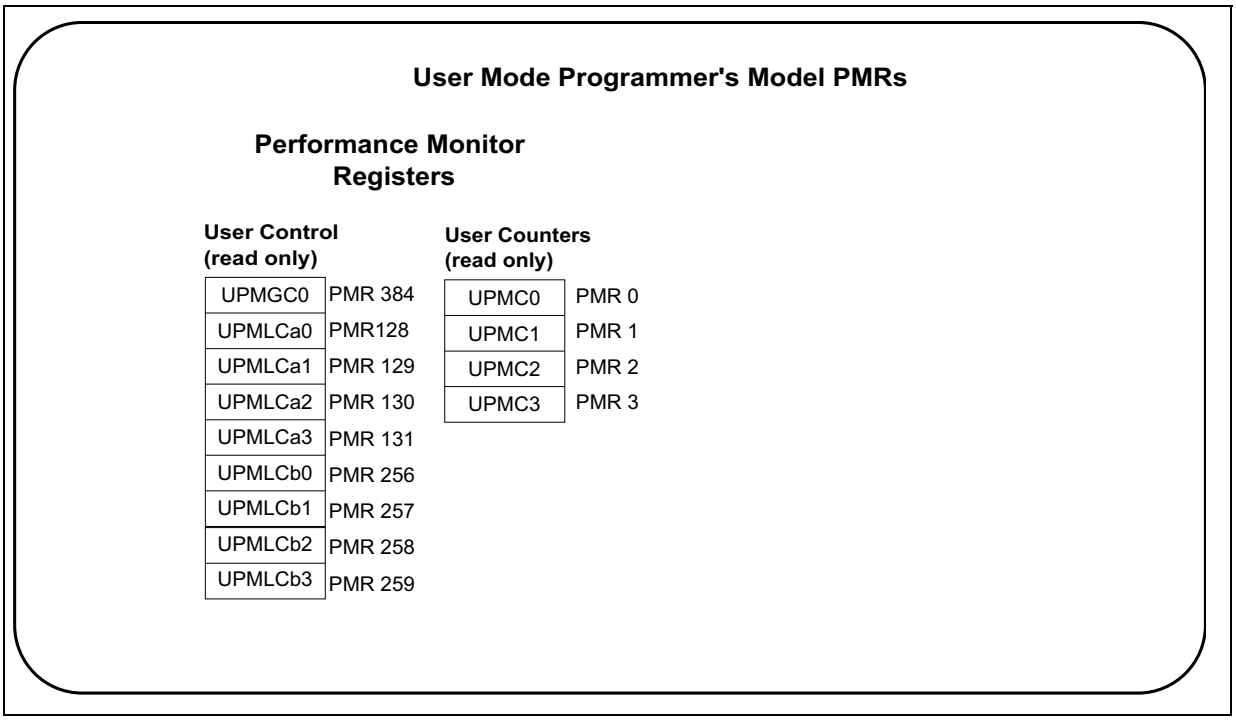

Figure 104. Core (z420n3) User Mode Programmer's Model PMRs

15.3 Dual Issue Operation

The instruction issue unit attempts to issue a pair of instructions each cycle to the execution units. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions which cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

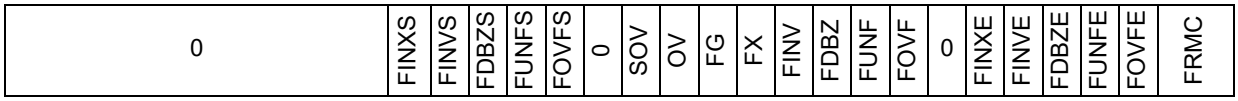
The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

Table 187 shows the Core (z420n3) concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue.

Table 187. Concurrent Instruction Issue Capabilities

Class of Instruction	branch	load/store	scalar integer	scalar float	vector integer non-MAC	vector integer MAC	special
branch	—	yes	yes	yes	yes	yes	—
load/store	yes	—	yes	yes	yes	yes	—
scalar integer	yes	yes	yes(1)	yes	yes	yes(2)	—
scalar float	yes	yes	yes	—	yes	yes	—
vector integer non-MAC	yes	yes	yes	yes	—	—	—
vector integer MAC	yes	yes	yes(2)	yes	—	—	—
special	—	—	—	—	—	—	—



1. excludes multiply or divide class instructions occurring in both issue slots
2. excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions

15.4 Reservation Instructions and Cache Interactions

The Zen core treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**., **sthcx**., and **stwcx**.) accesses as though they were cache inhibited, and forces a cache miss. A reservation access is always issued to the bus.

15.5 Signal Processing Extension / Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point uses the SPEFSCR register. The SPEFSCR register is implemented as special purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in *Figure 105*.

SPR - 512; Read/Write; Reset - 0x0

Figure 105. DSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in *Table 188*.

Table 188. EFPU Status and Control Register

Bits	Name	Description
0:9	—	Reserved
10	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF=1), but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1), but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
11	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
12	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
13	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
14	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
15	—	Reserved
16	SOV	Summary integer overflow Defined by LSP APU.
17	OV	Integer overflow Defined by LSP APU.
18	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.

Table 188. EFPU Status and Control Register (continued)

Bits	Name	Description
20	FINV	Embedded Floating-point Invalid Operation / Input error The FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0.
21	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24	—	Reserved
25	FINXE	Embedded Floating-point Inexact Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF=1) but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1 or FUNFH=1) but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs.
26	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction.
27	FDBZE	Embedded Floating-point Divide by Zero Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction.
28	FUNFE	Embedded Floating-point Underflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction.

Table 188. EFPU Status and Control Register (continued)

Bits	Name	Description
29	FOVFE	Embedded Floating-point Overflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction.
30:31	FRMC	Embedded Floating-point Rounding Mode Control 00 = Round to Nearest 01 = Round toward Zero 10 = Round toward +Infinity 11 = Round toward -Infinity

15.6 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.6.1 Cache Overview

The Core (z420n3) processor supports a 8 Kbyte 2-way set-associative instruction and 4 Kbyte 2-way set associative data cache with a 32-byte line size. The caches improve system performance by providing low-latency data to the Core (z420n3) instruction and data pipelines, which decouples processor performance from system memory performance.

Instruction and data addresses from the processor are used to index the cache array. If the access address matches a valid cache tag entry, the access hits in the cache.

15.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache as well as providing general control over disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in *Figure 106*.

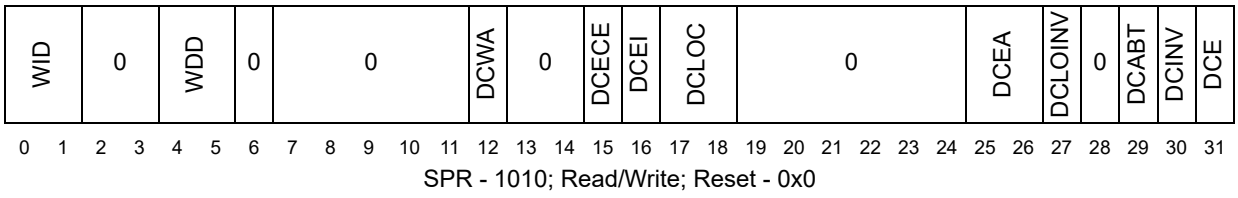


Figure 106. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 bits are described in *Table 189*.

Table 189. L1CSR0 Field Descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills. Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache.
2:3	—	Reserved(1)
4:5	WDD	Way Data Disable. 0 = The corresponding way in the data cache is available for replacement by data miss line fills. 1 = The corresponding way in the data cache is not available for replacement by data miss line fills. Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache.
8:11	—	Reserved(1)
12	DCWA	Data Cache Write Allocation Policy 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled When enabled is a write misses the cache the cache line is loaded into cache before writing data.
13:14	—	Reserved(1)
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits. This includes writes due to store hits as well as writes due to cache line refills. DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE=0.

Table 189. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
17:18	DCLOC	Data Cache Lockout Control 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error. **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of error conditions.
19:24	—	Reserved(1)
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 1x Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation When written to a ‘1’ in conjunction with writing DCINV to a ‘1’, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value.
28	—	Reserved(1)
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

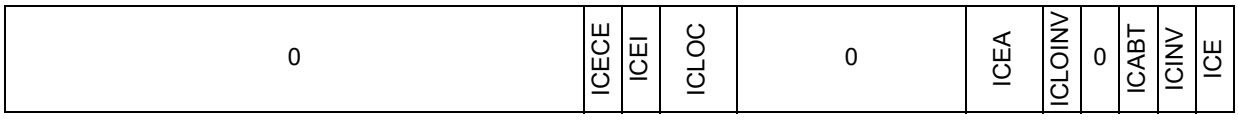

Table 189. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
30	DCINV	Data Cache Invalidate 0 No cache invalidate 1 Cache invalidation operation When written to a '1', a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to '0'. Writing a '1' while an invalidation operation is in progress will result in an undefined operation. Writing a '0' to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value.
31	DCE	Data Cache Enable 0 Cache is disabled 1 Cache is enabled When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE.

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in *Figure 107*.

SPR - 1011; Read/Write; Reset - 0x0

Figure 107. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 bits are described in *Table 190*.

Table 190. L1CSR1 Field Descriptions

Bits	Name	Description
0:14	—	Reserved(1)
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits. ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE=0.

Table 190. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
17:18	ICLOC	Instruction Cache Lockout Control 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error. **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of error conditions.
19:24	—	Reserved(1)
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 1x Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation When written to a ‘1’ in conjunction with writing ICINV to a ‘1’, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value.
28	—	Reserved(1)
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 190. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
30	ICINV	Instruction Cache Invalidate 0 No cache invalidate 1 Cache invalidation operation When written to a '1', a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to '0'. Writing a '1' while an invalidation operation is in progress will result in an undefined operation. Writing a '0' to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value.
31	ICE	Instruction Cache Enable 0 Cache is disabled 1 Cache is enabled When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE.

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the Core (z420n3) L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in *Figure 108*.

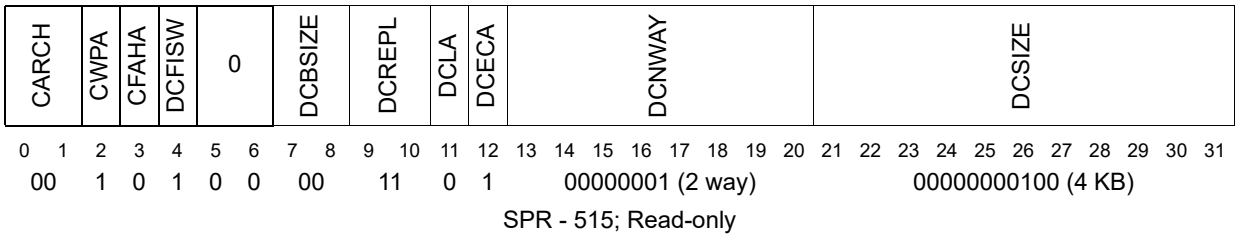

Figure 108. L1 Cache Configuration Register 0 (L1CFG0)

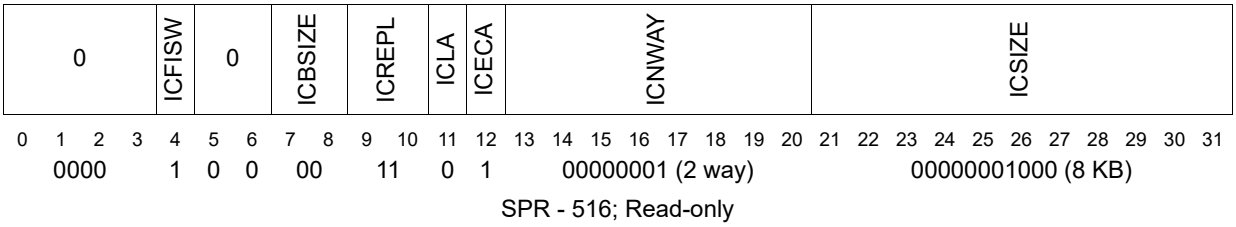
The L1CFG0 bits are described in *Table 191*.

Table 191. L1CFG0 Field Descriptions



Bits	Name	Description
0:1	CARCH	Cache Architecture 00 - The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 - The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 - The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 - The data cache supports invalidation by Set and Way via L1FINV0

Table 191. L1CFG0 Field Descriptions (continued)

Bits	Name	Description
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 - The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11- The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 - The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 - The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 - The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 - The size of the data cache is 4 Kbyte

15.6.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the Core (z420n3) L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in *Figure 109*.

SPR - 516; Read-only

Figure 109. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 bits are described in *Table 192*.

Table 192. L1CFG1 Field Descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 - The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 - The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 - The instruction cache implements a FIFO replacement policy

Table 192. L1CFG1 Field Descriptions (continued)

Bits	Name	Description
11	ICLA	Instruction Cache Locking APU Available 0 - The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 - The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 - The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 - The size of the instruction cache is 8 Kbyte

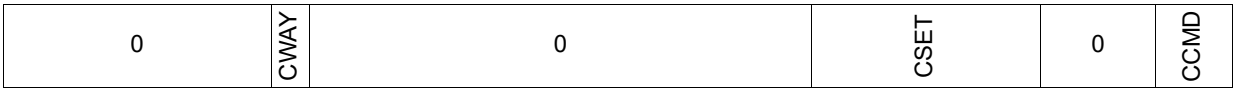
15.6.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

15.6.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided however for a Dcache line invalidation operation requested by an external hardware debugger to occur. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available DCache access cycle.



15.6.8 Cache Invalidate by Set and Way

Core (z420n3) supports cache set/way invalidation under software control. The caches may be invalidated by set and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

15.6.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in *Figure 110*.

SPR - 1016; Read/Write; Reset - 0x0

Figure 110. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in *Table 193*.

Table 193. L1FINV0 Field Descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8:20	—	Reserved for set extension
21:26	CSET	Cache Set Specifies the cache set to be selected
27:29	—	Reserved for set/command extension
30:31	CCMD	Cache Command 00 = The data contained in this entry is invalidated 01 = Reserved 1x = Reserved

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error.

15.6.8.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in *Figure 111*.

SPR - 959; Read/Write; Reset - 0x0

Figure 111. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in *Table 194*.

Table 194. L1FINV1 Field Descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:29	—	Reserved for set/command extension
30:31	CCMD	Cache Command 00 = The data contained in this entry is invalidated 01 = Reserved 1x = Reserved

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error.

15.6.9 Cache EDC/ECC Protection

Cache protection is supported for both the tag and data arrays of each cache. Tag arrays of both instruction and data caches support error detection and correction. Each doubleword in the data arrays of the ICache and for each word in the data arrays of the DCache, have single and double bit error detection.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error, to protect against internal addressing failures.

Tag ECC and data EDC checking is controlled by the $L1CSR0_{DCECE}$ and $L1CSR1_{ICECE}$ control fields. When error checking is enabled, checking is performed on each cache access.

For cache lookups due to instruction fetching, normal loads, or normal stores, if an uncorrectable tag ECC error is detected on any portion of the accessed tags, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, an error is also signaled.

Store hits to the Dcache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the Dcache during otherwise idle cycles once two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur, and one or more syndrome bits to be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled, or both may occur, depending on the error action control setting in the appropriate cache control register.

15.6.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the Icache and Dcache has a lockout indicator composed of a redundant set of lockout bits which can be selectively set when certain errors occur in either the tag or data portion of the cache line. Use of the lockout function and control over error conditions which cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines which encounter selected tag ECC or data EDC errors on normal cacheable instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Lockout indicators may be cleared by software performing a cache invalidation operation (setting $L1CSR\{0,1\}_{[D,I]CINV}$) in conjunction with a cache lockout indicator invalidation (setting

L1CSR{0,1}$_{[D,I]CLOINV}$). Three stored redundant lockout bits are provided to allow for single and double-bit parity errors to be detected on the lockout indicators themselves.

When operating in machine check mode, if lockout controls are enabled via L1CSR{0,1}$_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception. If correction/auto-invalidation is instead enabled, on each cache lookup operation, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by re-writing all lockout bits to the asserted state, and no machine check is generated.

Lockout bit parity errors are ignored for non-cacheable accesses in either error action mode. In addition, to avoid certain exception conditions and for consistency with error reporting, non-cacheable accesses and specialized load/store accesses do not set LO bits; instead, cache contents are ignored for those errors since the cache is bypassed. A future cacheable normal access will perform the lockout function if required.

15.6.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting EDC/ECC errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1$_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant EDC/ECC check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If L1CSR0$_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant EDC/ECC check bits inverted in the data array for each word loaded. Additionally, inverted bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the EDC/ECC bit errors, a cache invalidation or an invalidation of the lines which have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV[0,1] invalidation operation.

15.7 Exceptions

As specified by the PowerISA 2.06 architecture, interrupts can be either precise or imprecise, synchronous or asynchronous, and critical or non-critical. Asynchronous exceptions are caused by events external to the processor's instruction execution; synchronous exceptions are directly caused by instructions or an event somehow synchronous to the program flow, such as a context switch. A precise interrupt architecturally guarantees that no instruction beyond the instruction causing the exception has (visibly) executed. Critical interrupts are provided with a separate save/restore register pair (CSRR0/CSRR1) to allow certain critical exceptions to be handled within a non-critical interrupt handler. Machine check interrupts are also provided with a separate save/restore register pair (MCSRR0/MCSRR1) to allow machine check exceptions to be handled within a non-critical or critical interrupt handler. Debug interrupts are also provided with a separate

save/restore register pair (DSRR0/DSRR1) to allow debug exceptions to be handled within a critical, non-critical, or machine check interrupt handler.

Interrupts implemented in Zen and the exception conditions that cause them are listed in *Table 195*.

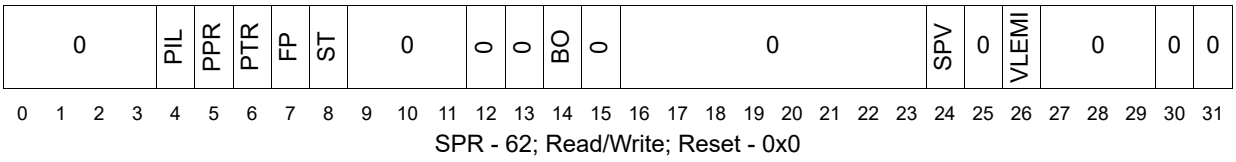


Table 195. Exceptions and Conditions

Interrupt Type	Interrupt Vector Offset Value	Causing Conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	1) Reset
Critical Input	0x00(1)	**p_critint_b** is asserted and MSR_{CE}=1.
Machine check	0x10	1) **p_mcp_b** transitions from negated to asserted 2) ISI or Bus Error on first instruction fetch for an exception handler 3) EDC/ECC Error signaled on cache or Local Memory access 4) External bus error 5) Stack limit check failure
Machine check (NMI)	0x10	1) Non-Maskable Interrupt.
Data Storage	0x20	1) Access control
Instruction Storage	0x30	1) Access control
External Input	0x40(2)	Interrupt Controller interrupt and MSR_{EE}=1
Alignment	0x50	1) **lmw**, **stmw** not word aligned 2) **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3) dcbz
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=1, MPU
EFPU Data Exception	0xA0	—
EFPU Round Exception	0xB0	—
TBD	0xC0-0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.7.1 Exception Syndrome Register

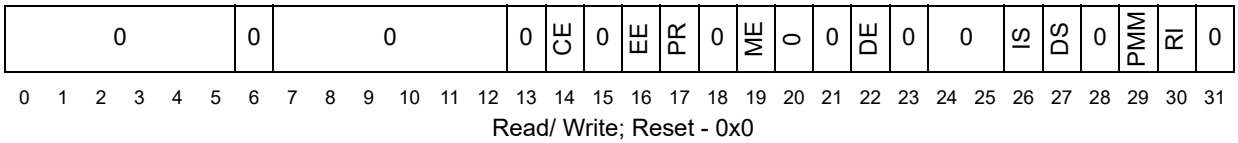
The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

SPR - 62; Read/Write; Reset - 0x0

Figure 112. Exception Syndrome Register

The ESR bits are defined in *Table 196*.

Table 196. ESR Bit Settings



Bit(s)	Name	Description	Associated Interrupt Type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception (For Core (z420n3), PIL is used for both illegal and unimplemented instructions)	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	--	Reserved	—
13	--	Reserved	—
14	BO	Byte Ordering exception Mismatched Instruction Storage exception	Instruction Storage
15	--	Reserved	—
16:23	—	Reserved	—
24	SPV	EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
25	—	Reserved	—

Table 196. ESR Bit Settings (continued)

Bit(s)	Name	Description	Associated Interrupt Type
26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

15.7.2 Machine State Register

The Machine State Register defines the state of the processor. The Zen MSR is shown in *Figure 113*.

Read/ Write; Reset - 0x0

Figure 113. Machine State Register (MSR)

The MSR bits are defined in *Table 197*.

Table 197. MSR Field Descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	—	Reserved
7:12	—	Reserved
13	—	Reserved
14	CE	Critical Interrupt Enable 0 - Critical Input interrupts are disabled. 1 - Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 - External Input interrupts are disabled. 1 - External Input interrupts are enabled.

Table 197. MSR Field Descriptions (continued)

Bit(s)	Name	Description
17	PR	Problem State 0 - The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 - The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 - Asynchronous Machine Check interrupts are disabled. 1 - Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 - Debug interrupts are disabled. 1 - Debug interrupts are enabled.
23	—	Reserved
24	—	Reserved
25	—	Reserved
26	—	Reserved
27	—	Reserved
28	—	Reserved
29	PMM	PMM Performance monitor mark bit. System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the Performance Monitor registers PMLCa n, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt - This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken
31	—	Reserved

15.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 114*.

SPR - 572; Read/Clear; Reset - 0x0

Figure 114. Machine Check Syndrome Register (MCSR)

Table 198 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write ‘1’ to clear”. Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME}=1.

Table 198. Machine Check Syndrome Register (MCSR)

Bit	Name	Description	Exception Type(1)	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved		—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Icache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Dcache for certain situations. May also be set on locked line refill error.	Async Mchk	—

11	NMI	NMI input pin	NMI	—

Table 198. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV=1,MEA=1 indicates that the MCAR contains an effective address and MEA=0 indicates that the MCAR contains a physical address	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an ECC error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved		—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved		—

Table 198. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved		—

1. The Exception Type indicates the exception type associated with a given syndrome bit

   - “Error Report” indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

   - “Status” indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

   - “NMI” indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a “1” to the bit position.

   - “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME}=1. If MSR_{ME}=0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

15.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the Interrupt Vector Prefix register (IVPR) to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 115*.

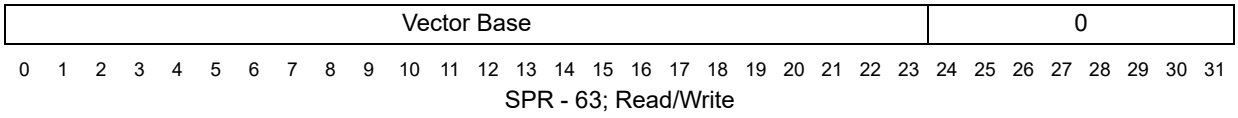

Figure 115. Interrupt Vector Prefix Registers (IVPR)

The IVPR fields are defined in *Table 199*.

Table 199. IVPR Register Fields

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.7.5 Interrupt Definitions

15.7.5.1 Critical Input Interrupt (Offset 0x00)

A Critical Input exception is signalled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 200 lists register settings when a Critical Input interrupt is taken.

Table 200. Critical Input Interrupt—Register Settings

Register	Setting Description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME— FE0 0 DE—/0(1)	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13])** || 2'b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.7.5.2 Machine Check Interrupt (Offset 0x10)

The Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome register (MCSR) to record the source(s) of machine checks, and a Machine Check Address register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 201*.

Table 201. Machine Check Interrupt - Register Settings

Register	Setting Description		
MCSRR0	On a best-effort basis sets this to the address of some instruction that was executing or about to be executing when the machine check condition occurred.		
MCSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME 0 FE0 0 DE 0/—(1)	FE1 0 IS 0 DS 0 PMM 0 RI 0
ESR	Unchanged		
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.		
Vector	$IVPR_{0:23}$ || 0x10		

1. Clearing of DE is optionally supported by control in HID0.

15.7.5.3 Data Storage Interrupt (Offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 202 lists register settings when a DSI is taken.

Table 202. Data Storage Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting load/store instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Access:	[ST], [SPV], VLEMI. All other bits cleared.	
MCSR	Unchanged		

Table 202. Data Storage Interrupt—Register Settings (continued)

Register	Setting Description
DEAR	For Access Control exceptions, set to the effective address of the access which caused the violation.
Vector	$IVPR_{0:23}$ || 0x20

15.7.5.4 Instruction Storage Interrupt (Offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

Table 203 lists register settings when an ISI is taken.

Table 203. Instruction Storage Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x30		

15.7.5.5 External Input Interrupt (Offset 0x40)

An External Input exception is signalled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 204 lists register settings when an External Input interrupt is taken.

Table 204. External Input Interrupt—Register Settings

Register	Setting Description
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table 204. External Input Interrupt—Register Settings (continued)

Register	Setting Description		
MSR	SPV0 WE0 CE— EE0 PR0	FP0 ME— FE00 DE—	FE10 IS0 DS 0 PMM 0 RI—
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged

15.7.5.6 Alignment Interrupt (Offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** not word aligned.
- The operand of **lwarx** or **stwcx.** not word aligned.
- The operand of **lharx** or **sthcx.** not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

Table 205 lists register settings when an alignment interrupt is taken.

Table 205. Alignment Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	[ST], VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Set to the effective address of a byte of the load or store access causing the violation.		
Vector	$IVPR_{0:23}$ || 0x50		

15.7.5.7 Program Interrupt (Offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

core will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- Instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

core will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR}=1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions which specify a SPRN value with $SPRN_5$=1 (even if the SPR is undefined).

core will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause a illegal instruction program exception.

Table 206 lists register settings when a Program interrupt is taken.

Table 206. Program Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt

MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x60		

15.7.5.8 System Call Interrupt (Offset 0x80)

A System Call interrupt occurs when a System Call (**se_sc**) instruction is executed and no higher priority exception exists.

Table 207 lists register settings when a System Call interrupt is taken.

Table 207. System Call Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the instruction *following* the system call instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x80		

15.7.5.9 Debug Interrupt (Offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM}$=1 (internal debug mode) and MSR_{DE}=1).

Table 208 lists register settings when a Debug interrupt is taken.

Table 208. Debug Interrupt—Register Settings

Register	Setting Description		
DSRR0(1)	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP. Set to the effective address of the next instruction to be executed *following* the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
DSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0(2) EE—/0(2) PR0	FP 0 ME— FE0 0 DE 0	FE1 0 IS 0 DS 0 PMM 0 RI—

1. Assumes that the Debug interrupt is precise
2. Conditional based on control bits in HID0
3. Note that multiple DBSR bits may be set

15.7.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signalled to the processor through the assertion of system-defined signals.

A System reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 209 lists register settings when a System Reset interrupt is taken.

Table 209. System Reset Interrupt—Register Settings

Register	Setting Description
CSRR0	Undefined.
CSRR1	Undefined.

Table 209. System Reset Interrupt—Register Settings (continued)

Vector	[**p_rstbase[0:29]**] || 2'b00		

15.7.5.11 Embedded Floating-point Data Interrupt (Offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and a EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

Table 210 lists register settings when a EFPU Floating-point Data interrupt is taken.

Table 210. Embedded Floating-point Data Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting EFPU instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—

MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0xB0		

15.7.5.13 Performance Monitor Interrupt (Offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 1; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 1; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 212 lists register settings when an performance monitor interrupt is taken.

Table 212. Performance Monitor Interrupt—Register Settings

Register	Setting Description		
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.		
SRR1/ DSRR1(1)	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0(2) EE 0/—(3) PR 0	FP 0 ME— FE0 0 DE—/0(4)	FE1 0 IS 0 DS 0 PMM 0 RI—

1. DSRR0/1 are used if $PMGC0_{UDI}$ = 1'
2. CE is cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLRCE}$ = 1
3. EE is not cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLREE}$ =0
4. DE is cleared if $PMGC0_{UDI}$ = 1'

15.8 MPU

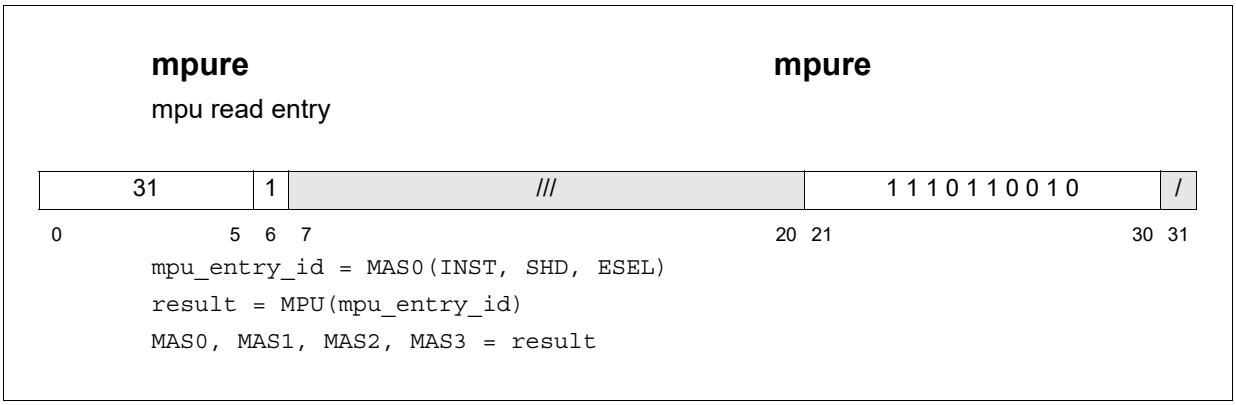
15.8.1 MPU Overview

The Core (z420n3) Memory Protection Unit (MPU) provides the capability of protecting regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints

Software managed by **mpure** and **mpuwe** instructions

15.8.2 Software Interface and MPU Instructions



The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MPU Assist registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with a **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with a **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

15.8.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

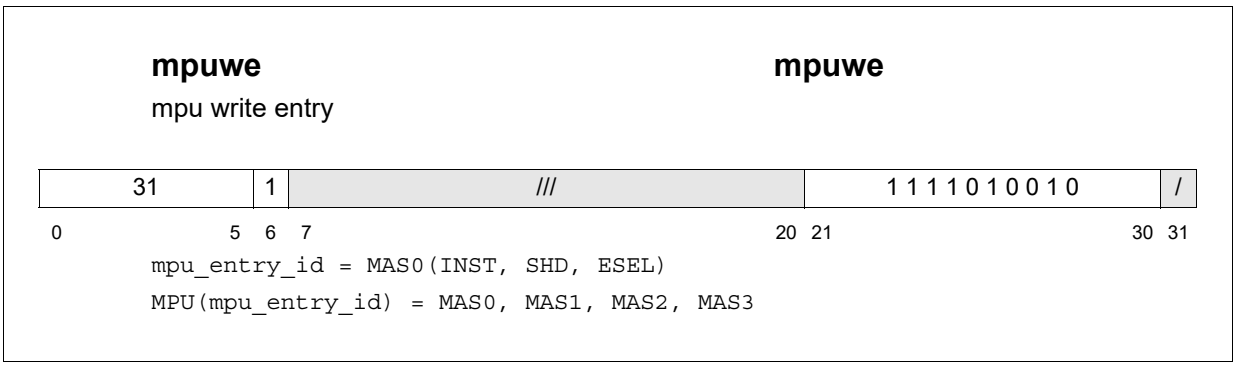


Figure 116. MPU Read Entry Instruction (mpure)

15.8.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

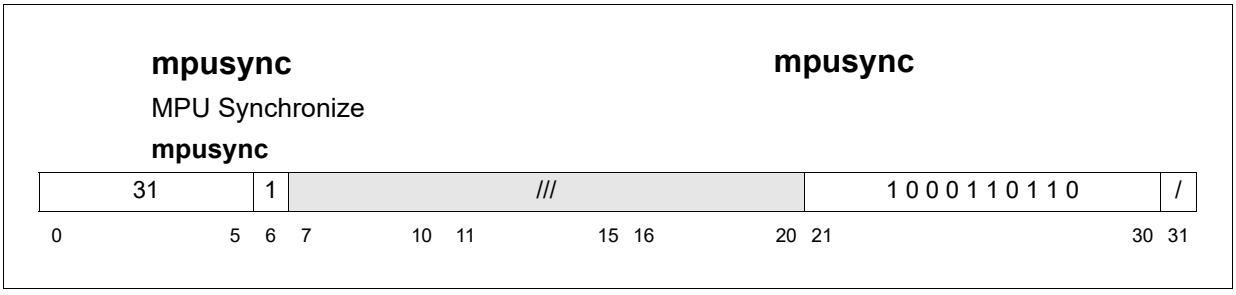

Figure 117. MPU Write Entry Instruction (mpuwe)

15.8.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the Core (z420n3).

Figure 118. MPU Synchronize Instruction (mpusync)

15.8.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the Core (z420n3) MPU design. The MMUCFG register is shown in *Figure 119*.

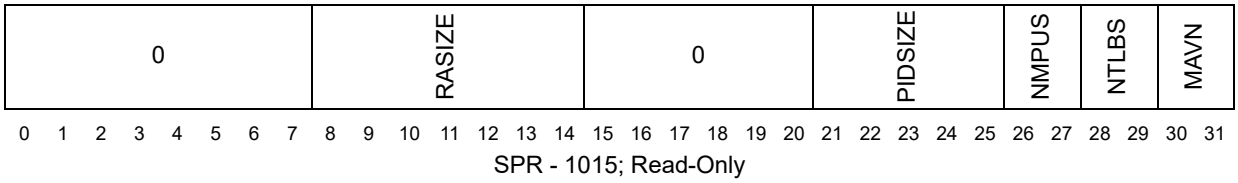

Figure 119. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 213*.

Table 213. MMUCFG Field Descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000- This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 - PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 - This version of the MMU implements one MPU structure: a fully-associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 - This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 - This version of the MMU implements Version 3.1 of the MMU Architecture

15.8.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the Core (z420n3) MPU. The MPU0CFG register is shown in *Figure 120*.

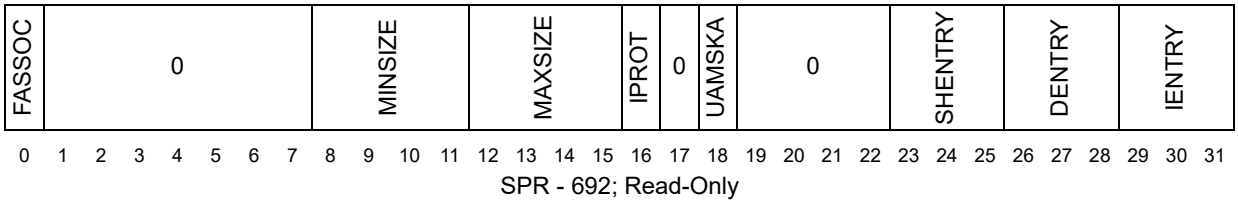

Figure 120. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in *Table 214*.

Table 214. MPU0CFG Field Descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 - Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size 0x0 - Smallest region size is 1 byte Note: due to the use of access address matching, the effective smallest region size is 8 bytes
12:15	MAXSIZE	Maximum Region Size 0xB - Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 - Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 - Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 - Indicates that MPU0 contains 6 shared entries
26:28	DENTRY	Number of Data Entries 0x4 - Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 - Indicates that MPU0 contains 6 dedicated Instruction entries

15.8.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in *Figure 121*.

0	BYPSR	BYPSW	BYPSX	BYPUR	BYPUW	BYPUX	0	DRDEN	DWDEN	IDEN	0	TIDCTL	0	MPUFI	MPUEN
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15	16	17	18	19	20	21	22 23	24	25	26	27	28	29	30	31

SPR - 1014; Read/ Write; Reset - 0x0

Figure 121. MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0CSR0 bits are described in *Table 215*.

Table 215. MPU0CSR0 - MPU0 Control and Status Register 0

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses 0 - No Bypass of MPU protections for Supervisor Read accesses 1 - Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
17	BYPSW	Bypass MPU protections for Supervisor Write accesses 0 - No Bypass of MPU protections for Supervisor Write accesses 1 - Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses 0 - No Bypass of MPU protections for Supervisor Instruction accesses 1 - Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
19	BYPUR	Bypass MPU protections for User Read accesses 0 - No Bypass of MPU protections for User Read accesses 1 - Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
20	BYPUW	Bypass MPU protections for User Write accesses 0 - No Bypass of MPU protections for User Write accesses 1 - Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).

Table 215. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
21	BYPUX	Bypass MPU protections for User Instruction accesses 0 - No Bypass of MPU protections for User Instruction accesses 1 - Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable 0 - MPU debug events are disabled for data read accesses 1 - MPU debug events are enabled for data read accesses This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events.
25	DWDEN	Data Write Debug Enable 0 - MPU debug events are disabled for data write accesses 1 - MPU debug events are enabled for data write accesses This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events.
26	IDEN	Instruction Debug Enable 0 - MPU debug events are disabled for instruction accesses 1 - MPU debug events are enabled for instruction accesses This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. When enabled, instruction accesses are not blocked from generating MPU debug events.
27	—	Reserved
28	TIDCTL	TID usage Control 0 - TID comparisons performed normally 1 - no TID comparisons are performed for matching while in Supervisor mode When TIDCTL is set to ‘1’, the TID match is disabled (forced match) in Supervisor mode.
29	—	Reserved

Table 215. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate 0 - No flash invalidate 1 - MPU1 invalidation operation When written to a '1', a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to '0'. Writing a '1' while an invalidation operation is in progress will result in an undefined operation. Writing a '0' to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. Note that entries which have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable 0 - MPU is disabled 1 - MPU is enabled This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG=1 if in EDM and hardware owns MPU Debug entries.

15.8.9 MPU Assist Registers (MAS)

The Core (z420n3) uses four special purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 122*. Fields are defined in *Table 216*.

VALID	IPROT	SEL	0	RO	DEBUG	INST	SHD	0	ESEL	0	UAMSK	UW	SW	UX/UR	SX/SR	IOVR	GOVR (1)	1	1	I	0	G (1)	0
0	1	2 3	4	5	6	7	8	9 10 11	12 13 14 15	16	17 18 19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 624; Read/ Write; Reset - Unaffected

Figure 122. MPU Assist Registers 0 (MAS0)

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST=1

Table 216. MAS0 —MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 - This MPU entry is invalid 1 - This MPU entry is valid
1	IPROT	Invalidation Protect 0 - Entry is not protected from invalidation 1 - Entry is protected from invalidation

Table 216. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 - Reserved, no access 01 - Reserved, no access 10 - Select MPU 11 - Reserved, no access
4	—	Reserved
5	RO	Read-Only 0 - This MPU entry is writable 1 - This MPU entry is Read-only When set to ‘1’, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs.
6	DEBUG	Debug Control for Entry 0 - This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 - This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access.
7	INST	Instruction Entry 0 - This MPU entry is used for matching data accesses only 1 - This MPU entry is used for matching instruction accesses only When SHD=0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD=1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry.
8	SHD	Shared Entry Select 0 - The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 - The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected. This bit is used to control selection of the Shared portion of the region descriptor table.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

Table 216. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
17:19	UAMSK	Upper Address Mask Control 000 - No upper address bits are masked, address matching uses all 32 address bits for accesses 001 - The most significant access address bit is forced to zero before matching 010 - The two most significant access address bits are forced to zero before matching 101 - The upper 5 access address bits are forced to zero before matching 11x - Reserved, do not use This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly.
20	UW	User Mode Write Permission 0 - No User mode Write permission 1 - User mode has Write permission Determines User mode Write (W) permission when INST=0. Ignored when INST=1.
21	SW	Supervisor Mode Write / Read Permission 0 - No Supervisor mode Write permission 1 - Supervisor mode has Write permission Determines Supervisor mode Write (W) permission when INST=0. Ignored when INST=1.
22	UX/UR	User Mode Execute / Read Permission 0 - No User mode Execute/ Read permission 1 - User mode has Execute/ Read permission Determines User mode Execute (X) permission when INST=1, or User mode Read (R) permission when INST=0.
23	SX/SR	Supervisor Mode Execute / Read Permission 0 - No Supervisor mode Execute/ Read permission 1 - Supervisor mode has Execute/ Read permission Determines Supervisor mode Execute (X) permission when INST=1, or Supervisor mode Read (R) permission when INST=0.
24	IOVR	Cache-Inhibit attribute Override 0 - No override of I attribute by entry 1 - Entry I bit overrides I attribute Determines whether this matching entry overrides the I bit settings of other matching entries and the Cache-Inhibited region configuration signals
25	GOVR/—	G attribute Override 0 - No override of G attribute by entry 1 - Entry G bit overrides G attribute Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
26	—	Reserved
27	—	Reserved

Table 216. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
28	I	Cache Inhibited 0 - This region is considered cacheable 1 - This region is considered cache-inhibited This attribute may be overridden by the cache-inhibited region configuration input settings.
29	—	Reserved
30	G/—	Guarded 0 - Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 - All loads and stores to this region are performed without speculation (i.e. they are known to be required) This attribute may be overridden by the guarded region configuration input settings. This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
31	—	Reserved

The MAS1 register is shown in *Figure 123*. Fields are defined in *Table 217*.

15.8.10 MAS Registers Summary

The MAS registers are summarized in *Figure 126*.

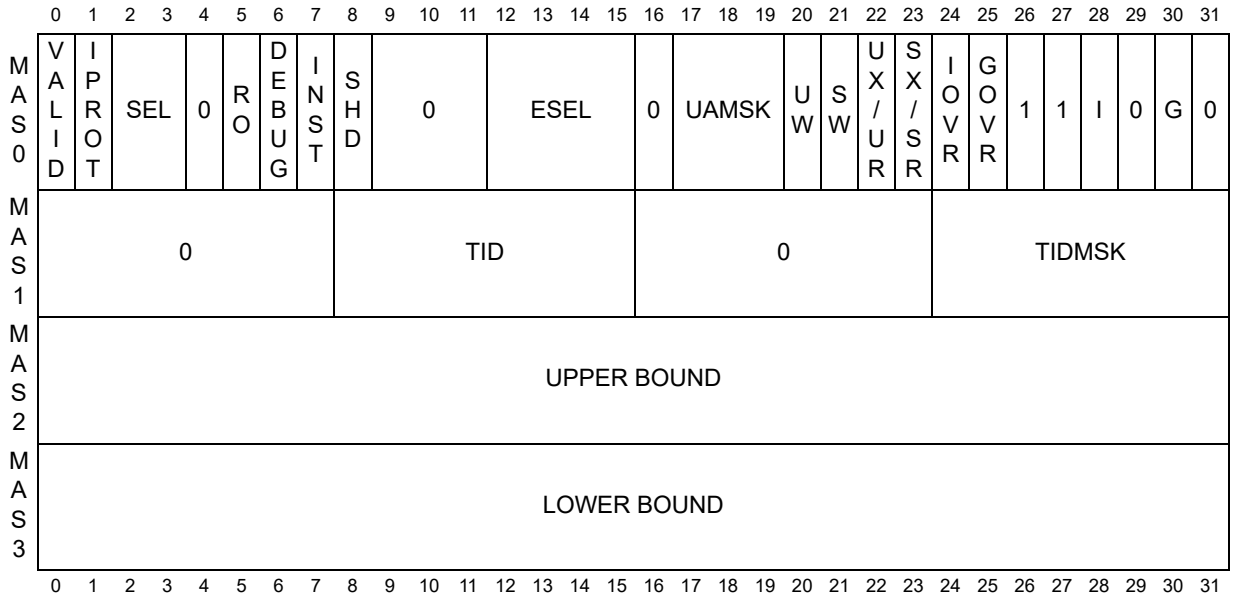

Figure 126. MPU Assist Registers Summary

15.9 Local memories

15.9.1 Local instruction and data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added to the next generation processor cores. These memories provide for low latency access (zero wait-state) similar to an instruction or data cache, but do not suffer from the overhead of cache miss or cache write through operations. Instead, they provide “tightly coupled” storage.

15.9.2 Local memory control and configuration

DMEM and IMEM local memory configuration is provided by a set of privileged read-only SPRs which are accessed using **mfspr** instructions. DMEM and IMEM local memory is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the Core (z425n3) local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 127*.

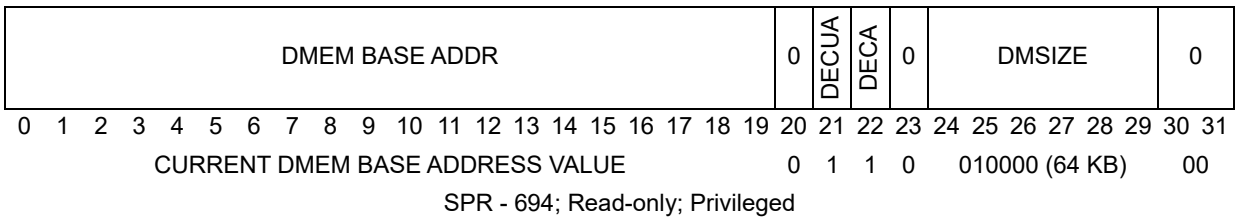

Figure 127. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 220*.

Table 220. DMEMCFG0 Field Descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** low order bits of this field are driven to 0's when the DMEM size is > 4 Kbyte
20	-	Reserved
21	DECUA	DECUE - DMEM Error Correction Update Available 0 - Error Correction Update is not available 1 - Error Correction Update is available for correction of a correctable single-bit error detected on a read access DECUA indicates an error scrubbing function for the DMEM is available.
22	DECA	DECUE - DMEM Error Correction Available 0 - Error Correction is not available 1 - Error Correction is available DECA indicates an error correction function for the DMEM is available.
23	-	Reserved
24:29	DMSIZE	DMSIZE - DMEM Size 010000 - The size of the DMEM is 64 Kbyte.
30:31	-	Reserved

15.9.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DCR - 496; Read/Write; Reset(1) - 19'b0 || p_dmem_rstcfg[8,6:7,0] || 4'b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 128. DMEM Control Register 0 (DMEMCTL0)

1. reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 221. DMEMCTL0 Field Descriptions

Bits	Name	Description
0:16	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
17:18	-	Reserved
19	DBYPCB	DBYPCB - DMEM Bypass Cache Bypass CPU accesses 0 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port 1 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses which target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input.
20	DBYPAT	DBYPAT - DMEM Bypass Atomic CPU accesses 0 - Atomic CPU accesses do not bypass the DMEM CPU port 1 - Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems which support reservation or decoration functionality (or both), since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input.

Table 221. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
21	DBYPDEC	DBYPDEC - DMEM Bypass Decorated CPU accesses 0 - Decorated Load and Store CPU accesses do not bypass the DMEM CPU port 1 - Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems which support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input.
22	DECUE	DECUE - DMEM Error Correction Update Enable 0 - Error Correction Update is disabled 1 - Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be re-written with the corrected data. (Write accesses perform this correction automatically during partial-width writes.) DECUE can be used to provide an error scrubbing function for the DMEM. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input.
23	-	Reserved
24	DBAPD	DBAPD - DMEM Base Address Port Disable 0 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses. This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses.
25	DPEIE	DPEIE - DMEM Processor Error Injection Enable 0 - Error Injection is disabled 1 - A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]). DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE=0.
26	DICWE	DICWE - DMEM Imprecise CPU Write Enable 0 - Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 - Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only). DICWE may allow for increased partial-width write performance when set.

Table 221. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
27:28	DSWCE	DSWCE - DMEM Slave port Write Check/Correct Enable 00 - Slave write data is not checked or corrected for errors. 01 - Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 - Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 - Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or double word writes are not checked or corrected for errors. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs.
29	DDAUEC	DDAUEC - DMEM Disable Address Use in Error Check 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input.
30	DCECE	DCPECE - DMEM CPU Port ECC Enable (CPU port) 0 - End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1- End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input.
31	DSECE	DSECE - DMEM Slave port Error Checking Enable (Slave port) 0 - End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 - End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input.

15.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally-sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses which target DMEM address range, regardless of

whether the access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB,}$ DBYPATF, DBYPDEC·

A single control field is used for each access based on the upper two address bits used to index into the DMEM. DURAC0 is used when these two bits = 2'b00

15.9.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the e200z420n3 local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in *Figure 130*.

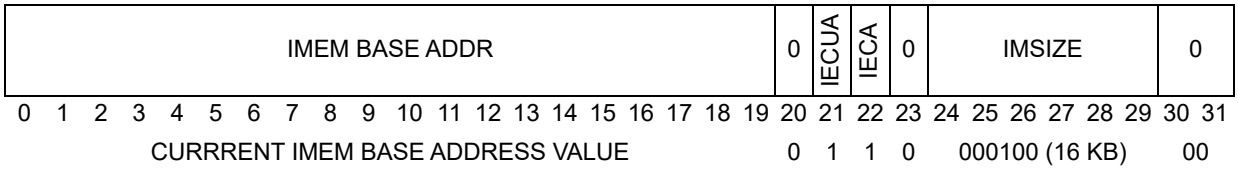

Figure 130. IMEM Configuration Register 0 (IMEMCFG0)

Table 223. IMEMCFG0 Field Descriptions

Bits	Name	Description
0:19	IMEM BASE ADDR	IMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the IMEM. This field reflects the value of the external IMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of IMEMCFG0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0's when the IMEM size is > 4 KBs.
20	-	Reserved
21	IECUA	IECUE - IMEM Error Correction Update Available 0 - Error Correction Update is not available 1 - Error Correction Update is available for correction of a correctable single-bit error detected on a read access IECUA indicates an error scrubbing function for the IMEM is available.
22	IECA	IECUE - IMEM Error Correction Available 0 - Error Correction is not available 1 - Error Correction is available IECA indicates an error correction function for the IMEM is available.
23	-	Reserved
24:29	IMSIZE	IMSIZE - IMEM Size 000100 - The size of the IMEM is 16 KBs
30:31	-	Reserved

15.9.2.5 IMEM Control Register 0 (IMEMCTL0)

The IMEM Control Register 0 (IMEMCTL0) controls operation of certain functions of the IMEM logic.

DCR - 497; Read/Write; Reset(1) - 22'b0 ||| p_imem_rstcfg[0] || 4'b0 || p_imem_rstcfg[1:5]; Privileged

Figure 131. IMEM Control Register 0 (IMEMCTL0)

1. reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 224. IMEMCTL0 Field Descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the ICache for the memory space to be occupied by the IMEM.
18:19	-	Reserved for Base Address extension
20:21	-	Reserved
22	IECUE	IECUE - IMEM Error Correction Update Enable 0 - Error Correction Update is disabled 1 - Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read or partial-width write cycles will cause the IMEM to be re-written with the corrected data. IECUE can be used to provide an error scrubbing function. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[0]** input.
23	-	Reserved
24	IBAPD	IBAPD - IMEM Base Address Port Disable 0 - The external IMEM base address port (**p_imem_baseaddr[0:n]**) is used to define the base address of the IMEM for CPU accesses. 1 - The external IMEM base address port (**p_imem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses. This bit controls usage of the external Base Address port (**p_imem_baseaddr[0:n]**) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses.
25:26	-	Reserved
27:28	ISWCE	ISWCE - IMEM Slave port Write Check/Correct Enable 00 - Slave write data is not checked or corrected for errors. 01 - Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 - Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 - Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_imem_rstcfg[1:2]** inputs.

Table 224. IMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
29	IDAUEC	IDAUEC - IMEM Disable Address Use in Error Check 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[3]** input.
30	ICECE	ICPECE - IMEM CPU Port ECC Enable (CPU port) 0 - End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1- End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[4]** input.
31	ISECE	ISECE - IMEM Slave port Error Checking Enable (Slave port) 0 - End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 - End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[5]** input.

15.9.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally-sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

0	ISXAC3	ISXAC2	ISXAC1	ISXAC0	0	IUXAC3	IUXAC2	IUXAC1	IUXAC0

16:23	-	Reserved

Table 225. IMEMCTL1 Field Descriptions (continued)

Bits	Name	Description
24:25	IUXAC3	IUXAC3 - IMEM User Instruction Fetch Access Control for Quadrant 3 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 3 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 3 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 3 of IMEM based on memory protection logic 11 - Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC3 is used when these two bits = 2‘b11
26:27	IUXAC2	IUXAC2 - IMEM User Instruction Fetch Access Control for Quadrant 2 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 2 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 2 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 2 of IMEM based on memory protection logic 11 - Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC2 is used when these two bits = 2‘b10
28:29	IUXAC1	IUXAC1 - IMEM User Instruction Fetch Access Control for Quadrant 1 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 1 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 1 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 1 of IMEM based on memory protection logic 11 - Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC1 is used when these two bits = 2‘b01
30:31	IUXAC0	IUXAC0 - IMEM User Instruction Fetch Access Control for Quadrant 0 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 0 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 0 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 0 of IMEM based on memory protection logic 11 - Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC0 is used when these two bits = 2‘b00

15.10 End-to-End ECC support

This section describes End-to-End Error detection and correction capability (e2eECC) enhancements the Core (z425n3) to address additional diagnostic capabilities for the next generation of embedded designs.

15.10.1 e2eECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

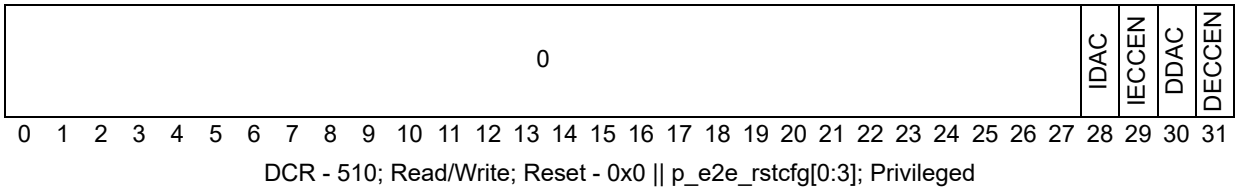

Figure 133. e2eECC Control Register 0 (E2ECTL0)

Table 226. E2ECTL0 Field Descriptions

Bits	Name	Description
0:27	-	These bits are reserved
28	IDAC	IDAC - Instruction Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Instruction AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 - End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 - End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.

Table 226. E2ECTL0 Field Descriptions (continued)

Bits	Name	Description
30	DDAC	DDAC - Data Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Data AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 - End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 - End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

Enabling of e2eECC operation is performed by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a one. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for non-zero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.10.1.2 End-to-end ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address or checkbit error on external bus write cycles, and then may read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus.

Note that Nexus3 accesses do not cause error injection or capturing of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 134 shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 134. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 227. E2EECSR0 Field Descriptions

Bits	Name	Description
0:3	-	These bits are reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	-	These bits are reserved
16:17	WRC	Write Control 00 - No write checkbit substitution is performed by this control bit 01 - Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 - Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11- Reserved **Note:** checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 - No error injection is performed by this control bit 01 - Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 - Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 - Reserved **Note:** checkbit substitution has priority over Error injection

Table 227. E2EECSR0 Field Descriptions (continued)

Bits	Name	Description
20:23	-	These bits are reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits /Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 - Checkbit is driven normally 1 - Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

16 Core (z425n3) description

16.1 Overview of the Core (z425n3)

Core (z425n3) is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general purpose registers (GPRs). The Core (z425n3) core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver vector and scalar results.

The Core (z425n3) processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

Core (z425n3) contains an 8 Kbyte Instruction Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit is also included which supports protections of various instruction and data memory areas.

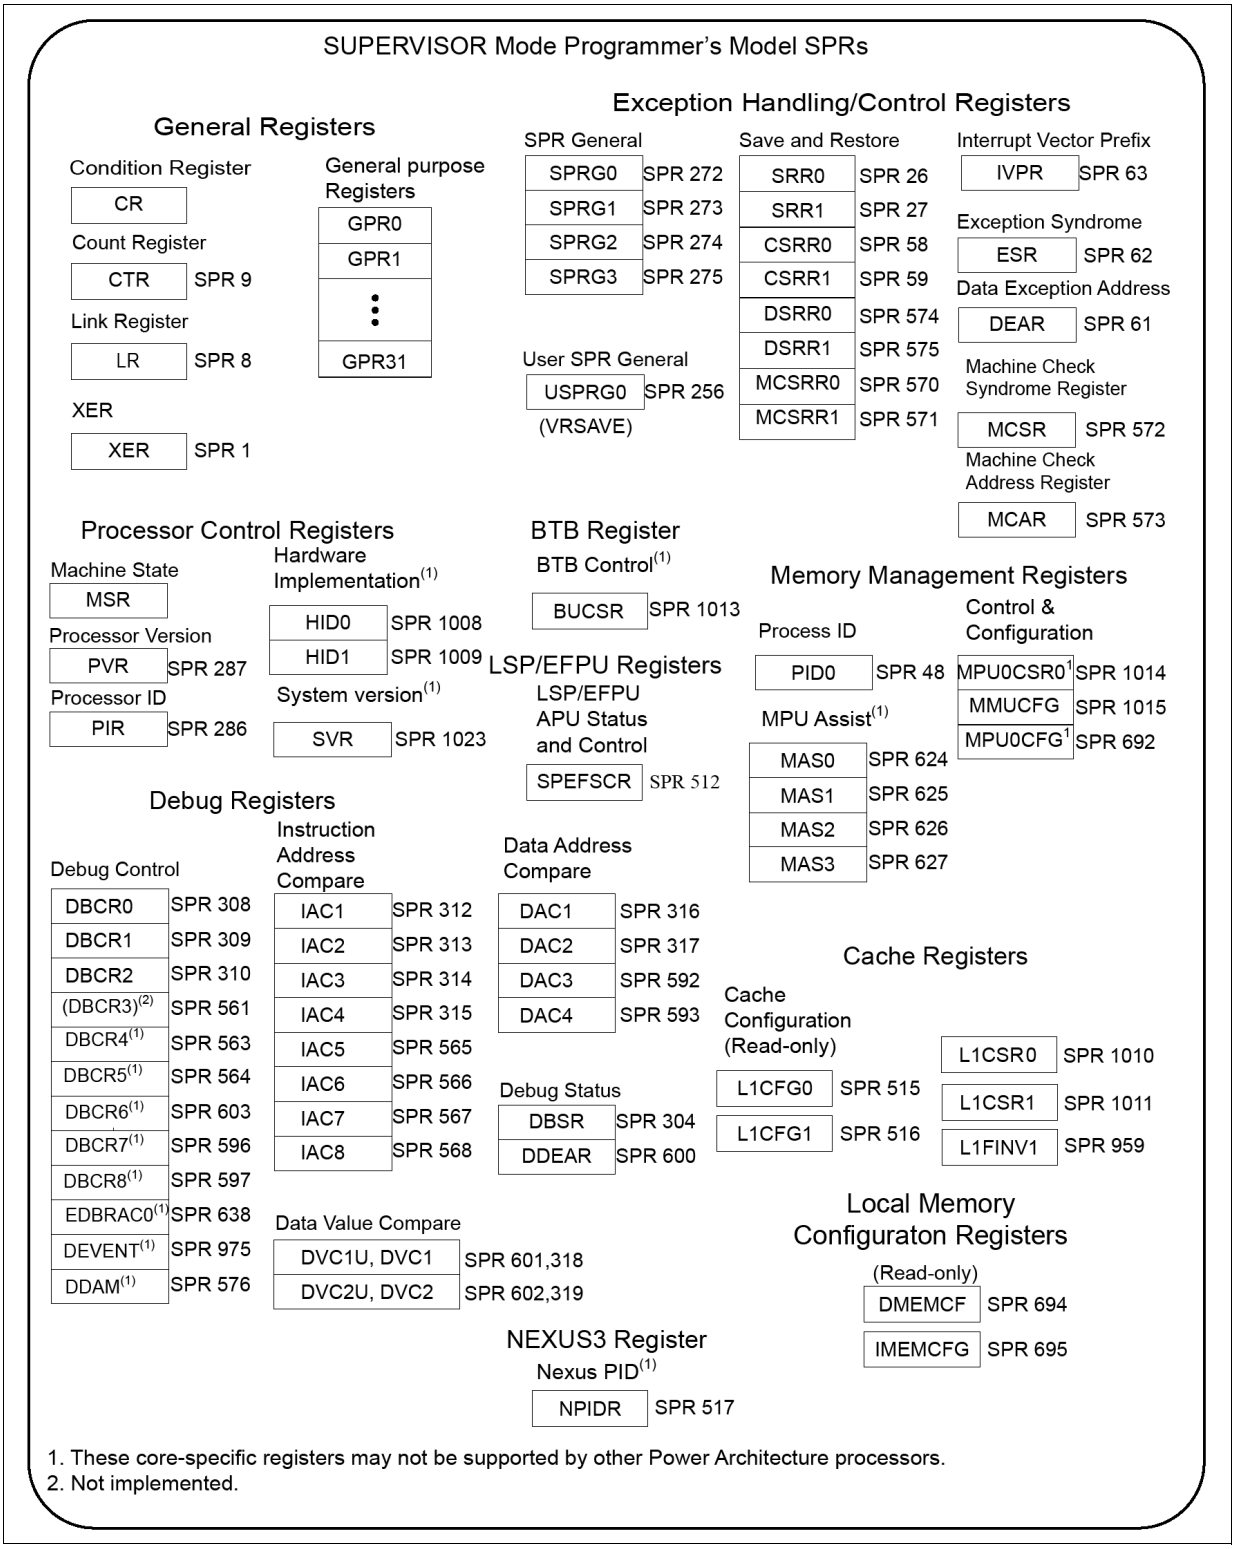
16.2 Register model

This section describes the registers implemented in the Core (z425n3) core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

Core (z425n3) extends usage of the General Purpose Registers to support LSP and EFPU and LSP APU operations operating on the 32-bit GPR registers.

Figure 135 and *Figure 136* show the complete Core (z425n3) register set, all of which are accessible in supervisor mode. *Figure 137* and *Figure 138* show the subset of registers which are accessible while in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 135. Core (z425n3) Supervisor Mode Programmer's Model SPRs



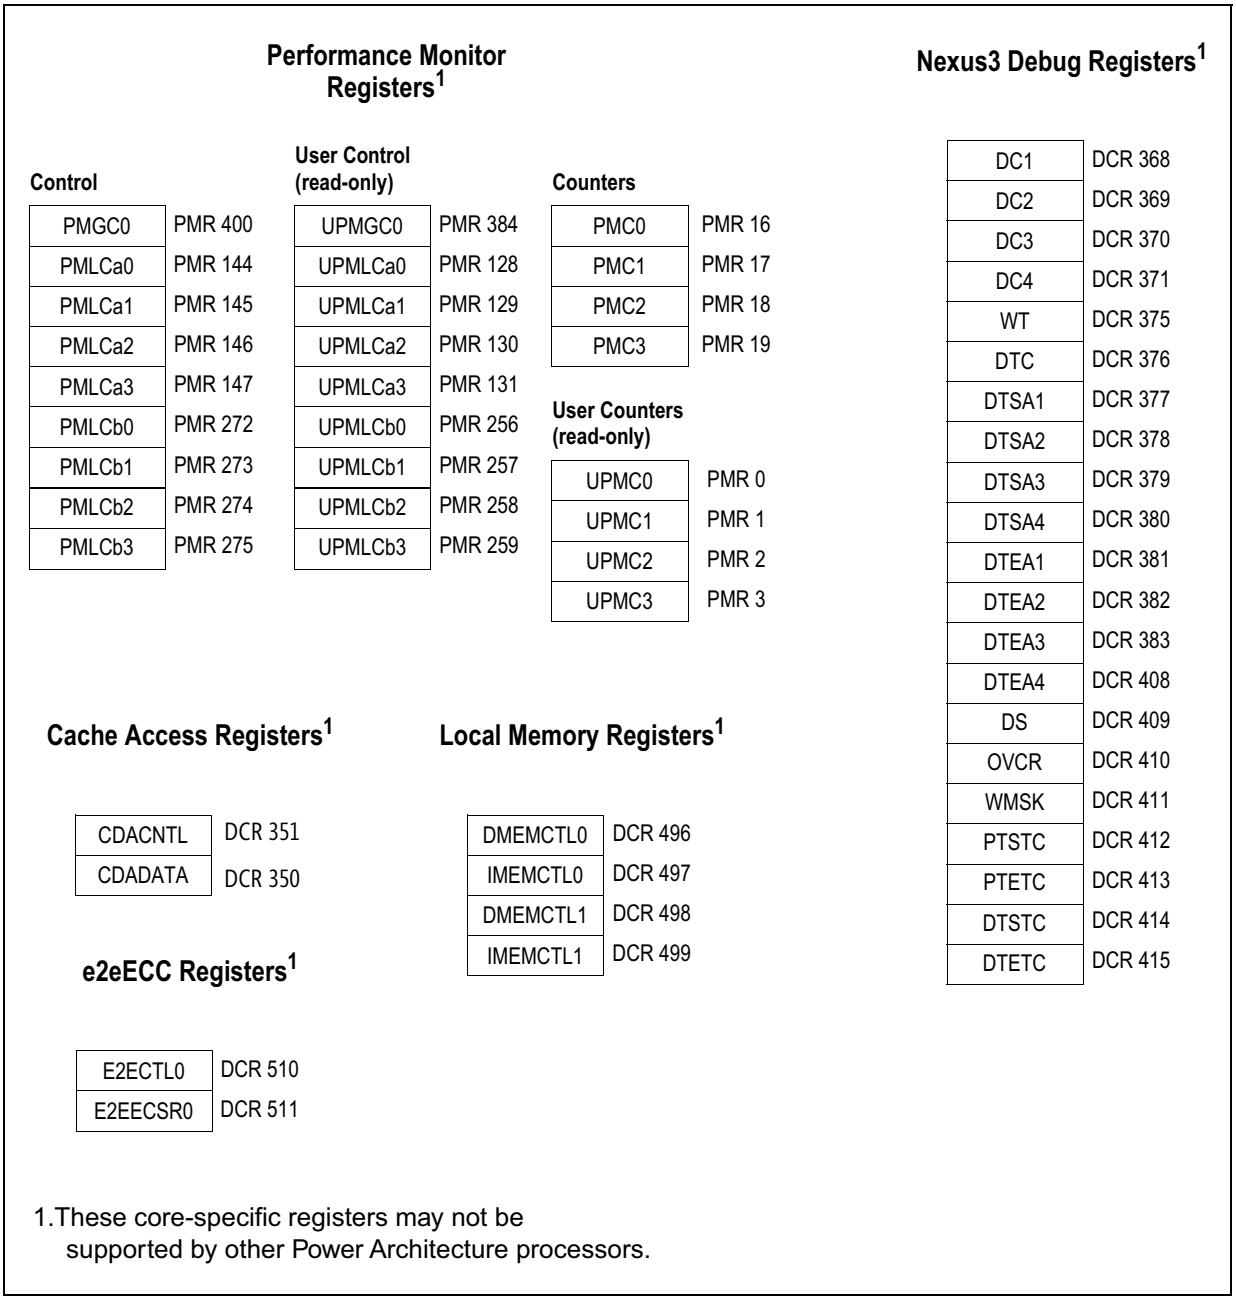


Figure 136. Core (z425n3) Supervisor Mode Programmer's Model DCRs and PMRs

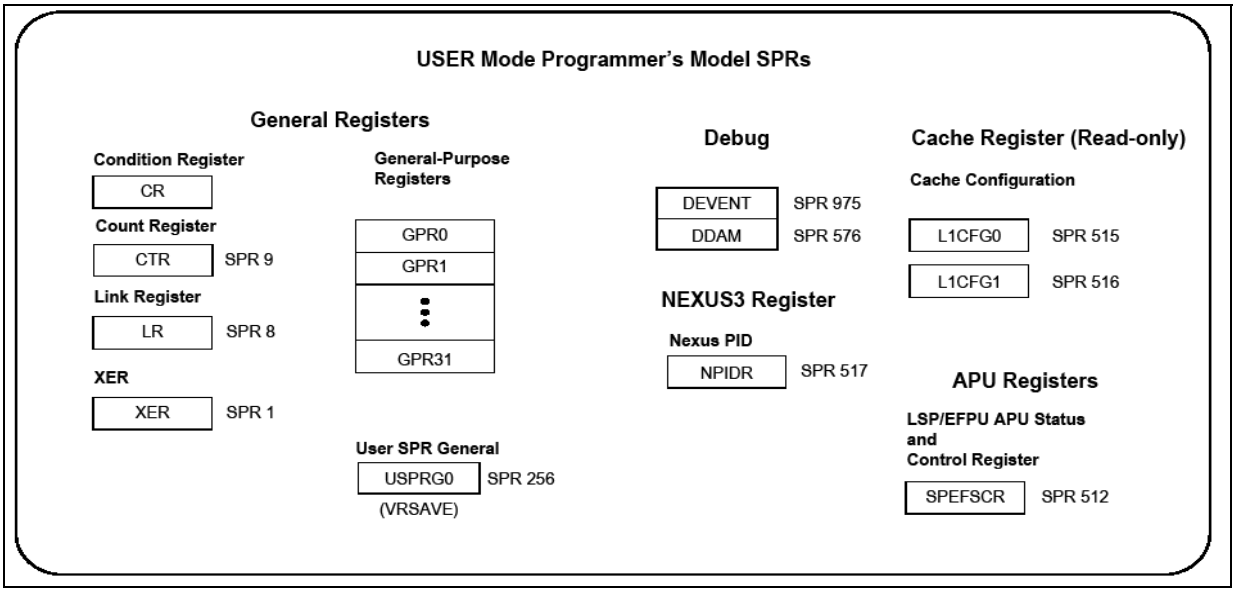
1.These core-specific registers may not be supported by other Power Architecture processors.

Figure 137. Core (z425n3) User Mode Programmer's Model SPRs



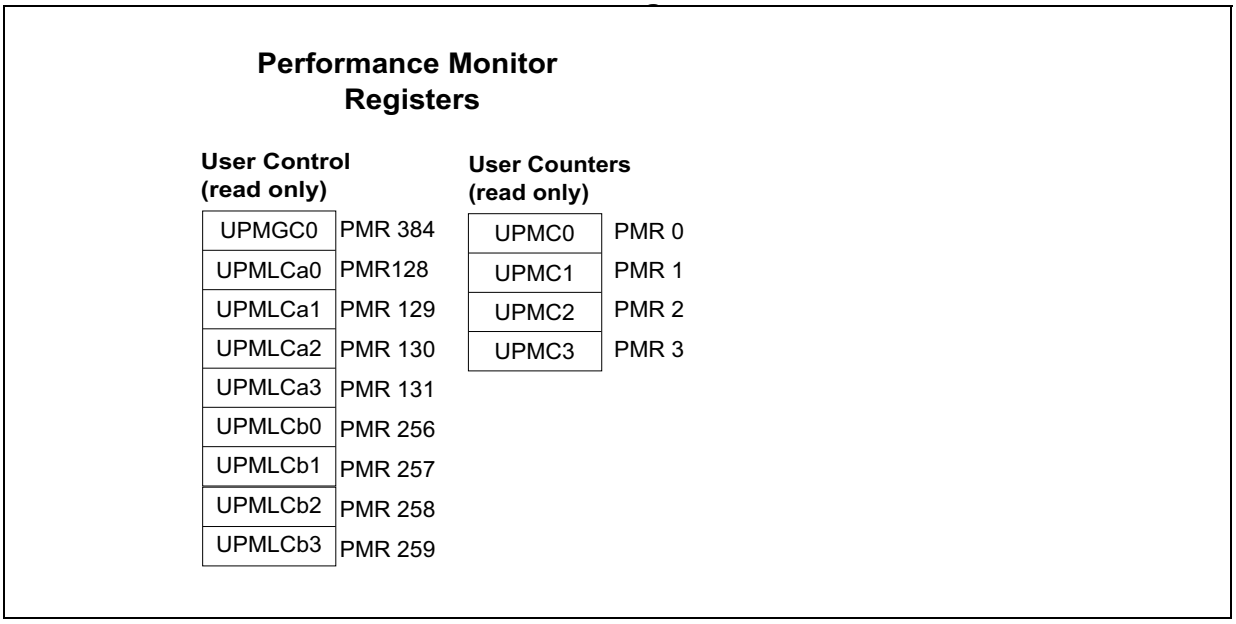


Figure 138. Core (z425n3) User Mode Programmer's Model PMRs

16.3 Dual issue operation

The instruction issue unit attempts to issue a pair of instructions each cycle to the execution units. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward multiplexers. Data or resource hazards may create stall conditions which cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

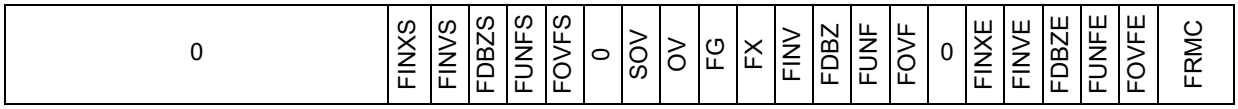
The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

Table 228 shows the Core (z425n3) concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue.

Table 228. Concurrent Instruction Issue capabilities

Class of Instruction	branch	load/store	scalar integer	scalar float	vector integer non-MAC	vector integer MAC	special
branch	—	yes	yes	yes	yes	yes	—
load/store	yes	—	yes	yes	yes	yes	—
scalar integer	yes	yes	yes(1)	yes	yes	yes(2)	—
scalar float	yes	yes	yes	—	yes	yes	—
vector integer non-MAC	yes	yes	yes	yes	—	—	—
vector integer MAC	yes	yes	yes(2)	yes	—	—	—
special	—	—	—	—	—	—	—



1. excludes multiply or divide class instructions occurring in both issue slots
2. excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions

16.4 Reservation instructions and cache interactions

The Zen core treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx.**, **sthcx.** and **stwcx.**) accesses as though they were cache inhibited. A reservation access is always issued to the bus.

16.5 Signal Processing Extension / Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point uses the SPEFSCR register. This register is also used by the LSP APU. The SPEFSCR register is implemented as special purpose register (SPR) number 512 and is read and written by the **mfspr** and **mtspr** instructions. The SPEFSCR is shown in *Figure 139*.

SPR - 512; Read/Write; Reset - 0x0

Figure 139. LSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in *Table 229*.

Table 229. LSP/EFPU Status and Control Register

Bits	Name	Description
0:9	—	Reserved
10	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF=1), but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1), but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
11	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
12	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
13	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
14	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
15	—	Reserved
16	SOV	Summary integer overflow Defined by LSP APU.
17	OV	Integer overflow Defined by LSP APU.
18	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.

Table 229. LSP/EFPU Status and Control Register (continued)

Bits	Name	Description
19	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.
20	FINV	Embedded Floating-point Invalid Operation / Input error The FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0.
21	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24	—	Reserved
25	FINXE	Embedded Floating-point Inexact Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF=1) but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1 or FUNFH=1) but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs.
26	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction.
27	FDBZE	Embedded Floating-point Divide by Zero Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction.
28	FUNFE	Embedded Floating-point Underflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction.

Table 229. LSP/EFPU Status and Control Register (continued)

Bits	Name	Description
29	FOVFE	Embedded Floating-point Overflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction.

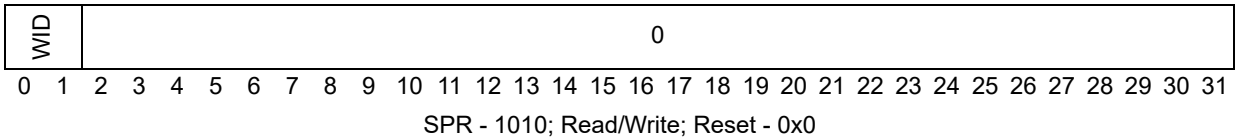
16.6 Cache

This chapter describes the cache registers, cache control instructions, and various cache operations.

16.6.1 Cache overview



The Core (z425n3) processor supports an 8 Kbyte 2-way set-associative instruction cache with a 32-byte line size. The cache improves system performance by providing low-latency data to the Core (z425n3) instruction pipeline, which decouples processor performance from system memory performance.

The Core (z425n3) processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction addresses from the processor are used to index the cache array. If the access address matches a valid cache tag entry, the access hits in the cache.

16.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of a data cache as well as providing general control over disabling ways in both caches. The L1CSR0 register implements the WID control field for instruction cache way disabling. The other fields are reserved. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in *Figure 140*.

SPR - 1010; Read/Write; Reset - 0x0

Figure 140. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 bits are described in *Table 230*.

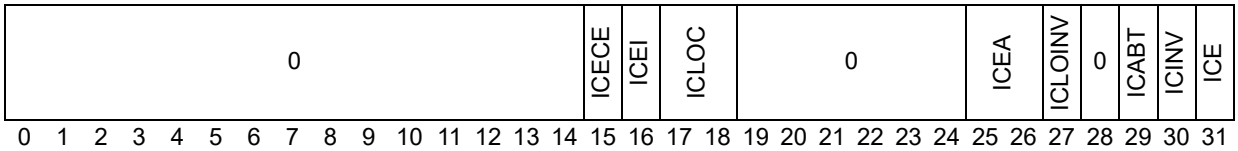


Table 230. L1CSR0 Field Descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable. 0 = The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 = The corresponding way instruction cache is not available for replacement by instruction miss line fills. Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache.
2:31	—	Reserved(1)

1. These bits are not implemented and should be written with zero for future compatibility.

16.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in *Figure 141*.

SPR - 1011; Read/Write; Reset - 0x0

Figure 141. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 bits are described in *Table 231*.

Table 231. L1CSR1 Field Descriptions

Bits	Name	Description
0:14	—	Reserved(1)
15	ICECE	Instruction Cache Error Checking Enable 0 - Error Checking is disabled 1 - Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable 0 - Cache Error Injection is disabled 1 - A double-bit error will be injected into each double word written into the cache by inverting the two uppermost parity check bits. ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE=0.

Table 231. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
17:18	ICLOC	Instruction Cache Lockout Control 00 - Cache line lockout is disabled (and array LO indicators are ignored). 01 - Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 - Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 - Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error. **Note:** for the **icbi** instruction, no lockout operation is performed, regardless of error conditions.
19:24	—	Reserved(1)
25:26	ICEA	Instruction Cache Error Action 00 - Error Detection causes Machine Check exception. 01 - Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 1x - Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 - No cache lockout bit invalidate 1 - Cache lockout indicator invalidation operation When written to a ‘1’ in conjunction with writing ICINV to a ‘1’, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value.
28	—	Reserved(1)
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 231. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
30	ICINV	Instruction Cache Invalidate 0 - No cache invalidate 1 - Cache invalidation operation When written to a ‘1’, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value.
31	ICE	Instruction Cache Enable 0 - Cache is disabled 1 - Cache is enabled When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE.

1. These bits are not implemented and should be written with zero for future compatibility.

16.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the Core (z425n3) L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in *Figure 142*.

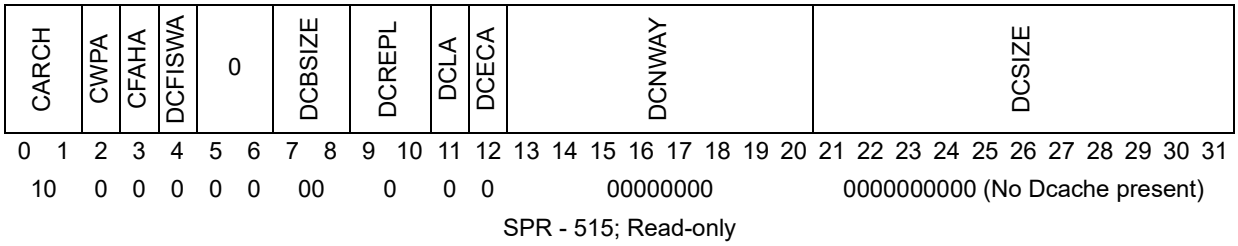

Figure 142. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 register indicates a cache architecture value (CARCH) of 2‘b10, indicating that an ICache but no DCache is present on Core (z425n3).

The L1CFG0 bits are described in *Table 232*.

Table 232. L1CFG0 Field Descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 - The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 - The caches support partitioning of way availability for I/D accesses

Table 232. L1CFG0 Field Descriptions (continued)

Bits	Name	Description
3	DCFAHA	Data Cache Flush All by Hardware Available 0 - The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 - The data cache supports invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 - The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11- The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 - The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 - The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 - The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 - The size of the data cache is 4 Kbyte

16.6.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the Core (z425n3) L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in *Figure 143*.

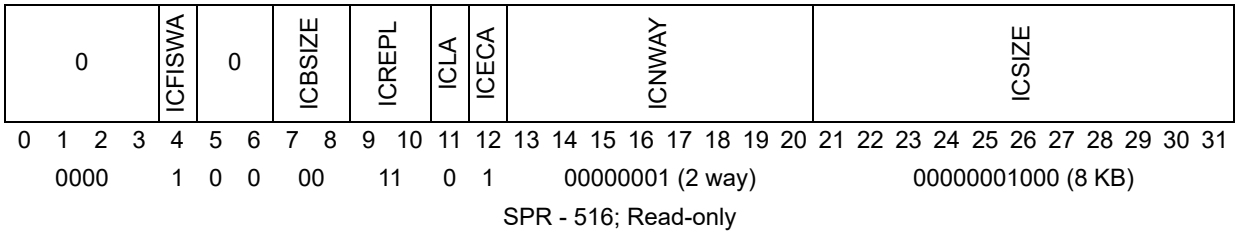

Figure 143. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 bits are described in *Table 233*.

Table 233. L1CFG1 Field Descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 - The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros

Table 233. L1CFG1 Field Descriptions (continued)

Bits	Name	Description
7:8	ICBSIZE	Instruction Cache Block Size 00 - The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 - The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 - The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 - The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 - The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 - The size of the instruction cache is 8 Kbyte

16.6.6 Cache Invalidate by Set and Way

Core (z425n3) supports cache set/way invalidation under software control. The instruction cache may be invalidated by set and way through a **mtspr l1finv1** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV1) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when the instruction cache is disabled.

16.6.6.1 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in *Figure 144*.

SPR - 959; Read/Write; Reset - 0x0

Figure 144. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in *Table 234*.

Table 234. L1FINV1 Field Descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected

Table 234. L1FINV1 Field Descriptions (continued)

Bits	Name	Description
27:29	—	Reserved for set/command extension
30:31	CCMD	Cache Command 00 = The data contained in this entry is invalidated 01 = Reserved 1x = Reserved

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error.

16.6.7 Cache EDC/ECC protection

Cache protection is supported for both the tag and data arrays of the instruction cache. Tag array support error detection and correction. Each double word in the data arrays of the ICache have single and double bit error detection.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error, to protect against internal addressing failures.

Tag ECC and data EDC checking is controlled by the $L1CSR1_{ICECE}$ control field. When error checking is enabled, checking is performed on each cache access.

For cache lookups, if an uncorrectable tag ECC error is detected on any portion of the accessed tags, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch occurs and a data EDC error is detected on any portion of the accessed data, an error is also signaled.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur, and one or more syndrome bits to be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled, or both may occur, depending on the error action control setting in the appropriate cache control register.

16.6.7.1 Cache line lockout

In addition to the ECC/EDC protection employed for the cache, each cache line in the Icache has a lockout indicator composed of a redundant set of lockout bits which can be selectively set when certain errors occur in either the tag or data portion of the cache line. Use of the lockout function and control over error conditions which cause a lockout to occur are controlled by $L1CSR1_{ICLOC}$. When the lockout function is enabled, lines which encounter selected tag ECC or data EDC errors on normal cacheable instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Lockout indicators may be cleared by software performing a cache invalidation operation (setting $L1CSR1_{ICINV}$) in conjunction with a cache lockout indicator invalidation (setting $L1CSR1_{ICLOINV}$). Three stored redundant lockout bits are provided to allow for single and double-bit parity errors to be detected on the lockout indicators themselves.

When operating in machine check mode, if lockout controls are enabled via $L1CSR1_{ICLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception. If correction/auto-invalidation is instead enabled, on each cache lookup operation, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by re-writing all lockout bits to the asserted state, and no machine check is generated.

Lockout bit parity errors are ignored for non-cacheable accesses in either error action mode. In addition, to avoid certain exception conditions and for consistency with error reporting, non-cacheable accesses and specialized load/store accesses, do not set LO bits; instead, cache contents are ignored for those errors since the cache is bypassed. A future cacheable normal access will perform the lockout function if required.

16.6.8 Cache error injection

Cache error injection provides a way to test error recovery by intentionally injecting EDC/ECC errors into the instruction or data cache, or both.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant EDC/ECC check bits inverted in the instruction cache data array for each double word loaded.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the EDC/ECC bit errors, a cache invalidation or an invalidation of the lines which have had an injected parity error may be performed. Line invalidation may be performed by an **icbi** instruction, or an L1FINV1 invalidation operation.

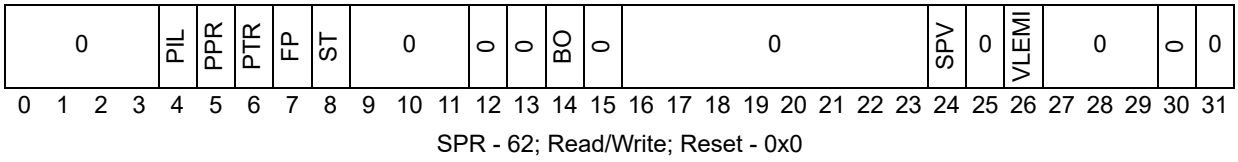
16.7 Exceptions

Interrupts implemented in Zen and the exception conditions that cause them are listed in *Table 235*.

Table 235. Exceptions and conditions

Interrupt Type	Interrupt Vector Offset Value	Causing Conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	1) Reset
Critical Input	0x00(1)	**p_critint_b** is asserted and MSR_{CE}=1
Machine check	0x10	1) **p_mcp_b** transitions from negated to asserted 2) ISI or Bus Error on first instruction fetch for an exception handler 3) EDC/ECC Error signaled on cache or Local Memory access 4) External bus error 5) Stack limit check failure
Machine check (NMI)	0x10	1) Non-Maskable Interrupt

Table 235. Exceptions and conditions (continued)



Interrupt Type	Interrupt Vector Offset Value	Causing Conditions
Data Storage	0x20	1) Access control
Instruction Storage	0x30	1) Access control
External Input	0x40(2)	Interrupt Controller interrupt and MSR_{EE}=1
Alignment	0x50	1) **lmw**, **stmw** not word aligned 2) **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3) dcbz 4) LSP ld and st instructions not properly aligned
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=1, MPU
EFPU Data Exception	0xA0	
EFPU Round Exception	0xB0	

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

16.7.1 Exception syndrome register

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

The ESR bits are defined in *Table 236*.

SPR - 62; Read/Write; Reset - 0x0

Figure 145. Exception Syndrome Register (ESR)

Table 236. ESR Bit Settings

Bit(s)	Name	Description	Associated Interrupt Type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception (For Core (z425n3), PIL is used for both illegal and unimplemented instructions)	Program

Table 237. MSR Field Descriptions (continued)

Bit(s)	Name	Description
29	PMM	PMM Performance monitor mark bit. System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the Performance Monitor registers PMLCa n, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt - This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken
31	—	Reserved

16.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 147*.

MCP	IC_DPERR	0	DC_DPERR	EXCP_ERR	IC_TPERR	DC_TPERR	IC_LKERR	DC_LKERR	0	NMI	MAV	MEA	U	IF	LD	ST	G	0	STACK_ERR	IMEM_PERR	DMEM_RDPERR	DMEM_WRPERR	0	BUS_IRERR	BUS_DRERR	BUS_WRERR	BUS_WRDSI	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 572; Read/Clear; Reset - 0x0

Figure 147. Machine Check Syndrome Register (MCSR)

Table 238 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write ‘1’ to clear”. Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME}=1.

Table 238. Machine Check Syndrome Register (MCSR)

Bit	Name	Description	Exception Type(1)	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved		—

Table 238. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
3	DC_DPERR(2)	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR(2)	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Icache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR(2)	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Dcache for certain situations. May also be set on locked line refill error.	Async Mchk	—
10:11	—	Reserved		—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV=1,MEA=1 indicates that the MCAR contains an effective address and MEA=0 indicates that the MCAR contains a physical address	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an ECC error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or an external bus error.	Error Report	Precise

Table 238. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved		—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved		—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved		—

1. The Exception Type indicates the exception type associated with a given syndrome bit

   - “Error Report” indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

   - “Status” indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

   - “NMI” indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a “1” to the bit position.

   - “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME}=1. If MSR_{ME}=0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a “1” to the bit position(s) to be cleared.

2. Will not be set by Core (z425n3) since no data cache is present.

16.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the Interrupt Vector Prefix register (IVPR) to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 148*.

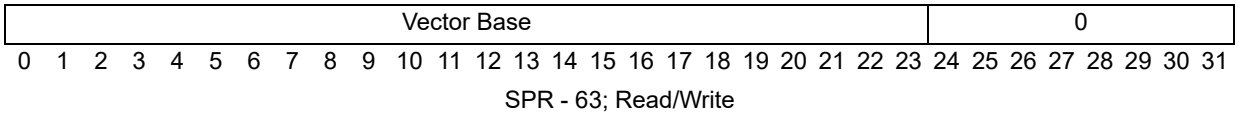

Figure 148. Zen Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in *Table 239*.

Table 239. IVPR Register Fields

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR’ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

16.7.5 Interrupt definitions

16.7.5.1 Critical input interrupt (Offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 240 lists register settings when a Critical Input interrupt is taken.

Table 240. Critical Input Interrupt—Register Settings

Register	Setting Description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME— FE0 0 DE—/0(1)	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13])** || 2‘b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

16.7.5.2 Machine check interrupt (Offset 0x10)

The Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome register (MCSR) to record the source(s) of machine checks, and a Machine Check Address register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 241*.

Table 241. Machine Check Interrupt - Register Settings

Register	Setting Description
MCSRR0	On a best-effort basis sets this to the address of some instruction that was executing or about to be executing when the machine check condition occurred.
MCSRR1	Set to the contents of the MSR at the time of the interrupt

Table 241. Machine Check Interrupt - Register Settings (continued)

Register	Setting Description		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME 0 FE0 0 DE 0/—(1)	FE1 0 IS 0 DS 0 PMM 0 RI 0
ESR	Unchanged		
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.		
Vector	$IVPR_{0:23}$ || 0x10		

1. Clearing of DE is optionally supported by control in HID0.

16.7.5.3 Data storage interrupt (Offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 242 lists register settings when a DSI is taken.

Table 242. Data Storage Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting load/store instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Access:	[ST], [SPV], VLEMI. All other bits cleared.	
MCSR	Unchanged		
DEAR	For Access Control exceptions, set to the effective address of the access which caused the violation.		
Vector	$IVPR_{0:23}$ || 0x20		

16.7.5.4 Instruction storage interrupt (Offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

Table 243 lists register settings when an ISI is taken.

Table 243. Instruction Storage Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x30		

16.7.5.5 External input interrupt (Offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 244 lists register settings when an External Input interrupt is taken.

Table 244. External Input Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Unchanged

DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x40 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13])** || 2'b00 (non-autovectored)		

16.7.5.6 Alignment interrupt (Offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** not word aligned.
- The operand of **lwarx** or **stwcx.** not word aligned.
- The operand of **lharx** or **sthcx.** not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of a LSP APU load or store instruction which is not properly aligned.

Table 245 lists register settings when an alignment interrupt is taken.

Table 245. Alignment Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	[ST], [SPV], VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Set to the effective address of a byte of the load or store access causing the violation.		
Vector	$IVPR_{0:23}$ || 0x50		

16.7.5.7 Program interrupt (Offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

core will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- Instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

core will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR}=1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions which specify a SPRN value with $SPRN_5$=1 (even if the SPR is undefined).

core will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause a illegal instruction program exception.

Table 246 lists register settings when a Program interrupt is taken.

Table 246. Program Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt

DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0x80

16.7.5.9 Debug interrupt (Offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM}$=1 (internal debug mode) and MSR_{DE}=1).

Table 248 lists register settings when a Debug interrupt is taken.

Table 248. Debug Interrupt—Register Settings

Register	Setting Description		
DSRR0(1)	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP. Set to the effective address of the next instruction to be executed *following* the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
DSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0(2) EE—/0(2) PR 0	FP 0 ME— FE0 0 DE 0	FE1 0 IS 0 DS 0 PMM 0 RI—

1. assumes that the Debug interrupt is precise.
2. conditional based on control bits in HID0.
3. Note that multiple DBSR bits may be set.

16.7.5.10 System reset interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 249 lists register settings when a System Reset interrupt is taken.

Table 249. System Reset Interrupt—Register Settings

Register	Setting Description

MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0xB0		

16.7.5.13 Performance monitor interrupt (Offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 1; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 1; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 252 lists register settings when an performance monitor interrupt is taken.

Table 252. Performance Monitor Interrupt—Register Settings

Register	Setting Description		
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.		
SRR1/ DSRR1(1)	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0(2) EE 0/—(3) PR 0	FP 0 ME— FE0 0 DE—/0(4)	FE1 0 IS 0 DS 0 PMM 0 RI—

Register	Setting Description
DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0x70

1. DSRR0/1 are used if $PMGC0_{UDI}$ = 1'.
2. CE is cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLRCE}$ = 1.
3. EE is not cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLREE}$ =0.
4. DE is cleared if $PMGC0_{UDI}$ = 1'.

16.8 MPU

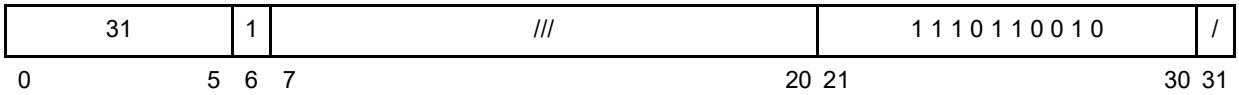
16.8.1 MPU overview

The Core (z425n3) Memory Protection Unit (MPU) provides the capability of protecting regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints

Software managed by **mpure** and **mpuwe** instructions

16.8.2 Software interface and MPU instructions



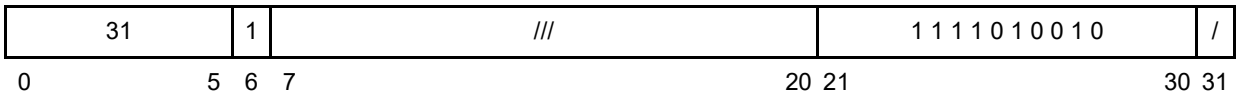
The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MPU Assist registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with a **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with a **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

16.8.3 MPU read entry instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure **mpure**
mpu readentry

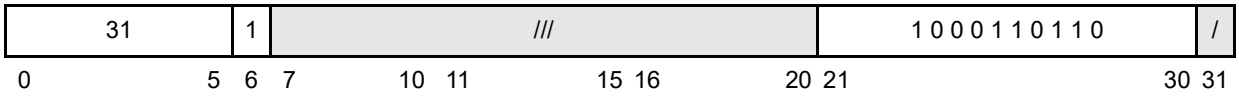


```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

16.8.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe **mpuwe**
mpu write entry



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

16.8.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the Core (z425n3).

mpusync **mpusync**
MPU Synchronize

mpusync

16.8.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the Core (z425n3) MPU design. The MMUCFG register is shown in *Figure 149*.

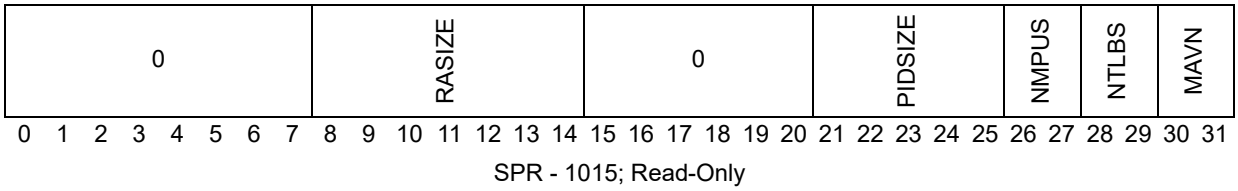


Figure 149. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 253*.

Table 253. MMUCFG Field Descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000- This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 - PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 - This version of the MMU implements one MPU structure: a fully-associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 - This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 - This version of the MMU implements Version 3.1 of the MMU Architecture

16.8.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the Core (z425n3) MPU. The MPU0CFG register is shown in *Figure 150*.

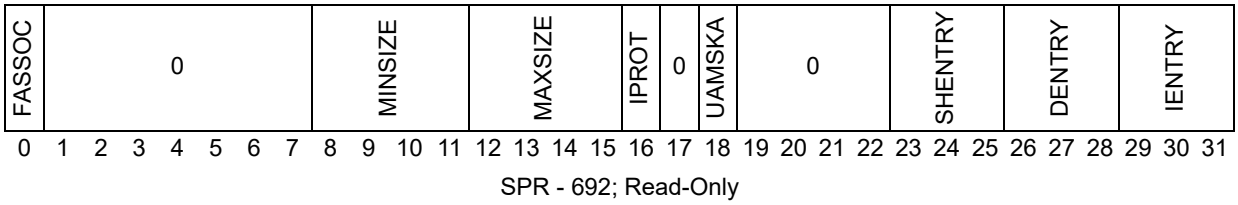

Figure 150. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in *Table 254*.

Table 254. MPU0CFG Field Descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 - Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size 0x0 - Smallest region size is 1 byte **Note:** due to the use of access address matching, the effective smallest region size is 8 bytes
12:15	MAXSIZE	Maximum Region Size 0xB - Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 - Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 - Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 - Indicates that MPU0 contains 6 shared entries
26:28	DENTRY	Number of Data Entries 0x4 - Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 - Indicates that MPU0 contains 6 dedicated Instruction entries

16.8.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in *Figure 151*.

SPR - 1014; Read/ Write; Reset - 0x0

Figure 151. MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0CSR0 bits are described in *Table 255*.

Table 255. MPU0CSR0 - MPU0 Control and Status Register 0

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses 0 - No Bypass of MPU protections for Supervisor Read accesses 1 - Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
17	BYPSW	Bypass MPU protections for Supervisor Write accesses 0 - No Bypass of MPU protections for Supervisor Write accesses 1 - Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses 0 - No Bypass of MPU protections for Supervisor Instruction accesses 1 - Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
19	BYPUR	Bypass MPU protections for User Read accesses 0 - No Bypass of MPU protections for User Read accesses 1 - Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
20	BYPUW	Bypass MPU protections for User Write accesses 0 - No Bypass of MPU protections for User Write accesses 1 - Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
21	BYPUX	Bypass MPU protections for User Instruction accesses 0 - No Bypass of MPU protections for User Instruction accesses 1 - Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
22:23	—	Reserved

Table 255. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
24	DRDEN	Data Read Debug Enable 0 - MPU debug events are disabled for data read accesses 1 - MPU debug events are enabled for data read accesses This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events.
25	DWDEN	Data Write Debug Enable 0 - MPU debug events are disabled for data write accesses 1 - MPU debug events are enabled for data write accesses This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events.
26	IDEN	Instruction Debug Enable 0 - MPU debug events are disabled for instruction accesses 1 - MPU debug events are enabled for instruction accesses This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. When enabled, instruction accesses are not blocked from generating MPU debug events.
27	—	Reserved
28	TIDCTL	TID usage Control 0 - TID comparisons performed normally 1 - no TID comparisons are performed for matching while in Supervisor mode When TIDCTL is set to ‘1’, the TID match is disabled (forced match) in Supervisor mode.
29	—	Reserved

Table 255. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate 0 - No flash invalidate 1 - MPU1 invalidation operation When written to a '1', a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to '0'. Writing a '1' while an invalidation operation is in progress will result in an undefined operation. Writing a '0' to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. Note that entries which have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable 0 - MPU is disabled 1 - MPU is enabled This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG=1 if in EDM and hardware owns MPU Debug entries.

16.8.9 MPU Assist registers (MAS)

The Core (z425n3) uses four special purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 152*. Fields are defined in *Table 256*.

VALID	IPROT	SEL	0	RO	DEBUG	INST	SHD	0	ESEL	0	UAMSK	UW	SW	UX/UR	SX/SR	IOVR	GOVR(1)	1	1	I	0	G(1)	0
0	1	2 3	4	5	6	7	8	9 10 11	12 13 14 15	16	17 18 19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 624; Read/ Write; Reset - Unaffected

Figure 152. MPU Assist Register 0 (MAS0)

1. This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1

Table 256. MAS0 —MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 - This MPU entry is invalid 1 - This MPU entry is valid
1	IPROT	Invalidation Protect 0 - Entry is not protected from invalidation 1 - Entry is protected from invalidation

Table 256. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 - Reserved, no access 01 - Reserved, no access 10 - Select MPU 11 - Reserved, no access
4	—	Reserved
5	RO	Read-Only 0 - This MPU entry is writable 1 - This MPU entry is Read-only When set to ‘1’, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs.
6	DEBUG	Debug Control for Entry 0 - This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 - This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access.
7	INST	Instruction Entry 0 - This MPU entry is used for matching data accesses only 1 - This MPU entry is used for matching instruction accesses only When SHD=0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD=1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry.
8	SHD	Shared Entry Select 0 - The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 - The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected. This bit is used to control selection of the Shared portion of the region descriptor table.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.

Table 256. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control 000 - No upper address bits are masked, address matching uses all 32 address bits for accesses 001 - The most significant access address bit is forced to zero before matching 010 - The two most significant access address bits are forced to zero before matching. 101 - The upper 5 access address bits are forced to zero before matching 11x - Reserved, do not use This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly.
20	UW	User Mode Write Permission 0 - No User mode Write permission 1 - User mode has Write permission Determines User mode Write (W) permission when INST=0. Ignored when INST=1.
21	SW	Supervisor Mode Write / Read Permission 0 - No Supervisor mode Write permission 1 - Supervisor mode has Write permission Determines Supervisor mode Write (W) permission when INST=0. Ignored when INST=1.
22	UX/UR	User Mode Execute / Read Permission 0 - No User mode Execute/ Read permission 1 - User mode has Execute/ Read permission Determines User mode Execute (X) permission when INST=1, or User mode Read (R) permission when INST=0.
23	SX/SR	Supervisor Mode Execute / Read Permission 0 - No Supervisor mode Execute/ Read permission 1 - Supervisor mode has Execute/ Read permission Determines Supervisor mode Execute (X) permission when INST=1, or Supervisor mode Read (R) permission when INST=0.
24	IOVR	Cache-Inhibit attribute Override 0 - No override of I attribute by entry 1 - Entry I bit overrides I attribute Determines whether this matching entry overrides the I bit settings of other matching entries and the Cache-Inhibited region configuration signals
25	GOVR/—	G attribute Override 0 - No override of G attribute by entry 1 - Entry G bit overrides G attribute Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
26	—	Reserved
27	—	Reserved

Table 256. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
28	I	Cache Inhibited 0 - This region is considered cacheable 1 - This region is considered cache-inhibited This attribute may be overridden by the cache-inhibited region configuration input settings.
29	—	Reserved
30	G/—	Guarded 0 - Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 - All loads and stores to this region are performed without speculation (that is they are known to be required) This attribute may be overridden by the guarded region configuration input settings. This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
31	—	Reserved

The MAS1 register is shown in *Figure 153*. Fields are defined in *Table 257*.

0								TID								0								TIDMSK							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

16.8.10 MAS registers summary

The MAS registers are summarized in *Figure 156*.

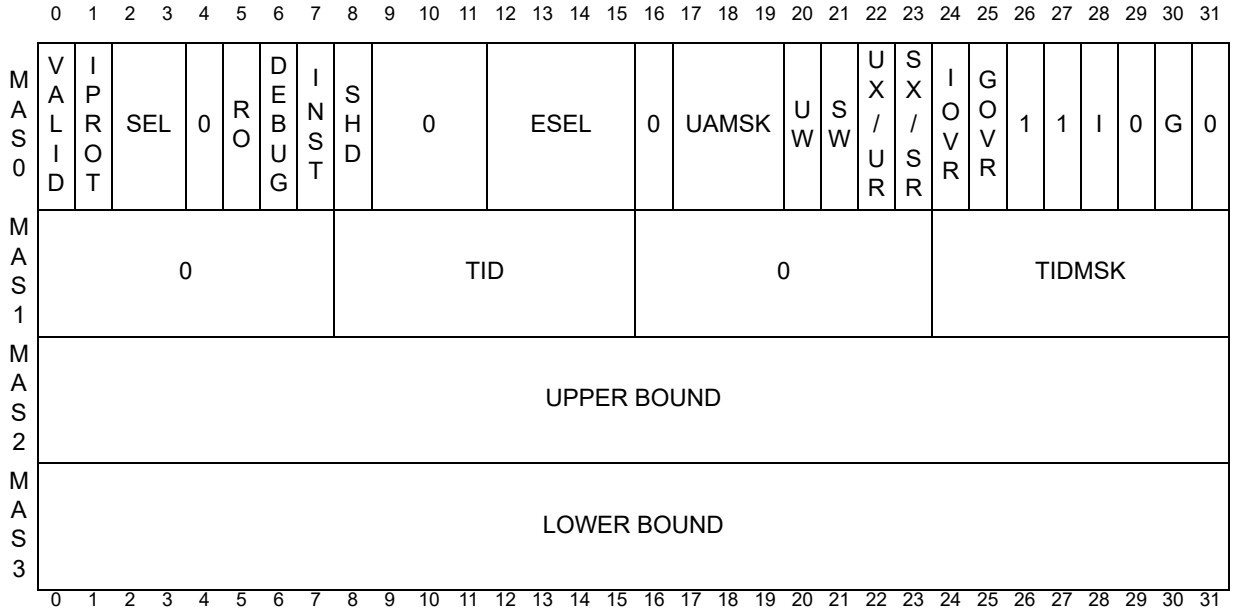

Figure 156. MPU Assist Registers Summary

16.9 Local memories

16.9.1 Local instruction and data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added to the next generation processor cores. These memories provide for low latency access (zero wait-state) similar to an instruction or data cache, but do not suffer from the overhead of cache miss or cache Writethrough operations. Instead, they provide “tightly coupled” storage.

16.9.2 Local memory control and configuration

DMEM and IMEM local memory configuration is provided by a set of privileged read-only SPRs which are accessed using **mfspr** instructions. DMEM and IMEM local memory is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

16.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the Core (z425n3) local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 157*.

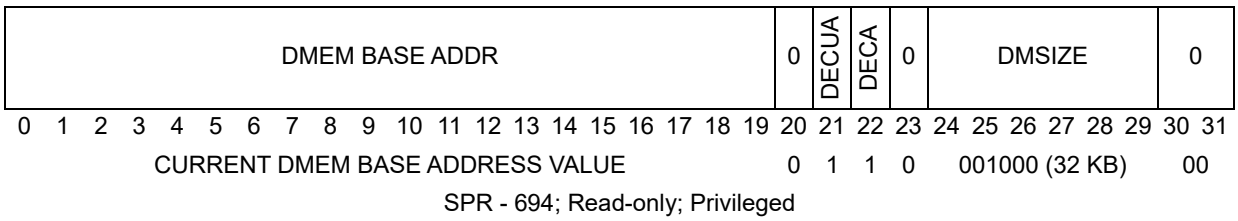

Figure 157. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 260*.

Table 260. DMEMCFG0 Field Descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCFG0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** low order bits of this field are driven to 0's when the DMEM size is > 4 Kbyte
20	-	Reserved
21	DECUA	DECUE - DMEM Error Correction Update Available 0 - Error Correction Update is not available 1 - Error Correction Update is available for correction of a correctable single-bit error detected on a read access DECUA indicates an error scrubbing function for the DMEM is available.
22	DECA	DECUE - DMEM Error Correction Available 0 - Error Correction is not available 1 - Error Correction is available DECA indicates an error correction function for the DMEM is available.
23	-	Reserved
24:29	DMSIZE	DMSIZE - DMEM Size 001000 - The size of the DMEM is 32 Kbyte
30:31	-	Reserved

16.9.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCECE	DSECE
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16	17 18	19	20	21	22	23	24	25	26	27 28	29	30	31

DCR - 496; Read/Write; Reset(1) - 19‘b0 || p_dmem_rstcfg[8,6:7,0] || 4‘b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 158. DMEM Control Register 0 (DMEMCTL0)

1. reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 261. DMEMCTL0 Field Descriptions

Bits	Name	Description
0:16	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
17:18	-	Reserved
19	DBYPCB	DBYPCB - DMEM Bypass Cache Bypass CPU accesses 0 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port 1 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses which target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input.
20	DBYPAT	DBYPAT - DMEM Bypass Atomic CPU accesses 0 - Atomic CPU accesses do not bypass the DMEM CPU port 1 - Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems which support reservation or decoration functionality (or both), since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input.

Table 261. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
21	DBYPDEC	DBYPDEC - DMEM Bypass Decorated CPU accesses 0 - Decorated Load and Store CPU accesses do not bypass the DMEM CPU port 1 - Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems which support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input.
22	DECUE	DECUE - DMEM Error Correction Update Enable 0 - Error Correction Update is disabled 1 - Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be re-written with the corrected data. (Write accesses perform this correction automatically during partial-width writes.) DECUE can be used to provide an error scrubbing function for the DMEM. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input.
23	-	Reserved
24	DBAPD	DBAPD - DMEM Base Address Port Disable 0 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses. This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses.
25	DPEIE	DPEIE - DMEM Processor Error Injection Enable 0 - Error Injection is disabled 1 - A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]). DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE=0.
26	DICWE	DICWE - DMEM Imprecise CPU Write Enable 0 - Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 - Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only). DICWE may allow for increased partial-width write performance when set.

Table 261. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
27:28	DSWCE	DSWCE - DMEM Slave port Write Check/Correct Enable 00 - Slave write data is not checked or corrected for errors. 01 - Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 - Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 - Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or double word writes are not checked or corrected for errors. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs.
29	DDAUEC	DDAUEC - DMEM Disable Address Use in Error Check 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input.
30	DCECE	DCPECE - DMEM CPU Port ECC Enable (CPU port) 0 - End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1- End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input.
31	DSECE	DSECE - DMEM Slave port Error Checking Enable (Slave port) 0 - End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 - End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input.

16.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally-sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses which target DMEM address range, regardless of

whether the access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB,}$ DBYPATF, DBYPDEC·

DCR - 498; Read/Write; Reset(1) - 32‘b0; Privileged

A single control field is used for each access based on the upper two address bits used to index into the DMEM. DURAC0 is used when these two bits = 2‘b00

16.9.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the Core (z425n3) local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in *Figure 160*.

IMEM BASE ADDR	0	IECUA	IECA	0	IMSIZE	0
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19	20	21	22	23	24 25 26 27 28 29	30 31
CURRRENT IMEM BASE ADDRESS VALUE	0	1	1	0	000100 (16 KB)	00

SPR - 695; Read-only; Privileged

Figure 160. IMEM Configuration Register 0 (IMEMCFG0)

The IMEMCFG0 fields are described in *Table 263*.

Table 263. IMEMCFG0 Field Descriptions

Bits	Name	Description
0:19	IMEM BASE ADDR	IMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the IMEM. This field reflects the value of the external IMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of IMEMCFG0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** low order bits of this field are driven to 0's when the IMEM size is > 4 Kbyte
20	-	Reserved
21	IECUA	IECUE - IMEM Error Correction Update Available 0 - Error Correction Update is not available 1 - Error Correction Update is available for correction of a correctable single-bit error detected on a read access IECUA indicates an error scrubbing function for the IMEM is available.
22	IECA	IECUE - IMEM Error Correction Available 0 - Error Correction is not available 1 - Error Correction is available IECA indicates an error correction function for the IMEM is available.
23	-	Reserved
24:29	IMSIZE	IMSIZE - IMEM Size 000100 - The size of the IMEM is 16 Kbyte
30:31	-	Reserved

16.9.2.5 IMEM Control Register 0 (IMEMCTL0)

The IMEM Control Register 0 (IMEMCTL0) controls operation of certain functions of the IMEM logic.

IMEM BASE ADDR	0	0	IECUE	0	IBAPD	0	ISWCE	IDAUEC	ICECE	ISECE
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17	18 19	20 21	22	23	24	25 26	27 28	29	30	31

DCR - 497; Read/Write; Reset(1) - 22'b0 ||| p_imem_rstcfg[0] || 4'b0 || p_imem_rstcfg[1:5]; Privileged

Figure 161. IMEM Control Register 0 (IMEMCTL0)

1. reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 264. IMEMCTL0 Field Descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the ICache for the memory space to be occupied by the IMEM.
18:19	-	Reserved for Base Address extension
20:21	-	Reserved
22	IECUE	IECUE - IMEM Error Correction Update Enable 0 - Error Correction Update is disabled 1 - Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read or partial-width write cycles will cause the IMEM to be re-written with the corrected data. IECUE can be used to provide an error scrubbing function. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[0]** input.
23	-	Reserved
24	IBAPD	IBAPD - IMEM Base Address Port Disable 0 - The external IMEM base address port (**p_imem_baseaddr[0:n]**) is used to define the base address of the IMEM for CPU accesses. 1 - The external IMEM base address port (**p_imem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses. This bit controls usage of the external Base Address port (**p_imem_baseaddr[0:n]**) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses.
25:26	-	Reserved
27:28	ISWCE	ISWCE - IMEM Slave port Write Check/Correct Enable 00 - Slave write data is not checked or corrected for errors. 01 - Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 - Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 - Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the values of the **p_imem_rstcfg[1:2]** inputs.

Table 264. IMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
29	IDAUEC	IDAUEC - IMEM Disable Address Use in Error Check 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[3]** input.
30	ICECE	ICPECE - IMEM CPU Port ECC Enable (CPU port) 0 - End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1- End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[4]** input.
31	ISECE	ISECE - IMEM Slave port Error Checking Enable (Slave port) 0 - End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 - End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[5]** input.

16.9.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally-sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

28:29	IUXAC1	IUXAC1 - IMEM User Instruction Fetch Access Control for Quadrant 1 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 1 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 1 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 1 of IMEM based on memory protection logic 11 - Reserved **Note:** individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC1 is used when these two bits = 2‘b01
30:31	IUXAC0	IUXAC0 - IMEM User Instruction Fetch Access Control for Quadrant 0 00 - User-mode CPU instruction fetch accesses are allowed to quadrant 0 of IMEM 01 - User-mode CPU instruction fetch accesses are not allowed to quadrant 0 of IMEM 10 - User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 0 of IMEM based on memory protection logic 11 - Reserved **Note:** individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC0 is used when these two bits = 2‘b00

16.10 End-to-End ECC support

This chapter describes End-to-End Error detection and correction capability (e2eECC) enhancements the Core (z425n3) to address additional diagnostic capabilities for the next generation of embedded designs.

16.10.1 e2eECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

16.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

Note: Even if e2eECC is disabled, storage are protected by ECC as reported in Section 6.4.4: ECC.

DCR - 510; Read/Write; Reset - 0x0 || p_e2e_rstcfg[0:3]; Privileged

Figure 163. e2eECC Control Register 0 (E2ECTL0)

Table 266. E2ECTL0 Field Descriptions

Bits	Name	Description
0:27	-	These bits are reserved
28	IDAC	IDAC - Instruction Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Instruction AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 - End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 - End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.

Table 266. E2ECTL0 Field Descriptions (continued)

Bits	Name	Description
30	DDAC	DDAC - Data Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Data AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 - End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 - End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

Enabling of e2eECC operation is performed by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a one. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for non-zero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

16.10.1.2 End-to-end ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address or checkbit error on external bus write cycles, and then may read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus.

Note that Nexus3 accesses do not cause error injection or capturing of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 164 shows the layout of E2EECSR0.

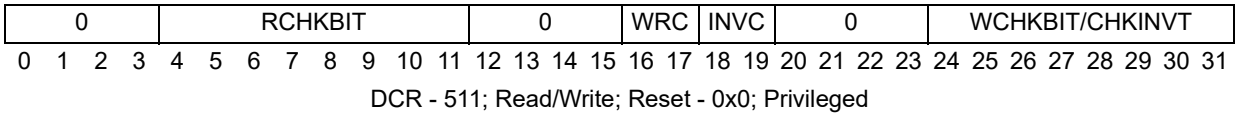

Figure 164. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 267. E2EECSR0 Field Descriptions

Bits	Name	Description
0:3	-	These bits are reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	-	These bits are reserved
16:17	WRC	Write Control 00 - No write checkbit substitution is performed by this control bit 01 - Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 - Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11- Reserved **Note:** checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 - No error injection is performed by this control bit 01 - Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 - Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 - Reserved **Note:** checkbit substitution has priority over Error injection

Table 267. E2EECSR0 Field Descriptions (continued)

Bits	Name	Description
20:23	-	These bits are reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits /Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 - Checkbit is driven normally 1 - Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

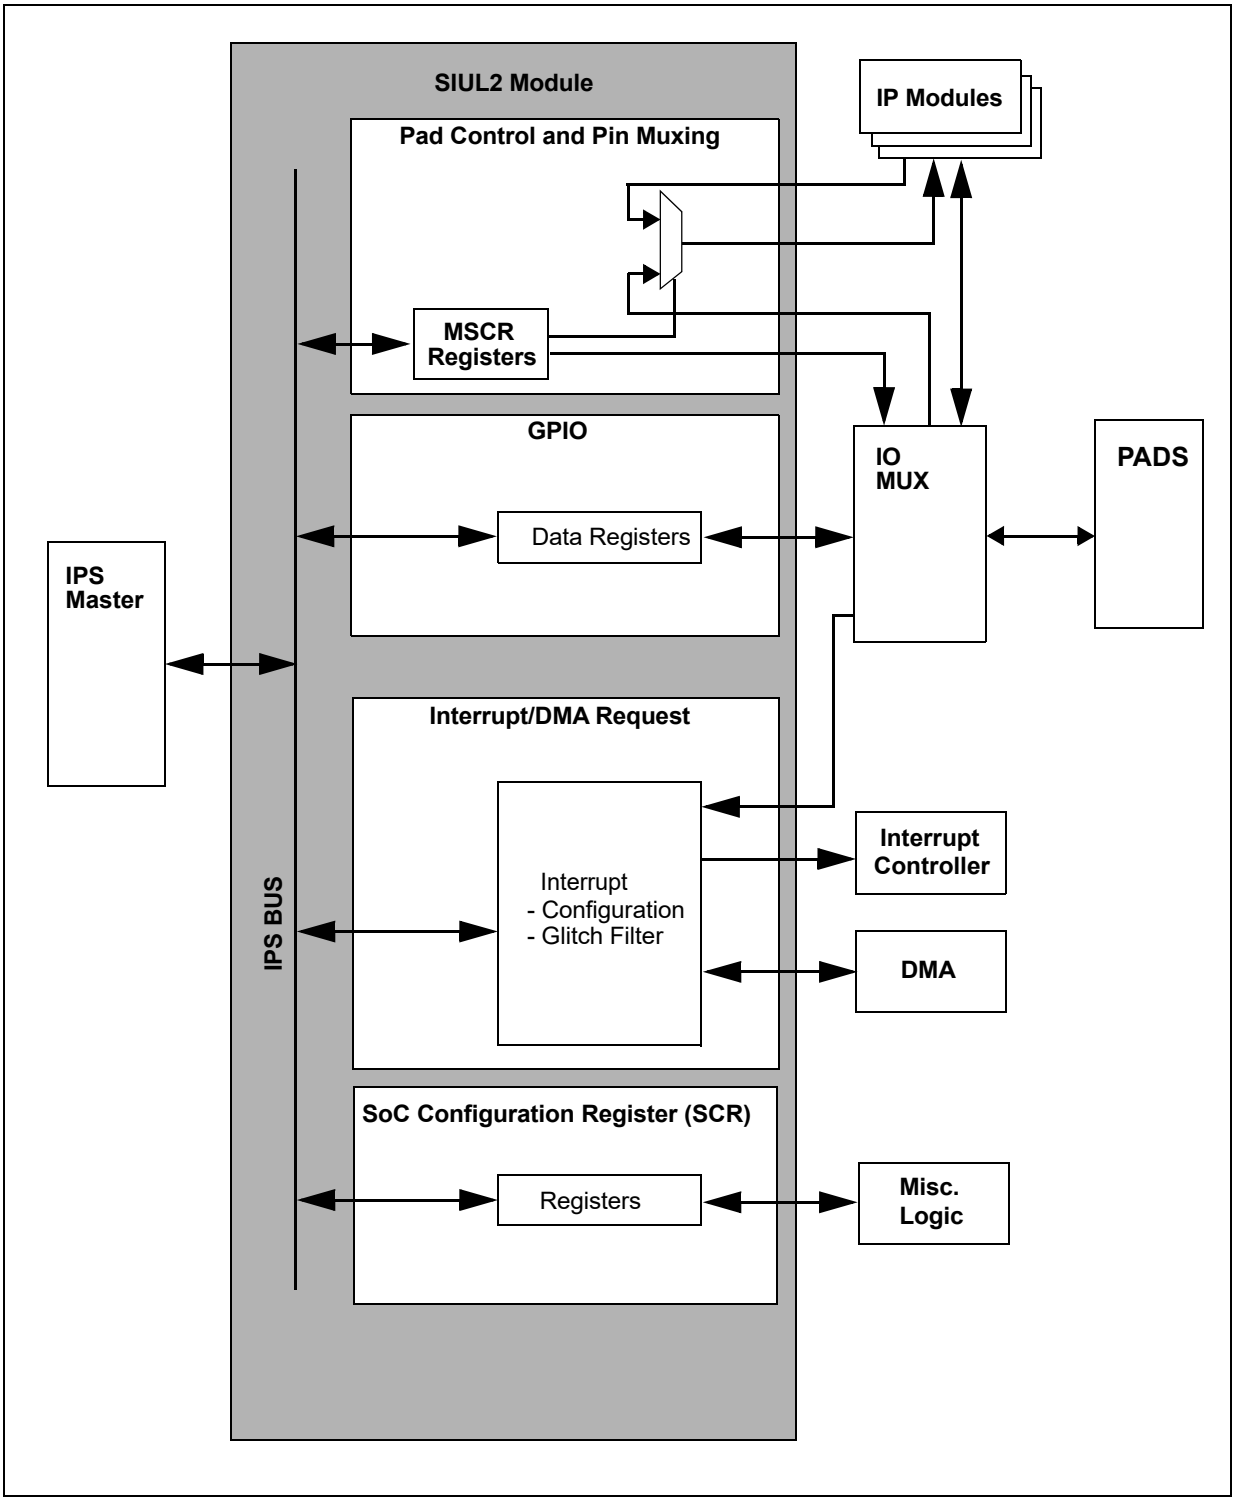
17 System Integration Unit Lite2 (SIUL2)

17.1 Introduction

17.1.1 Overview

The System Integration Unit Lite2 (SIUL2) provides control over all the I/O ports on this device and supports 13 ports with up to 16 bits of bidirectional, general-purpose input and output signals. It supports 16 external interrupts with trigger event configuration. *Figure 165* is the block diagram of SIUL2 and its interfaces to other system components for this device.

The SIUL2 provides the GPIO ports on the device.



- When configured as output, you can write to the internal GPDO register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from the internal GPDI register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the driven value on the associated I/O pad.

In order to assist in software development, there are different access mechanisms to the GPIO data registers. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation:

- Access to two 16-bit ports in one access
- Read/Write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access

There are 16 external interrupts and 16 DMA inputs to the SIUL2 that map to EIRQ pins on the device. The interrupt/DMA sources can be configured to have a digital filter to reject short glitches on the inputs.

Figure 165. SIUL2 block diagram[9]

9. For pinout details, refer to the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document.

17.1.2 Features

The SIUL2 supports these distinctive features:

- 13 GPIO ports with data control[10]
  - Drive data to up to 16 independent I/O channels
  - Sample data from up to 16 independent I/O channels
- Two 16-bit registers can be read/written with one access to a 32-bit port if needed.
- External interrupt/DMA request support with:
  - 2 system interrupt vectors for 16 interrupt sources (16 connected to EIRQ pins for this device) with independent interrupt mask
  - 16 programmable digital glitch filters (one for each EIRQ)
  - Independent DMA channels for each EIRQ pin
  - Edge detection

Details about the electrical parameters and setting of functional pads can be found in the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document. These are used to configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control of JTAG and FlexRay pins
- Internal weak pull control
- Pin function assignment
- Safe mode behavior configuration
- TTL, CMOS and Automotive input levels

17.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0(SIUL2_DIRER0)
- SIUL2 DMA/Interrupt Request Select Register 0(SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0(SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0(SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0(SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

Details about the protected registers at specific addresses can be found in *Chapter 91: Register Protection (REG_PROT)* and *Chapter 7: Device configuration*.

10. For pinout details, refer to the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document.

17.2 Memory map and register description

This section provides a detailed description of all registers accessible in this module.

17.2.1 Memory map

Table 268 gives an overview of the SIUL2 registers implemented.

Note: Reserved registers will be read as 0, write will have no effect. If supported and enabled in this MCU, a transfer error will be issued when trying to access completely reserved register space. A 8-bit or 16-bit access to an "only 32-bit supported access register" gives a transfer error. Unimplemented register accesses give transfer error, that is due to register not being present.

For SIUL2_MSCR_MUX_512-SIUL2_MSCR_MUX1023, only 32/16-bit accesses are supported (8-bit writes do not occur and read zeros).

Table 268. SIUL2 memory map

17.2.2.3 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set irrespective of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) is enabled. The EIF bit remains set until cleared by software or through

the servicing of a DMA request. The EIF bits are cleared by writing a '1' to the bits. A write of '0' has no effect.

This register contains the interrupt flags.

Figure 168. SIUL2 DMA/Interrupt Status Flag Register (SIUL2_DISR0)

Table 271. SIUL2_DISR0 field descriptions

Field	Description
16:31 EIF[15:0]	External Interrupt Status Flag x This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

17.2.2.4 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

Field	Description
16:31 EIRE[15:0]	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR

17.2.2.5 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

Table 277. SIUL2_IFMCR*n* field descriptions

Field	Description
28:31 MAXCNT	Maximum Interrupt Filter Counter setting (MAXCNTx) Filter Period = TCK*MAXCNTx + n*TCK where (n = -1 to 3) MAXCNT can be 0 to 15 (for MAXCNT<3 filter will behave as all PASS filter) TCK is the Prescaled filter clock period, which is the IRC clock prescaled to IFCP value, specified in SIUL2_IFCPR T(IRC): Basic filter clock period 62.5 ns (f = 16 MHz) Note that filter delay is 2 system clock cycles more than filter period. In general, Filter Period and Filter delay are not integer multiple of TCK because input to Filter is asynchronous whereas output is synchronous with respect to the TCK. T(DELAY) = (1 to 5) * TCK + MAXCOUNT * TCK. The SW is to expect the worst filter delay value

17.2.2.10 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register configures a clock prescaler that selects the clock for all digital filters. The prescaler is applied to the input clock to the SIUL2, which is the system PBRIDGE clock counter in the SIUL2. Refer to *Chapter 27: Clocking* for information on clocking.

Table 278. SIUL2_IFCPR field descriptions

Field	Description
28:31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15.

17.2.2.11 Soc Configuration Register 0 (SIUL2_SCR0)

The ETHERNET_0_MODE bit is used to select between the Media Independent Interface (MII) and the Reduced Media Independent Interface (RMII) mode for the Ethernet.

MASK_OPCn is used to prevent the SSWU OPC channel n to drive the pad during standby.

PADn_MUX_SEL is used to maintain the pad value at standby exit (PADn_MUX_SEL = 0)

Note: PADn_MUX_SEL must be set to 1 to be able to change the pads value and direction after stand-by while system is in the RUN mode.

17.2.2.12 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO*n*)

Refer to *Section 17.2.3: Multiplexed Signal Configuration Registers* for an introduction to the MSCRs.

This section defines the I/O pin MSCRs. These registers select the output function on the associated I/O pin. The I/O MSCRs control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, and safe-mode operation of the associated I/O pin.

Note: Not all pads have all bits, such as only some pads have hysteresis. Refer to the I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document.

Note that when an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs, and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

All bits and fields in the I/O MSCRs are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The MSCR reset state is detailed in the I/O Signal Table of the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document.

Figure 177. I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO*n*)

Table 280. SIUL2_MSCR_IO*n* field description

Field	Description
2:3 OERC	Output Edge Rate Control Specifies the output impedance, drive strength and slew rate of the associated pin. Refer to output Impedance columns in the I/O Signal Description Table for the applicable edge rates for each I/O pin on the device. The I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) are attached to the IO_Definition document. Refer to the device Data Sheet for the electrical characteristics of the weak, medium, strong, and very strong pad types **Note:** OERC[2] programming is required for forward compatibility. 00 Weak drive 01 Medium drive 10 Strong drive 11 Very Strong drive
5:7 ODC	Output Drive Control Specifies the type of output drive control for the associated pin. 000 Output buffer disabled 001 Open-drain 010 Push-pull 011 Open-source 100 Microsecond Channel LVDS 101 LFAST LVDS 110 Reserved 111 Reserved **Note:** In order to configure the LVDS-Input functionality of the pins supporting it, set ODC=000 (Output buffer disabled)
8 SMC	Safe Mode Control Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. Resets to 0 except for PB[11] ERROR0 pin which resets to 1. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Does not disable

Table 280. SIUL2_MSCR_IO*n* field description (continued)

Field	Description
10:11 ILS	Input Level Selection Specifies the logic family for the associated pin, which determines its logic switching levels. Refer to the device Data Sheet for the electrical characteristics of the I/O pad input buffer types. – in case of pin with MSCR[10] bit configurable, following logic levels are valid: 00 Automotive for SPC58xEx, Reserved for SPC58xGx 01 TTL 10 LVDS 11 CMOS **Note:** In order to configure the LVDS-Input functionality of the pins supporting it, set – in case of pin with MSCR[10] bit not configurable, following logic levels are valid: MSCR[10] – not implemented, don't care MSCR[11] = 0: CMOS for SPC58xGx, Auto for SPC58xEx MSCR[11] = 1: TTL for SPC58xGx/SPC58xEx Refer to the IO_Definition excel file to check if MSCR[10] bit of a specific pin is configurable or not
12 IBE	Input Buffer Enable Enables the associated pin's input buffer. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. If pin has analog input-only functionality: when WPDE and WPUE are both enabled that pin is configured with Strong pulldown. On all other pins (including analog bidirectional) this configuration means neither a pullup nor a pulldown. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. If pin has analog input-only functionality: when WPDE and WPUE are both enabled that pin is configured with Strong pulldown. On all other pins (including analog bidirectional) this configuration means neither a pullup nor a pulldown. 0 Disabled 1 Enabled

Table 280. SIUL2_MSCR_IO*n* field description (continued)

Field	Description
16 INV	Invert The output selected by the corresponding MSCR SSS field can be inverted before it is driven on the I/O pin with the INV bit. **Note:** Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection. 0 The output selected by the SSS field is not inverted before being driven to the pin 1 The output selected by the SSS field is inverted before being driven to the pin
24:31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. Refer to *Section 17.2.3.1* and *Section 17.2.3.2*.

Table 281. I/O MSCR Reset State Exceptions

Port	Critical Function	SMC	WPDE	WPUE
PA[4]	—	0	0	1
PA[5]	JCOMP	1	1	0
PA[6]	TCK	1	1	0
PA[7]	TMS	1	0	1
PA[8]	TDI	0	0	1
PA[9]	TDO	0	0	1(1)
PA[14]	—	0	0	1
PB[11]	ERROR	1	0	0
PC[10:15]	—	0	0	1
PD[6:7]	—	0	0	1

PF[13]	—	0	0	1
PI[14:15]	—	0	0	1
PK[12:15]	—	0	0	1
PM[0:8]	—	0	0	1

1. When JTAG is enabled (JCOMP asserted) during reset, the TDO pin is pulled up during reset, but Hi-Z after. If JTAG is disabled, the TDO pin defaults to input/pull-up during and after reset.

17.2.2.13 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_MUX*n*)

Refer to *Section 17.2.3: Multiplexed Signal Configuration Registers* for an introduction to the MSCRs.

This section defines the multiplexed input selection MSCRs. These registers select the input source for IP blocks on the device that have inputs from multiple sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

Table 282. SIUL2_MSCR_MUX*n* field descriptions

Field	Description
16 INV	Invert The input source signal selected by the corresponding SSS field for this MSCR can be inverted before it connects to the destination input with the INV bit. 0 SSS selected input signal is connected directly to the destination input 1 SSS selected input signal is inverted before it is connected to the destination input
24:31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. Refer to *Section 17.2.3.1* and *Section 17.2.3.2*.

17.2.2.14 GPIO Pad Data Output Registers (SIUL2_GPDO*n*)

These registers can be used to set or clear a single GPIO pad with a byte access. For mapping of ports to GPDO registers, refer to the I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document. Note that the GPDO registers do not apply for ports PA[5], PA[6] and PA[7]. The PA ports are JTAG pins with no GPIO. Writes to the GPDO register corresponding to these ports have no effect.

Note: For the exact number of registers, refer to the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document.

Field	Description
7 PDI	Pad Data In This bit stores the value of the external GPIO pad associated with this register. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

17.2.2.16 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be

written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write. Note that the PGPDO registers do not apply for ports PA[5], PA[6] and PA[7]. These PA ports are JTAG pins with no GPIO. Writes to the PGPDO register corresponding to these ports have no effect.

Note: The SIUL2_PGPDO registers access the same physical resources as the SIUL2_PDO and SUIL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

Offset: 0x1700 + n*0x2 (n=0 to 12) Access: User read/write

Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit indexes define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

17.2.2.17 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read. Note that the GPDI registers do not apply for ports PA[5], PA[6] and PA[7]. These ports are JTAG pins with no GPIO. The GPDI values corresponding to these ports always read a value of zero.

Field	Description
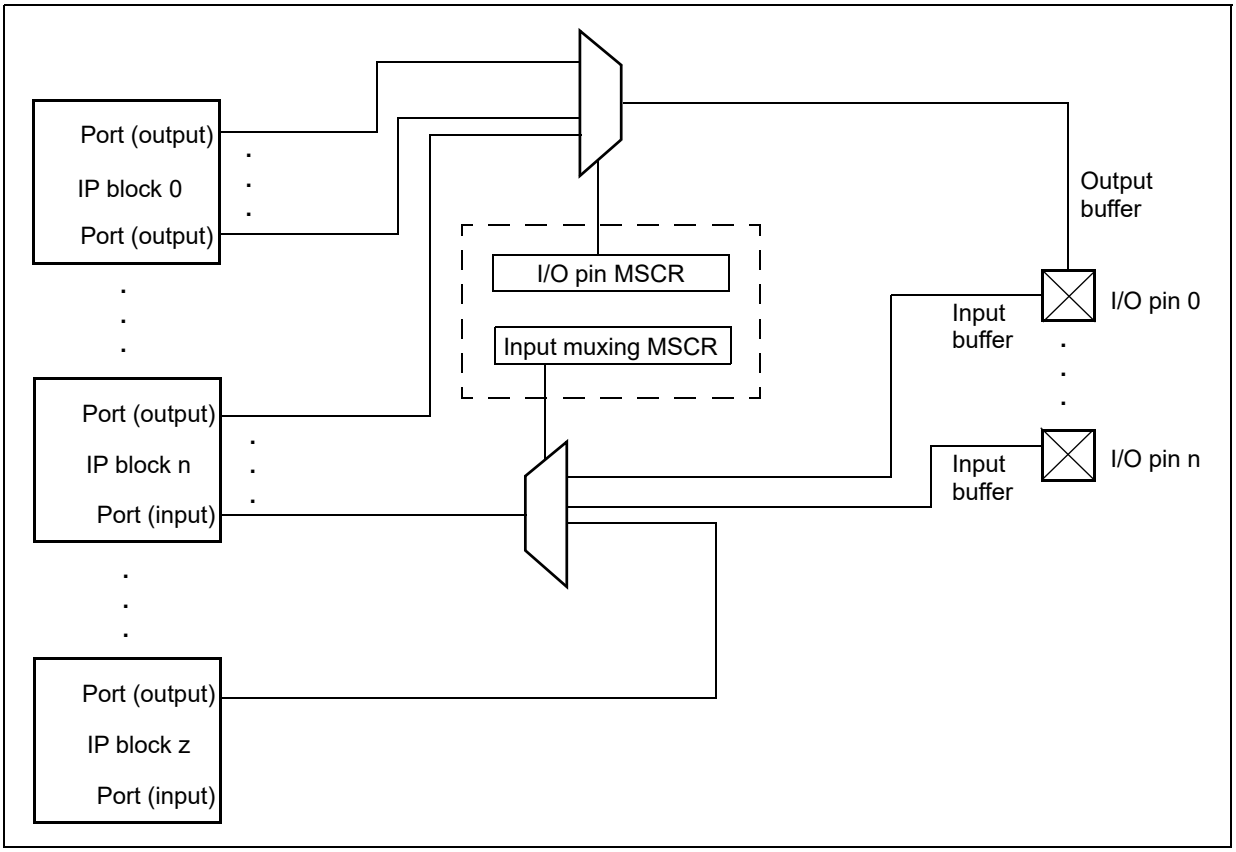
0:15 MASK	Mask Field Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0 The associated bit value in the MPPDO[x] field is ignored 1 The associated bit value in the MPPDO[x] field is written
16:31 MPPDO	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO). The x and y bit indexes define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x * 16) + y]

17.2.3 Multiplexed Signal Configuration Registers



The MSCRs control the I/O pin function and electrical properties for each pin on the device, and are used to select the input signal for IP blocks on the device that have multiple input sources. There is a dedicated MSCR register for each I/O pin on the device. Each MSCR register is independent of the others, except in the case of an LVDS configuration, where two MSCR registers must be configured together in this mode. When LVDS is configured, CMOS pad is disabled (ibe and obe = 0) and when LVDS is not configured, (either of two MSCRs not configured for lvds) then the lvds pad is disabled (lvds_ibe and lvds_obe = 0).

The MSCRs are divided into two sets:

- I/O pin control registers, refer to *Section 17.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*
- Multiplexed input selection registers, refer to *Section 17.2.2.13: Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_MUXn)*

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in *Figure 184*.

Figure 184. MSCR I/O pin and IP block port connectivity

17.2.3.1 Chip-pin MSCR assignments and related information

For device pin MSCR register definitions, refer to the SPC58xEx/SPC58xGx I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document.

17.2.3.2 Module-port MSCR assignments and SSS values

For each internal module port that is or can be configured as an input and has more than one possible source. Refer to the SPC58xEx/SPC58xGx I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document. The Input Multiplexing Table shows the assigned MSCR, and the SSS values and their corresponding source signals.

17.3 Functional description

17.3.1 General

This section provides a complete functional description of the SIUL2.

17.3.2 Pad control

The SIUL2 controls the electrical characteristics of the pads on the device through the MSCR registers. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2.

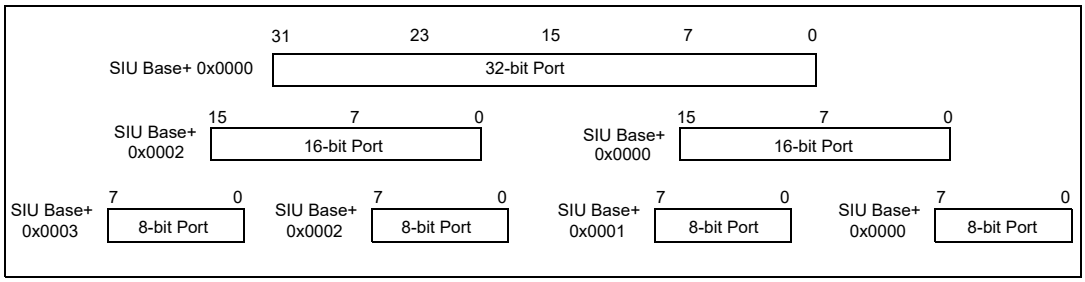
The required controls are:

- Slew rate control
  - This is needed to offer improved EMC performance.
  - Support for a fast and slow slew rate.
- Output Impedance Control
  - 4 output impedances, drive strength and slew rates supported.
- Internal weak pull capability
  - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
  - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Safe Mode behavior configuration
- Open drain/source enable
  - Needed to support different pads muxed (for example mux IIC, with non open drain pads).
- Pin Function Assignment
  - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

17.3.3 General purpose input or output pads (GPIO)



The SIUL2 allows each pad to be configured as either a General Purpose Input Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 202 GPIO pads (205 pads less 3 reserved for JTAG) organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in *Figure 185*, all port accesses are identical with each read or write being performed only at a different location to access a different port width.

Figure 185. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

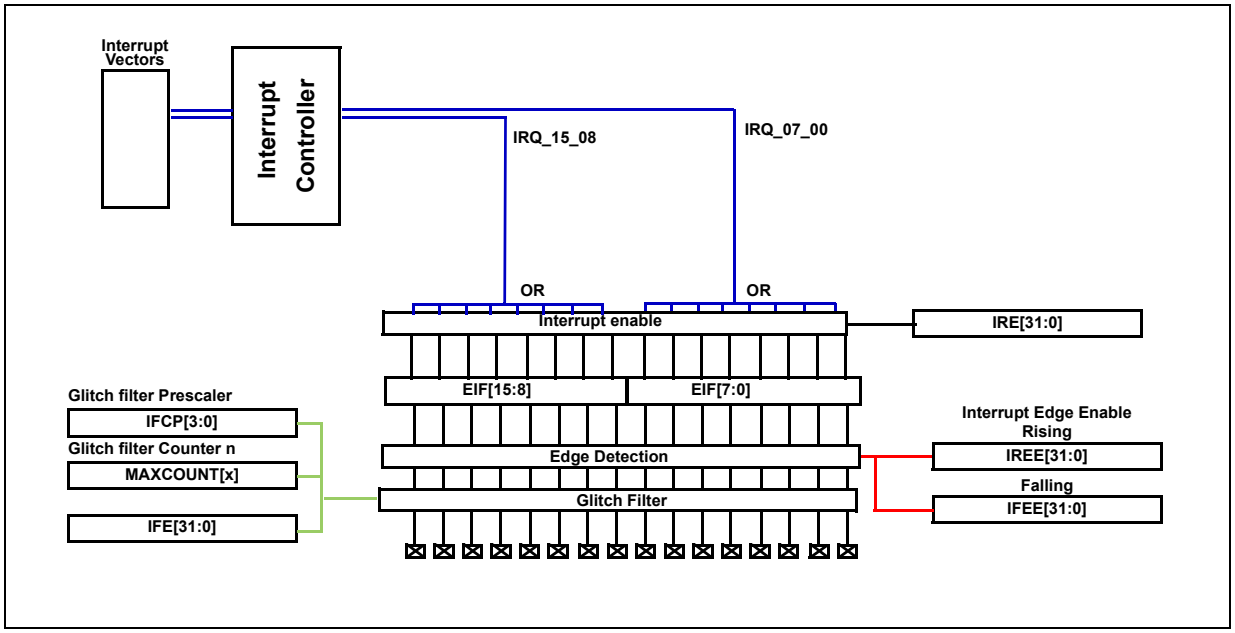
The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note: In case the bidirectional operation impacts some performances (for example ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only".



17.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports 16 external interrupts which are allocated to EIRQ pins on the device

The SIUL2 supports 2 interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support eight external interrupt sources from the device pads.

Refer to *Figure 186* for an overview of the external interrupt implementation.

Figure 186. External interrupt pad diagram

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

17.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
  - Clear the ODC bits to do disable output.
  - Set the IBE bit to enable the pin’s input buffer.
  - If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note: MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

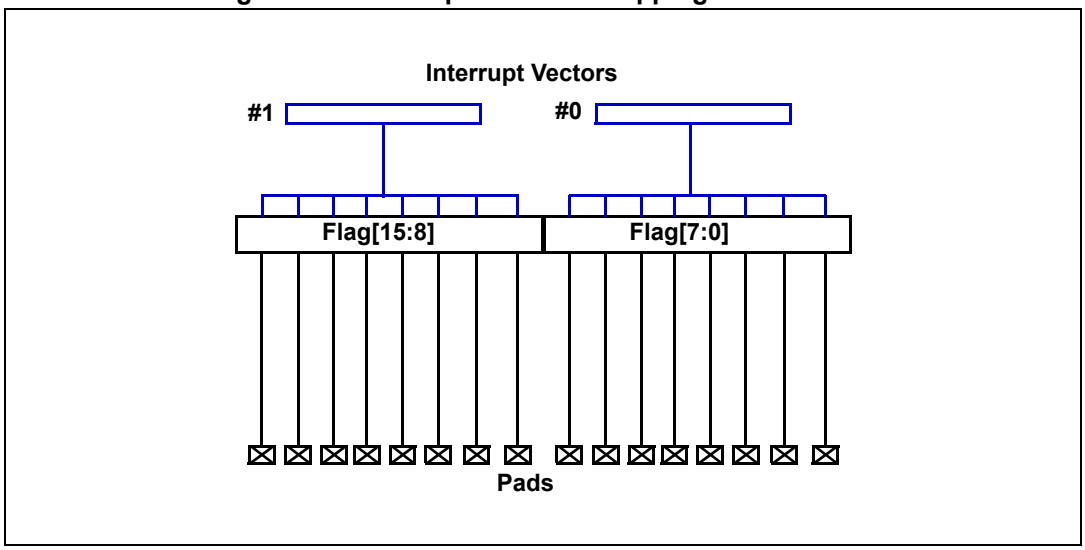
- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
  - Then enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

Note: The glitch filter clock runs on the internal RC oscillator clock whereas the SIUL logic runs on the PBRIDGEx clock. The IRC clock is at a fixed frequency of 16 MHz. The PBRIDGEx clock can on higher clock (refer to the Clocking chapter)

The glitch filter is enabled on IRC clock, so make sure at least one IRC clock occurs after enabling it before trying to detect glitchless events.

- Write to EIFn bits in DISR0 to as desired to clear any flags (for DMA it is self clearing).
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

17.3.4.2 External interrupt management



Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (SIUL2_DIRER0). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

The SPC58xEx/SPC58xGx device supports 2 SIUL2 interrupt vectors aggregating a total of 16 external interrupt sources as shown in *Figure 187*.

Figure 187. Interrupt to vector mapping at MCU level

17.3.4.3 External interrupt request

The EIRQ input pins on the device are sources for interrupt or DMA requests. The 16 EIRQ pins for the device map to 2 interrupt requests. The mapping of interrupt requests and EIRQ pins is given in *Table 288*.

Table 288. Interrupt source mapping to SIUL2 interrupt request output

Interrupt requests	EIRQ pins
0	EIRQ0 | EIRQ1 | EIRQ2 | EIRQ3 | EIRQ4 | EIRQ5 | EIRQ6 | EIRQ7
1	EIRQ8 | EIRQ9 | EIRQ10 | EIRQ11 | EIRQ12 | EIRQ13 | EIRQ14 | EIRQ15

17.3.4.4 Interrupt Vector

The 16 EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note: Refer to INTC configuration section in the Chapter Device Configuration for the Interrupt Vector table.

17.3.4.5 DMA requests

The 16 EIRQ pins on the device map to an independent DMA request channel in the DMA controller.

Note: Refer to the DMA controller configuration section in the Chapter Device Configuration for DMA request mapping table.

18 Crossbar switch (XBAR)

18.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

18.2 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
  - Concurrent accesses from different masters to different slaves
  - Configurable slave arbitration attributes on a slave-by-slave basis
- 64-bit datapath width
- Support for 8-, 16-, 32-, and 64-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers including a 4-beat, 64-bit burst for cache line accesses
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

18.3 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require two system bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. Refer to Section 7.3.3: Crossbar switch in Chapter 7: Device configuration for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

Table 289. XBAR memory map

Address offset (hex)	Register name	Location

18.3.1 XBAR Priority Registers Slave (XBAR_PRS*n*)

The priority registers (XBAR_PRS*n*) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. The XBAR_PRS*n* register is read-only; attempts to write to it have no effect on it and result in a bus-error response to the master initiating the write.

Refer to *Section 7.3.3: Crossbar switch* in *Chapter 7: Device configuration* for XBAR_PRS*n* priority values.

Figure 189. XBAR Control Register (XBAR_CRS*n*)

Table 291. XBAR_CRS*n* field descriptions

Field	Description
0 RO	Read only Forces both of the slave port's registers to be read-only. After set, only a hardware reset clears it. 0 The slave port's registers are writable. 1 The slave port's registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
1 HRP	Halt Request Priority Determines if a request to halt the crossbar is treated as the highest priority request, or the lowest priority request. 0 The halt request has the highest priority for arbitration on this slave port. 1 The halt request has the lowest initial priority for arbitration on this slave port.
8:15 HPE[7:0]	High Priority Enable (HPEx) Determines if Master x is able to temporarily elevate its request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master x are ignored and are treated the same as regular requests. 1 High Priority requests from Master x can temporarily elevate the priority level of the master's request to the slave.
22:23 ARB	Arbitration mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved

Table 291. XBAR_CRS*n* field descriptions (continued)

Field	Description
26:27 PCTL	Parking control Determines the slave port's parking control. The low-power park feature results in overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11 Reserved
29:31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **Note:** Only select master ports that are actually present on the device. If not, undefined behavior may occur. Also, take care of the hardwired connections between Master and Flash slaves ports for applying meaningful parking configuration. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

18.4 Functional description

This section provides the functional details of the crossbar switch.

18.4.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes. When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to

a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by the XBAR_CRS*n*[PARK]. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using XBAR_CRS*n*[PCTL].

18.4.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

18.4.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

18.4.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the XBAR_PRS*n* (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer or a locked transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master's priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

18.4.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Hand-off occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

18.5 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

19 Crossbar Integrity Checker (XBIC)

19.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistence of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core's decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

19.2 Features

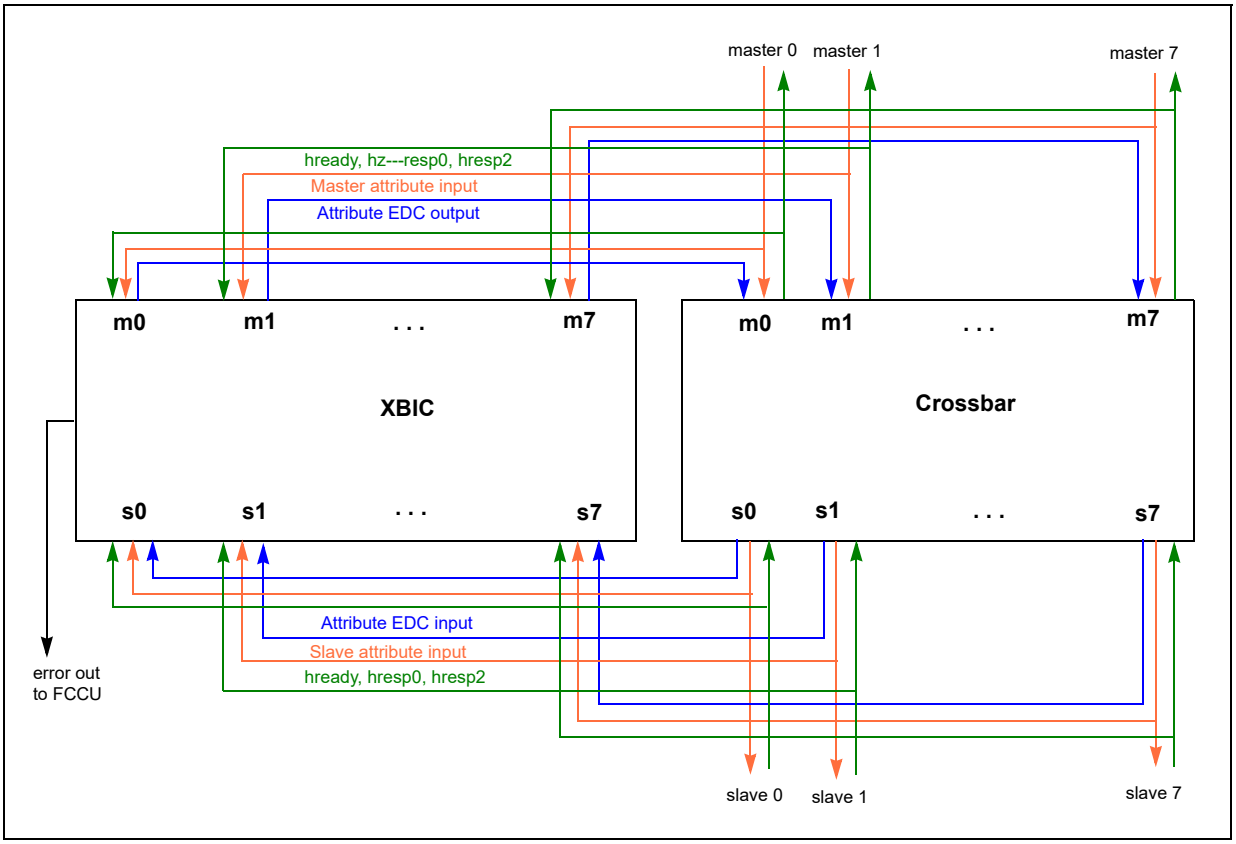
The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
  - hready, hresp0, and hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

19.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in *Figure 191* and *Figure 192*.

Figure 191. XBIC system block diagram



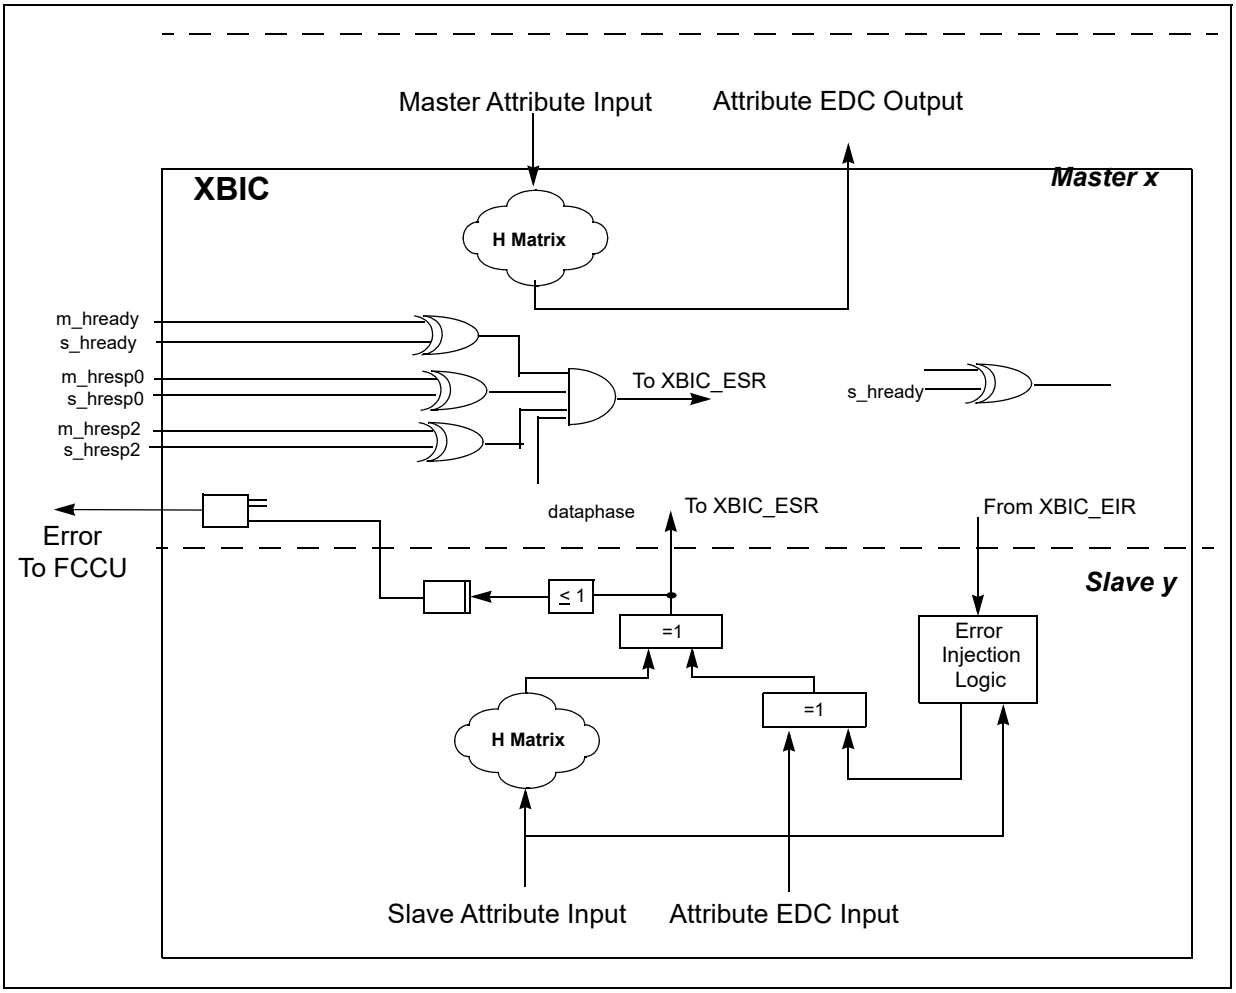


Figure 192. XBIC block diagram

19.4 External signal description

The XBIC has no external interface signals.

19.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

19.5.1 Memory map

The XBIC memory map is shown in *Table 293*.

Table 293. XBIC memory map

19.5.2.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Offset: 0x0004 Access: Supervisor Read/Write

Table 295. XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable 0 Error injection disabled 1 Error injection enabled
17:19 SLV	Target Slave Port (1) Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20:23 MST	Target Master ID (2) Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24:31 SYN	Syndrome This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

1. For the list of the target slave ports refer to the table ‘Crossbar switch slave assignments’ in section ‘Crossbar switch’ from ‘Device Configuration’ chapter.
2. For the list of the target master IDs refer to the table ‘SMPU logical bus master assignments’ in section ‘Crossbar switch’ from ‘Device Configuration’ chapter.

19.5.2.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the *last* transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are captured in the DPSE0*x* and DPME*x* fields.

This register is cleared only on reset.

19.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

Forwarding errors (master to slave) are detected during the AHB address phase. When a forwarding error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in *Table 298*. Any other syndrome indicates a multi-bit error.

XBIC also detects backward signal (slave to master) errors during AHB data phase. For the three slave driven signals (hready, hresp0, and hresp2), XBIC performs the comparison between the input of the slave port and output of the master port during the AHB data phase. When a mismatch occurs, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE*x*, and the current master port will be registered in XBIC_ESR bit field DSME*x*.

20 Peripheral Bridge (PBRIDGE)

20.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space (not all peripheral slots may be used. Refer to Device Configuration chapter or the Memory Map chapter for details on slot assignment).
The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

20.1.1 Features

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality.

20.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map. Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots.
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots.

All other 64-bit accesses result in an error response.

1. The following address spaces when programmed, will not terminate in an error. Software should not program these address spaces.
2. Access to this address space will terminate in an error.

20.2.1 Master Privilege Register A (MPRA)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. Refer to Device Configuration chapter for details about the master assignments to these registers.

The MPROT*n* field is defined as shown in *Figure 197*.

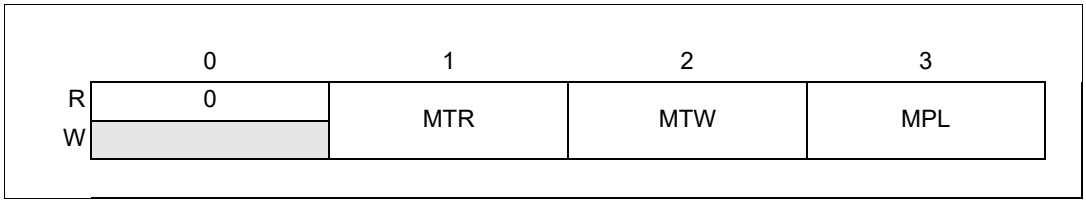

Figure 197. MPROT*n* fields

20.2.3 Peripheral Access Control Register (PACR*x*)

Each of the on-platform peripherals has a four-bit PACR*n* field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. Refer to Memory Map chapter for the assignments of the device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeros, and writes are ignored.

The PBRIDGE registers themselves are mapped into the PACR0 address space and can only be accessed in supervisor mode by trusted bus masters.

Table 304 shows the top-level structure of the PACRs.

Table 304. PACR memory map

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

20.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

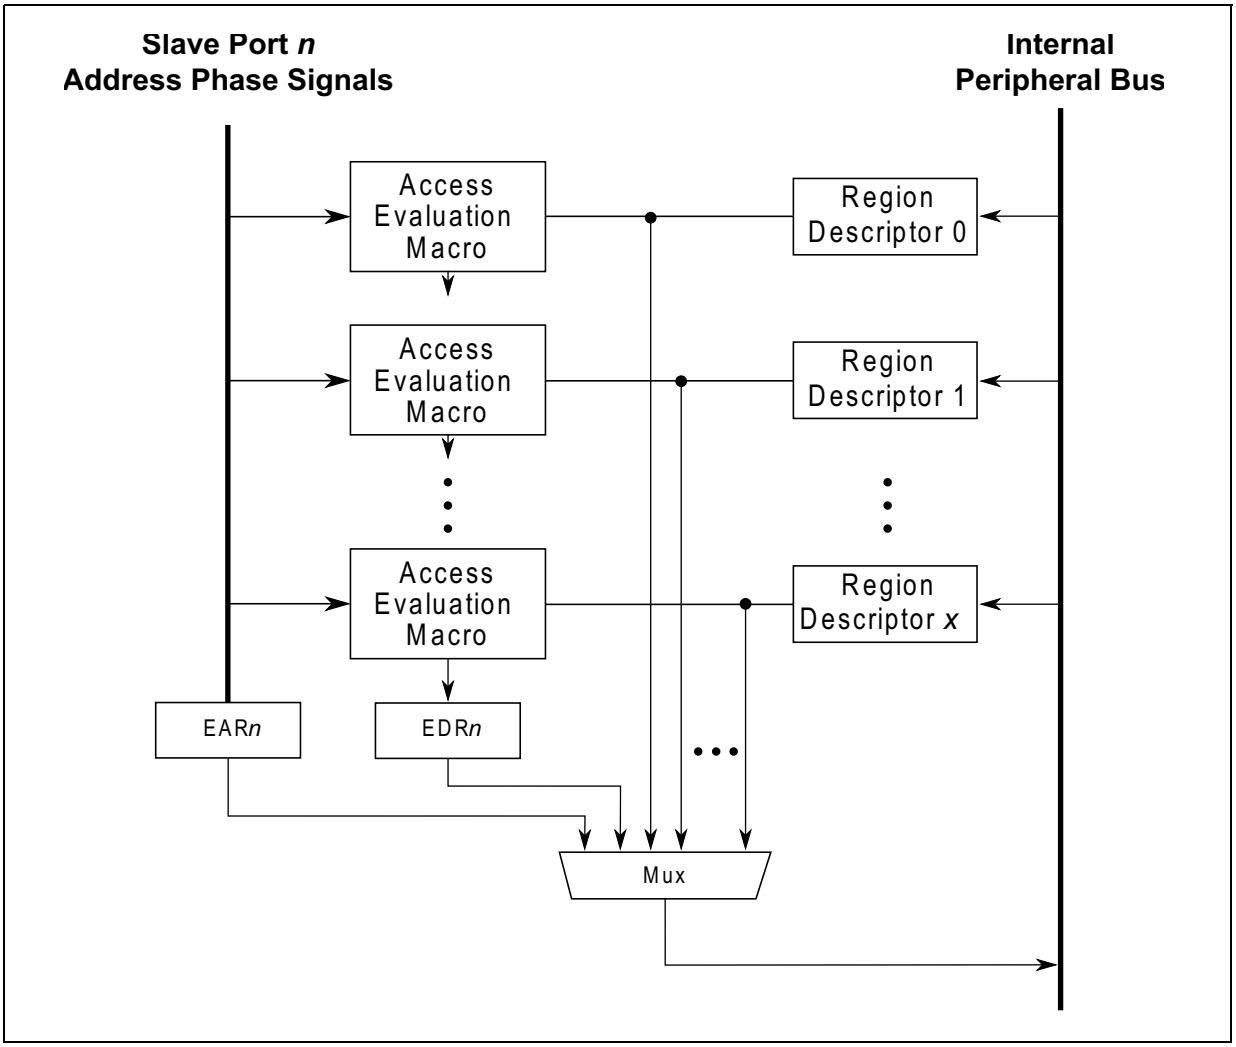
20.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

21 System Memory Protection Unit (SMPU)

21.1 Overview



The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

21.2 Block diagram

A simplified block diagram of the SMPU module is shown in *Figure 204*. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, refer to *Section 21.5.1: Access evaluation macro*.

Figure 204. SMPU block diagram

21.3 Features

The SMPU feature set includes:

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24)
  - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
    Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
  - Read/write access control permissions defined in region descriptor
  - Cache-inhibit attribute indicator per region descriptor
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
  - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports
- Detects access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (refer to the documentation related to the core for details).
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit

21.4 Memory map and register definition

21.4.1 Memory map

The programing model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programing model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

Note: Refer to the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to 8 region descriptors.

Field	Description
0:15 MERR	Master *n* error, where the bus master number matches the bit number Indicates a captured error in EAR*n* and EDR*n*. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing '1' to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master *n*. 1 An error has occurred for bus master *n*.
16	Reserved This read-only bit is reserved and always has the value '1'.
28:30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

Field	Description
0:15 MEOVR	Master *n* error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master *n* has occurred before the previous error was processed. The details of the first error are recorded in the EAR*n* and EDR*n* registers, and no information on subsequent errors is recorded until the associated CESR0.MERR flag is cleared. 0 No error overrun condition has been detected for bus master *n.* 1 An error overrun condition has been detected for bus master *n.*
16	Reserved This read-only bit is reserved and always has the value ‘1’.
28:31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

21.4.2.3 Error Address Register, Bus Master *n* (EAR*n*)

When the SMPU detects an access error on bus master *n*, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0.MERR is set. Additional information about the faulting access is captured in the corresponding EDR*n* at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Field	Description
0:31 EADDR	Error address Indicates the reference address from bus master *n* that generated the access error.

21.4.2.4 Error Detail Register, Bus Master *n* (EDR*n*)

When the SMPU detects an access error associated with bus master *n*, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0.MERR is set. Information on the faulting address is captured in the corresponding EAR*n* register at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Table 314. EDR*n* field descriptions

Field	Description
0:23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDR*n* contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24	Reserved This read-only bit is reserved and always has the value ‘1’.
25:26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28:31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

Field	Description
0:31 ENDADDR	End address Defines the byte end address of the memory region. **Note:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

21.4.2.7 Region Descriptor *n*, Word 2 Format 0 (RGD*n*_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3.FMT field.

Note: RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: 0x0408 + *n**0x10 (*n* = 0 to 23) Access: Supervisor read/write

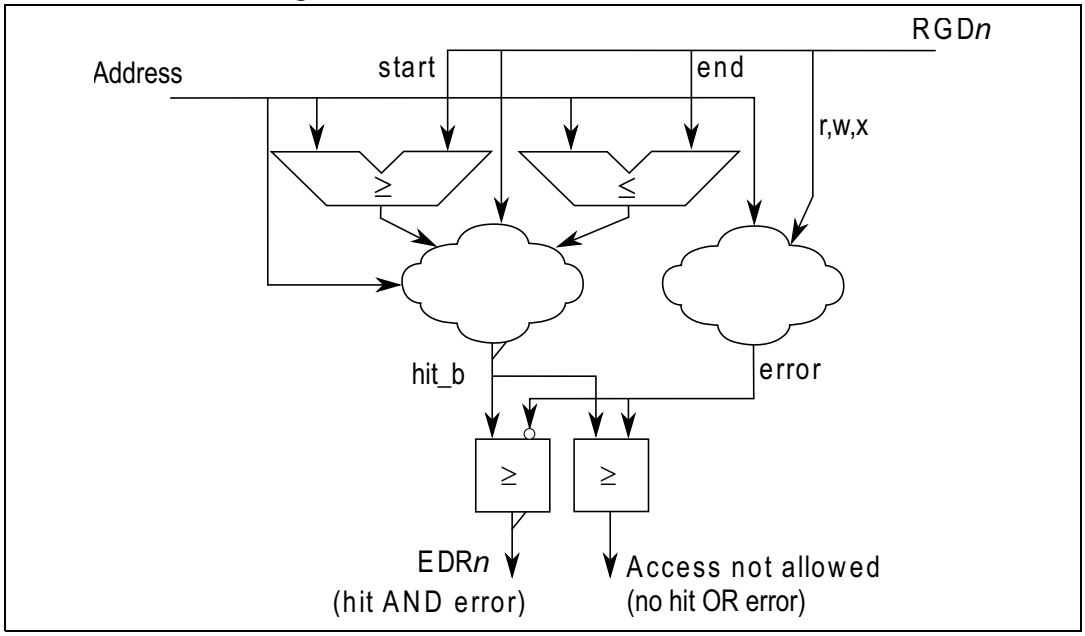
Figure 212. Region Descriptor n, Word 3 (RGDn_WORD3)

Table 318. RGD*n*_WORD3 field descriptions

Field	Description
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. **Note:** A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies. 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **Note:** Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect. 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.

Table 318. RGD*n*_WORD3 field descriptions (continued)

Field	Description
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **Note:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals that the region descriptor is valid. Any write to RGD*n*_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.



21.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

21.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in *Figure 213*, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD*n*), then performs two major functions: region hit determination and detection of an access protection violation. *Figure 213* shows a functional block diagram.

Figure 213. SMPU access evaluation macro

21.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
      (addr[0:31] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

Where addr is the current reference address, RGDn_Word0.SRTADDR and RGDn_Word1.ENDADDR are the start and end addresses, and RGDn_Word3.VLD is the valid bit.

Note: The SMPU does not verify that ENDADDR ≥ SRTADDR.

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

21.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in *Table 319*.

Table 319. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

21.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, refer to *Section 21.7*.

21.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGD*n*_Word3.VLD. Setting CESR0.GVLD enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0.GVLD = 0). Next, load the appropriate region descriptors (RGD*n*), including the setting of the RGDn_Word3.VLD bits. Finally, set CESR0.GVLD to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

21.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region: Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Modifying a region descriptor: Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor: Clearing RGD*n*_Word3.VLD deletes an existing region descriptor.
- Accessing the SMPU: Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error: The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0.MERR signals. The error registers contain the captured fault data.
- Overlapping region descriptors: Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters: the two processors (CP0, CP1) and two DMA engines (DMA1, a traditional data movement engine transferring data between RAM and peripherals, and DMA2, a second engine transferring data to/from the RAM only). Consider the following region descriptor assignments:

Table 320. Overlapping region descriptor example

Region description	RGDn		CP0	CP1	DMA1	DMA2	System memory map space
CP0 code	0		rwx	r--	—	—	Flash
CP1 code	1		r--	rwx	—	—	
CP0 data & stack	2		rw-	—	—	—	RAM
CP0 → CP1 shared data	2	3	r--	r--	—	—	
CP1 → CP0 shared data	4						
CP1 data & stack	4		—	rw-	—	—	
Shared DMA data	5		rw-	rw-	rw	rw	
SMPU	6		rw-	rw-	—	—	Peripheral space
Peripherals	7		rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map (flash, RAM, and peripheral space). Each region indicates the specific permissions for each of the four bus masters, and this definition provides an assigned set of shared, private, and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1, and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the peripheral bus is partitioned into two regions: one containing the SMPU's programming model accessible only to the two processor cores and the remaining peripheral region accessible to both processors and the traditional DMA1 master.

This simple example is intended to show one possible application of the capabilities of the SMPU in a typical system.

22 Intelligent AHB Gasket (IAHBG)

22.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 321 lists the available operation modes.

Table 321. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

22.2 Timing modes

22.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

22.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

22.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master.The 1:4 mode is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write.

23 Semaphores2 (SEMA42)

23.1 Introduction

The peripheral platform shell includes a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve “lock and unlock” operations via a single write access. The hardware semaphore module is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

23.1.1 Multi-core programming

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism that is then used by system software to control access to shared data structures, shared hardware resources, and so on. These gating mechanisms are used by the software to serialize (and synchronize) writes to shared data or resources, or both to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered to be locking (or closing) a software gate. Once the gate has been locked, a properly architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate; in other words, other processes/processors are locked out. Many software implementations include a spin-wait loop within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a “gate” variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor are useful for system-level debugging.

23.1.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 16, 32, or 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent core processor *X*.
  - Gates appear as an *n*-entry byte-size array with read and write accesses (*n* = 16, 32, 64).
    - Processors lock gates by writing “processor_number+1” to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked

      if gate = 0x1, then state = locked by processor (master) 0

      if gate = 0x2, then state = locked by processor (master) 1

      ...

      if gate = 0xF, then state = locked by processor (master) 14
    - Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
    - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
  - Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.
- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses

A simplified block diagram of the Semaphores module is shown in *Figure 214*. In the diagram, the register blocks named gate0, gate1,..., gate (*n* – 2), gate (*n* – 1) include the finite state machines implementing the semaphore gates.

Figure 214. Semaphores2 block diagram

23.2 Memory map/register definition

Table 322. Memory map/register definition

Address offset	Register name	Access	Reset value	Section/page

Table 322. Memory map/register definition (continued)

Address offset	Register name	Access	Reset value	Section/page
0x0040	Semaphores2 Reset Gate (SEMA4_RSTGT)	R/W	0x0000	*Section 23.2.2*
0x0042–0xFFFF	Reserved			

23.2.1 Semaphores2 Gate *n* Register (SEMA4_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (processor_number + 1) are simply treated as “no operation” and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Table 323. SEMA4_GATE*n* field descriptions

Field	Description
4:7 GTFSM	Gate Finite State Machine The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14. **Note:** The state of the gate reflects the last processor that locked it, which can be useful during system debug. For more details, see *Section 23.2.1: Semaphores2 Gate n Register (SEMA4_GATEn)*.

23.2.2 Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a “secure” reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a “don’t_care” for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]), and the gate number(s) last cleared

(SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

Offset: 0x0040 Access: Supervisor Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

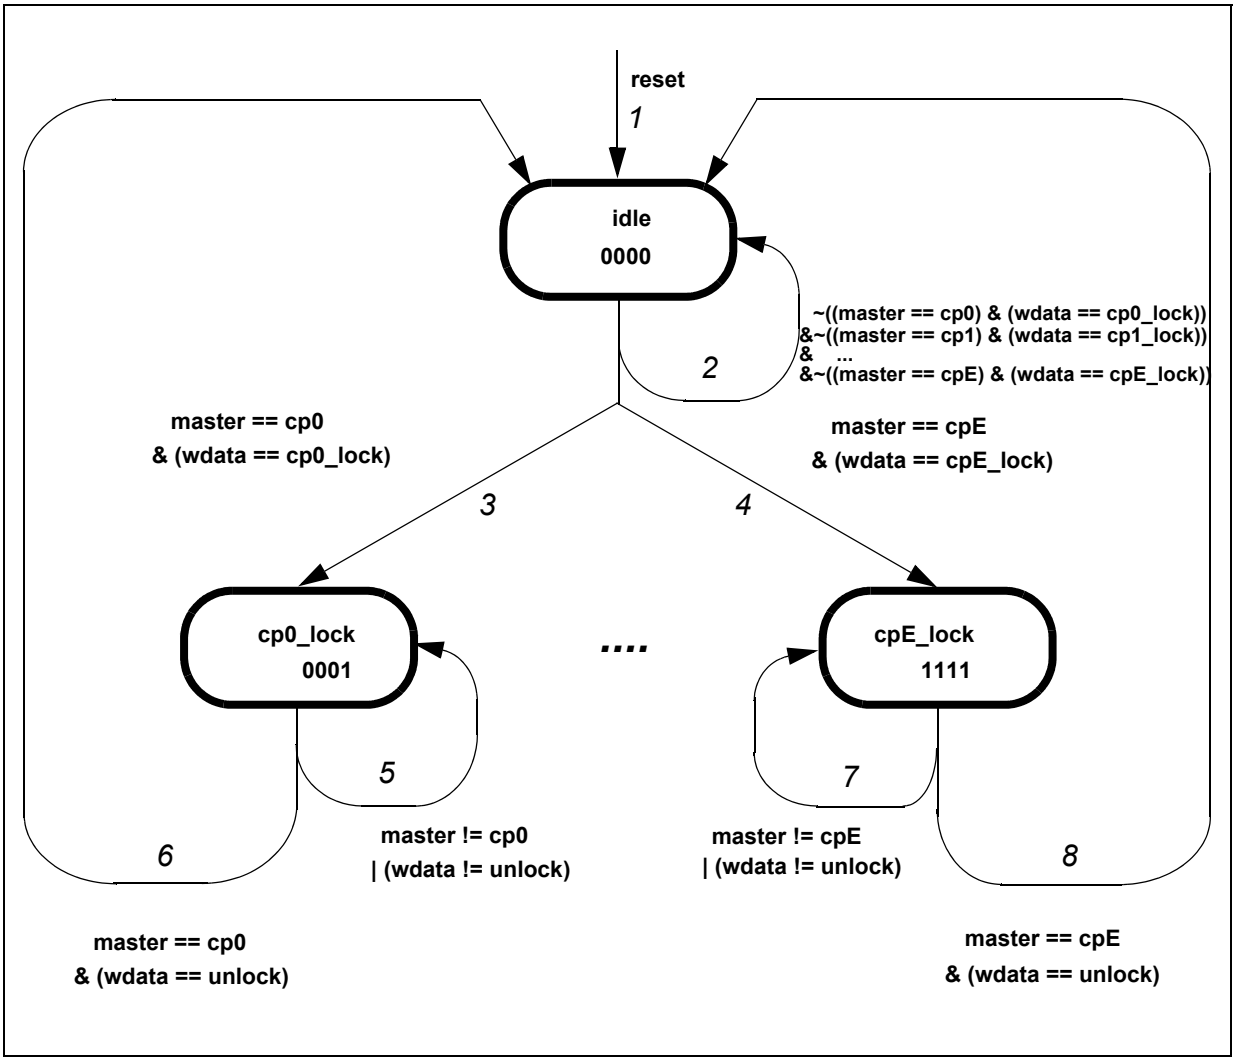
Figure 216. Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)

Table 324. SEMA4_RSTGT field descriptions



Field	Description
0:7 RSTGDP	Reset Gate Data Pattern This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP=0xE2 while the second write requires RSTGDP=0x1D.
2:3 RSTGSM	Reset Gate Finite State Machine The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The “10” state persists for only one clock cycle. Software will never be able to observe this state. 11 This state encoding is never used and therefore reserved. Reads of the SEMA4_RSTGT register return the encoded state machine value. Note that the RSTGSM=10 state is valid for only a single machine cycle, so it is impossible for a read to return this value.
4:7 RSTGMS	Reset Gate Bus Master This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8:15 RSTGTN	Reset Gate Number This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then *reset the single gate* defined by RSTGTN, else *reset all the gates*.

23.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA4_GATE*n* registers are provided as follows.

As described previously, each of the SEMA4_GATE*n* registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in *Figure 217*.

Figure 217. SEMA4_GATE*n* state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the PBRIDGE controller and drives the signal to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATE*n* are defined in *Table 325*.

Table 325. SEMA4_GATE*n* state transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.

Table 325. SEMA4_GATE*n* state transitions (continued)

Current State	Next State	Transition	Description
idle	cp0_lock	3	When a write of the “cp0_lock” data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cpE_lock	4	When a write of the “cpE_lock” value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

As previously noted, the following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

24 Interrupt Controller (INTC)

24.1 Introduction

Note: For the chip-specific implementation details of this module's instances, refer to the Section 7.3.6: Interrupt controller (INTC) configuration.

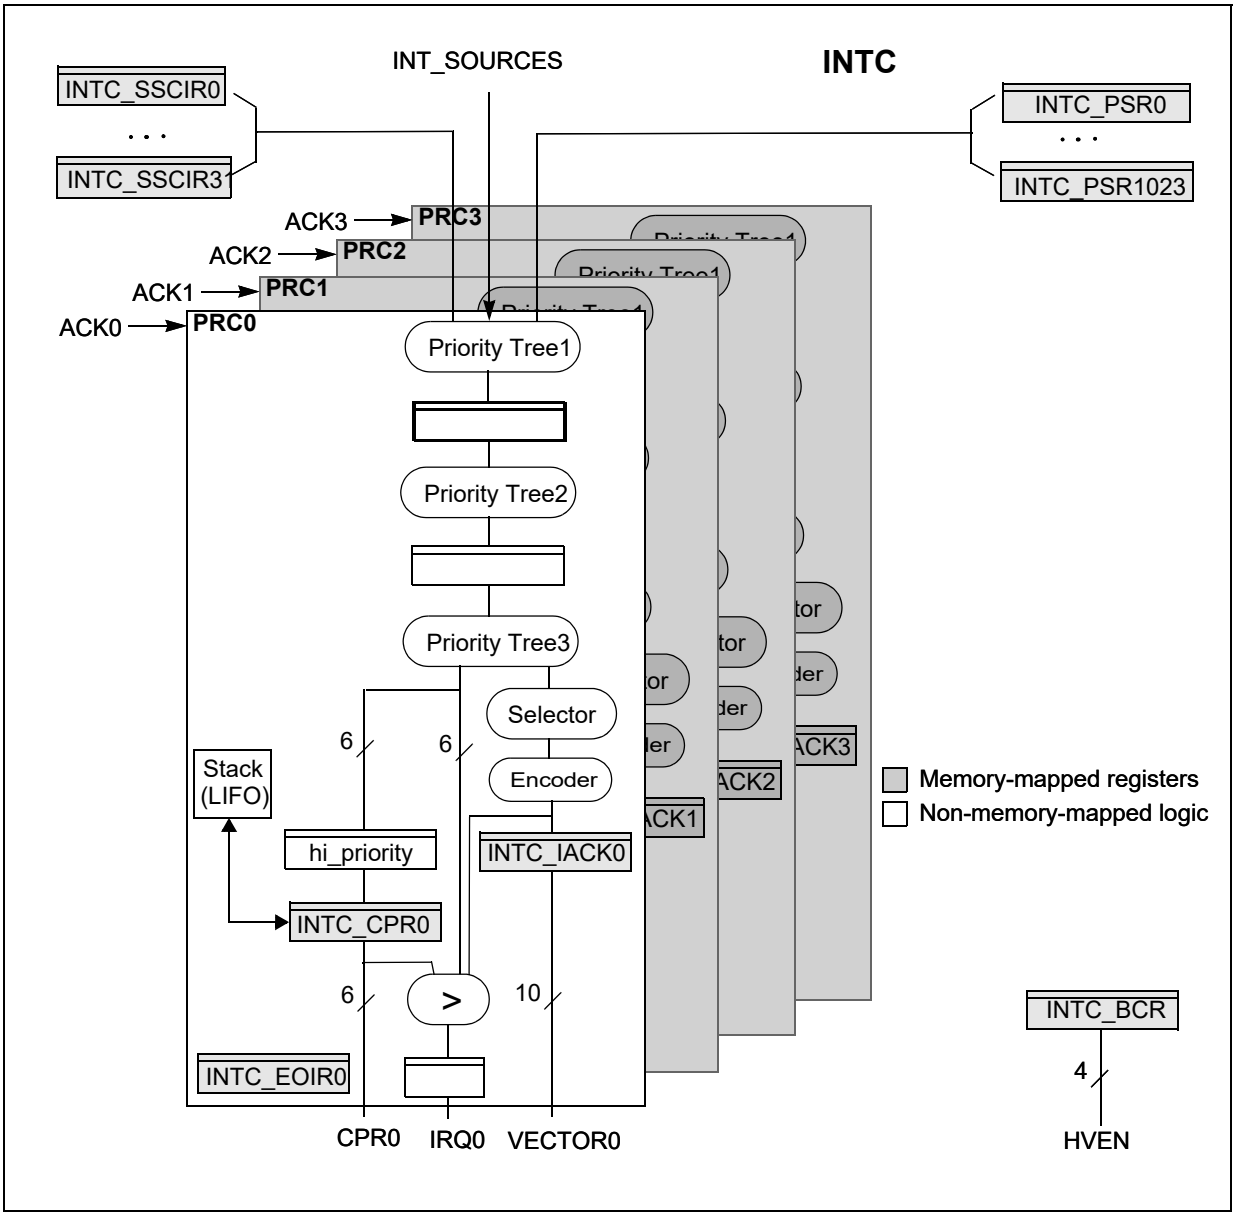
The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.



When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

24.2 Block diagram

The block diagram for the INTC is shown in *Figure 218*.

Figure 218. INTC block diagram

24.3 Features

- Each peripheral interrupt source is software-steerable to processors 0, 1 or 2 or any combination of interrupt request outputs
- 32 software-settable interrupt request sources
- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request

24.4 Modes of operation

The interrupt controller operates with the following handshaking modes: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN*x*], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ). In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

24.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN*x* bit in INTC_BCR (refer to *Section 24.5.2.1*) is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN*x* bit is negated. The vector is read from the INTC_IACKR*x* registers (refer to *Section 24.5.2.4*). Reading the INTC_IACKR*x* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in INTC_CPR*x* (refer to *Section 24.5.2.3*) onto the associated LIFO, and updates PRI in the associated INTC_CPR*x* with the new priority.

24.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVEN*x* bit in INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKR*x*, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*x* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*x* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*x* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs (refer to *Section 24.5.2.6: INTC Software Set/Clear Interrupt Register n (INTC_SSCIRn)*) is written at a time such that the PRI value in the associated INTC_CPR*x* register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*x* is updated with the new priority, and the associated LIFO is neither pushed nor popped.

24.5 Memory map and register definition

24.5.1 Memory map

Table 326 is the INTC memory map.

The actual availability and number of registers are chip-specific. For this information, refer to the chapter that describes how modules are configured and connected.

Table 326. INTC memory map

Address offset	Register	Location
0x0000	INTC Block Configuration Register (INTC_BCR)	*Section 24.5.2.1*
0x0004	INTC Master Protection Register (INTC_MPROT)	*Section 24.5.2.2*
0x0008–0x000F	Reserved	
0x0010	INTC Current Priority Register for Processor 0 (INTC_CPR0)	*Section 24.5.2.3*
0x0014	INTC Current Priority Register for Processor 1 (INTC_CPR1)	*Section 24.5.2.3*
0x0018	INTC Current Priority Register for Processor 2 (INTC_CPR2)	*Section 24.5.2.3*
0x001C–0x001F	Reserved	
0x0020	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)	*Section 24.5.2.4*
0x0024	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)	*Section 24.5.2.4*

Table 326. INTC memory map (continued)

Address offset	Register	Location
0x0028	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)	*Section 24.5.2.4*
0x002C–0x002F	Reserved	
0x0030	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)	*Section 24.5.2.5*
0x0034	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)	*Section 24.5.2.5*
0x0038	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)	*Section 24.5.2.5*
0x003C–0x003F	Reserved	
0x0040–0x005F	INTC Software Set/Clear Interrupt Register 0–31 (INTC_SSCIR0–INTC_SSCIR31)	*Section 24.5.2.6*
0x0060–0x085F	INTC Priority Select Registers 0–1023 (INTC_PSR0–INTC_PSR1023)	*Section 24.5.2.7*
0x0860–0x0FFF	Reserved	

Note: A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

24.5.2 Register descriptions

With the exception of the INTC_SSCIR*n* and INTC_PSR*n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR*x*) are the same regardless of the size of the read. In software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR*x*) does not affect the operation of the write.

24.5.2.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

The master ID is used to determine if this register can be written by a given processor. Only the processor with master ID zero will be allowed write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT] = 0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Figure 220. INTC Master Protection Register (INTC_MPROT)

Table 328. INTC_MPROT field descriptions

Field	Description
26:27 ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. 00 master0 (reset default) 01 master1 10 master2
31 MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

24.5.2.3 INTC Current Priority Register for Processor *x* (INTC_CPR*x*)

The INTC_CPR*x* masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*x*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*x*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*x*) is written, the LIFO is popped into the INTC_CPR*x* PRI field. An exception case in hardware vector mode to this behavior is described in *Section 24.4.2*.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. Refer to *Section 24.7.5*.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT] = 0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Note: A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. Refer to Section 24.7.5.2, for example code to ensure coherency.

Field	Description
26:31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

24.5.2.4 INTC Interrupt Acknowledge Register for Processor *x* (INTC_IACKR*x*)

The Interrupt Acknowledge Register for Processor *x* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*x* has side effects from reads unless INTC_MPROT[MPROT] = 1 and processor with master ID 0, 1 or 2 != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKR*x* does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT] = 0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

Table 330. INTC_IACKR*x* field descriptions

Field	Description
0:19 VTBA	Vector table base address Must be set with the base address of the vector table prior to enabling interrupts.
20:29 INTVEC	Interrupt vector Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.

24.5.2.5 INTC End of Interrupt Register for Processor *x* (INTC_EOIR*x*)

Writing to the INTC_EOIR*x* signals the end of the servicing of the interrupt request. When the INTC_EOIR*x* is written, the priority last pushed on the LIFO is popped into INTC_CPR*x*. The values and size of data written to the INTC_EOIR*x* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*x* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT] = 0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

0:31 EOI	End of Interrupt Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

24.5.2.6 INTC Software Set/Clear Interrupt Register *n* (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Figure 224 shows the structure of the first INTC_SSCIR. The other registers follow the same structure.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIR*n* registers. The CLR bit will only be writable by the processor which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR*n*[PRC_SEL*x*]. An attempt by any other processor to write the CLR bit and not the SET bit will result in a termination error.

Note: Since the four software settable interrupts in a word can be assigned to different processors, the cores with non-zero master IDs must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIR*n* registers.

If INTC_MPROT[MPROT] = 0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit and not the SET bit, otherwise, a termination error is asserted.

Note: If INTC_MPROT[MPROT] is enabled, processors with master ID != INTC_MPROT[ID] must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Table 332. INTC_SSCIR*n* field descriptions

Field	Description
6 SET	Set flag bit Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bit CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

24.5.2.7 INTC Priority Select Register *n* (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSR*n* is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32–1023, and their priorities are configured in INTC_PSR32–1023, respectively.

Figure 225 and *Figure 226* show the structure and numbering scheme of the first and last PSRs, respectively. The other registers follow the same numbering scheme.

Only the processor with master ID zero will be allowed to write the INTC_PSR*n*[PRC_SEL*x*,SWT]. When writing the INTC_PSR[PRI], only the processor with master ID 0 and the processor whose master ID matches the setting of the INTC_PSR*n*[PRC_SEL*x*] will be allowed to write the INTC_PSR*n*[PRI]. An attempt by any other processor to write the INTC_PSR*n*[PRI] will result in a termination error.

If INTC_MPROT[MPROT] = 0 (disabled), all processors have write access.

Note: If INTC_MPROT[MPROT] = 1 (enabled), the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SELx,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID 0, 1 or 2 = INTC_MPROT[ID] and the processor who's master ID 0, 1 or 2 matches the setting of the INTC_PSRn[PRC_SELx] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

Interrupts are not detected while the PSRs are being written.

Note: If INTC_MPROT[MPROT] is enabled, the core with master ID 0, 1 or 2 = INTC_MPROT[ID] will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SELx] (the even byte) will result in a termination error.

Note: The core with master ID 0 will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SELx] (the even byte) will result in a termination error.

Table 334. INTC_PSR*n* field descriptions

Field	Description
0 PRC_SEL0	Processor 0 select bit If an interrupt source is enabled, PRC_SEL0 selects whether the interrupt request is to be sent to processor 0.
1 PRC_SEL1	Processor 1 select bit If an interrupt source is enabled, PRC_SEL1 selects whether the interrupt request is to be sent to processor 1.
2 PRC_SEL2	Processor 2 select bit If an interrupt source is enabled, PRC_SEL2 selects whether the interrupt request is to be sent to processor 2.
7 SWT	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
10:15 PRI	Priority select Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

24.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

24.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*x*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or

software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*x* is updated with the corresponding PRI value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

24.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

24.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any processor x will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the processor x which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR*n*[PRC_SEL*x*] bits.

24.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

24.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*x* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*x*. The results of those comparisons are used to manage

the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

24.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in *Figure 218* are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*x*, and if in hardware vector mode, for the interrupt vector provided to the processor.

24.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

24.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

24.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

24.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*x*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*x*, or the PRI value in the associated INTC_CPR*x* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*x* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI in INTC_PSR*n* are zero will not cause a preemption because their PRI will not be higher than PRI in the associated INTC_CPR*x*.

Another function of the comparator is to signal an update of the INTC_IACKR*x* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*x* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

24.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*x*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*x* does not need to be loaded from the associated INTC_CPR*x* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored in the associated INTC_CPR*x*.

The PRI value in the associated INTC_CPR*x* is pushed onto the LIFO when the associated INTC_IACKR*x* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*x* whenever the associated INTC_EOIR*x* is written. An exception case in hardware vector mode to this behavior is described in *Section 24.4.2*.

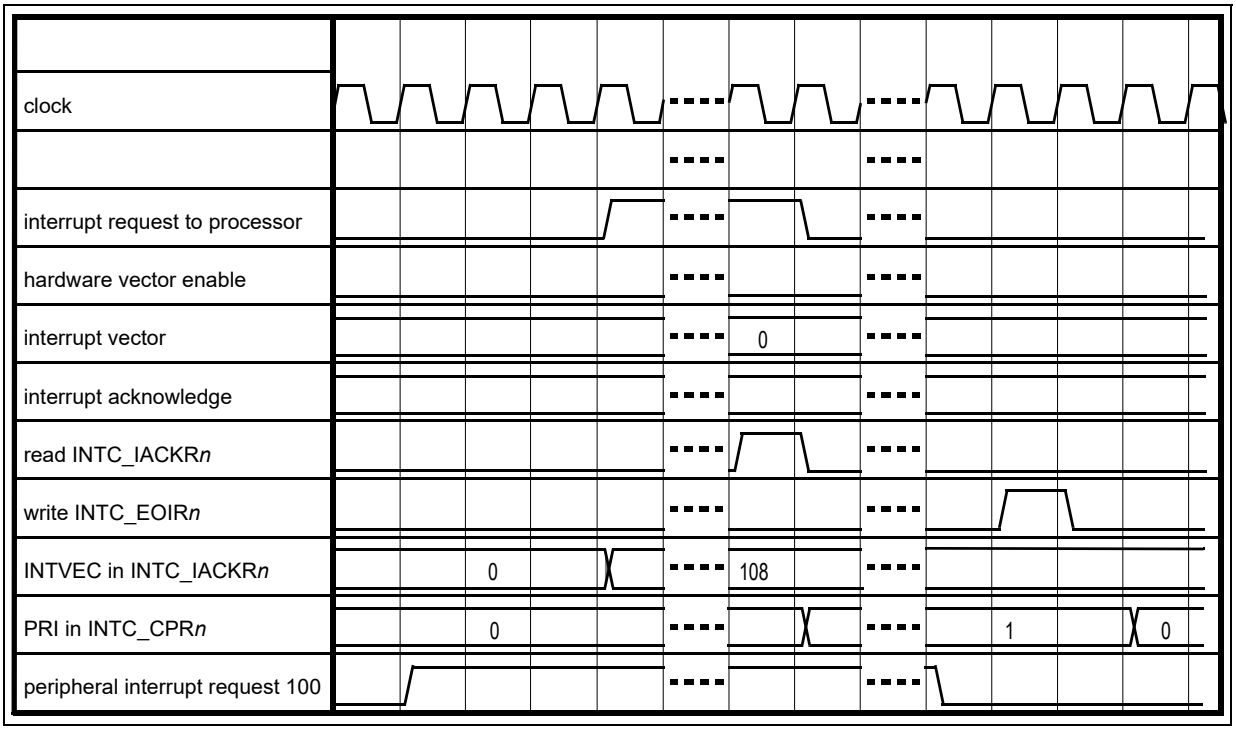
Although the INTC supports up to 64 priorities, an ISR executing with PRI in the INTC_CPR*x* equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

24.6.3 Handshaking with processor

24.6.3.1 Software vector mode handshaking

24.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to *Figure 227*.



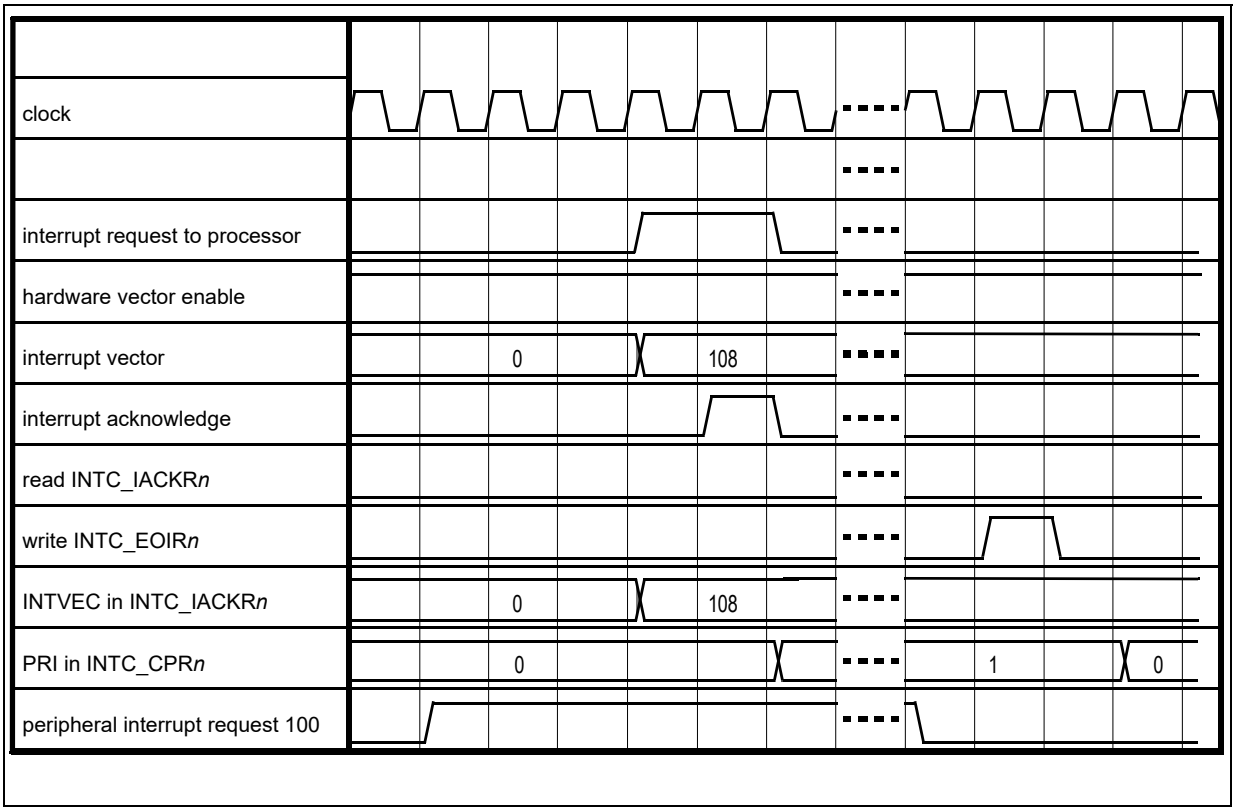
A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 227*. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*x*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*x* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in *Section 24.4.1*.

24.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*x* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*x*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*x* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 227. Timing diagram of software vector mode handshaking



24.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 228*. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*x*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*x* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*x*. The rest of the handshaking is described in *Section 24.4.2*.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*x*, is the same as in software vector mode. Refer to *Section 24.6.3.1.2: End of interrupt exception handler*.

Figure 228. Timing diagram for hardware vector mode handshaking

24.7 Initialization/application information

24.7.1 Initialization flow

After exiting reset, all of the PRI and PRC_SEL*x* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPR*x* registers is 31. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- Interrupt_request_initialization:
  - Configure HVEN*x* in INTC_BCR.
  - Configure VTBA in INTC_IACKR*x.*
  - Raise the PRI fields and set the PRC_SEL*x* fields to the desired processor in INTC_PSR*n*.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC_CPR*x* to zero.
  - Enable processor(s) recognition of interrupts.

24.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

24.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

24.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*x* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*x* priority 0 and outside the control of the RTOS while RTOS executes at INTC_CPR*x* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPR*x* priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*x* while the shared resource is being accessed.

An ISR whose PRI in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

24.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in *Table 335* shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 335. Order of ISR execution example

		Code executing at end of step						
Step#	**Step Description**	**RTOS**	**ISR108[1]**	**ISR208**	**ISR308**	**ISR408**	**interrupt exception handler**	**PRI in INTC_CPR at end of step**
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*x*.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*x*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*x*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*x*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

24.7.5 Priority ceiling protocol

24.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*x*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR0 to *x*, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*x* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

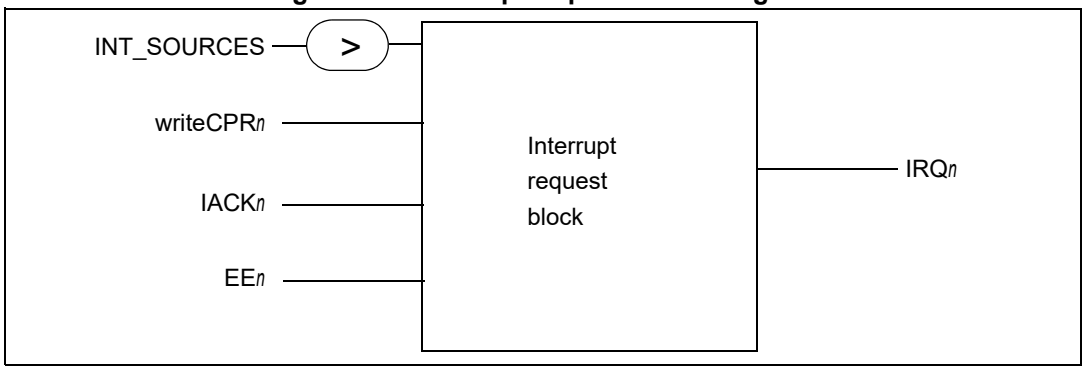
24.7.5.2 Ensuring coherency

24.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*x*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*x* can be made by those system services with the code sequence:

Figure 229. OSEK Code Sequence



```
GetResource:
   wrteei  0       # disable external interrupts to the Processor
   raise   PRI     # Write to CPR, cache inhibit, guarded
   mbar            # flush out writes from store buffer
   wrteei  1       # enable external interrupts to the Processor
   isync           # re-fetch Processor pipeline

ReleaseResource:
   mbar            # flush out writes from store buffer
   wrteei  0       # disable external interrupts to the Processor
   lower   PRI     # Write to CPR, cache inhibit, guarded
   wrteei  1       # enable external interrupts to the Processor
```

24.7.5.2.1.1 Interrupt request to processor

Referencing *Figure 218*, the interrupt request logic to the processor is shown in *Figure 230*.

Figure 230. Interrupt request block diagram

Assuming that there are no IRQ*n* deasserted (no pending interrupt requests to processor *x*), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPR*x*, then interrupt request to the processor (IRQ*n*) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACKR*x*) is asserted
- If the EE*n* bit has been cleared by the wrteei instruction (refer to *Figure 229*), IRQ*n* will be re-evaluated when processor *x* writes to the INTC_CPR*x* while processor *x* ignores IRQ*n*

This provides a safe way to guarantee that no interrupts will be recognized by processor x while updating the INTC_CPR*x*.

24.7.5.2.2 Raised priority preserved

Before the instruction and after the GetResource system service executes, all pending transactions are complete. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in INTC_CPR*x*. The shared coherent data block now can be accessed coherently. *Figure 231* shows the timing diagram for this scenario, and *Table 336* explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 231. Timing diagram of raised priority preserved

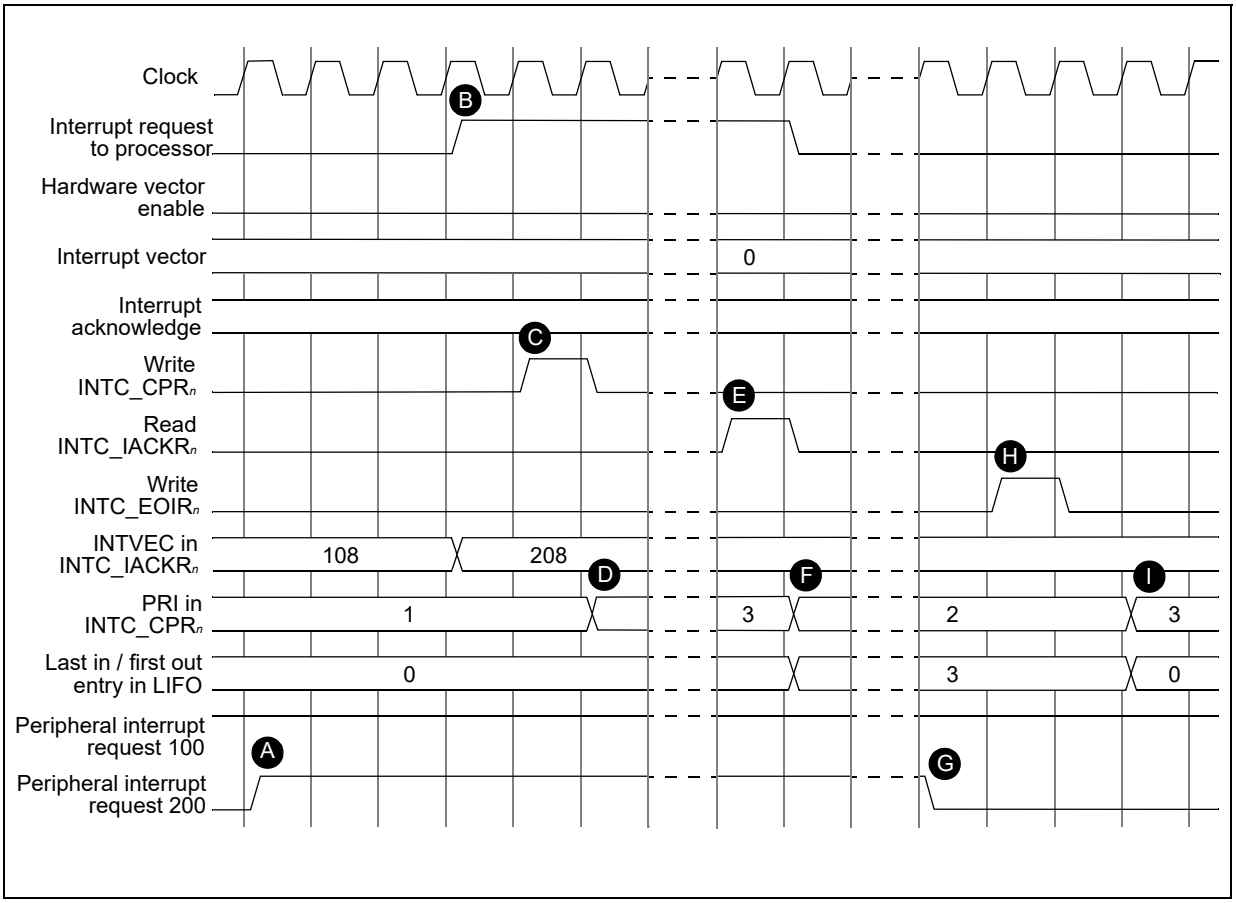


Table 336. Raised priority preserved events

Event	Description
A	Peripheral interrupt request with name equal to 200, asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKR*x* updates with vector for that peripheral interrupt request.
C	ISR108 writes to INTC_CPR*x* to raise priority to 3 before accessing shared coherent data block.
D	PRI in INTC_CPR*x* now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
E	Interrupt exception handler prolog acknowledges interrupt by reading INTC_IACKR*x*.
F	PRI of 3 pushed onto LIFO. PRI in INTC_CPR*x* updates to 2, the priority of ISR208.
G	ISR208 clears its flag bit, deasserting its peripheral interrupt request.
H	Interrupt exception handler epilog writes to INTC_EOIR*x*.
I	LIFO pops 3, restoring the raised priority onto PRI in INTC_CPR*x*. Next value to pop from LIFO is the priority from before peripheral interrupt request with name equal to 100 interrupted. ISR108 now can access data block coherently after interrupt exception handler executes rfi instruction.

24.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

24.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

24.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*x* with the interrupt acknowledge. The ISR, however, can have a portion of it which need not be executed at this higher priority. Therefore, executing this later portion which need not be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit in INTC_SSCIR*n*. Writing a 1 to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

24.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

24.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in *Section 24.7.7.1*) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note: Lowering the PRI value in INTC_CPRx within an ISR to below the ISR's corresponding PRI value in INTC_PSRn allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

24.7.9 Negating an interrupt request outside of its ISR

24.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

24.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

24.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI

values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to *Section 24.6.3.1.2* for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI value in INTC_PSR*n*.

24.7.10 Examining LIFO contents

Normally the user does not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*x*). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
pop_lifo:
   store to INTC_EOIRx
   load INTC_CPRx, examine PRI, and store onto stack
   if PRI is not zero or value when interrupts were enabled, branch to
pop_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

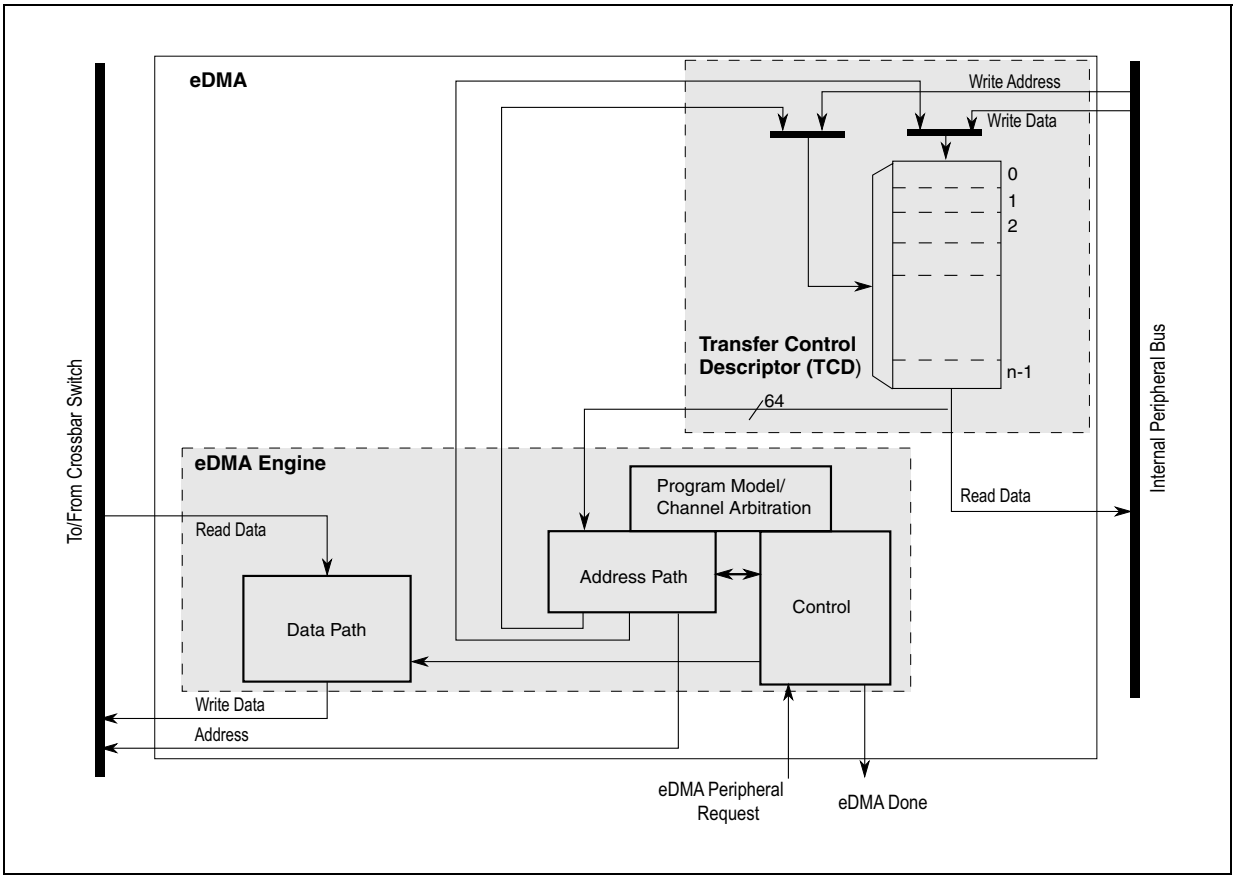
```
push_lifo:
   load stacked PRI value and store to INTC_CPRx
   load INTC_IACKRx
   if stacked PRI values are not depleted, branch to push_lifo
```

Note: Reading the INTC_IACKRx acknowledges the interrupt request to the processor and updates the INTC_CPRx[PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, because the peripheral or software-settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPRx[PRI] is lower than the priorities of those peripheral or software-settable interrupt requests.

24.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, refer to the chapter that describes how modules are configured and connected.

25 Enhanced Direct Memory Access (eDMA)



Note: For the chip-specific implementation details of this module's instances, please refer to the device configuration section.

25.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 64 channels.

Figure 232 illustrates the eDMA module.

Figure 232. eDMA block diagram

25.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data

size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- Data movements via dual-address transfers: read from source, write to destination:
  - Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes.
- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor.
  - Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers.
  - Connections to the crossbar switch for bus mastering the data movements.
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations.
  - 32-byte TCD stored in local memory for each channel.
  - An inner data transfer loop defined by a minor byte transfer count.
  - An outer data transfer loop defined by a major iteration count.
- Channel activation via one of three methods:
  - Explicit software initiation.
  - Initiation via a channel-to-channel linking mechanism for continuous transfers.
  - Peripheral-paced hardware requests (one per channel).
- Fixed-priority and round-robin channel arbitration.
- Channel completion reported via optional interrupt requests.
  - One interrupt per channel, optionally asserted at completion of major iteration count.
  - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller.
- Optional support for scatter/gather DMA processing.
- Support for complex data structures.
- Support to cancel transfers via software.

Throughout this chapter, *n* is used to reference the channel number.

25.2 Modes of operation

The eDMA supports the following modes of operation.

25.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

25.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

25.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

25.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. *Table 337* provides a 32-bit view of the eDMA's memory map.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 63. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

25.3.1 Control Register (eDMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in four groups (0, 1, 2, 3) of 16 channels each. Group 3 contains channels 63–48; group 2 contains channels 47–32; group 1 contains channels 31–16; and group 0 contains channels 15–0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (refer to the DCHPRI*n* registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

Note: Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRP*n*PRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

1. The number of channel groups and the reset value of eDMA_CR register are eDMA module specific. eDMA_0_CR = 0x0000_0400 and eDMA_1_CR = 0x0000_E400. Refer to the Device Configuration chapter for details.

Figure 233. Control Register (eDMA_CR)

Table 338. eDMA_CR field descriptions

Field	Description
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to canceling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt.
16:17 GRP3PRI	Channel group 3 priority Group 3 priority level when fixed-priority group arbitration is enabled. **Note:** This bit-field is valid and applicable only for eDMA_1 module.
18:19 GRP2PRI	Channel group 2 priority Group 2 priority level when fixed-priority group arbitration is enabled. **Note:** This bit-field is valid and applicable only for eDMA_1 module.
20:21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22:23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCD*n*.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCD*n*.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.

Table 338. eDMA_CR field descriptions (continued)

Field	Description
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection within each group. 1 Round-robin arbitration is used for channel selection within each group.
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.

25.3.2 Error Status Register (eDMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

Refer to *Section 25.4.3*, for more details.

Figure 234. Error Status Register (eDMA_ES)

Table 339. eDMA_ES field descriptions

Field	Description
0 VLD	ERRH and ERRL status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
14 UCE	Uncorrectable ECC error 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error.
15 ECX	Transfer canceled 0 No canceled transfers. 1 The last recorded entry was a zeroed transfer by the error cancel transfer input.

Table 339. eDMA_ES field descriptions (continued)

Field	Description
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18:23 ERRCHN	Error channel number or canceled channel number GPE or last recorded error canceled transfer.
24 SAE	Source address error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCD*n*_SADDR field. TCD*n*_SADDR is inconsistent with TCD*n*_ATTR[SSIZE].
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SOFF field. TCD*n*_SOFF is inconsistent with TCD*n*_ATTR[SSIZE].
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DADDR field. TCD*n*_DADDR is inconsistent with TCD*n*_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DOFF field. TCD*n*_DOFF is inconsistent with TCD*n*_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_NBYTES or TCD*n*_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD*n*_CSR[ESG] is enabled. TCD*n*_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read.
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write.

25.3.3 Enable Request Register High (eDMA_ERQH)

The ERQ{H,L} registers provide a bitmap for the 64 implemented channels to enable the request signal for each channel. ERQH supports channels 63–32, while EQRL covers

channels 31–00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ{H,L}.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

25.3.5 Enable Error Interrupt Register High (eDMA_EEIH)

The EEI{H,L} registers provide a bit map for the 64 channels to enable the error interrupt signal for each channel. EEIH supports channels 63–32, while EEIL covers channels 31–00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI{H,L} registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

25.3.6 Enable Error Interrupt Register Low (eDMA_EEIL)

The Enable Error Interrupt Register Low (DMA_EEIL) provides a bit map for the 64 channels to enable the error interrupt signal for each channel. EEIH supports channels 63–32, while EEIL covers channels 31–00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI{H,L} registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

0:31 EEI[31:0]	Enable error interrupt x 0 The error signal for corresponding channel does not generate an error interrupt. 1 The assertion of the error signal for corresponding channel generates an error interrupt request.

25.3.7 Set Enable Request Register (eDMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQ{H,L} to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ{H,L} to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0x0018 Access: User write-only

1 SAER	Set all enable requests 0 Set only those ERQ bits specified in the SERQ field 1 Set all bits in ERQ{H,L}
2:7 SERQ	Set enable request Sets the corresponding bit in ERQ{H,L}

25.3.8 Clear Enable Request Register (eDMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQ{H,L} to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ{H,L} to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

25.3.9 Set Enable Error Interrupt Register (eDMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEI{H,L} to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI{H,L} contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 SEEI	Set enable error interrupt Sets the corresponding bit in EEI{H,L}

25.3.10 Clear Enable Error Interrupt Register (eDMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEI{H,L} to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI{H,L} contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEI{H,L}

25.3.11 Clear Interrupt Request Register (eDMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INT{H,L} to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT{H,L} to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT{H,L} to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0x001C Access: User write-only

1 CAIR	Clear all interrupt requests 0 Clear only those INT bits specified in the CINT field 1 Clear all bits in INT{H,L}
2:7 CINT	Clear interrupt request Clears the corresponding bit in INT{H,L}

25.3.12 Clear Error Register (eDMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR{H,L} to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR{H,L} to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR{H,L} contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 CAEI	Clear all error indicators 0 Clear only those ERR bits specified in the CERR field 1 Clear all bits in ERR
2:7 CERR	Clear error indicator Clears the corresponding bit in ERR{H,L}

25.3.13 Set START Bit Register (eDMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 SSRT	Set START bit Sets the corresponding bit in TCD*n*_CSR[START]

25.3.14 Clear DONE Status Bit Register (eDMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 CDNE	Clear DONE bit Clears the corresponding bit in TCD*n*_CSR[DONE]

25.3.15 Interrupt Request Register High (eDMA_INTH)

The Interrupt Request Register High (DMA_INTH) provides a bit map for the upper half of 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptions, the eDMA engine generates an interrupt on a data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

25.3.16 Interrupt Request Register Low (eDMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the lower half of the 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

0:31 INT[31:0]	Interrupt request x 0 The interrupt request for corresponding channel is cleared. 1 The interrupt request for corresponding channel is active.

25.3.17 Error Register High (eDMA_ERRH)

The ERR{H,L} provides a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63–32, while ERRL covers channels 31–00. The eDMA engine signals the occurrence of a error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16, 32, and 64 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The content of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

25.3.18 Error Register Low (eDMA_ERRL)

The ERR{H,L} provides a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63–32, while ERRL covers channels 31–00. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 , 32, and 64 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

25.3.19 Hardware Request Status Register High (eDMA_HRSH)

The HRS{H,L} provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. HRSH supports channels 63–32, while HRSL covers channels 31–00. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQ{H,L} fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ{H,L} bits.

Field	Description
0:31 HRS[31:0]	Hardware request status channel x 0 A hardware service request for the corresponding channel is not present. 1 A hardware service request for the corresponding channel is present.

25.3.21 Channel *n* Priority Register (eDMA_DCHPRI*n*)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRI*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not

affected by writes to the DCHPRI*n* registers. The group priority is assigned in the DMA control register.

Table 358. eDMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel *n* cannot be suspended by a higher priority channel's service request. 1 Channel *n* can be temporarily suspended by the service request of a higher priority channel.
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel *n* can suspend a lower priority channel. 1 Channel *n* cannot suspend any channel, regardless of channel priority.
2:3 GRPPRI	Channel *n* current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4:7 CHPRI	Channel *n* arbitration priority Channel priority when fixed-priority arbitration is enabled. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.

25.3.22 Channel *n* Master ID Register (eDMA_DCHMID*n*)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (a core, for example) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID*n* registers.

Figure 256. TCD Transfer Attributes (eDMA_TCD*n*_ATTR)

Table 361. eDMA_TCD*n*_ATTR field descriptions

Field	Description
0:4 SMOD	Source address modulo 0 Source address modulo feature is disabled. Not 0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5:7 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte 110 Reserved 111 Reserved
8:12 DMOD	Destination address modulo See the SMOD definition.
13:15 DSIZE	Destination data transfer size See the SSIZE definition.

25.3.25 TCD Signed Source Address Offset (eDMA_TCD*n*_SOFF)

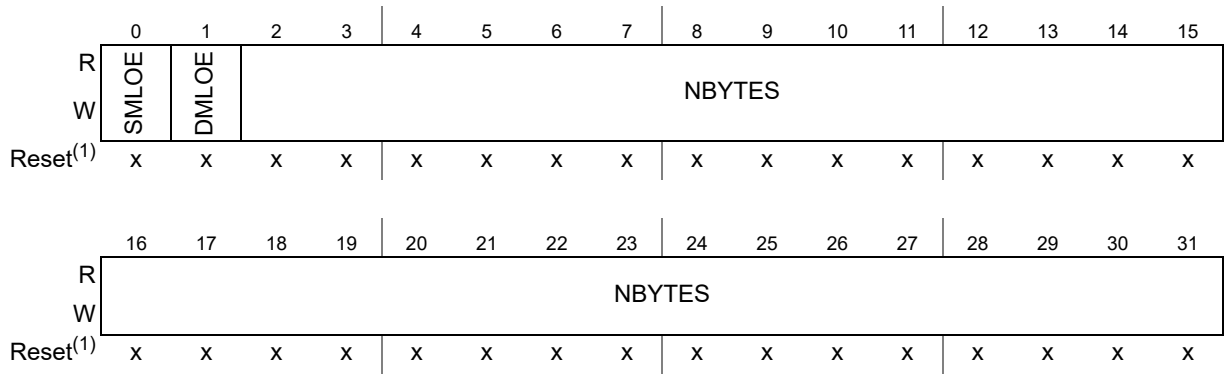
Figure 258. TCD Minor Byte Count (Minor Loop Disabled) (eDMA_TCD*n*_NBYTES_MLNO)

Table 363. eDMA_TCD*n*_NBYTES_MLNO field descriptions



Field	Description
0:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **Note:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

25.3.27 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (eDMA_TCD*n*_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

Address: 0x1008 + *n**0x20 (*n* = 0 to 63) Access: User read/write

1. x = Undefined at reset.

Figure 259. TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (eDMA_TCD*n*_NBYTES_MLOFFNO)

Table 364. eDMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

25.3.28 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (eDMA_TCD*n*_NBYTES_MLOFFYES)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset enabled (SMLOE or DMLOE = 1)

Address: 0x1008+ *n**0x20 (*n* = 0 to 63) Access: User read/write

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
1:6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.
7:15 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (for example: final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **Note:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

25.3.32 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (eDMA_TCD*n*_CITER_ELINKNO)

See TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) register figure and DMA_TCDn_CITER_ELINKNO field descriptions table as follows.

Field	Description

0:31
DLASTSGA
	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).
	If (TCD*n*_CSR[ESG] = 0) then
	– Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure.
	else
	– This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, else a configuration error is reported.

25.3.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCD*n*_BITER_ELINKYES)

Figure 269. TCD Control and Status (eDMA_TCD*n*_CSR)

Table 374. eDMA_TCD*n*_CSR field descriptions

Field	Description
0:1 BWC	Bandwidth control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBS). **Note:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w

2:7
MAJORLINKCH
	Link channel number
	If (MAJORELINK = 0) then
	– No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted.
	else
	– After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.

8 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **Note:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
9 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.

Table 374. eDMA_TCD*n*_CSR field descriptions (continued)

Field	Description
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. **Note:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **Note:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable request {H,L} 0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **Note:** If BITER is set to 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
15 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

25.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

25.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
  - Address path:

    This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

    When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n* _{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the TCD*n* _CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
  - Data path:

    This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

    The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
  - Program model/channel arbitration:

    This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
  - Control:

    This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-

bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

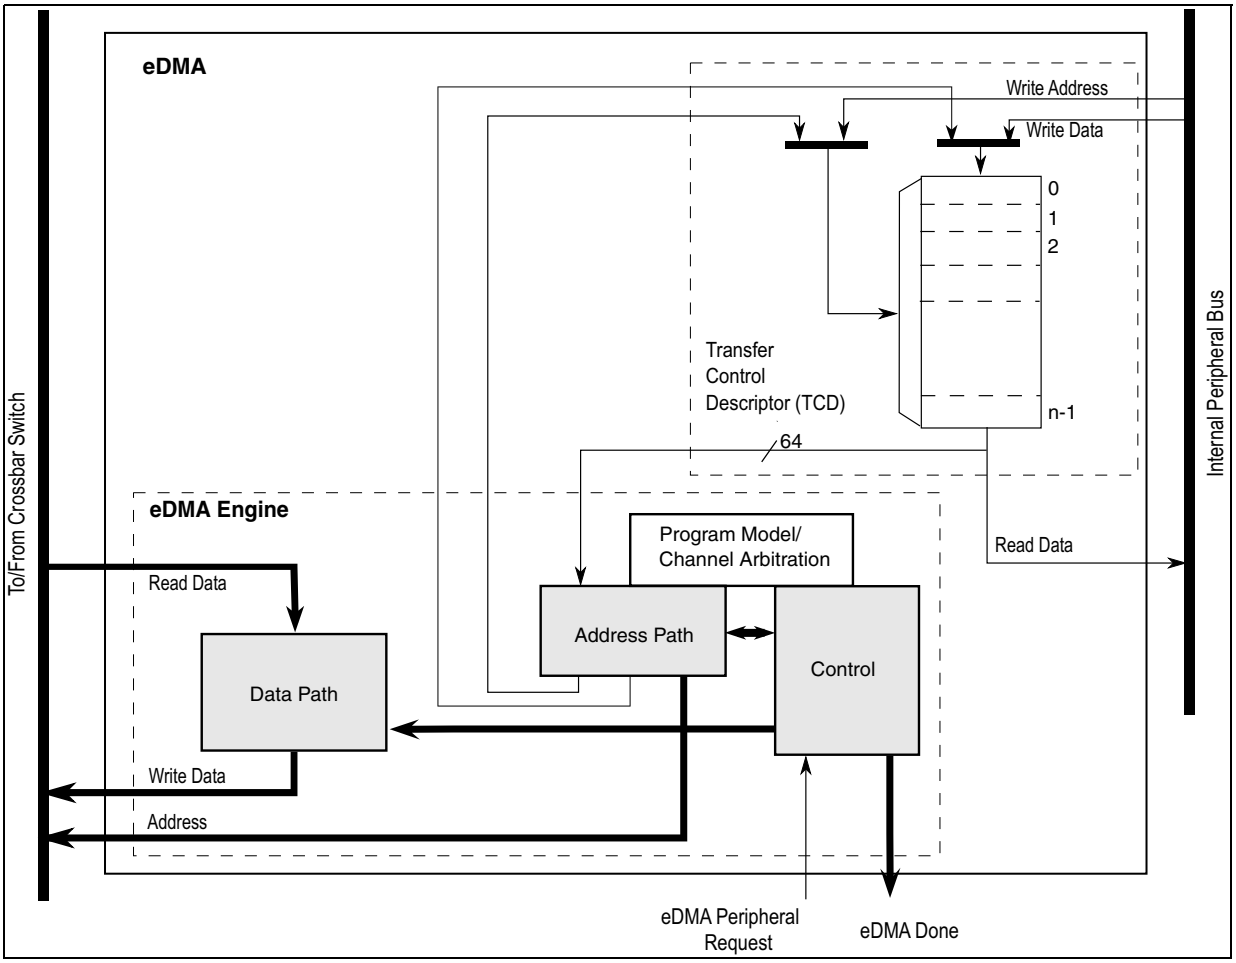
- Transfer control descriptor memory
  - Memory controller:

    This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

    As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
  - Memory array:

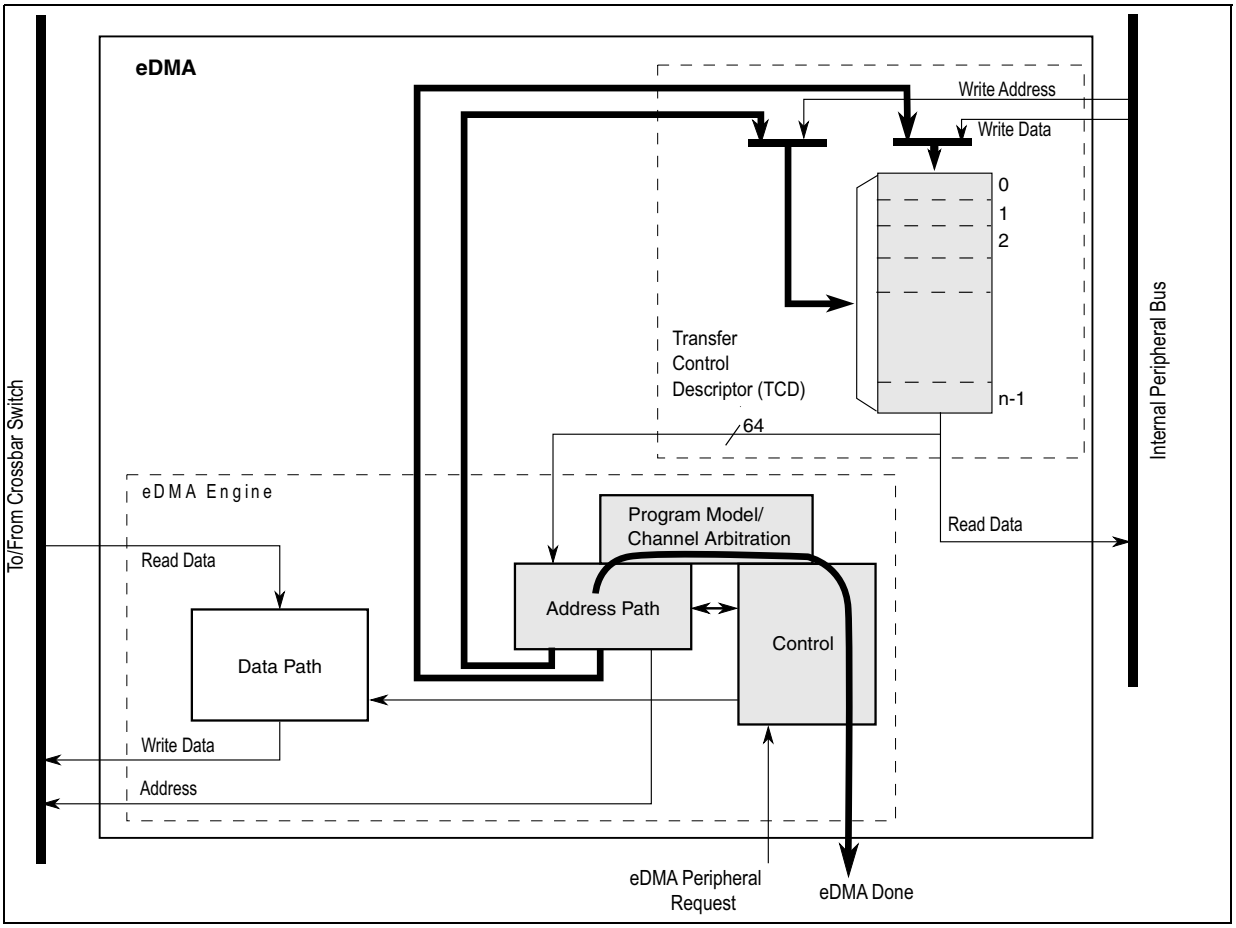
    TCD storage is implemented using a single-port, synchronous RAM array.

25.4.2 eDMA basic data flow



The basic flow of a data transfer can be partitioned into three segments. As shown in *Figure 270*, the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

Figure 270. DMA operation, part 1



In the second part of the basic data flow as shown in *Figure 271* the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

Figure 271. DMA operation, part 2

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as a possible fetch of a new TCD from memory does using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in *Figure 272*.

Figure 272. DMA operation, part 3

25.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle.

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes is detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively.
- In Fixed Arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups.

All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when Fixed Arbitration mode is enabled.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD*n*_CITER[E_LINK] bit does not equal the TCD*n*_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be canceled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the canceled channel number and ECX is set. The TCD of a canceled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is canceled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

25.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRI*n*[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRI*n*[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

25.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in *Table 375* and *Table 376*. The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- All internal peripheral bus accesses are 32 bits in size.
- All internal SRAM accesses are 64 bits in size.

Table 375 presents a peak transfer rate comparison, measured in megabytes per second.

Table 375. eDMA peak transfer rates (Mbyte/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD*n* _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* Word 7).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
- Cycles 8 to $x^{(11)}$: The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

  The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles. For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles.
- Cycle $x^{(11)}$ + 1: This cycle represents the data phase of the last destination write.
- Cycle $x^{(11)}$ + 2: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* Word 7 is read and checked for channel linking or scatter/gather requests.
- Cycle $x^{(11)}$ + 3: The appropriate fields in the first part of the TCD*n* are written back into the local memory.
- Cycle $x^{(11)}$ + 4: The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle $x^{(11)}$ + 5: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles (4 + (3 + 3)/2 + 3). This is the time from Cycle 4 to Cycle *x* + 5. The resulting peak request rate, as a function of the system frequency, is shown in *Table 376*. This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

11. "*x*" represents an undefined cycle value dependent on transfer sizes and response times for the channel's read and write accesses.

Table 376. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

Equation 1 PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to internal peripheral bus transfer,

Equation 2 PEAKreq = 150 MHz / [4 + (1 + 0) + (1 + 1) + 3] cycles = 15.0 Mreq/s

For an internal peripheral bus-to-SRAM transfer,

Equation 3 PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 0) + 3] cycles = 15.0 Mreq/s

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCD*n*_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

25.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

25.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by software (setting the TCD*n*_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in *Table 377*) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD*n*_SADDR) to the destination (as defined by the destination address, TCD*n*_DADDR) continue until the specified number of bytes (TCD*n*_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

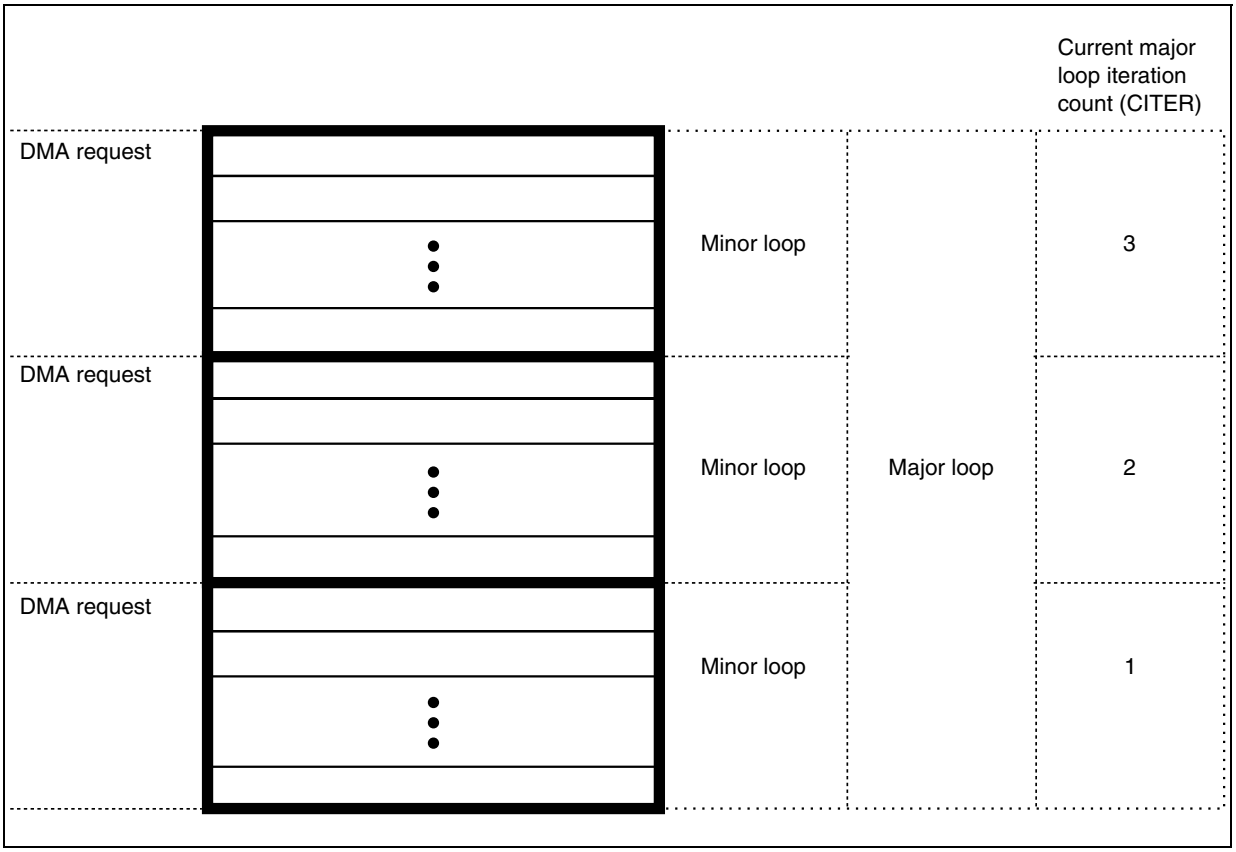
Table 377. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

Figure 273 shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of

minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 273. Example of multiple loop iterations



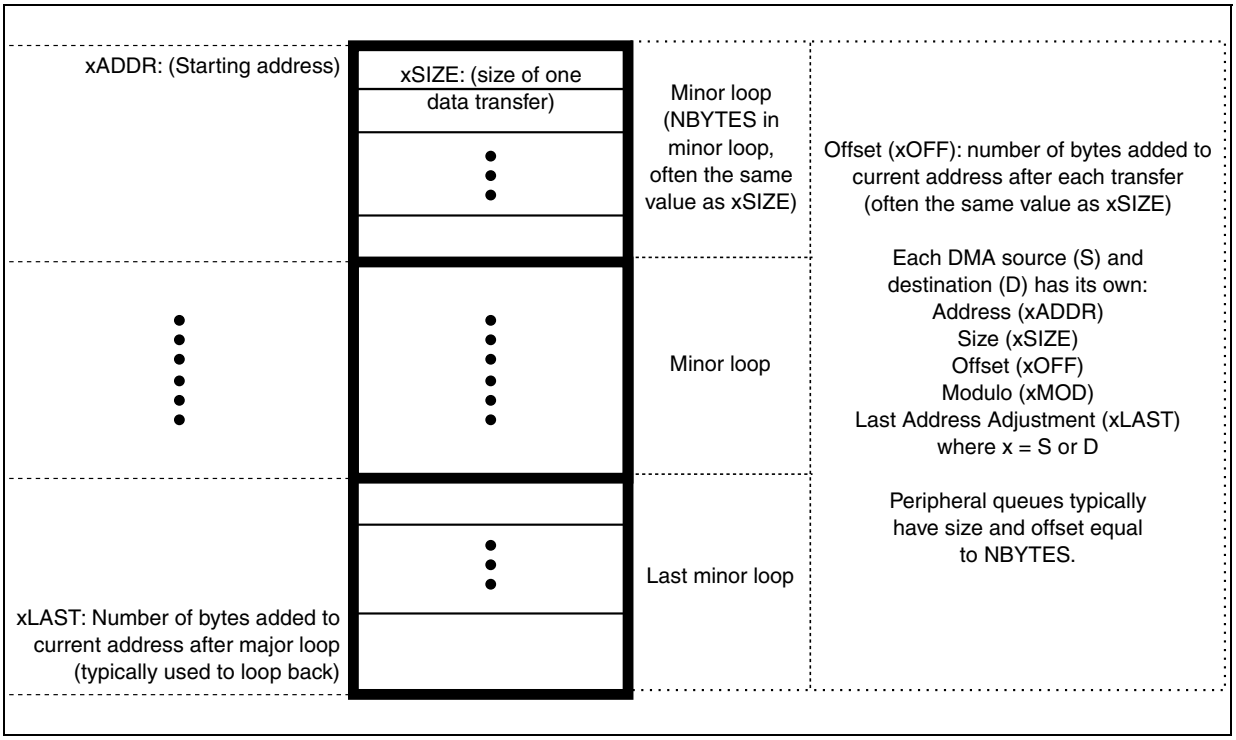


Figure 274 lists the memory array terms and how the TCD settings interrelate.

Figure 274. Memory array terms

25.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: the group priority error (ES[GPE]) and the channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes.
2. Group 3 is the highest priority and all channels are unique in that group.
3. Group 2 is the next highest priority and has two channels with the same priority level.
4. If Group 3 has any service requests, those requests will be executed.
5. Once all of Group 3 requests have completed, Group 2 will be the next active group.
6. If Group 2 has a service request, then an undefined channel in Group 2 will be selected and a channel priority error will occur.
7. This repeats until all of the Group 2 requests have been removed or a higher priority Group 3 request comes in.

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the

selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

25.5.3 DMA Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

25.5.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller—that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

25.5.3.2 Round-robin group arbitration, fixed-channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with a service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

25.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in *Section 25.5.3.2: Round-robin group arbitration, fixed-channel arbitration*, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel

service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

25.5.3.4 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in *Section 25.5.3.1: Fixed-group arbitration, fixed-channel arbitration* but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get much longer as the group priority decreases.

25.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

25.5.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have
 been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h) Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

25.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as the previous one. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.

c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h) Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a) Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b) Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c) Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d) Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e) Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f) Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g) Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h) Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2(TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

25.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address + offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

Table 378 shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 378. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

25.5.5 eDMA TCD*n* status monitoring

This section discusses how to monitor eDMA status.

25.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute a sequence for a software activated channel as shown in *Table 379*.

Table 379. TCD status sequence – software activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute a sequence for a hardware-activated channel as shown in *Table 380*.

Table 380. TCD status sequence – hardware activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit. The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

25.5.5.2 Active channel TCD*n* reads

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

25.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in Fixed-Group, Fixed-Channel Arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and group priorities are treated as equal (constantly rotating) when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

25.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop

except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note: The TCDn_CITER[E_LINK] bit and the TCDn_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

Table 381 summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 381. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

25.5.7 Dynamic programming

25.5.7.1 The following sections describe dynamic programming.

25.5.7.2 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode.
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

25.5.7.3 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in *Table 382* is recommended when executing a dynamic channel link request.

Table 382. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: – If TCD.major.e_link = 1b, the dynamic link attempt was successful. – If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

25.5.7.4 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is

retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

25.5.7.4.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in *Table 383* may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 383. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to theTCD.d_req bit. *Note: Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.*
3	Write theTCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

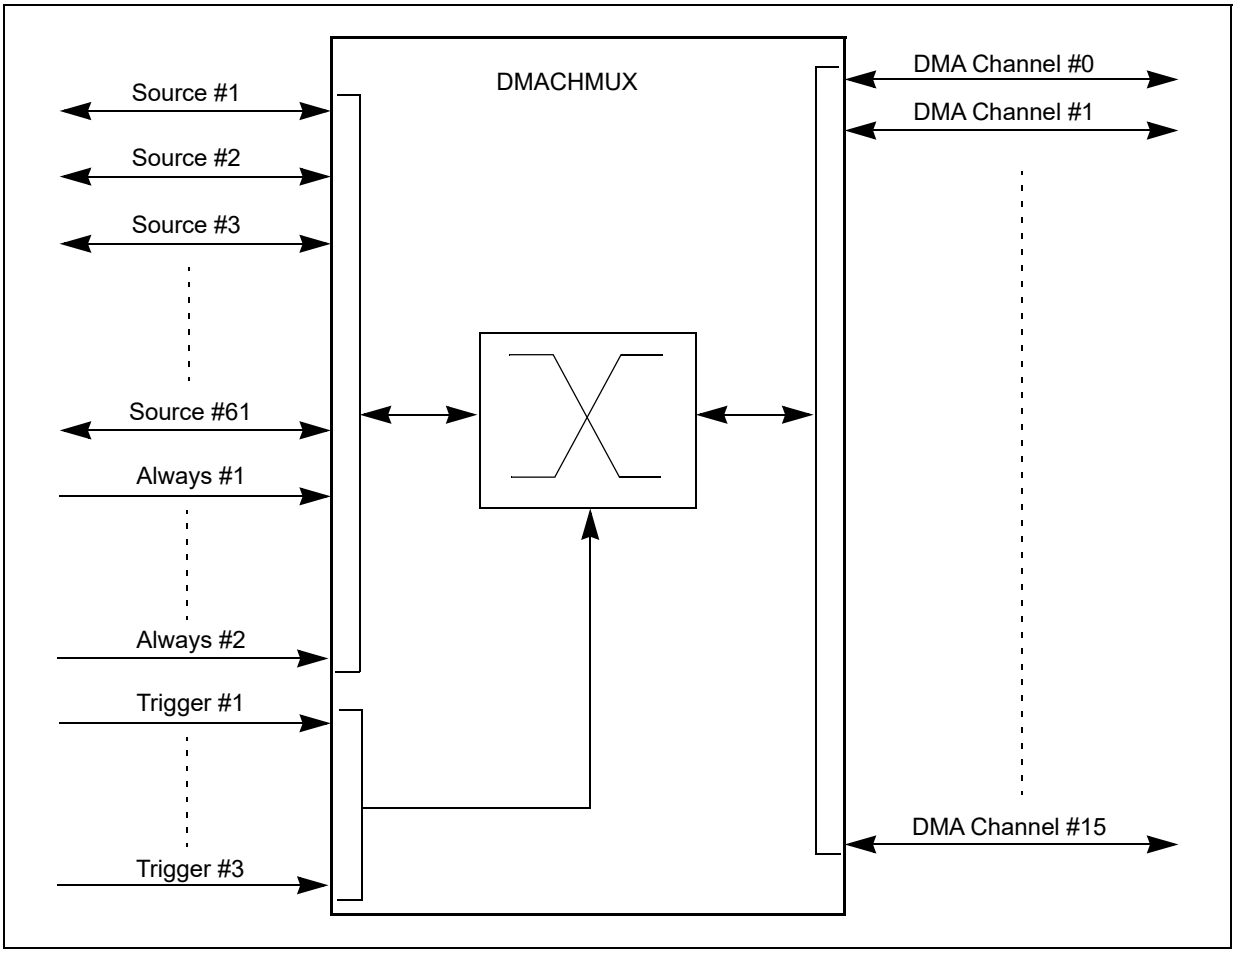
25.5.7.4.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in *Table 384* may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 384. Coherency model for method 2

Step	Action
1	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
2	Write theTCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b, read the 32 bit TCD dlast_sga field. – If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

26 DMA channel multiplexer (DMACHMUX)



26.1 Introduction

Note: For the chip-specific implementation details of this module's instances, refer to the chip configuration information.

26.1.1 Overview

The DMA channel multiplexer (DMACHMUX) allows to route 61 DMA peripheral sources (called slots) to 16 DMA channels. This is illustrated in *Figure 275*.

Figure 275. DMACHMUX block diagram

26.1.2 Features

The DMACHMUX provides these features.

- 61 peripheral slots + 2 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channels routers.
  - The first 3 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of 61 possible peripheral DMA slots or to one of the 2 always-on slots.

26.1.3 Modes of operation

The following operation modes are available.

- Disabled Mode
  In this mode, the DMA channel is disabled. Since disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMACHMUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place (for example, changing the period of a DMA trigger).
- Normal Mode
  In this mode, a DMA source (such as DSPI transmit or DSPI receive for example) is routed directly to the specified DMA channel. The operation of the DMACHMUX in this mode is completely transparent to the system.
- Periodic Trigger Mode
  In this mode, a DMA source may only request a DMA transfer (such as when a transmit buffer becomes empty or a receive buffer becomes full) periodically. Configuration of the period is done in the registers of the Periodic Interrupt Timer (PIT). This mode is only available for channels 0–2 of each DMACHMUX instance.

26.2 External signal description

26.2.1 Overview

The DMACHMUX has no external pins.

26.3 Memory map and register definition

Table 385 lists the DMACHMUX memory-mapped registers. All addresses are offsets; the absolute address can be computed by adding the specified offset to the base address of the DMACHMUX.

Table 385. DMACHMUX memory map

Address offset	Register	Access	Location
eDMA channel registers per channel (*n* = 0 to 15)			
0x0000 + *n* * 0x1	Channel *n* Configuration registers (CHCFG*n*)	R/W	*Section 26.3.1.1*

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, CHCFG0 through CHCFG3 are accessible by a 32-bit READ/WRITE to address 'Base + 0x00', but performing a 32-bit access to address 'Base + 0x01' is illegal.

26.3.1 Register descriptions

This section provides a detailed description of the memory-mapped registers in the DMACHMUX.

26.3.1.1 Channel *n* Configuration registers (CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMACHMUX slots (peripheral slots or always-on slots) in the system.

Address: 0x0000 + *n* * 0x1 (*n* = 0 to 15) Access: User read/write

	0	1	2	3	4	5	6	7
R W	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

Figure 276. Channel Configuration registers (CHCFG*n*)

Table 386. CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable ENBL enables the DMA Channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMACHMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable (for triggered channels only) TRIG enables the periodic trigger capability for the DMA Channel. 0 Triggering is disabled. If triggering is disabled, and the ENBL bit is set, the DMA Channel will simply route the specified source to the DMA channel 1 Triggering is enabled
2:7 SOURCE	DMA Channel Source (DMACHMUX slot) SOURCE specifies which DMA source, if any, is routed to a particular DMA channel. Refer to the *Chapter 7: Device configuration* for further details about the peripherals and their slot numbers

Table 387. Channel and trigger enabling

ENBL	TRIG	Function	Mode
0	X	DMA Channel is disabled	Disabled Mode
1	0	DMA Channel is enabled with no triggering (transparent)	Normal Mode
1	1	DMA Channel is enabled with triggering	Periodic Trigger Mode

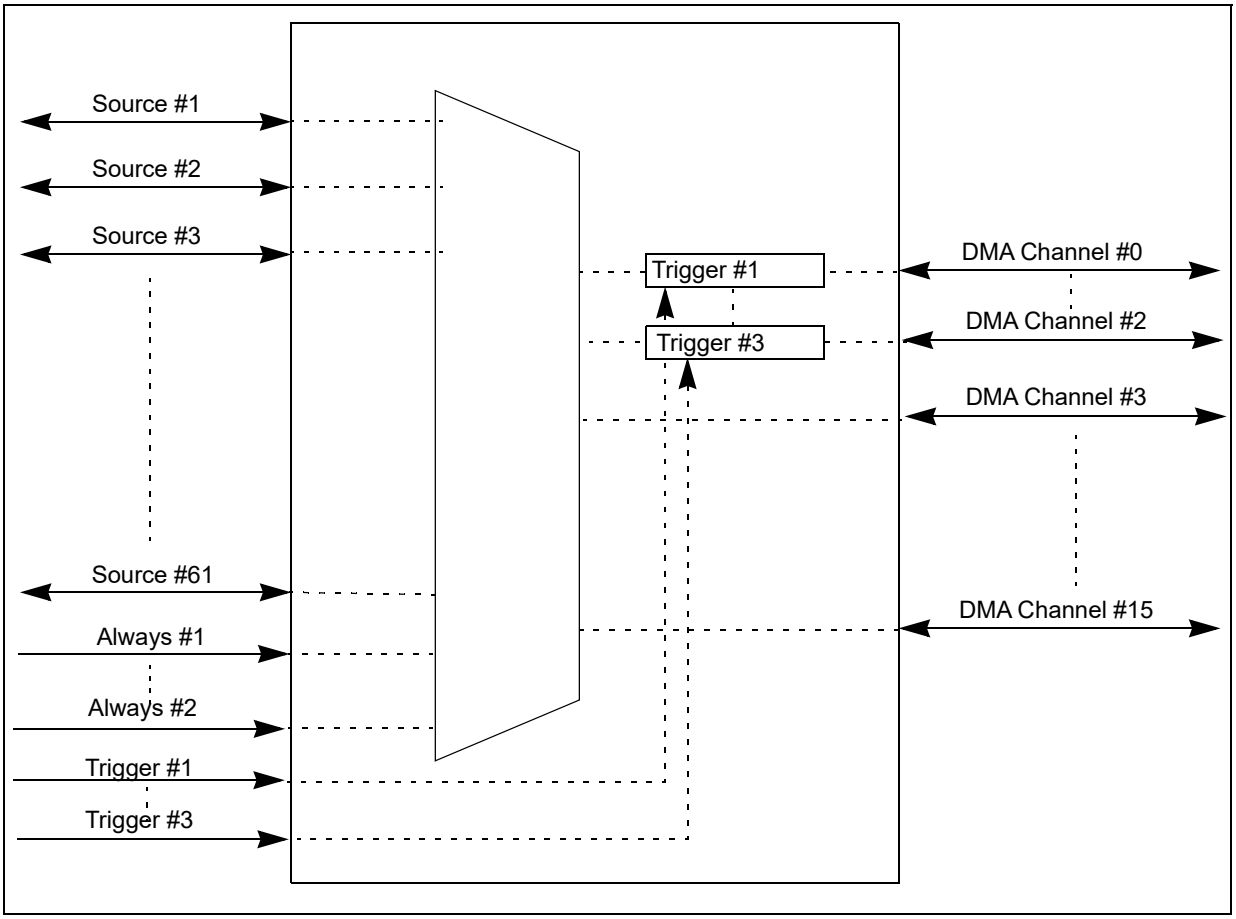
Note: Setting multiple CHCFG registers with the same source value will result in unpredictable behavior.

Before changing the trigger or source settings a DMA channel must be disabled via the CHCFG[n].ENBL bit.

26.4 Functional description

This section provides a functional description of the DMACHMUX. The primary purpose of the DMACHMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMACHMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in *Section 26.5.2: Enabling and configuring sources* is followed, the configuration of the DMACHMUX may be changed during the normal operation of the system.

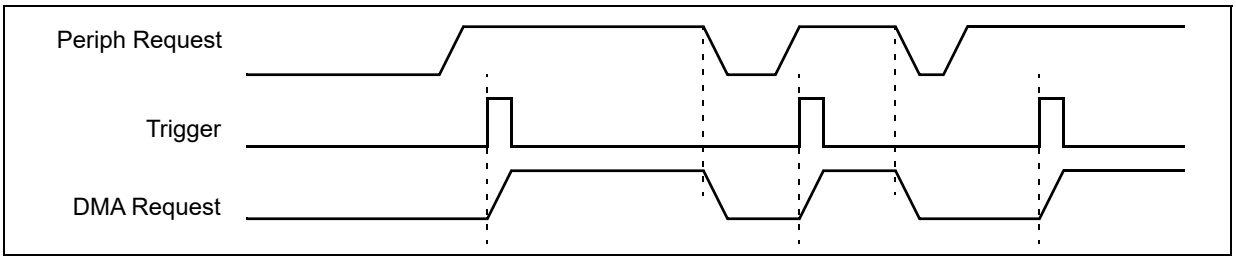
Functionally, the DMACHMUX channels may be divided into two classes.



- Channels which implement the normal routing functionality plus periodic triggering capability.
- Channels which implement only the normal routing functionality.

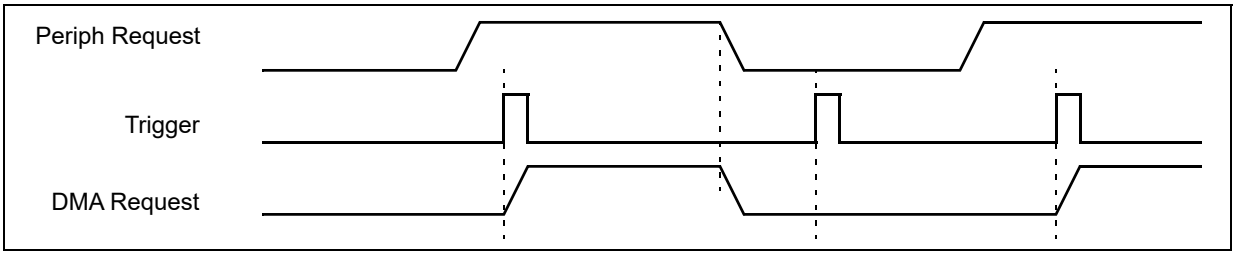
26.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 3 channels of the DMACHMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames or packets at fixed intervals without the need for processor intervention. The trigger is generated by the Periodic Interrupt Timer (PIT): such as the configuration of the periodic triggering interval is done via configuration registers in the PIT. Refer to *Chapter 50: Periodic Interrupt Timer (PIT)* for more information on this topic.



Note: Because of the dynamic nature of the system (such as DMA channel priorities, bus arbitration, interrupt service routine lengths), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 277. DMACHMUX triggered channels



The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the Peripheral to the DMA until a trigger event has been seen. This is illustrated in *Figure 278*.

Figure 278. DMACHMUX channel triggering: normal operation

Once the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral re-asserts its request AND the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, that trigger will be ignored. This situation is illustrated in *Figure 279*.

Figure 279. DMACHMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations.

- Periodically polling external devices on a particular bus. As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. Once setup, the SPI will request DMA transfers (presumably from memory) as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO Ports to drive or sample waveforms. By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger (such as resolution, range of values) may be found in *Chapter 50: Periodic Interrupt Timer (PIT)* and in the *Chapter 56: Ethernet*.

26.4.2 DMA channels with no triggering capability

The other channels of the DMACHMUX provide the normal routing functionality as described in *Section 26.1.3: Modes of operation*.

26.4.3 “Always Enabled” DMA sources

In addition to the peripherals that can be used as DMA sources, there are 2 additional DMA sources that are “always enabled”. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the *“always enabled”* sources provide no such “throttling” of the data transfers. These sources are most useful in the following cases:

- Doing DMA transfers to/from GPIO: Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Doing DMA transfers from memory to memory: Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Doing DMA transfers from memory to the external bus (or vice-versa): Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation: Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, a *“always enabled”* DMA source can be used to provide maximum flexibility. When activating a DMA channel via

software, subsequent executions of the minor loop require a new "*start*" event be sent. This can either be a new software activation, or a transfer request from the DMACHMUX. The options for doing this are:

- Transfer all data in a single minor loop. By configuring the DMA to transfer all of the data in a single minor loop (that is major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will incur on the system. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use explicit software reactivation. In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel (by writing to the DMA registers) *after every minor loop*. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use a *"always enabled"* DMA source. In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMACHMUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an *"always enabled"* source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

26.5 Initialization/application information

26.5.1 Reset

The reset state of each individual bit is shown within the register description section (refer to *Section 26.3.1: Register descriptions*). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

26.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 2 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

Note: The following is an example. Refer to the chip configuration details for the number of this device's DMA channels that have triggering capability.

Example 1 Configure source #5 Transmit for use with DMA Channel 2, with periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #4 above:

In file **registers.h:**

```
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
#include "registers.h"
   :
   :
*CHCFG2 = 0x00;
*CHCFG2 = 0xC5;
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 3 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

Note: The following is an example. Refer to the chip configuration details for the number of this device's DMA channels that have triggering capability.

Example 2 Configure source #5 Transmit for use with DMA Channel 2, with no periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #3 above:

In File **registers.h:**

```
  #define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
  /* Following example assumes char is 8-bits */
  volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
  volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
  volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
  volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
  volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
  volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
  volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
  volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
  volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
  volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
  volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
  volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
  volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
```

```
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG2 = 0x00;
  *CHCFG2 = 0x85;
```

Disabling a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module specific configuration may be necessary. Refer to the appropriate section for more details.

Switching the source of a DMA Channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the ENBL and TRIG bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the ENBL and TRIG bits are set.

Example 3 Switch DMA Channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 does not have triggering capability.
2. Write 0x00 to CHCFG8 (Base Address + 0x08).
3. Write 0x87 to CHCFG8 (Base Address + 0x08). (In this example, setting the TRIG bit would have no effect, due to the assumption that channels 8 does not support the periodic triggering functionality).

The following code example illustrates steps #2 and #3 above.

In File **registers.h:**

```
  #define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
  /* Following example assumes char is 8-bits */
  volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
  volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
  volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
  volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
  volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
```

```
  volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
  volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
  volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
  volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
  volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
  volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
  volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
  volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG8 = 0x00;
  *CHCFG8 = 0x87;
```

27 Clocking

27.1 Introduction

This chapter describes the architecture of the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive Clock Switching (PCS)

Note: This chapter only covers clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The system clock (SYS_CLK) services the computational shell modules (include the main CPUs Main Core_0/1/2 and Checker Core_0s/2s), that run in the high-speed domain, memories and debug logic. Its independence from the peripheral clocks allows SYS_CLK to be a frequency modulated (FM) clock with reduced electromagnetic emissions while having a precise clock for the peripheral timer and communication functions. It can be reduced during low computational activity periods to lower power consumption while providing a fixed frequency to the communication interfaces and timers.

The internal 16 MHz RC oscillator (IRCOSC) services device boot up and may be enabled via the Mode Entry Module in the event of PLL or external oscillator failure. See the “Mode Entry Module (MC_ME)” chapter for details.

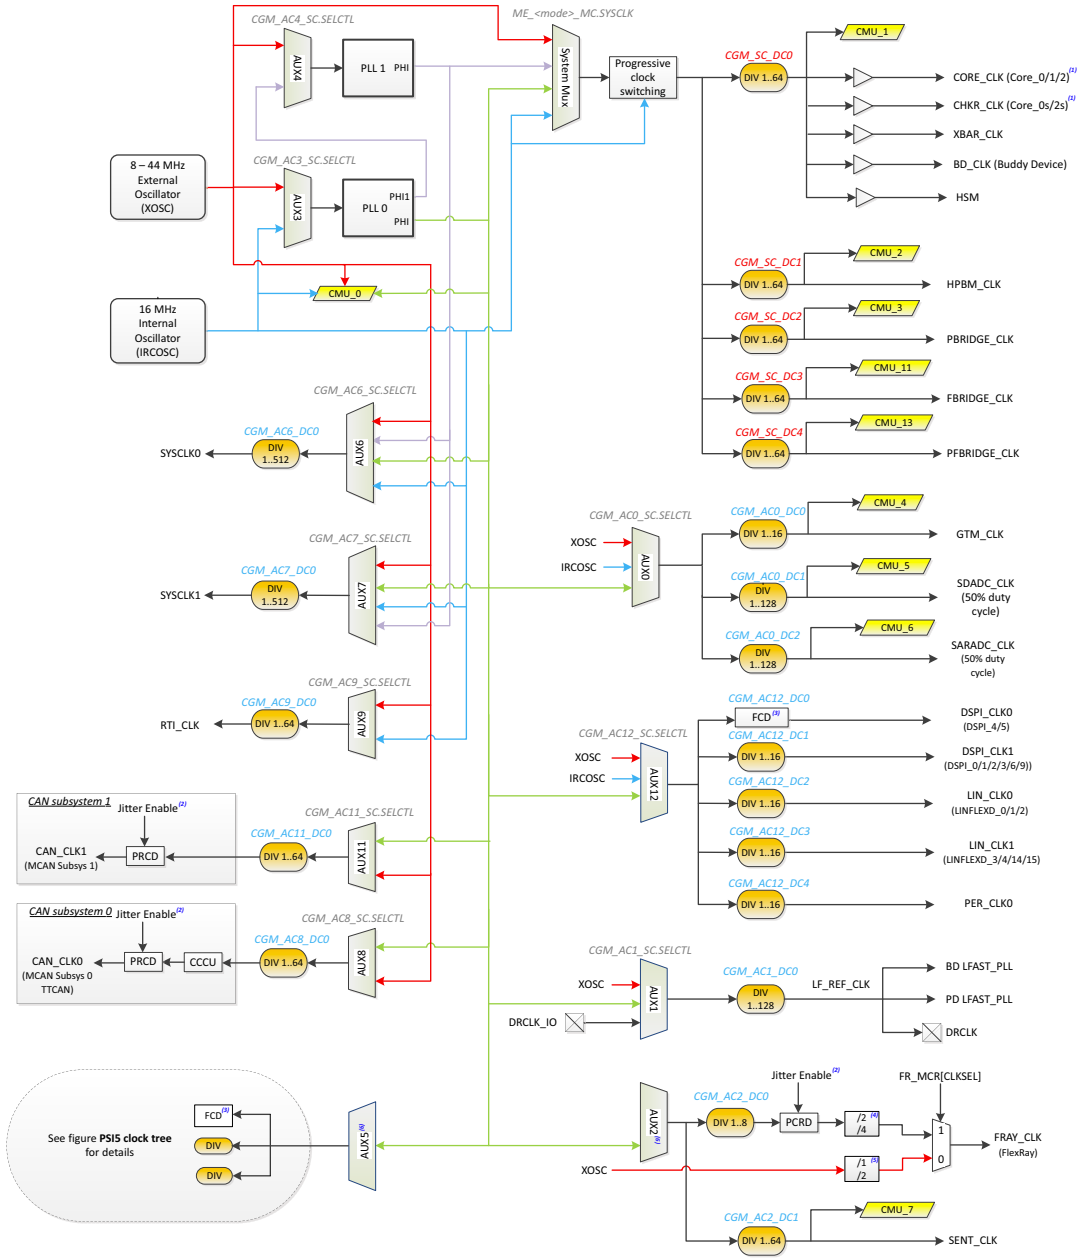
The alternative clock sources are:

- External oscillator/crystal (XOSC)
- Internal 16 MHz RC oscillator (IRCOSC)
- PLL0 (PLL0_PHI)
- PLL1 (PLL1_PHI)

Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM) allow developers to select an independent clock source for each system peripheral. There is an additional System Clock Selector used exclusively for the system clock.

The outputs of the module clock selectors have individual dividers that can divide the clock selector outputs by up to 1024 for a given peripheral.

Clock Monitor Units (CMUs) are connected to outputs of clock dividers to verify that clock frequencies stay within operating limits and can be configured to signal an interrupt or initiate a system reset when an issue with a clock is found.



27.2 Clock generation

The top-level clock generation architecture can be seen in *Figure 280* and *Figure 282*. See *Chapter 30: Clock Generation Module (MC_CGM)* for details on the Fractional Clock Dividers. All clock selectors and dividers are located and programmed in the MC_CGM, with

the exception of the Hardware Security Module (HSM) clock divider. All dividers are integer dividers (1, 2, 3, …, *n*) with the ranges shown in the divider blocks in *Figure 280* and *Figure 281*. All dividers connected to the System Clock Selector must have 50 % duty cycle outputs.

Note: Clock Monitoring Units CMU1 to CMU13 in Figure 280 and *Figure 281 use IRCOSC as their reference clock. The user can select either IRCOSC or XOSC as the reference clock for CMU_0.*

Figure 280. Clock generation[1][2] (part 1 of 2)

All dividers shown in the diagram are integer dividers with a range of 1, 2, 3,...., n. FCD are fractional clock dividers. All clock dividers are 50% duty cycle.

Note: See the Clock Generation Module (MC_CGM) for specifics on register implementation.			

1. CMU_0 is not shown in the table since it does not monitor an output clock from the MC_CGM.

27.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in *Table 389*.

Table 389. Maximum system level clock frequencies

Clock Selector	Nominal programmed max output frequency for input to dividers (MHz)	SC_DC number	Divider logic	Divider setting when SYS_CLK is running on PLL clock (fast clock mode)	Divider setting when SYS_CLK is running on XOSC or IRCOSC (slow clock mode)
System clock selector(1)	180	0	CORE_CLK	SYS_CLK / 1	SYS_CLK / 1
System clock selector(1)	180	1	HPBM_CLK	SYS_CLK / 2	SYS_CLK / 1
System clock selector(1)	180	2	PBRIDGE_CLK	SYS_CLK / 4	SYS_CLK / 1
System clock selector(1)	180	3	FBRIDGE_CLK	SYS_CLK / 1	SYS_CLK / 1
System clock selector(1)	180	4	PFBRIDGE_CLK	SYS_CLK / 1 (2) or SYS_CLK / 2 or SYS_CLK / 4	SYS_CLK / 1
System clock selector(1)	180	—	HSM_CLK (3)	SYS_CLK / 2	

Note: The user is responsible to verify that these values are not exceeded.

Note: Refer to *Figure 280* and *Figure 281* for clocking architecture overview.

1. System clock selection is a component of the device run mode switching process. Refer to the Mode Entry Module (MC_ME) chapter for details.
2. PFBRIDGE_CLK max frequency supported is 160MHz. So SYS_CLK/1 is possible only if System clock frequency is less than or equal to 160MHz.
3. Maximum frequency is related to HSM core clock (HSM_CLK). Refer to *Figure 283* for details.

Table 390. Maximum auxiliary level clock frequencies

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)

Aux Clock 5 Selector	400	CDC22	PSI5_S_WD_CLK2	25
Aux Clock 5 Selector	400	CDC23	PSI5_S_WD_CLK3	25
Aux Clock 6 Selector	400	0	SYSCLK0	Refer to the Data Sheet, section “I/O output DC characteristics”

Table 390. Maximum auxiliary level clock frequencies (continued)

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
Aux Clock 7 Selector	400	0	SYSCLK1	Refer to the Data Sheet, section “I/O output DC characteristics”
Aux Clock 8 Selector	400	0	CAN_CLK0	If CCCU is enabled: 400 If CCCU is bypassed: 80
Aux Clock 9 Selector	40	0	RTI_CLK	40
Aux Clock 11 Selector	400	0	CAN_CLK1	80
Aux Clock 12 Selector	400	0	DSPI_CLK0(2)	100
Aux Clock 12 Selector	400	1	DSPI_CLK1(2)	100
Aux Clock 12 Selector	400	2	LIN_CLK0	100
Aux Clock 12 Selector	400	3	LIN_CLK1	100
Aux Clock 12 Selector	400	4	PER_CLK0	100
Note: The user is responsible to verify that these values are not exceeded. **Note:** Refer to the *Figure 280* and *Figure 281* for clocking architecture overview.				

1. 80 MHz maximum frequency is at aux divider output. The maximum frequency of FRAY_CLK after the multiplexer is 40 MHz.
2. DSPI_CLK0/1 frequency should always be greater than or equal to 1.25 times of PBRIDGE_CLK.

27.3.1 JTAG frequencies

Table 391 shows the maximum frequencies of the JTAG interface.

Table 391. JTAG frequencies

Device	Configuration	e200z4 max. internal JTAG frequency	Buddy device max. RWA internal frequency	Max. external JTAG frequency	Notes
PD(1)	Unconfigured clock	—	N/A	Refer to electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock on PD (IRC) with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 200 MHz	100 MHz			JTAG usable at 1/2 CPU frequency
ED(2)	BD only powered	N/A	22.4 MHz		BD clocked by internal 64 MHz RC clock (RCOSC64) with +/- 30% tolerance and BD RWA usable at /2 frequency
	PD and BD powered, unconfigured clock	—	—		ED clocked by internal 8 MHz RC clock (IRC) with +/- 1.5% tolerance, and BD RWA usable at /2 frequency
	PD and BD powered, PD clock configured clock to 200 MHz	100 MHz	100 MHz		100 MHz JTAG achievable using LFAST mode debug, or s/w mode JTAGM. JTAG messages are generated internally by JTAGM and stay within BD and PD domain. The external tool interface is LFAST only

1. PD = Production Die
2. ED = Emulation and Debug Device = Production Die + Buddy Die

27.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to ‘1’ at power on reset, except for the HSM, which is set to its maximum value.

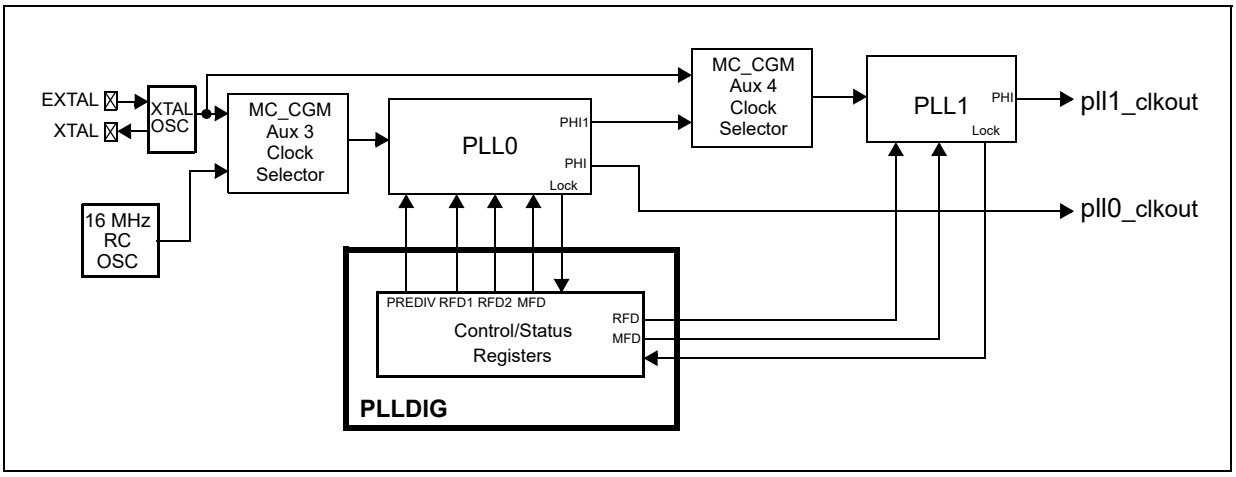
27.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (SSCG - Spread Spectrum Clock Generator (FM))
- External oscillator (XOSC)
- External Clock (EXTAL Bypass)
- 16 MHz internal RC oscillator (IRCOSC)

IRCOSC is also the system clock available during the STANDBY and it is placed in STANDBY power domain.

Additionally, there are two low power oscillators in STANDBY domain:



- Low power RC oscillator 1024 KHz (LPRC)
- Slow external crystal oscillator 32 KHz (SXOSC)

These two low power oscillators can be used as clock for counters of API/RTC.

27.5.1 PLL

The Dual PLL provides separate system and peripheral clocks as shown in *Figure 280*. The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in *Figure 282*.

Figure 282. SPC58xEx/SPC58xGx PLL digital interface block diagram

27.5.1.1 PLL0: base PLL (non-FM)

This primary PLL provides a clock that is not Frequency Modulated to the peripheral IPs and the reference clock to PLL1.

The input clock sources for PLL0 are:

- XOSC
- IRCOSC
- The external reference clock (input on the EXTAL pin)

The output clocks from PLL0 are:

- PHI: drives the peripheral clock and the system clock when PLL1 is not locked or active.
- PHI1: provides the input reference clock for PLL1.

27.5.1.2 PLL1: FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

The input clocks to PLL1 are:

- PHI1 output clock from PLL0
- The external reference clock.

The output clock from PLL1 is:

PHI: drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

27.5.1.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the “Dual PLL Digital Interface” chapter.

27.5.1.4 PLL register write protection

The PLL registers defined in *Table 392* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the PLL register write protection (refer to *Section 7.10.5: Register protection (REG_PROT) configuration* in *Chapter 7: Device configuration* for details).

Table 392. PLL register write protection

Offset	Register
0x00	PLL0 Control Register (PLL0CR)
0x04	PLL0 Status Register (PLL0SR)
0x08	PLL0 Divider Register (PLL0DIVR)
0x20	PLL1 Control Register (PLL1CR)
0x24	PLL1 Status Register (PLL1SR)
0x28	PLL1 Divider Register (PLL1DIVR)
0x2C	PLL1 Frequency Modulation Register (PLL1FMR)
0x30	PLL1 Fractional Divider Register (PLL1FDR)
Note: Refer to Register Protection Configuration chapter for bit field details.	

27.5.1.5 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in *Table 393*. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 393. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset value (hex)
0x0008	PLL0 Divider Register (PLL0DV)	0x0000_0000
0x0028	PLL1 Divider Register (PLL1DV)	0x0000_0000
0x0034	Reserved	—
0x0038	Reserved	—

27.5.1.6 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition.

27.5.1.7 PLLDIG initialization information

Configure PLL0 and related modules.

1. With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.
2. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].
3. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).
4. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

Turn on XOSC and PLL0.

5. Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<mode>_MC[XOSCON] = 1 and MC_ME_<mode>_MC[PLL0ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0(PLL0 PHI output) as the sysclk.
6. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

7. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

   XOSC counter expires (if the new mode configuration changes MC_ME_<mode>_MC[XOSCON] = 1), and

   PLL is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL0ON] = 1)
8. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Configure PLL1 and related modules.

9. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.
10. Program PLL1DV[MFD] and PLL1DV[RFDPHI].
11. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

Turn on PLL1.

12. Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL1 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<mode>_MC[XOSCON] = 1, MC_ME_<mode>_MC[PLL1ON] = 1 and MC_ME_<mode>_MC[PLL1ON] = 1. If desired, also set

MC_ME_<mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.

13. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

14. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

    XOSC counter expires (if the new mode configuration changes XOSCON to 1), and

    PLL1 is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL1ON] = 1).

15. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Note: Refer to the "Mode Entry Module (MC_ME)" chapter in this Reference Manual for more details.

27.5.2 External oscillator (XOSC)

The external oscillator (XOSC):

- Is a reference for the on-chip PLLs.
- Can be used as a clock source for the ADCs, timer, serial interfaces, RTI, LFAST and as a system clock source.
- Is available for observation on either of the SYSCLK0/1 pins.
- Is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators
- Automatic Loop Control (ALC) to remove need for external series resistor
- Gain selection for <= 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues
- Reference clock to PLL0
- Reference clock to CMU0 (IRCOSC trimming)
- Option to drive the CAN and FlexRay protocol clocks directly from the XOSC

The XOSC provides support for 4 MHz - 40 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor

27.5.2.1 XOSC Start-up

Enabling of the oscillator at startup is determined by a bit of Miscellaneous DCF in UTEST Flash memory (refer to *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*). The default value has the XOSC disabled:

UTEST Miscellaneous[24] = 0 (XOSC_EN).

If enabled, the oscillator is started in PHASE 3 of the reset sequence: after negation of the internal POR circuits but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors:

UTEST Miscellaneous[25] = 1 (XOSC_EXT_LOAD).

Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. Refer to the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During PHASE 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module. Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values:

UTEST Miscellaneous[26:30] = 00000b (XOSC_LOAD_CAP_SEL).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value causing an undetectable error in the system.

The XOSC has the ability to be started with 4 MHz - 40 MHz crystal. The default value of this field is for an 35 MHz - 40 MHz:

UTEST Miscellaneous[19:21] = 111b (XOSC_FREQ_SEL).

Refer to the FLASH memory chapter for more information on the UTEST row programming.

27.5.2.2 XOSC register write protection

The XOSC registers defined in *Table 394* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the XOSC register write protection.

Table 394. XOSC register write protection

Offset	Register	Protections
0x00	XOSC Control Register (XOSC_CTL)	Yes
Note: refer to “Register Protection Configuration” chapter for bit field details		

27.5.2.3 XOSC reset value

Table 395 shows the default reset value for the XOSC registers.

Table 395. XOSC register reset values

Offset	Register	Reset value
0x00	XOSC Control Register (XOSC_CTL)	0x8030_8000

27.5.3 16 MHz internal RC oscillator (IRCOSC)

The 16 MHz internal RC oscillator default clock is always enabled on reset and can be the clock source for the PLLs. The register interface is for user trimming of the oscillator and dividing output from 1 to 32.

27.5.3.1 IRCOSC register interface

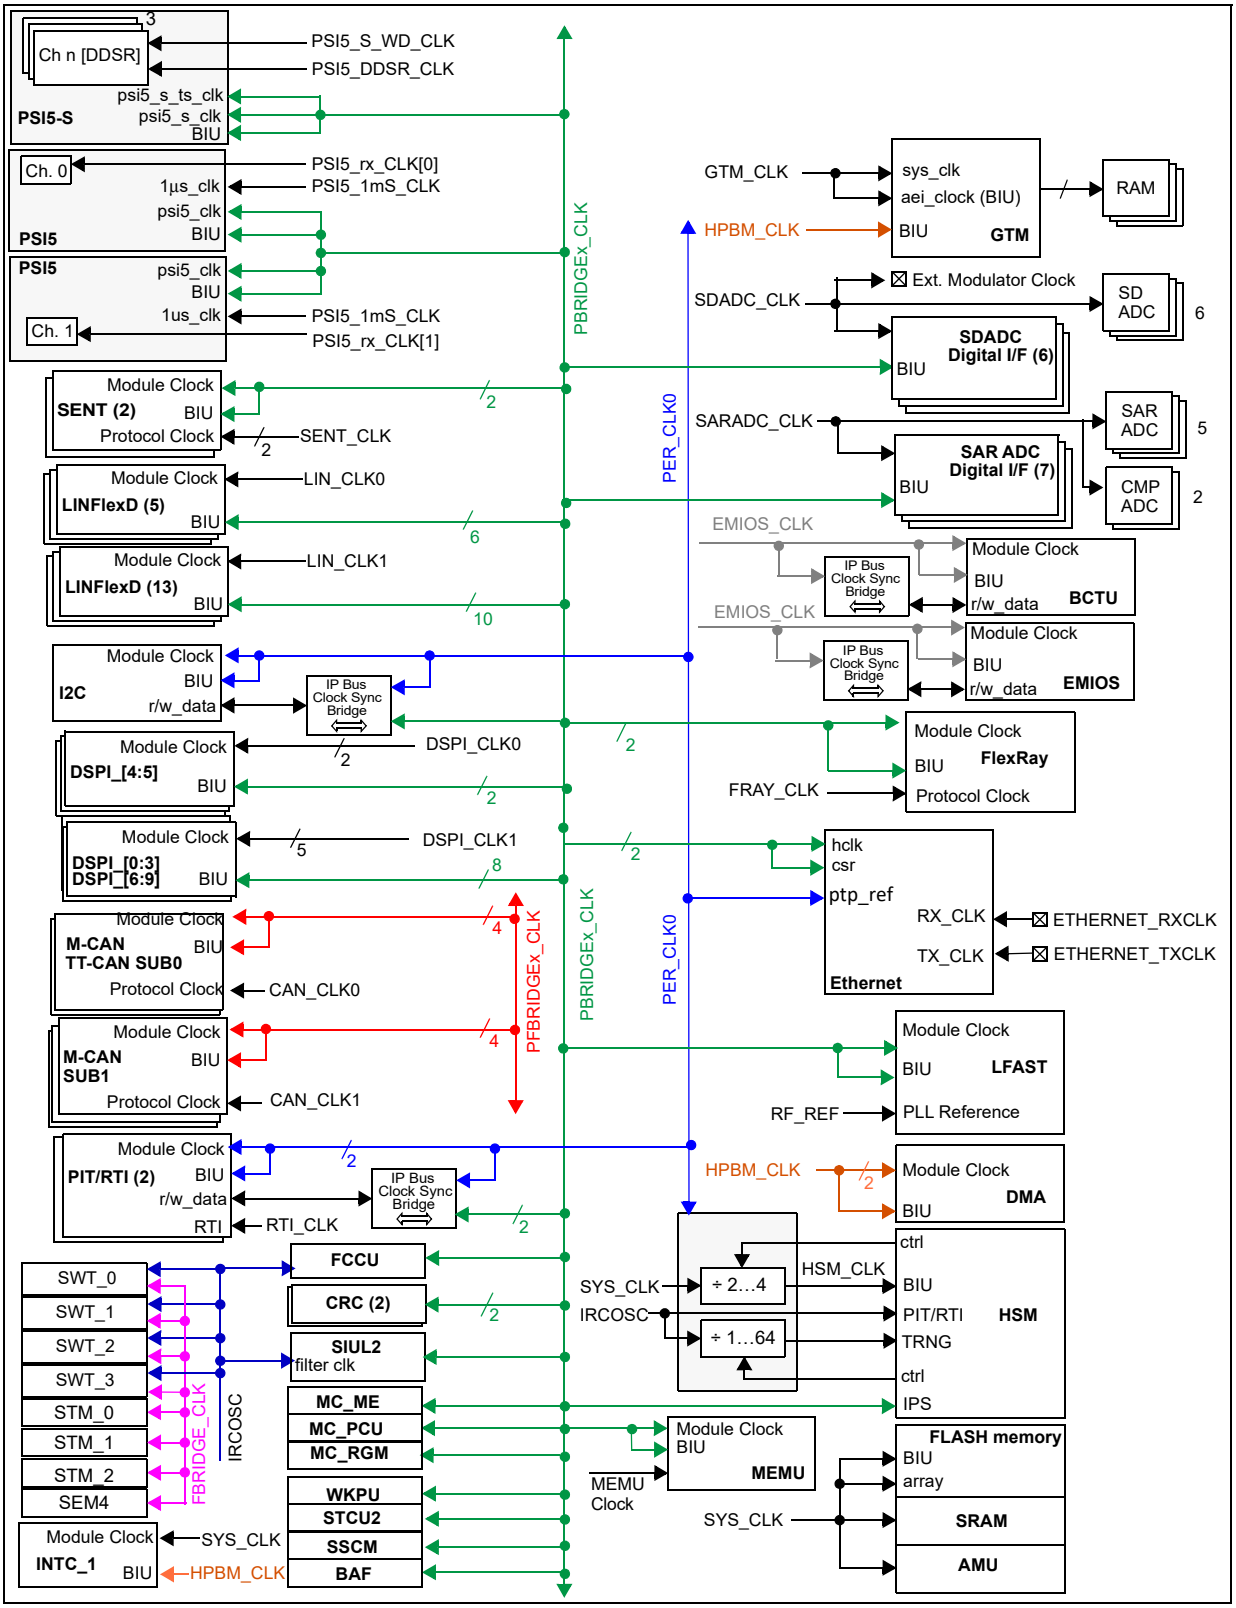
A dedicated digital interface for the IRCOSC has a user register for fine tuning the IRCOSC frequency. Other read-only registers contain settings and values for the IRCOSC temperature sensor, voltage regulator and capacitor trimming.

27.5.3.2 IRCOSC reset value

Table 396 shows the default reset value for the IRCOSC registers.

Table 396. IRCOSC register reset values

Offset	Register	Reset value
0x04	Native Trimming Register (NT)	0x0000_0000
0x08	Temperature Trimming Register (TT)	0x0000_0000



27.5.3.3 IRCOSC register write protection

The IRCOSC registers do not utilize write protection.

27.6 Peripheral clocks

Figure 283 shows the clock distribution to the cores and peripheral modules.

Figure 283. Clock distribution

Note: The frequency of the MEMU clock is equal to the frequency of the SYSTEM clock.

27.6.1 HSM clock divider

The clock dividers for the HSM core and random number generator (TRNG) are located outside the HSM, but not in the MC_CGM. These dividers are controlled by the HSM. The minimum possible divider after reset is ‘divide by 2’.

The HSM contains an internal PIT/RTI block, which is clocked by the IRCOSC.

The HSM has an internal clock monitor on its input clock, so there is no need for a Clock Monitoring Unit (CMU) for the HSM_CLK in *Figure 280*.

27.6.2 PSI5 clock dividers

The SPC58xEx/SPC58xGx microcontroller includes two PSI5 modules, all of which use the three common clocks shown in *Figure 280*. The required frequencies for these clocks are generated from PLL0 as follows:

- $F_{PSI5_f189_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC0[DIV] + 1) / 10CGM_AC5_DC0[FMT]) = 6.048 MHz ±0.1%
- $F_{PSI5_f125_CLK} = F_{PLL0_PHI}$ / (CGM_AC5_DC1[DIV] + 1) = 4 MHz
- $F_{PSI5_1us_CLK} = F_{PLL0_PHI}$ / (CGM_AC5_DC2[DIV] + 1) = 1 MHz

The nine PSI5-S clocks are generated by dividing the PSI5_1µs_CLK further via a second and a third level of 'cascaded' clock dividers. The individual frequencies are, therefore, derived from the PLL0 PHI frequency as follows:

- $F_{PSI5_S_TS_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC0[DIV]+1))
- $F_{PSI5_S_DDSR0_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC10[DIV]+1))
- $F_{PSI5_S_DDSR1_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC11[DIV]+1))
- $F_{PSI5_S_DDSR2_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC12[DIV]+1))
- $F_{PSI5_S_DDSR3_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC13[DIV]+1))
- $F_{PSI5_S_WD0_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC20[DIV]+1))
- $F_{PSI5_S_WD1_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC21[DIV]+1))
- $F_{PSI5_S_WD2_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC22[DIV]+1))
- $F_{PSI5_S_WD3_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC23[DIV]+1))

27.6.3 LFAST clocking

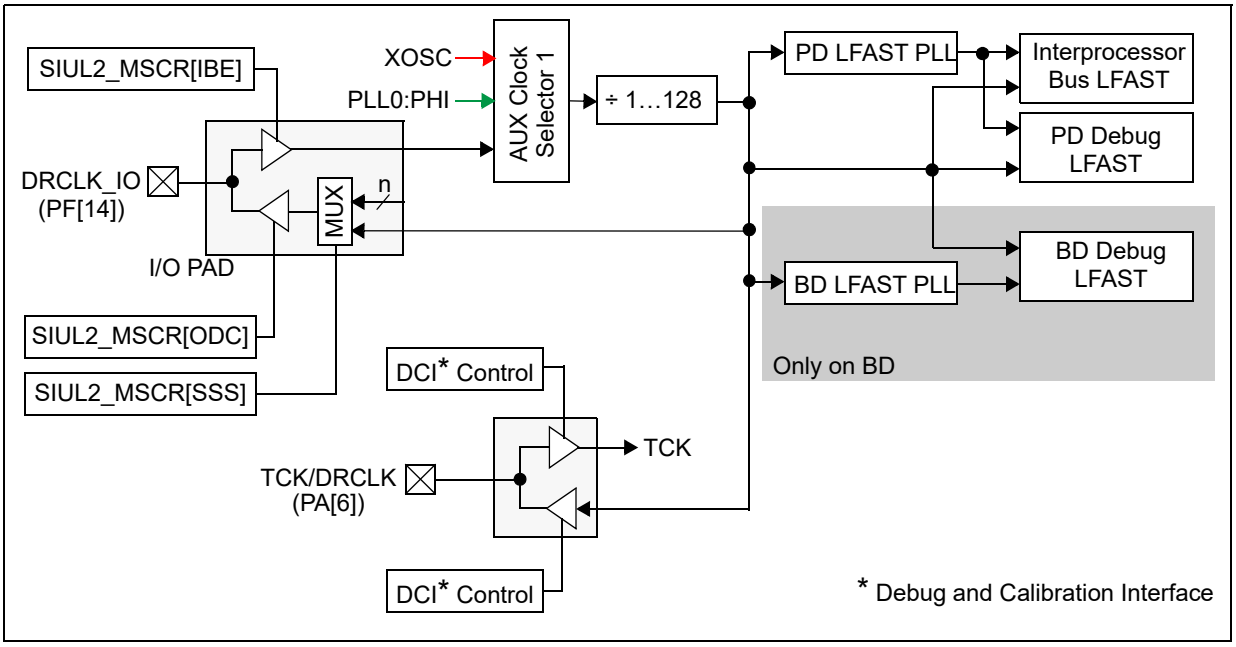
The SPC58xEx/SPC58xGx includes two LFAST modules:

- In conjunction with the SIPI module for interprocessor communications
- In conjunction with the JTAGM module for high speed debug

High-speed operation of both LFAST modules is supported by a single LFAST PLL requiring a 10–20 MHz reference. Low-speed LFAST operation uses the reference clock directly.

The LFAST PLL reference clock source may be:

- PLL0:PHI output
- External oscillator (XOSC)
- Input from the external LFAST device via the DRCLK_IO package pin



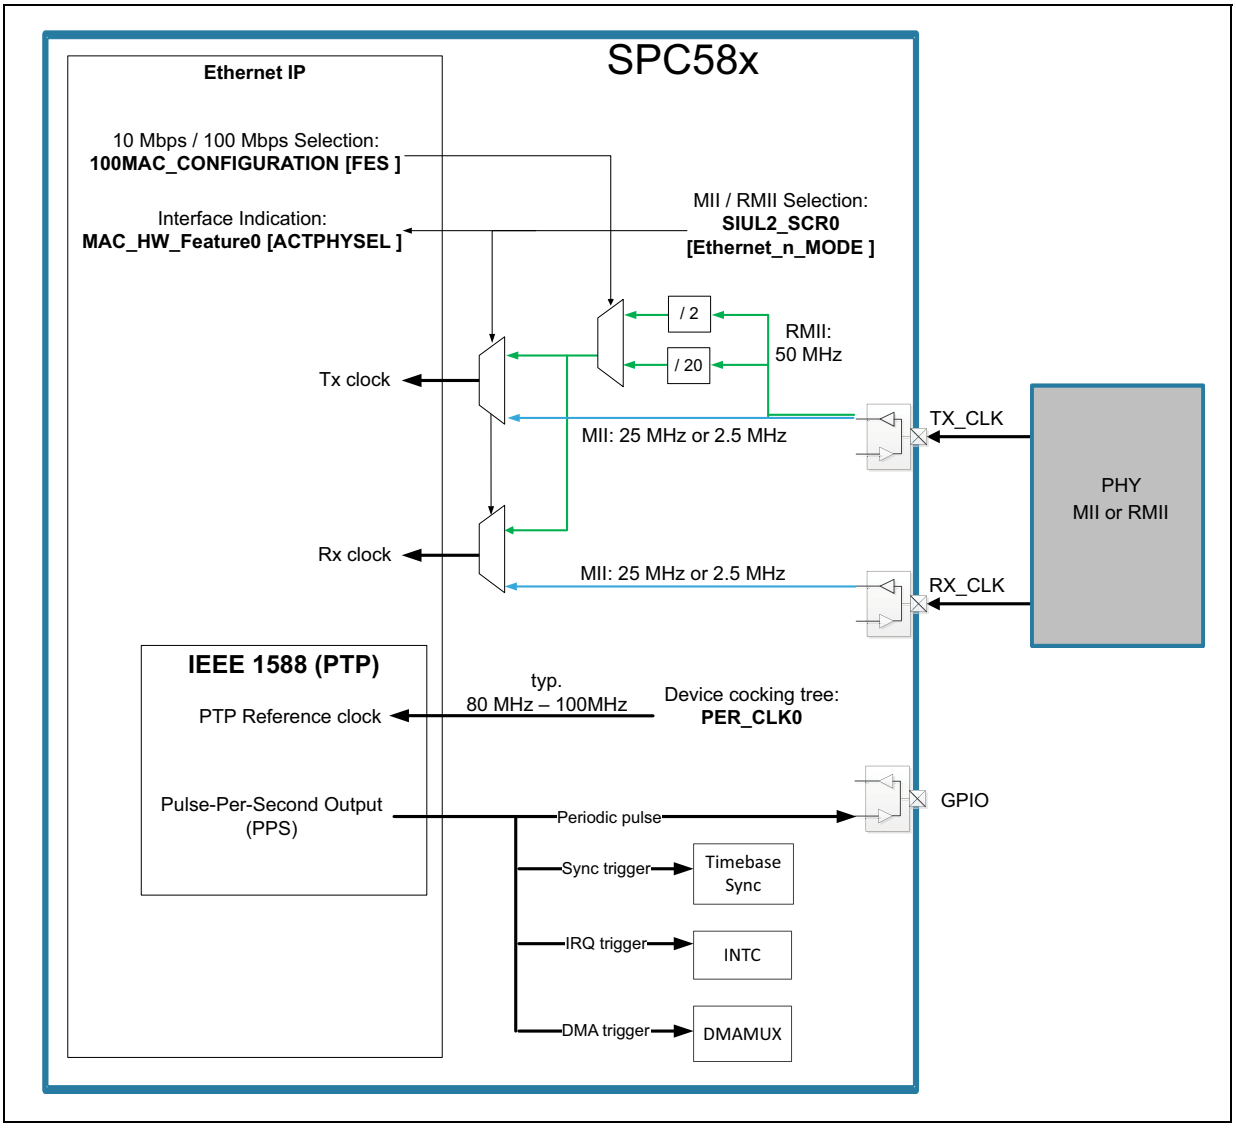
When the reference clock is generated internally, it can be output on the DRCLK_IO pin

The debug LFAST module only supports the operation mode where it outputs the reference clock to a connected LFAST capable tool as the DRCLK pin only supports output of the DRCLK reference.

On Emulation and Debug Devices (ED), the Buddy Device (BD) LFAST module connects to the package debug pins in place of the Production Device (PD) debug LFAST module. This module has a separate, dedicated LFAST PLL and the DRCLK pin only supports output of the reference clock to a connected LFAST capable tool (as with the Production Device).

Figure 284 shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

Figure 284. Device LFAST clocking



27.6.4 Ethernet clocking

The Ethernet module requires external protocol clock sources for MII and RMII interface modes. The MII clock is 25 MHz in 100 Mbps mode and 2.5 MHz in 10 Mbps mode. The RMII clock is 50 MHz in both modes.

The connections for the Ethernet clocks are as described below.

Figure 285. Ethernet clocking

The RX_CLK pin is an input used in MII mode only and ignored in RMII mode. The TX_CLK pin is an input used in MII mode and RMII mode.

27.6.4.1 Reference Clock for PTP Timestamp Logic

The Ethernet Module supports the Precision Time Protocol (PTP) as defined in IEEE 1588. The PTP Reference clock is the clock at which the PTP system time gets updated. It is connected to PER_CLK0 clock tree provided by the system clock generation module.

Based on the PTP a configurable Pulse-Per-Second signal can be generated as trigger source for several other modules on the device or as periodic pulse as alternate output on a GPIO (refer to *Figure 285*).

27.6.5 FlexRay clocking

The FlexRay protocol clock is sourced from the PLL0_PHI clock or the external oscillator (XOSC), but its source selection is different from other modules:

1. PLL0_PHI enters the MC_CGM where it is divided by a value configured in the CGM_AC2_DC0 register and output as FRAY_PLL_CLK.
2. FRAY_PLL_CLK passes through the Pseudo Random Clock Divider (PRCD) which:
   Divides FRAY_PLL_CLK by 16.
   Adds approximately 40% of random jitter to both edges of the clock.
3. An internal multiplexer selects the PRCD output or XOSC as the resultant FRAY_CLK.

PLL0_PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

When XOSC is the input clock to the FlexRay controller, a 40 MHz crystal is required for proper operation. Both edges of the clock are used by the module to achieve the required 80 MHz frequency.

Selection of PLL or XOSC as the FlexRay clock is shown in *Chapter 30: Clock Generation Module (MC_CGM)*.

27.6.6 M_TTCAN/M_CAN clocking

27.6.6.1 M_CAN/M_TTCAN subsystem 0

The CAN_CLK0 is configured in the CGM via the following registers:

- CGM_AC8_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC8_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

The CAN_0 clock passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

27.6.6.2 M_CAN subsystem 1

The CAN_CLK1 is configured in the CGM via the following registers:

- CGM_AC11_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC11_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

The CAN_1 clock passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

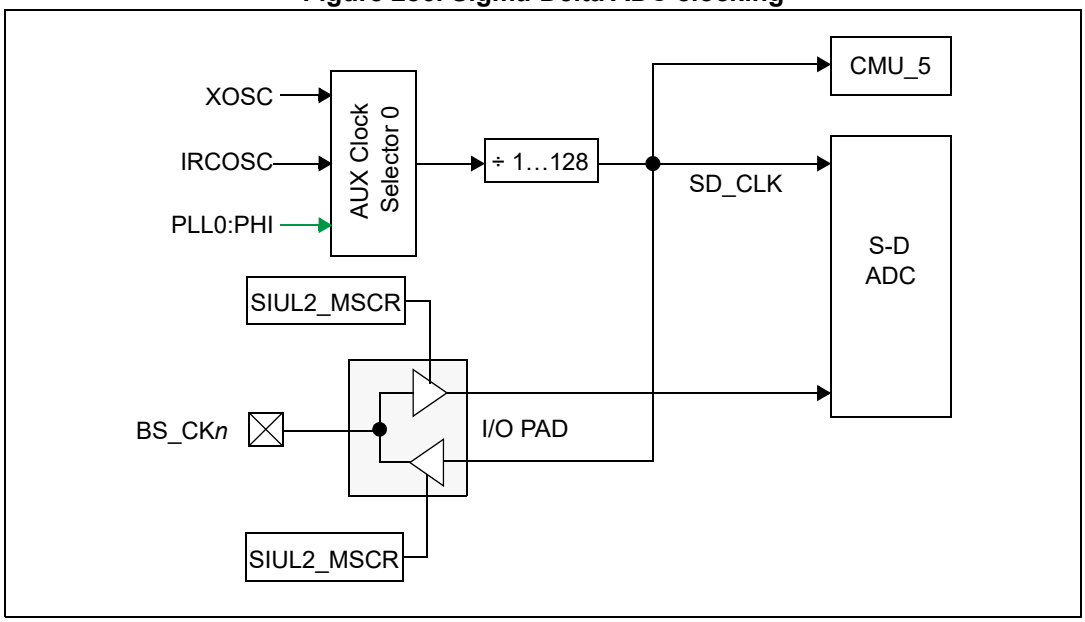
PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

27.6.7 Sigma-Delta ADC clocking

The analog portion of the Sigma-Delta ADC (SDADC) works with either an internal or external modulator.

When the internal modulator in the SDADC is enabled the internal clock (SD_CLK) is always used, refer to *Figure 283*).

When the external modulator is enabled (by disabling the internal modulator), an SDADC internal mux selects either:



- An external input clock (BS_CK).
- An internally generated output clock (SD_CLK) connected to the external modulator clock package pin (BS_CK).

In order to provide an internal clock option when the internal modulator is enabled, the SD_CLK output from the MC_CGM must be connected to the BS_CK pin as shown in *Figure 286*.

The MSCR in the SIUL2 control of the input/output direction of the BS_CK pin.

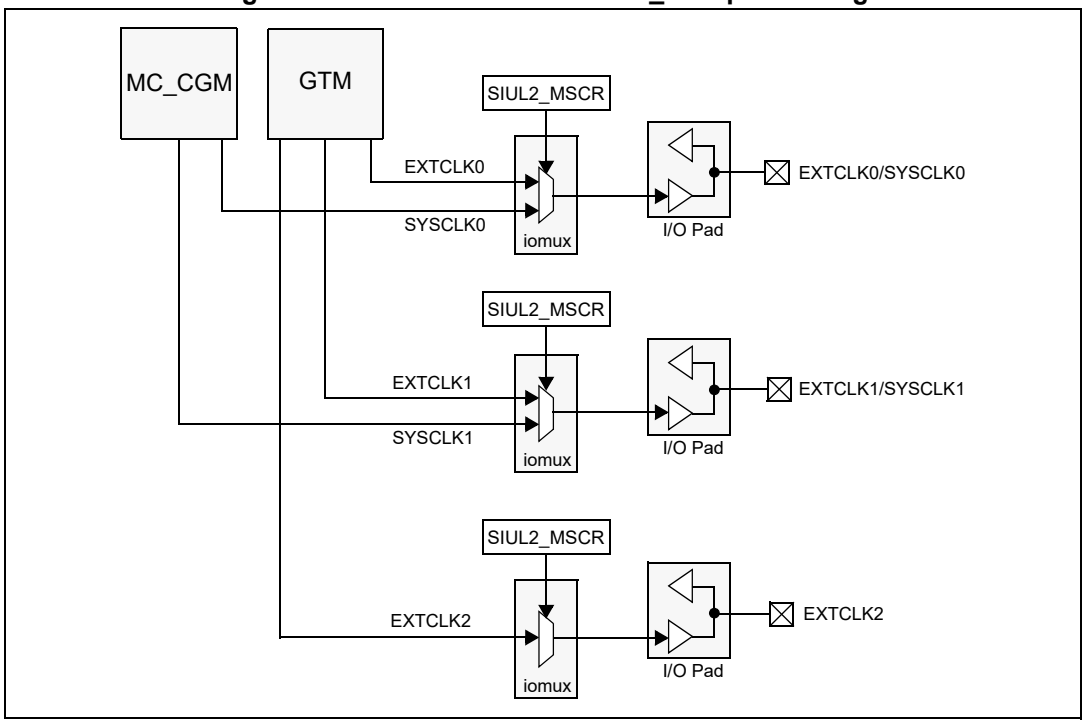
Each SDADC is connected as shown in *Figure 286*, with the SD_CLK being common to all modules, but each SDADC having a dedicated BS_CK pin.

Figure 286. Sigma-Delta ADC clocking

27.6.8 System Clock/GTM output clock

The two system clocks (SYSCLK[1:0]) have an independent source clock selected from:

- PLL0_PHI and PLL1_PHI.
- Internal oscillator (IRCOSC)
- External oscillator (XOSC)
- RTC clock (only for SYSCLK0)



The registers CGM_AC6_SC and CGM_AC7_SC configure the clocks for SYSCLK0 and SYSCLK1 respectively. Refer to *Figure 280*.

There are three GTM output clocks available on package pins, EXTCLK[2:0]:

- EXTCLK[1:0] are muxed on the same pins as SYSCLK[1:0].

The selection of EXTCLK[*n*], SYSCLK[*n*] is handled in the SIUL2_MSCR registers. Refer to *Figure 287*.

Figure 287. SYSCLK/EXTCLK/REF_CLK pin muxing

27.7 Clock monitoring

For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency.

Each CMU is programmed independently (refer to *Figure 280* for CMU distribution) and uses the IRCOSC or XOSC as the clock monitor reference.

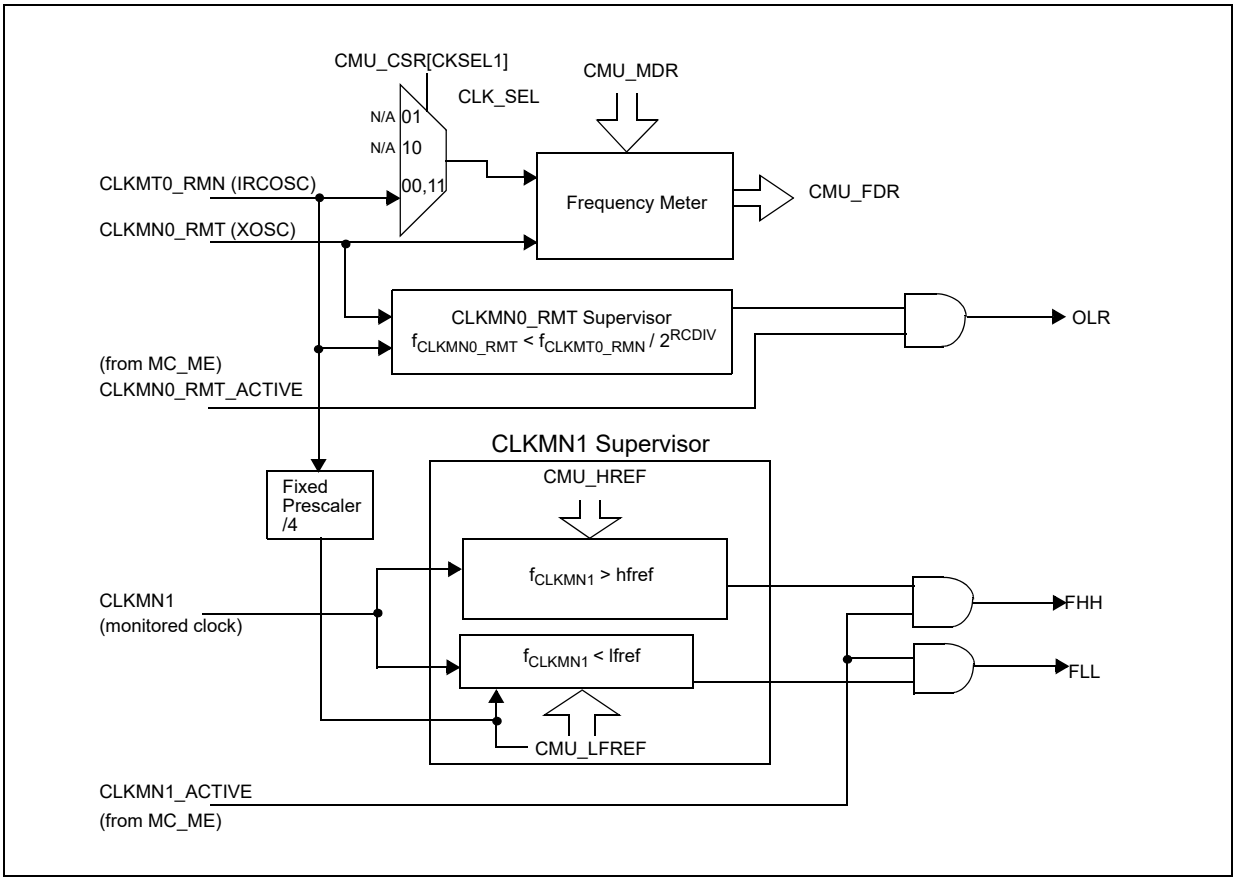
Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

27.7.1 CMU configuration

This section explains the CMU configuration.

Figure 288 shows the block diagram for CMU0 on the SPC58xEx/SPC58xGx.

Figure 288. CMU0 block diagram



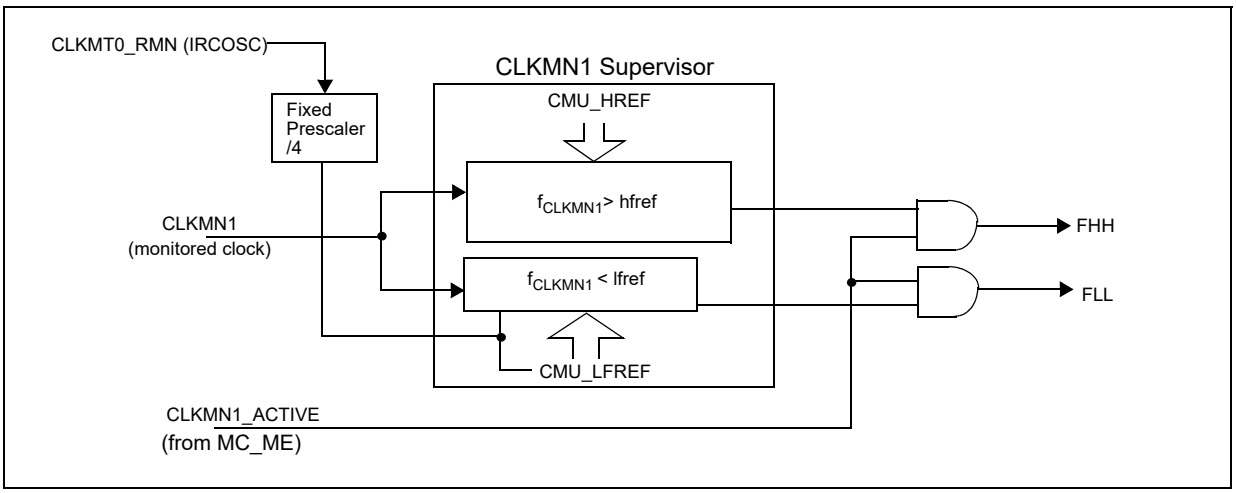


Figure 289 shows the block diagram for the other CMUs on the SPC58xEx/SPC58xGx.

Figure 289. Other CMUs block diagram

27.7.1.1 Clock input sources

Table 397 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC

monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 397. Clock input sources

Clock module	Monitored clock	CMU group
CMU_0_PLL0_XOSC_IRCOSC	PLL0:PHI, XOSC, IRCOSC	—
CMU_1_CORE_XBAR_BD	CHKR_CLK, CORE_CLK, XBAR_CLK, BD_CLK	CMU_Platform
CMU_2_HPBM	HPBM_CLK	CMU_Platform
CMU_3_PBRIDGE	PBRIDGE_CLK	CMU_Platform
CMU_4_GTM	GTM_CLK	CMU_other
CMU_5_SDADC	SDADC_CLK	CMU_other
CMU_6_SARADC	SARADC_CLK	CMU_other
CMU_7_SENT	SENT_CLK	CMU_other
CMU_8_F189	PSI5_f189_CLK	CMU_other
CMU_9_F125	PSI5_f125_CLK	CMU_other
CMU_10_1us	PSI5_1us_CLK	CMU_other
CMU_11_FBRIDGE	FBRIDGE_CLK	CMU_Platform
CMU_12_EMIOS	EMIOS_CLK, BCTU_CLK	CMU_other
CMU_13_PFBRIDGE	PFBRIDGE_CLK	CMU_other

27.7.1.2 CMU registers and field availability

Table 398 specifies which registers and fields are available for a given CMU.

Table 398. CMU register availability

Address offset	Register	CMU	Note
0x0000	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CKSEL1] in CMU0 only.
0x0004	CMU_FDR	CMU0	—
0x0008	CMU_HFREFR	All	—
0x000C	CMU_LFREFR	All	—
0x0010	CMU_ISR	All	CMU_ISR[OLRI] in CMU0 only.
0x0014	Reserved	—	—
0x0018	CMU_MDR	CMU0	—

27.7.1.3 CMU register write protection

The CMU registers defined in *Table 399* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the CMU register write protection (refer to *Section 7.10.5: Register protection (REG_PROT) configuration* in *Chapter 7: Device configuration* for details).

Table 399. CMU register write protection

Offset	Register(1)
0x0000	CMU Control Status Register (CMU_CSR)
0x0004	CMU Frequency Display Register (CMU_FDR)
0x0008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)
0x000C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)
0x0010	CMU Interrupt Status Register (CMU_ISR)
0x0014	Reserved
0x0018	CMU Measurement Duration Register (CMU_MDR)

1. Refer to Register Protection chapter for bit field details.

27.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

27.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

27.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

27.7.5 System clock monitors

A CMU is assigned to monitor the frequency of the cores, XBAR, peripheral bridges, peripheral, PSI5, SENT and ADC clocks (refer to *Figure 280*). The HSM does not have an assigned CMU since it has its own internal clock monitor.

27.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. *Figure 290* gives a high-level view of the loss of clock logic.

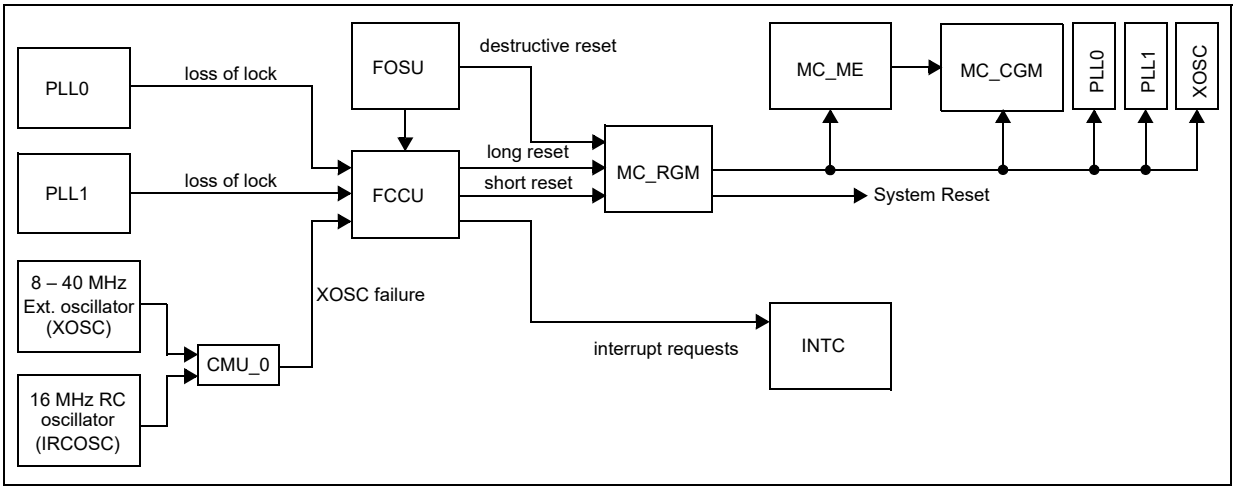
27.8.1 Loss of PLL/XOSC clock

As shown in *Figure 290*, each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU.

When a clock failure occurs, the FCCU can be programmed to generate:

- A short reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC.
- A long reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC.

There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).



Note: In case of failures related to clocks, device functionality is no more granted till next reset. User should program properly all the safety mechanisms available in oder to reach a device safe-state.

27.8.2 Loss of IRCOSC clock

There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot clock, a failure is a catastrophic failure.

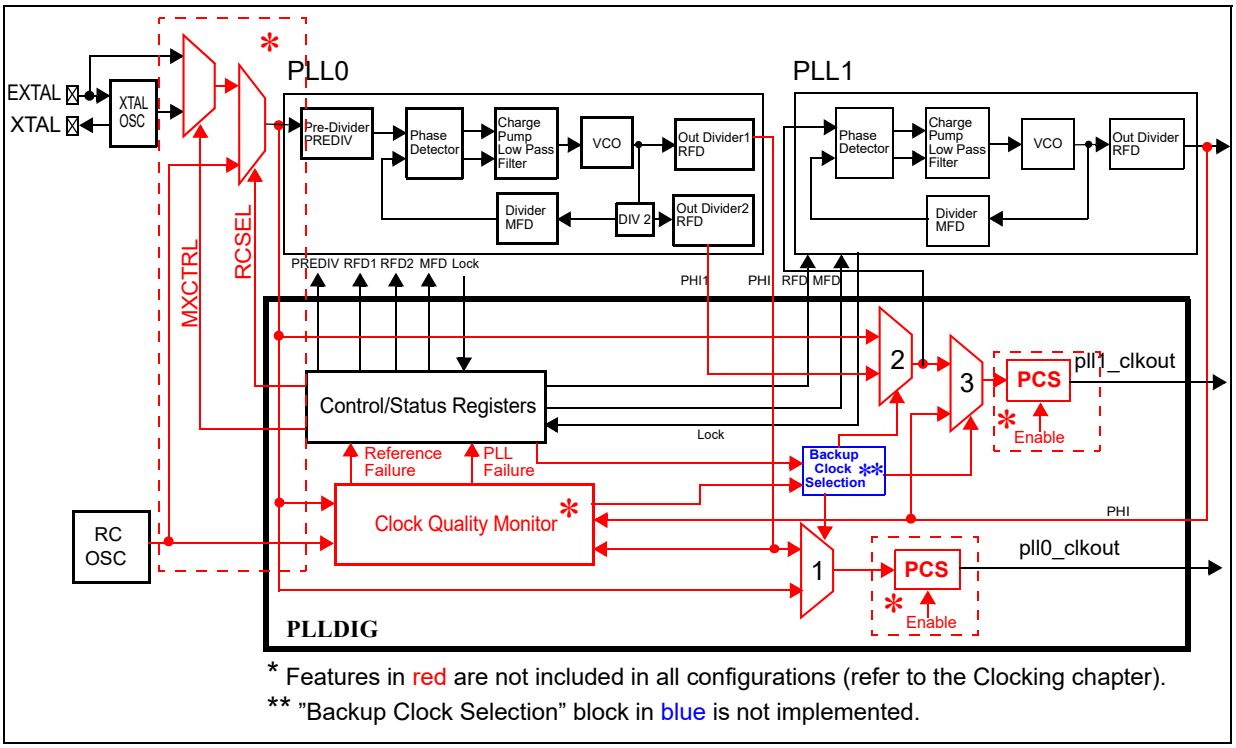
Figure 290. Loss of clock logic

27.9 Progressive clock switching

The Progressive Clock Switching (PCS) blocks are shown in the system-level clock diagram in *Figure 280*. They are used for ramping the system. Refer to *Section 30.4.1.2: Progressive system clock switching* from *Chapter 30: Clock Generation Module (MC_CGM)* for more information on the PCS.

28 Dual PLL digital interface (PLLDIG)

28.1 Introduction



The MCU provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 blocks (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1 as shown in *Chapter 27: Clocking*. The key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1 PHI frequency modulated output.

Note: For chip-specific implementation details, refer to Chapter 27: Clocking.

28.2 Block diagram

Figure 291 shows the block diagram of the PLL Digital Interface.

Figure 291. Dual PLL digital interface block diagram

28.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for reducing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- The frequency range after the prescaler is required to be 8-20Mhz.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
  - User-selectable ability to generate an interrupt request upon loss of lock.
  - The loss of lock indication is sent to the FCCU via the system glue logic.

Note: Refer to the device datasheet for information on the input and output clock frequency range.

28.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The mode of operation for the PLL is defined below:

Normal mode with reference, and either PLL0 or both PLLs enabled.

Note: Mode changes are controlled by configuring the Mode Entry mode configuration registers (<ME_mode>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

When PLL0 is powered down and working in bypass mode, PLL1 should be bypassed and powered down. PLL1 should be configured to work in normal mode only after PLL0 has achieved lock (for example, bypass with PLL0 running or PLL0 in normal mode, PLL*n*SR[LOCK] = 1).

28.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In the normal mode, PLL0 receives an input clock from the reference and the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0_PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, output divider (Reduced Frequency Divider) and whether the PLL1 is modulated or not can be programmed by writing to the PLL1FM register, *Section 28.5.2.7: PLL1 frequency modulation register (PLL1FM)*.

Note: While powering down the PLLs, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Note: Only when the PLL0 achieves lock should PLL1 be configured to work in either mode by programming the appropriate <ME_mode>_MC register (see Section 28.7: Initialization information).

28.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs.

28.5.1 Memory map

Table 400 shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

Table 400. Dual PLL digital interface memory map

Offset (hex)	Register	Section
0x0000	PLL0 Control Register (PLL0CR)	*Section 28.5.2.1*
0x0004	PLL0 Status Register (PLL0SR)	*Section 28.5.2.2*

Figure 293. PLL0 status register (PLL0SR)

Table 402. PLL0SR field descriptions

Field	Description
24 EXTPDF	External power down cycle complete indication interrupt flag This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
28 LOLF	Loss of lock flag This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested 1 Loss of lock detected. Interrupt service requested
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

28.5.2.3 PLL0 divider register (PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider.
The values of PREDIV and MFD should not be changed when the PLL is on and locked (working in Normal mode). If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled.
The reduced frequency divider fields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective after PLL0 is disabled, then re-enabled.

Table 405. PLL1SR field descriptions

Field	Description
24 EXTPDF	External power down cycle complete indication interrupt flag This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
28 LOLF	Loss of lock flag This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested 1 Loss of lock detected. Interrupt service requested
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

28.5.2.6 PLL1 divider register (PLL1DV)

The PLL1DV register provides the output clock reduced frequency dividers and loop divider values.
The value of MFD should not be changed when the PLL is on and locked (working in Normal mode). If the field is changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled.
The reduced frequency divider field (RFDPHI) can be modified at anytime, but the changes only become effective after PLL1 is disabled, then reenabled.

The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. 0x10 Divide by 16 0x11 Divide by 17 .... 0x21 Divide by 33 0x22 Divide by 34 All other settings are reserved

28.5.2.7 PLL1 frequency modulation register (PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down).
Changing the values of PLL1FM[MODEN] and PLL1FM[MODSEL] fields once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.
The modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock, however, the output clock from PLL may have an incorrect frequency for a few cycles after either of these updates (as defined in the datasheet).

Figure 298. PLL1 frequency modulation register (PLL1FM)

Table 407. PLL1FM field descriptions

Field	Description
1 MODEN	Modulation enable This bit enables the frequency modulation. 0 Frequency modulation disabled 1 Frequency modulation enabled
2 MODSEL	Modulation selection This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Modulation centered around nominal frequency 1 Modulation spread below nominal frequency
3:15 MODPRD	Modulation period This 13-bit field is the binary equivalent of the modulation period variable derived from the formula: $MODPRD = round(\frac{f_{ref}}{4 \times f_{mod}})$ where f_{ref} represents the frequency of the feedback divider and f_{mod} represents the modulation frequency (refer to equation in *Section 28.6.3*).
17:31 INCSTP	Increment step This 15-bit field is the binary equivalent of the INCSTP variable derived from the formula: $INCSTEP = round(\frac{(2^{15} - 1) \times MD \times PLL1CR[MFD]}{100 \times 5 \times MODPRD})$ where *md* represents the peak modulation depth in percentage (+/- *MD* for centered modulation, -2**MD* for modulation below nominal frequency), and MFD represents the nominal value of the feedback loop divider (refer to equation in *Section 28.6.3*).

28.5.2.8 PLL1 fractional divider register (PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.
The dither disable and fractional divider fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates .

Figure 299. PLL1 fractional divider register (PLL1FD)

Table 408. PLL1FD field descriptions

Field	Description
1 FDEN	Fractional divide enable This bit enables the fractional divider in the loop divider for PLL1. 0 Fractional divide disabled 1 Fractional divide enabled
14:15 DTHDIS	Dither disable Bit 14 and bit 15 control noise of SSCG and Fractional controller. 00 Increase PLL multiplication factor by 1/2^13 and has maximum noise control of SSCG and Fractional controller. 01 Increase PLL multiplication factor by 1/2^13 and has some noise control of SSCG and Fractional controller. 10 No influence on PLL multiplication factor and has some noise control of SSCG and Fractional controller. 11 No influence on PLL multiplication factor and no noise control of SSCG and Fractional controller.
20:31 FRCDIV	Fractional divide input When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV[MFD]} + (\text{FRCDIV} \div 2^{12}))$ where FRCDIV is the decimal equivalent of the FRCDIV bits (refer to *Section 28.6.2*). **Note:** Depending on DTHDIS value the multiplication factor can change as described in DTHDIS field description.

28.5.3 Register classification for safety requirements

This module is classified as a safety Vital Module (ViMo). Hence, the registers of this module have been classified as shown in the SPC58xEx/SPC58xGx Reference Manual “Functional Safety” chapter.

28.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

28.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for each PLL are discussed in detail in the *SPC58xEx/SPC58xGx datasheet*.

28.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV and PLL1FD registers, and calculated according to the following equations:

Equation 4

$$f_{pll0_phi} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]}$$

Equation 5

$$f_{pll0_phi1} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]}$$

Equation 6

$$f_{pll1_phi} = f_{pll1_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Note: Depending on DTHDIS value the multiplication factor of *Equation 6* can change as described in PLL1DV[DTHDIS] field description (refer to *Table 408*).

The relationship between the VCO frequency f_{VCO} and the output frequency of the PLLs is determined by the configuration of the PLL0DV, PLL1DV and PLL1FD registers, according to the following equations:

Equation 7

$$f_{pll0_VCO} = \frac{f_{pll0_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

Equation 8

$$f_{pll1_VCO} = f_{pll1_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} \right)$$

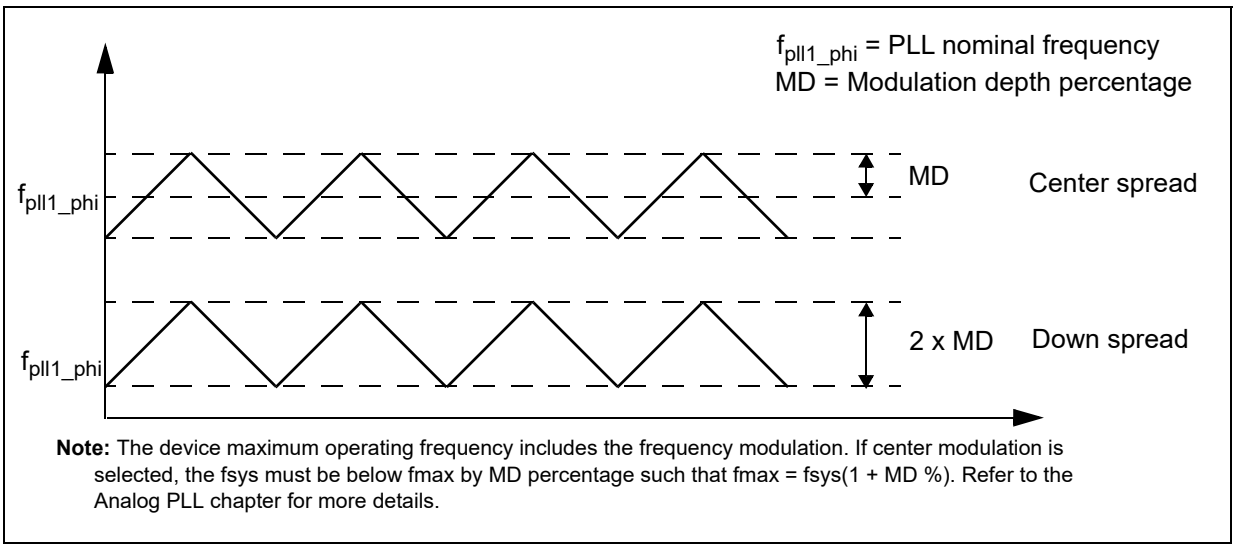
Note: Depending on DTHDIS value the multiplication factor of Equation 8 can change as described in PLL1DV[DTHDIS] field description (refer to Table 408).

Note: f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1.

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification for PLL0 or PLL1 (refer to the device datasheet). Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of PLL*n*DV are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.



Note: The PLL must be powered down and powered up by configuring <ME_mode>_MC before PLL0CR[PREDIV], PLL0CR[MFD], PLL1CR[MFD] or the input reference clock values are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Section 28.7.

28.6.3 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 300. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 300. Triangular frequency modulation

Note: The device maximum operating frequency includes the frequency modulation. If center modulation is selected, the fsys must be below fmax by MD percentage such that fmax = fsys(1 + MD %). Refer to the Analog PLL chapter for more details.

The following equations define how to calculate PLL1FM[MODPRD] (Equation 9) and PLL1FM[INCSTP] (Equation 10) based on the frequency of the feedback divider (f_{pll1_ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD):

Equation 9

$$\text{PLL1FM[MODPRD]} = \text{round}\left(\frac{f_{pll1_ref}}{4 \times f_{mod}}\right)$$

Equation 10

$$\text{PLL1FM[INCSTP]} = \text{round}\left(\frac{(2^{15} - 1) \times MD \times \text{PLL1DV[MFD]}}{100 \times 5 \times \text{PLL1FM[MODPRD]}}\right)$$

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

Equation 11

$$(\text{PLL1FM[MODPRD]} \times \text{PLL1FM[INCSTP]}) < 2^{15}$$

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is given by the following formula:

Equation 12

$$\text{ModulationDepth} = \text{round}\left(\frac{\text{PLL1FM[MODPRD]} \times \text{PLL1FM[INCSTP]} \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV[MFD]}}\right)$$

As an example, suppose the following configuration:

- Input frequency: 40 MHz
- Loop divider (PLL1DV[MFD]): 20
- Input divider: 1
- Output divider RFD: 5
- VCO frequency: 40 MHz × 20 = 800 MHz
- PLL output frequency: 800 MHz / 2*RFD = 800 MHz / 10 = 80 MHz
- Center spread (PLL1FM[MODSEL] = 0)
- Modulation frequency: 200 kHz
- Modulation depth: ± 1.9% (3.8% peak-to-peak)
- PLL1FM[MODPRD] = Round[(40 × 10^6) / (4 × 200 × 10^3)] = Round[50] = 50
- PLL1FM[INCSTP] = Round[((2^{15} – 1) × 1.9× 20) / (100 × 5 × 50)] = Round[49.8] = 50
- PLL1FM[MODPRD] × PLL1FM[INCSTP] = 50 × 50 = 2500 (which is less than 2^{15})
- MD (quantized) = ((50 × 50 × 100 × 5) / ((2^{15} – 1) × 20) = 1.90740 %

In this example, the modulation error is 0.00740 %.

The FM parameters do not get reset when PLL0 looses its lock. These parameters get reset on destructive reset. Whenever PLL0 gets relocked FM modulation starts with the previous values. The sequence for reprogramming the FM is:

1. Power down PLL1[12]
2. Program the PLL1FM while PLL1 is powered down
3. Power up the PLL1[13]

28.7 Initialization information

Coming out of reset the PLLs are disabled per the DRUN mode configuration register (<*ME*>_DRUN_MC). The recommended procedure[14] to program the PLLs and enter normal mode is:

1. Configure PLL0 and related modules.

   Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   a) With PLL0 disabled, program PLL0 clock source in <CGM_ACn>_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write <CGM_ACn>_SC[SELCTL] = 1 to select XOSC as source.

   b) Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   c) If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the Mode Entry module).

   d) If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

2. Turn on XOSC and PLL0.

   a) Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, <ME>_DRUN_MC) set <ME_mode>_MC[XOSCON] = 1 and <ME_mode>_MC[PLL0ON] = 1. If desired, also set <ME_mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0 PHI output) as the sysclk.

   b) Enter that mode by two writes to <ME>_CTRL register to enter that mode. This is required even if re-entering the same mode.

3. Wait for the mode transition to complete.

   a) Wait for the mode transition to complete by polling <ME>_GS[S_MTRANS] or enabling an interrupt for flag <ME>_IS[I_MTC]. A timer, even if it is the watchdog,

12. By writing <ME_mode>_MC[PLL1ON] = 0b.
13. By writing <ME_mode>_MC[PLL1ON] = 1b.
14. The steps from 1 to 6 describe a recommended way to initialize the PLLs. But the mode_transition from DRUN to RUNx with the PLLs ON (with PLL1 as sys_clk and PLL0_PHI1 as source of PLL1 and all other clk sources enabled) can be done with a single mode transition. The only software requirement is to ensure that the reference clocks are also configured ON when the derived clock is configured ON in the target mode.

should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- XOSC counter expires (if the new mode configuration changes <ME_mode>_MC[XOSCON] to 1), and

- PLL is locked (if the new mode configuration changes <ME_mode>_MC[PLL0ON] = 1).

b) Confirm the desired target mode was entered by checking the status of <ME>_GS[S_CURRENT_MODE].

4. Configure PLL1 and related modules
   a) With PLL1 disabled, program PLL1 clock source in <CGM_ACn>_SC[SELCTL]. Default is <CGM_ACn>_SC[SELCTL] = which selects XOSC.
   b) Program PLL1DV[MFD] and PLL1DV[RFDPHI].
   c) If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.
5. Turn on PLL1
   a) Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL0 on. In a mode configuration register (for example, <ME>_DRUN_MC), initialize <ME_mode>_MC[XOSCON] = 1, <ME_mode>_MC[PLL0ON] = 1 and <ME_mode>_MC[PLL1ON] = 1. If desired, also set <ME_mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.
   b) Enter that mode by two writes to <ME>_CTRL register to enter that mode. This is required even if re-entering the same mode.
6. Wait for the mode transition to complete.
   a) Wait for the mode transition to complete by polling <ME>_GS[S_TRANS] or enabling an interrupt for flag <ME>_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

      XOSC counter expires (if the new mode configuration changes <ME_mode>_MC[XOSCON] = 1), and PLL1 is locked (if the new mode configuration changes <ME_mode>_MC[PLL1ON] = 1).

   b) Confirm the desired target mode was entered by checking the status of <ME>_GS[S_CURRENT_MODE].

Note: Refer to the Mode Entry module chapter for more details.

29 Clock Monitor Unit (CMU)

29.1 Introduction

The Clock Monitor Unit (CMU), also referred to as clock quality checker or clock fault detector, serves three purposes:

- Measures the frequency of clock sources CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and also detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the division factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate events when the CLKMN1 frequency is less than the CLKMT0_RMN frequency divided by four or if CLKMN1 leaves an upper or lower frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of one clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note: Refer to the clocking chapter for the number of instances of the CMU in this device.

29.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as the reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN/n clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN / 4.
- Event generation for various failures detected inside monitoring unit.

29.2 Block diagram

The block diagram of the CMU module(s) is shown in the clocking chapter of this reference manual.

29.3 Signals

Table 409 describes the signals on the boundary of the CMU (in alphabetical order).

Table 409. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference: Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1: Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference: Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

Note: Refer to the clocking chapter for device specific clock sources of each CMU.

29.4 Memory map and register definition

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in *Table 410*.

Table 410. CMU memory map

1. Not all CMU blocks will utilize this feature. Refer to clocking chapter for device specific CMU implementation details.

Figure 301. CMU Control Status Register (CMU_CSR)

Table 411. CMU_CSR field descriptions

Field	Description
8 SFM	Start Frequency Measure The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR register. CMU_MDR[MD] must be written before enabling frequency measurement (CMU_CSR[SFM] = 1). Do not write CMU_MDR[MD] while CMU_CSR[SFM] = 1. Software should only read the value of CMU_FDR[FD] bits once the hardware has cleared the CMU_CSR[SFM] bit. 0 Frequency measurement is completed or not yet started. 1 Frequency measurement is not completed.
22:23 CKSEL1	Frequency measure clock selection bit CKSEL1 selects the clock to be measured by the frequency meter. This only effects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected. 01 Reserved 10 Reserved. 11 CLKMT0_RMN is selected.

Table 411. CMU_CSR field descriptions (continued)

Field	Description
29:30 RCDIV	CLKMT0_RMN division factor These bits specify the CLKMT0_RMN division factor. The output clock frequency is f_{CLKMT0_RMN} divided by the factor 2^{RCDIV}. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV] otherwise the operation can lead to a spurious OLR event. The clock division coding is as follows: 00 CLKMT0_RMN divided by 1 (No division). 01 CLKMT0_RMN divided by 2. 10 CLKMT0_RMN divided by 4. 11 CLKMT0_RMN divided by 8.
31 CME	CLKMN1 monitor enable CMU_HFREF and CMU_LFREF registers must be written before enabling the clock monitoring (CMU_CSR[CME] =1) 0 CLKMN1 monitor is disabled. 1 CLKMN1 monitor is enabled.

29.4.1.2 CMU Frequency Display Register (CMU_FDR)

The FDR is used to determine the measured frequency being monitored by the CMU.

2. Field is read only.

Figure 305. CMU Interrupt Status Register (CMU_ISR)

Table 415. CMU_ISR field descriptions

Field	Description
29 FHHI	CLKMN1 frequency higher than high reference event status This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than f_{CLKMT0_RMN} / 2^{RCDIV} event status This bit is set by hardware when the f_{CLKMN0_RMT} is less than f_{CLKMT0_RMN} / 2^{RCDIV} frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No OLR event 1 OLR event occurred

Note: All the flags in CMU_ISR are set asynchronously. This register must be read only after a fault event is triggered by the CMU and mapped on FCCU.

Otherwise, the read access on this register may fetch an incorrect value.

Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

29.4.1.6 CMU Measurement Duration Register (CMU_MDR)

Figure 306. CMU Measurement Duration Register (CMU_MDR)

Table 416. CMU_MDR field descriptions

Field	Description
12:31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

29.5 Functional description

This section describes the functionality of the CMU.

29.5.1 Frequency meter

The purpose of frequency meter is to evaluate the deviation from the nominal metered source (such as, CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the Clocking chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

Equation 13 $f_{sel} = (f_{CLKMN0_RMT} \times MDR[MD]) / FDR[FD]$

29.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than frequency of CLKMT0_RMN divided by $2^{CMU_CSR[RCDIV]}$ and CLKMN0_RMT is ‘ON’ as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

29.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If fCLKMN1 is greater than the reference value determined by field CMU_HFREFR[HFREF] and CLKMN1 is ‘ON’ as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

Note: An example of determining the HFREFActual value is as follows. Assume a fCLKMT0_RMN = 16 MHz with an accuracy of +/-5 %. In order to monitor fCLKMN1 = 200 MHz, the ideal HFREFIdeal = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration (HFREFActual = (HFREFIdeal + 2) × 1.05).

If fCLKMN1 is lower than CMU_LFREFR[LFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

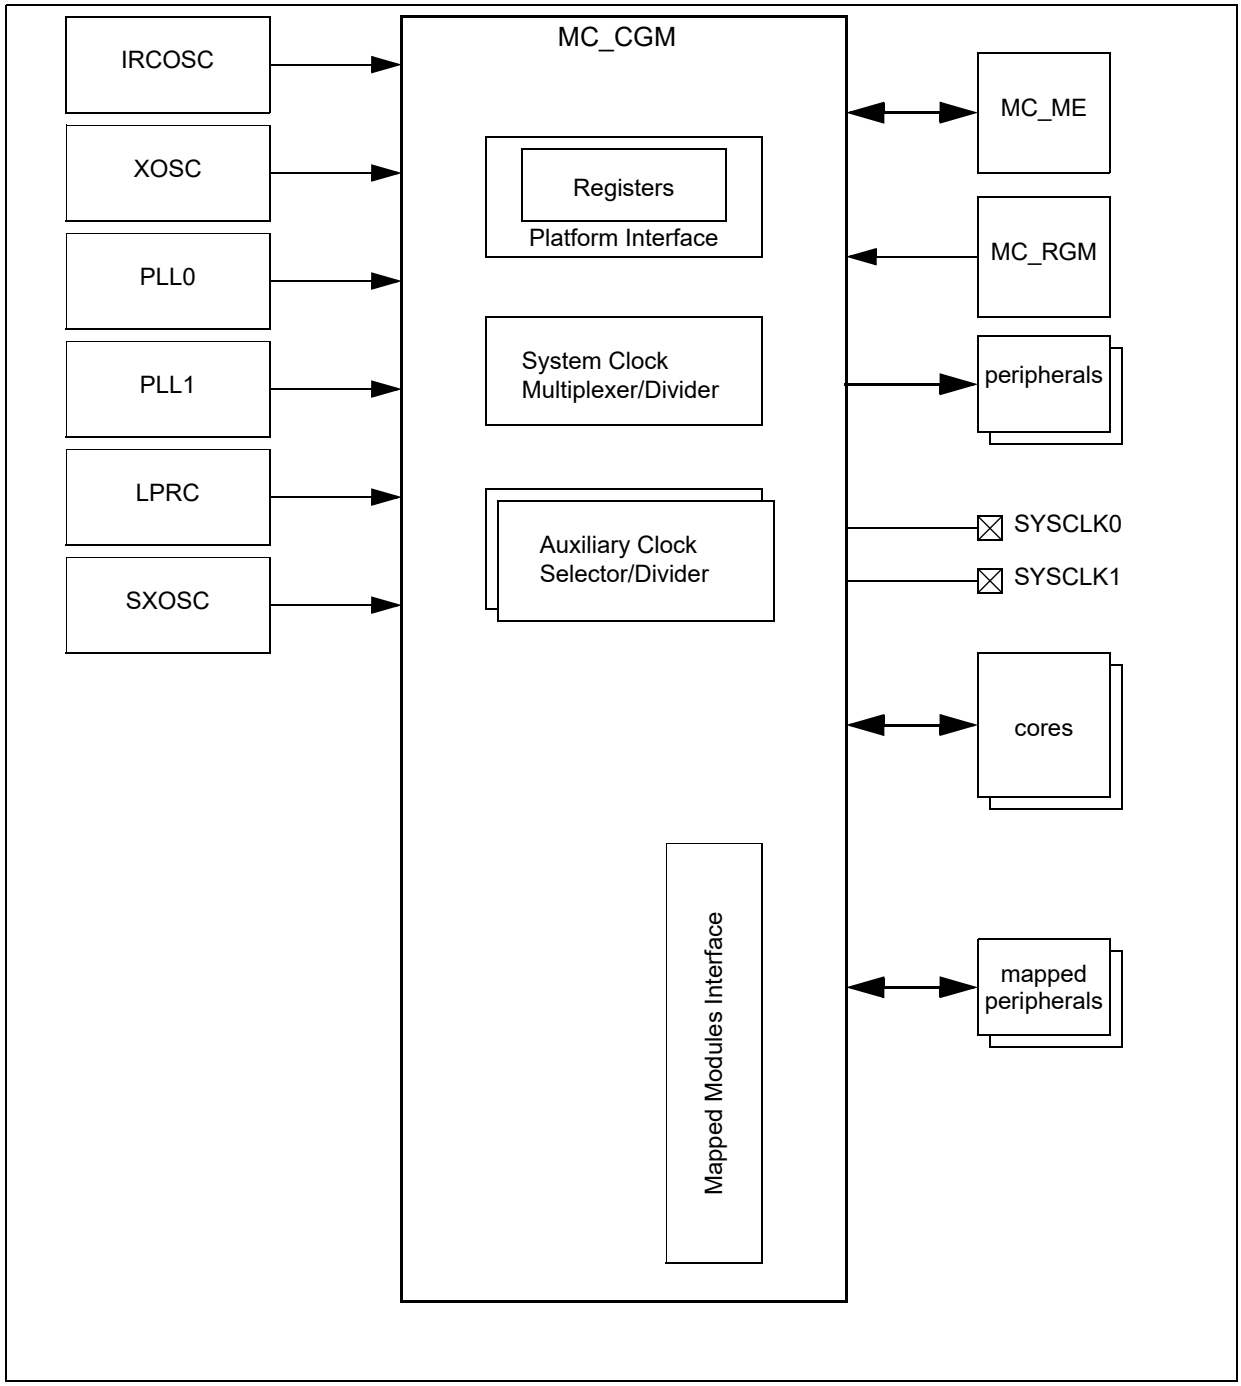
Note: The low reference value must be programmed considering the following factors:

- *Two cycles of f_{CLKMN1} which is the built-in tolerance of the monitor implementation*
- *Frequency variation % of f_{CLKMT0_RMN} across PVT*

For example, assuming f_{CLKMT0_RMN} is 16 MHz with +/-5 % variation, in order to monitor the f_{CLKMN1} (200 MHz), the ideal $LFREF_{Ideal}$ is 800. The adjusted value considering the tolerances will be 758 ($LFREF_{Actual}$ = ($LFREF_{Ideal}$ - 2) x 0.95).

The minimum value that can be programmed in CMU_LFREFR[LFREF] is 3. The minimum frequency that can be monitored using the CLKMN1 supervisor must be >= f_{CLKMT0_RMN} / 16.

30 Clock Generation Module (MC_CGM)



30.1 Introduction

30.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the modules on the chip. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). A set of MC_CGM registers controls the clock dividers which are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

Figure 307 shows the MC_CGM block diagram.

Figure 307. MC_CGM block diagram

30.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control
- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

30.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use or observation or both.

30.3 Memory map and register definition

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0104, as a half-word at address offset 0x0106, or as a byte at address offset 0x0107.

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

30.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0104, as a half-word at address offset 0x0106, or as a byte at address offset 0x0107.

30.3.1.1 Auxiliary Clock 5 Cascaded Divider 0 Configuration Register (CGM_AC5_CDC0)

This register controls auxiliary clock 5 cascaded divider 0.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Address: 0x0080 Access: User read/write, Supervisor read/write, Test read/write

Field	Description
0:7 SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of IRCOSC cycles.

30.3.1.13 PCS Divider Change Register 1 (CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the XOSC on ramp-up and ramp-down, respectively. See *Section 30.4.1.2: Progressive system clock switching*, for details on how to set these values. This register is reset only on a power-on reset.

Note: Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Address: 0x0104 Access: User read/write, Supervisor read/write, Test read/write

Table 437. CGM_PCS_DIVE4 field descriptions

Field	Description
12:31 DIVE	Divider End Value This is the clock divider end value for the clock ramp-down phase when switching from the PLL1 PHI.

30.3.1.21 PCS Divider Start Register 4 (CGM_PCS_DIVS4)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the PLL1 PHI on ramp-up. See *Section 30.4.1.2: Progressive system clock switching* for details on how to set this value. This register is reset only on a power-on reset.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Address: 0x0130 Access: User read/write, Supervisor read/write, Test read

Figure 328. PCS Divider Start Register 4 (CGM_PCS_DIVS4)

Table 438. CGM_PCS_DIVS4 field descriptions

Field	Description
12:31 DIVS	Divider Start Value This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.

30.3.1.22 System Clock Divider Ratio Change Register (CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations. An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from

1:2 to 1:3. The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

Caution: Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

Address: 0x01D0 Access: User read/write, Supervisor read/write, Test read

30.3.1.23 Divider Update Type Register (CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.

Address: 0x01D4 Access: User read/write, Supervisor read/write, Test read

Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type 0 The configuration for each system clock divider is updated immediately on writing to the corresponding CGM_SC_DCi register 1 The configuration for each system clock divider is pre-loaded on writing to the corresponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register

30.3.1.24 Divider Update Trigger Register (CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to ‘1’ in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

Address: 0x01D8 Access: User read/write, Supervisor read/write, Test read

Field	Description
0:31 DIV_UPD_TRIGGER	Writing any value to this register causes all dividers that have corresponding bits set to '1' in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register always returns all zeroes.

30.3.1.25 Divider Update Status Register (CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the CGM_DIV_UPD_TYPE[i] is '0', CGM_DIV_UPD_STAT[i] is set to '1' immediately on writing to one of the corresponding divider configuration registers. Otherwise, CGM_DIV_UPD_STAT[i] is set to '1' immediately on writing to the CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. CGM_DIV_UPD_STAT[i] is cleared to '0' as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

Figure 378. Auxiliary Clock 12 Divider 4 Configuration Register (CGM_AC12_DC4)

Table 488. CGM_AC12_DC4 field descriptions

Field	Description
0 DE	Divider Enable 0 Disable auxiliary clock 12 divider 4 1 Enable auxiliary clock 12 divider 4
12:15 DIV	Divider Division Value The resultant PER_CLK0 will have a period 'DIV + 1' times that of auxiliary clock 0. If DE is set to 0 (divider 0 is disabled), any write access to the DIV field is ignored and the PER_CLK0 remains disabled.

30.4 Functional description

30.4.1 System clock generation

Figure 280: Clock generation(1)(2) (part 1 of 2) shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see

MC_RGM chapter for more details). The safe clock request forces the selector to select the IRCOSC as the system clock and to ignore the system clock select.

30.4.1.1 System clock source selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

30.4.1.2 Progressive system clock switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency down or up or both, based on the power level values of the current and target modes. During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVC*n*, and CGM_PCS_DIVE*n* registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVC*n*, and CGM_PCS_DIVS*n* registers, where *n* corresponds to the target system clock source selection.

30.4.1.2.1 Generic clock change requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in *Equation 14*.

Equation 14

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

30.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of IRCOSC. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

30.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the PCS_DIVC*n*[RATE] register is given in *Table 489*.

Table 489. MC_CGM CGM_PCS_DIVC*n*[RATE] values

a_{max}	d	CGM_PCS_DIVC*n*[RATE]
0.05	0.012	12
0.10	0.048	48
0.15	0.112	112
0.20	0.184	184

30.4.1.2.4 Generic clock change properties

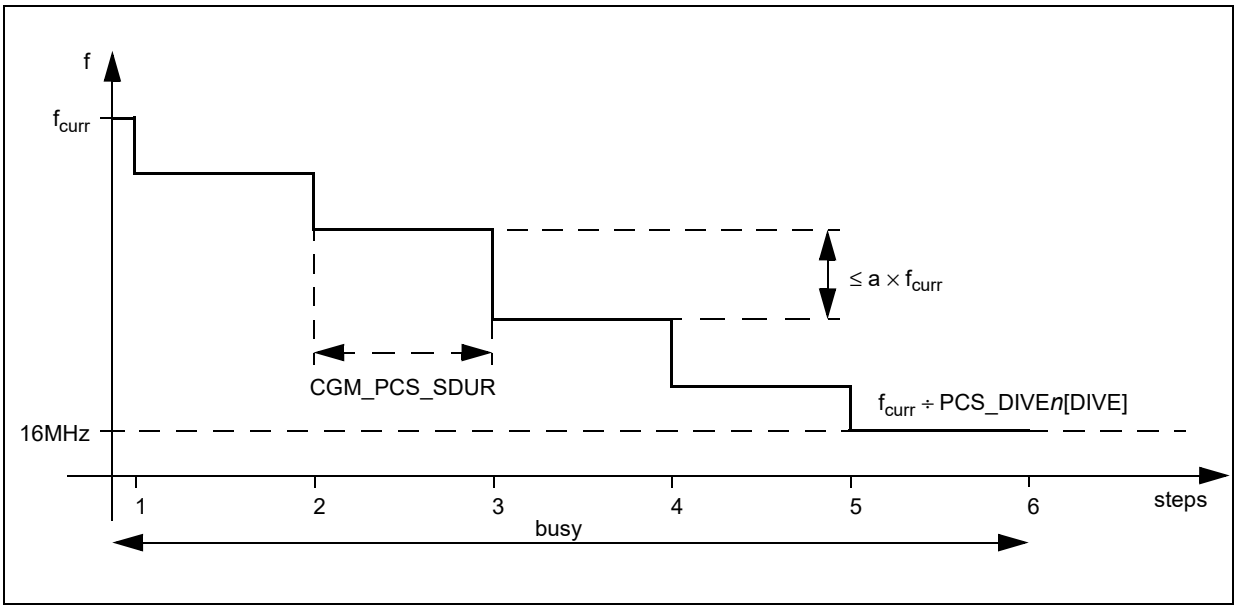
The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in *Equation 15*.

Equation 15

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

30.4.1.2.5 Clock ramp-down

The clock ramp-down starts with the divider value 1 and with the given divider increment value PCD_DIVC*n*[RATE] and ends with the given divider value PCS_DIVE*n*[DIVE].



The divider end value for clock ramp-down is given in *Equation 16*.

Equation 16

$$\textbf{PCS_DIVEn[DIVE]} = \frac{f_{src}}{16MHz} \times 1000 - 1$$

Where f_{curr} is the frequency of the currently selected system clock source.

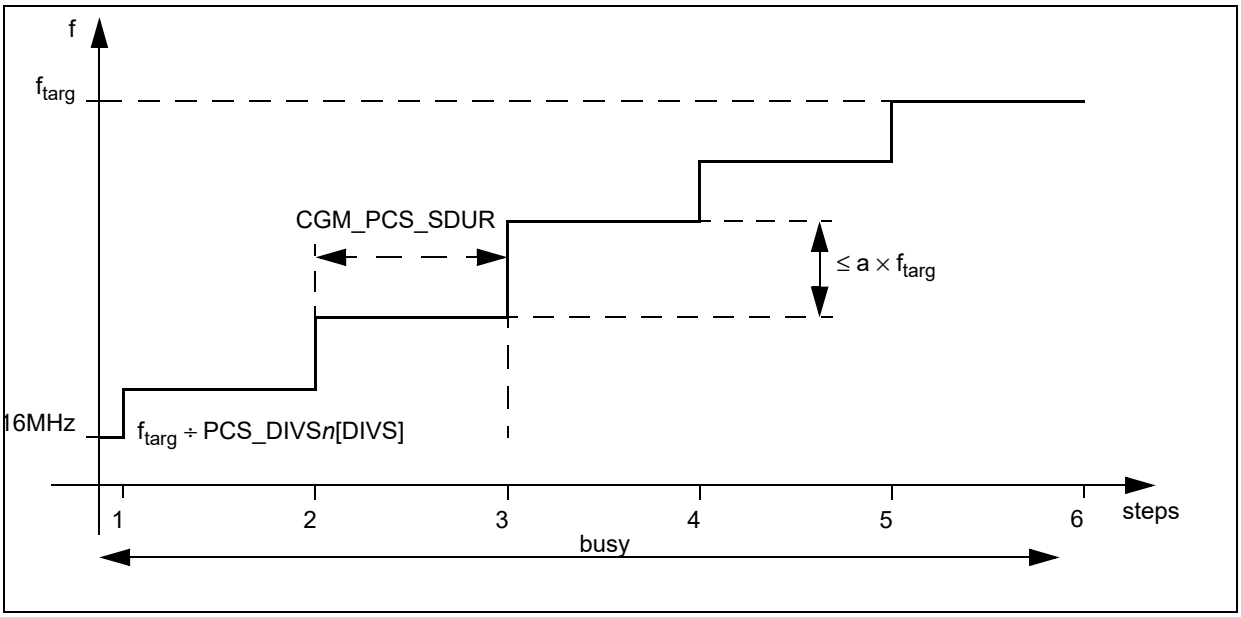
Figure 379. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

30.4.1.2.6 Clock ramp-up

The clock ramp-up starts with the given divider value PCS_DIVS*n*[DIVS] and with the given divider decrement value PCD_DIVC*n*[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVC*n*[INIT] for system clock ramp-up is given in *Equation 17*.

Equation 17



$$\text{PCS_DIVCn[INIT]} = d \times k \times 1000 - 1$$

Where k is calculated from *Equation 15* using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in *Equation 18*.

Equation 18

$$\text{PCS_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Figure 380. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

30.4.1.3 System clock disable

During the TEST mode, the system clock can be disabled by the MC_ME.

30.4.1.4 System clock dividers

The MC_CGM generates the following derived clocks from the system clock. :

- SYS_CLK - controlled by the CGM_SC_DC0 register
- HPBM_CLK - controlled by the CGM_SC_DC1 register
- PBRIDGE_CLK - controlled by the CGM_SC_DC2 register
- FBRIDGE_CLK - controlled by the CGM_SC_DC3 register
- PFBRIDGE_CLK - controlled by the CGM_SC_DC4 register

30.4.1.4.1 System clock divider synchronization

The system clock dividers are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the

synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

The allowed combinations of division factors is given in *Table 389: Maximum system level clock frequencies*.

30.4.1.4.2 System clock divider update triggering

As opposed to the auxiliary clock dividers, which update immediately on a configuration change, the system clock dividers are updated only with the next software triggered mode change. This is to ensure that the system clock dividers are updated simultaneously and that no intermediate inconsistent configurations can occur. It also ensures that the divider configurations are aligned with the target mode's system clock selection.

The system clock divider configuration update sequence is as follows:

1. Configure the target mode in the MC_ME to select the desired system clock source.
2. Configure the CGM_SC_DC0-4 registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in *Section 30.4.1.4.1: System clock divider synchronization*.
3. Request a mode change in the MC_ME to the desired target mode.
4. When mode change has completed and the system clock switching has been successful, the new system clock divider configuration will be in effect.

See *Chapter 69: Mode Entry Module (MC_ME)*, for details on how to configure modes and make mode change requests.

30.4.2 Auxiliary clock generation

Figure 280: Clock generation(1)(2) (part 1 of 2) and *Figure 281: Clock generation (part 2 of 2) - PSI5 clock tree* show the block diagrams of the generation logic for the various auxiliary clocks.

See the following sections for auxiliary clock selection control:

- *Section 30.3.1.32: Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)*
- *Section 30.3.1.38: Auxiliary Clock 1 Select Control Register (CGM_AC1_SC)*
- *Section 30.3.1.43: Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)*

30.4.3 Dividers functional description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System clock divider configuration registers
  - CGM_SC_DC0-4 (*Section 30.3.1.27* to *Section 30.3.1.31*)
- Auxiliary clock divider configuration registers
  - CGM_AC0_DC0-3 (*Section 30.3.1.34* to *Section 30.3.1.37*)
  - CGM_AC1_DC0 (*Section 30.3.1.40*)
  - CGM_AC2_DC0-1(*Section 30.3.1.41* and *Section 30.3.1.42*)
  - CGM_AC5_DC0-2 (*Section 30.3.1.47* to *Section 30.3.1.49*), CGM_AC5_CDC0-2, CGM_AC5_CDC10-13, CGM_AC5_CDC20-23 (Auxiliary clock 5 cascaded divider configuration registers, see *Section 30.3.1.1* to *Section 30.3.1.11*)
  - CGM_AC6_DC0 (*Section 30.3.1.52*)
  - CGM_AC7_DC0 (*Section 30.3.1.55*)
  - CGM_AC8_DC0 (*Section 30.3.1.58*)
  - CGM_AC9_DC0 (*Section 30.3.1.61*)
  - CGM_AC11_DC0 (*Section 30.3.1.64*)
  - CGM_AC12_DC0-4 (*Section 30.3.1.67* to *Section 30.3.1.71*)

The reset value of all counters is ‘1’. If a divider has its DE bit in the respective configuration register set to ‘0’ (the divider is disabled), any value in its DIV field is ignored.

30.4.3.1 Divider jitter injection

The clock dividers for the FRAY_CLK and the CAN_CLK0 inject a jitter so that off-chip communication via the associated peripherals is not possible. For details on enabling this feature, see the “Production Disable” and “CAN Jitter Enable” sections of the PASS chapter.

In addition, PLL0 PHI is always selected to source the FRAY_CLK when jitter injection is enabled.

30.4.3.2 Fractional divider details

The clock divider used to generate the PSI5_f189_CLK and the DSPI_CLK0 divides the selected clock source frequency by a fractional value given by the DIV and DIV_FMT fields of the CGM_AC5_DC0 and the CGM_AC12_DC0 registers.

Equation 19

$$F_{\text{divided clock}} = F_{\text{source clock}} \div ((\mathbf{DIV} + 1) \div 10^{\mathbf{DIV_FMT}})$$

The divided clock frequency is actually an average frequency, since the divider uses only the available rising and falling edges of the source clock. Therefore, the actual frequency switches between two frequencies which are the two frequencies closest to the desired frequency (above and below) which can be extracted by a division factor *n*/2, where *n* is an integer greater than 1. The switching between the two frequencies is such that the resultant clock’s rising edge never deviates from the ideal clock’s rising edge by more than 25% of

the source clock period and that the resultant average frequency over DIV + 1 source clock periods (= 10^{DIV_FMT} divided clock periods) is the desired frequency.

Example 1 Fractional clock division

Desired division factor = 2.3

DIV = 22

DIV_FMT = 1

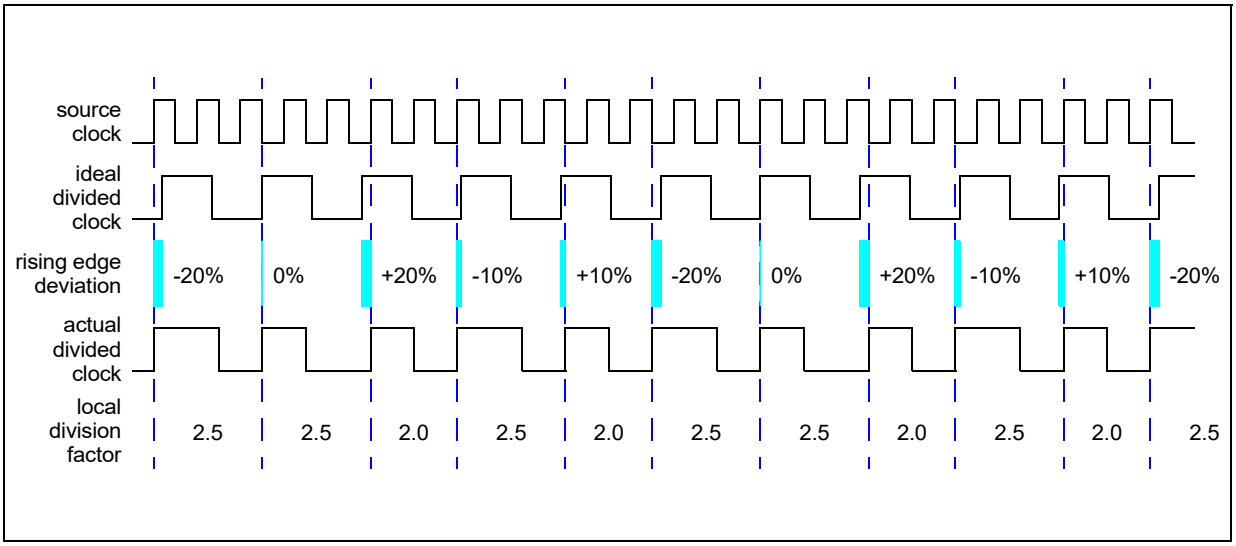

Figure 381. MC_CGM fractional division example waveform (divide by 2.3)

Equation 20

$$F_{\text{divided clock}}\big|_{max} = F_{\text{source clock}} \div 2.0$$

Equation 21

$$F_{\text{divided clock}}\big|_{min} = F_{\text{source clock}} \div 2.5$$

Equation 22

$$F_{\text{divided clock}}\big|_{ave} = F_{\text{source clock}} \div \frac{((2.5 \times 6) + (2.0 \times 4))}{10}$$

Therefore,

Equation 23

$$F_{\text{divided clock}}\big|_{ave} = F_{\text{source clock}} \div 2.3$$

As can be seen in *Figure 381*, the rising edge of the actual divided clock is 'snapped' to the rising or falling edge of the source clock closest to the rising edge of the ideal divided clock. This results in a theoretical maximum deviation, or jitter, of ±25% of the source clock period. In this particular case, the maximum deviation is ±20% of the source clock period.

30.4.3.3 Divider Update Triggering

There are two methods for updating the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the CGM_DIV_UPD_TYPE register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the CGM_UPD_STAT register is set. This bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

30.4.3.3.1 Immediate Divider Update

If a divider group has been configured to be updated immediately (the corresponding CGM_DIV_UPD_TYPE register bit = '0'), the configuration of a divider in that group will be applied immediately on the write to that divider's configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

30.4.3.3.2 Software-triggered divider update

If a divider group has been configured to be updated via a software trigger (the corresponding CGM_DIV_UPD_TYPE register bit = '1'), the configuration of a divider in that group will not be applied immediately on the write to that divider's configuration register. Instead, the configuration in the corresponding configuration register will be applied only when software writes any value to the CGM_DIV_UPD_TRIG register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

In the case of the system clock dividers, if the SYS_DIV_RATIO_CHNG bit in the CGM_SC_DIV_RC register = '1', the crossbar switch is requested to halt its ongoing transactions, and only after the crossbar switch has acknowledged the request does the update of the system clock dividers take place. Once these updates have completed, the halt request to the crossbar is deasserted.

Note: If halting the crossbar can cause a bus master to starve and thus lead to lost data or other problems, it is recommended to vary the system clock divider configurations without changing the ratios and to set CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] to '0'.

Note: In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (that is all relevant bits in the CGM_DIV_UPD_STAT register are '0') before triggering a new update via the CGM_DIV_UPD_TRIG register.

31 OSC digital interface (XOSC)

31.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provides the register interface for the programmable features. Selection of the XOSC as a source clock is controlled the Clock Generation module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

31.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that can used as an input to PLL(s) and can be selected as the reference clock for many of the peripherals on the device.

Table 491 shows the possible configurations of the XOSC.

Table 491. XOSC configurations

OSC EN	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC output	XOSC mode
0	0	No crystal, high-impedance	No crystal, high-impedance	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

31.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<*mode*>_MC[XOSCON] controls the power-down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

31.2.2 Oscillator startup delay

A bit in the UTEST Flash memory determines whether the oscillator is enabled at power-up of the device (if the DCF client miscellaneous has been programmed, otherwise the valid configuration is the value present in *Chapter 9: Device Configuration Format (DCF) Records*, *Table 129: DCF client list*). If enabled, the oscillator is started after Phase3 of the

device reset sequence. In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL(s)).

The default value for this field after reset depends on implementation and can be found in the XOSC section of the Device Configuration chapter. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note: It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

31.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

31.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software, and is only cleared by a system reset. In bypass mode, the oscillator is disabled, and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

Note: The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

31.2.4.1 Automatic Level Control (ALC)

The function of the ALC block is to provide high drive current during oscillator start up, and reduce current after oscillation in order to reduce power, distortion, RFI; and to avoid overdriving the crystal. ALC block can be controlled via DCF by configuring the UTEST miscellaneous bit 17 [XOSC_ALC_DIS]. Comparing the configurations with ALC disabled respect the case with ALC enabled, there are the following attributes:

- Higher oscillation amplitudes at crystal
- Distorted oscillation with several harmonics
- Increased EMI
- Higher crystal drive level
- Less susceptible to noise

The ALC enable configuration is suitable for most applications. The amplitude of oscillations is lower, hence less distortion in oscillations, less EMI, and also less crystal drive level. Feedback resistor is integrated thus, it does not require external resistors by offering a lower cost solution and simpler PCB design.

Note: It is recommended to make ALC feature enabled (that is, XOSC_ALC_DIS = 0) for low dissipation in crystal (crystal drive level).

Consult with crystal supplier for determining the need of extra resistance in XTAL to avoid crystal overdrive.

31.3 Memory map and register definition

Table 492 shows the memory map of the XOSC registers.

Table 492. XOSC memory map

Offset	Register	Location

Figure 382. XOSC Control register (XOSC_CTL)

Table 493. XOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
8:15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.

Table 493. XOSC_CTL field descriptions (continued)

Field	Description
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
24 I_OSC	Crystal oscillator clock interrupt This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV $\times$ 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.

32 IRCOSC digital interface

32.1 Introduction

The Internal RC Oscillator digital interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC)

It provides access to trimming information used for safety implementations.

32.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see Data Sheet for timing information) which is required for stabilization. The IRCOSC status indication is found in the MC_ME_GS[S_IRC] field (see the “Mode Entry Module MC_ME” chapter).

During a power on reset sequence the following are initialized from TEST Flash memory:

- Native trimming bits
- Fine trimming bits

For safety reasons, these bits can be accessed through the IRCOSC Native Trimming register (NT). The main IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[5:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

32.3 Memory map and register definition

Table 494 shows the memory map of the IRCOSC registers.

33 LPRC digital interface

33.1 Introduction

The LPRC digital interface controls the internal Low Power RC oscillator (LPRC). It holds control and status registers accessible for application.

33.2 Low Power RC oscillator

The Low Power RC oscillator provides a low frequency clock of 1.024 MHz with a good stability with respect to supply and temperature variation.

In all modes except STANDBY0, Low Power RC oscillator should be enabled by PMC digital interface (clearing MISC_CTRL_REG[RCOSC1M_ENB] bit). In STANDBY0 mode instead, Low Power RC oscillator is always enabled. After switch on, the output clock is available only after 8.5 us which is required for stabilization. The clock source status is updated in the S_LPRC bit of LPRC_CTL register.

The LPRC clock can be further divided by a configurable division factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by the LPRCDIV[4:0] bits of LPRC_CTL register.

The LPRC oscillator output frequency can be trimmed by LPRCTRIM[4:0] bits of LPRC_CTL register. These bits can be programmed to modify internal capacitor/resistor values so that the output clock frequency is within the +/- 1% of F_{LPRC} over the process. Once trimmed within this range using these bits, the variation over the voltage and temperature is the value given in SPC58xEx/SPC58xGx datasheet. After power on reset, the trimming bits are provided by the flash options. Only after first write access, the value specified by LPRCTRIM<5:0> bits will control the trimming.

33.3 Memory map and register definition

The LPRC registers are listed in *Table 497*.

34 OSC32K digital interface (OSC32K)

34.1 Introduction

The OSC32K digital interface controls the operation of the 32 KHz slow external crystal oscillator. It holds control and status registers accessible for application.

The programmable features of the OSC32K digital interface are as follows:

- Oscillator power-down control and status
- Oscillator clock available interrupt
- Oscillator bypass mode control
- Output clock division factors ranging from 1 to 32

34.2 Memory map and register definition

Table 499 shows the memory map of the OSC32K registers.

Table 499. XOSC32K memory map

1. You can read this field, and you can write a value of “1” to it. Writing a “0” has no effect. A reset will also clear this bit.
2. You can write a value of "0" or "1" to this field. However, writing a "1" will clear this field, and writing "0" will have no effect on the field value.

Figure 386. OSC32K Control register (SXOSC_CTL)

Table 500. SXOSC_CTL register field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock 1 EXTAL is used as root clock
8:15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked 1 Crystal oscillator clock interrupt is enabled
19:23 OSCDIV	Crystal oscillator clock division factor These bits specify the crystal oscillator output clock division factor. The output clock is divided by the factor OSCDIV+1.

Table 500. SXOSC_CTL register field descriptions (continued)

Field	Description
24 I_OSC	Crystal oscillator clock interrupt This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV × 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred 1 Oscillator clock interrupt pending
30 S_OSC	Crystal oscillator status 0 Crystal oscillator output clock is not stable 1 Crystal oscillator is providing a stable clock
31 OSCON	Crystal oscillator power-down control 0 Crystal oscillator is switched off 1 Crystal oscillator is switched on

34.3 Functional description

The OSC32K circuit includes an internal oscillator driver and an external crystal circuitry. It can be used as a reference clock to specific modules depending on system needs.

The OSC32K can be controlled via the SXOSC_CTL register. The OSCON bit controls the power-down while bit S_OSC provides the oscillator clock available status.

After system reset, the oscillator is put to power-down state and software has to switch on when required. Whenever the OSC32K is switched on from off state, the OSCCNT counter starts and when it reaches the value EOCV[7:0] × 512, the oscillator clock is made available to the system. Also, an interrupt pending SXOSC_CTL[I_OSC] bit is set. An interrupt will be generated if the interrupt mask bit M_OSC is set.

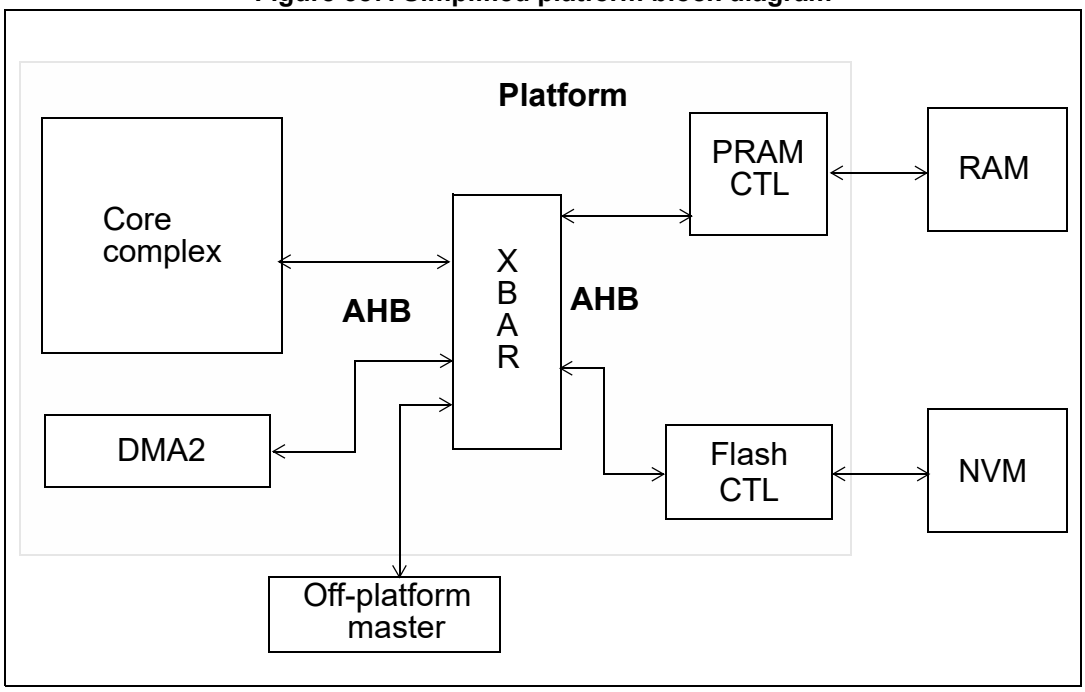
The oscillator circuit can be bypassed by writing SXOSC_CTL[OSCBYP] bit to ‘1’. This bit can only be set by software. A system reset is needed to reset this bit. In this bypass mode, the output clock has the same polarity as the external clock applied on the OSC32K_EXTAL pin and the oscillator status is forced to ‘1’. The bypass configuration is independent of the power-down mode of the oscillator.

Table 501 shows the truth table of different configurations of the oscillator.

Table 501. OSC32K configurations

SXOSC_CTL fields		OSC32K_XTAL	OSC32K_EXTAL	OSC32K	Oscillator mode
OSCON	OSCBYP				
0	0	No crystal, high Z	No crystal, high Z	0	Power-down, IDDQ
x	1	x	External clock	OSC32K_EXTAL	Bypass, OSC Disabled
1	0	Crystal	crystal	OSC32K_EXTAL	Normal, OSC Enabled
		Ground	External clock	OSC32K_EXTAL	Normal, OSC Enabled

The OSC32K clock can be further divided by a configurable factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by SXOSC_CTL[OSCDIV] field.



35 Platform RAM controller AHB (PRAMC_AHB)

35.1 Introduction

This section provides an overview of the Platform RAM Controller. The PRAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The PRAM controller supports two 64-bit AHB and one 64-bit RAM array interfaces. The first AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The second AHB port provides a connection from the flash controller to facilitate calibration overlay access. *Figure 387* is a simplified block diagram depicting the position of the PRAM controller within a typical platform architecture:

Figure 387. Simplified platform block diagram

The following list summarizes the key features of the PRAM controller:

- System bus supports 64-bit data and 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data and 8-bit ECC interface
- Late-write support via 64-bit data and 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than 64-bit data

The address path of the PRAM controller contains a multiplexer that chooses among the addresses presented on the system bus during read/write requests to RAM. These addresses are transferred to RAM array either immediately, for read accesses, or, for write accesses, through a temporary write address buffer or through a late-write address buffer.

The temporary write address buffer contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to simultaneously present the address and associated write data, because the write data is not valid until the AHB data phase. The late-write buffer holds write requests which are delayed to facilitate single-cycle responses on the system bus.

The read data is the result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire data path of the PRAM controller, including the late-write buffer, to support end-to-end ECC (e2eECC) coverage.

The write data path contains the multiplexer that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and stored directly in the RAM.

35.2 SRAM controller memory map and register definitions

The PRAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses will generate an IPS error.

Table 502. PRAMC_AHB memory map

Address offset (hex)	Register name	Reset value (hex)	Location

Table 503. PRCR1 field descriptions

Field	Description
22:23 PRI	AHB port arbitration mode Use this register to select the AHB port arbitration mode. 00 Round robin 01 Port p0 has priority over p1 10 Port p1 has priority over p0 11 Reserved
24 P1_BO_DIS	Port p1 read burst optimization disable 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response(1) when PRCR[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response(1) when PRCR[FT_DIS]=1
25 P0_BO_DIS	Port p0 read burst optimization disable 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response(1) when PRCR[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response(1) when PRCR[FT_DIS]=1
26 P1_RB_DIS	Port p1 read buffer disable 0 Read buffer enabled and is used for servicing sequential, less-than 64-bit read requests 1 Read buffer disabled and invalidated, and all read requests generate array accesses

Table 503. PRCR1 field descriptions (continued)

Field	Description
27 P0_RB_DIS	Port p0 read buffer disable 0 Read buffer enabled and is used for servicing sequential, less-than 64-bit read requests 1 Read buffer disabled and invalidated, and all read requests generate array accesses
31 FT_DIS	Flow through disabled This field defines the AHB read response of the PRAM controller . The state of this field has no impact on the write response latency. This bit is cleared by hardware reset. **Note:** Do not change the FT_DIS bit value while accessing system RAM. Realocate code programming the FT_DIS bit to another area (for example, local core memory). 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

1. The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM Controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM Controller clock frequency.

35.3 Functional description

35.3.1 Read/Write introduction

The PRAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The PRAM controller captures read data from the RAM array and drives it onto the AHB along with the associated dataphase termination signals. To facilitate operating at higher frequencies, the PRAM controller can optionally incur a single wait state on the AHB response.

35.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

35.3.1.2 Optional read wait-state

The PRAM controller can be optionally programed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCR1[FT_DIS] = 0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCR1[FT_DIS] = 1, and a WRAP4 burst will have an access time of 3-2-2-2

35.3.2 Writes

35.3.2.1 64-bit writes

Aligned **64**-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Instead, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

35.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the PRAM controller performs single-error correction, double-error detection on the read data. The write data is merged into the appropriate byte lanes along with the potentially-corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. For details on the ECC coding scheme, refer to *Section 35.5: Safety considerations*.

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of less than 64 bits require the insertion of one wait state before the data phase can be completed.

35.3.2.3 Unaligned writes

The PRAM controller is compliant with the AMBA-AHB2.v6 extensions specification concerning byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

Note: Unaligned writes always generate read-modify-write operations in the PRAM controller in order to preserve the validity of the ECC codeword.

35.4 Initialization/application information

Prior to reading, the ECC must be initialized by writing a known 64-bit value to each memory address. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Reading from an uninitialized address is likely to generate an uncorrectable ECC event.

The PRAM memory space can be initialized by storing a 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

35.5 Safety considerations

35.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named after M.Y. Hsiao, an IBM researcher who published a paper in the early 1970s about SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns
2. Every column is distinct
3. Every column contains an odd number of ones, and hence is “odd weight”

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in *Table 504*. A ‘*’ in *Table 504* indicates the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

35.5.1.1 E2EECC considerations on less-than-64-bit write transactions

Recall that writes of less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme 64 bits granularity. In the case of a read-modify-write action, the PRAM controller performs SEC/DED on the read data. The PRAM controller uses the following checkbit manipulation technique to ensure that any faults in the PRAM control logic, associated with performing the read-modify-write action, will ultimately be detectable by e2eECC:

- On an 8-bit, 16-bit or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non pertinent byte lanes zeroed out, and the associated checkbit is based on this “zero-padded” write data.
  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

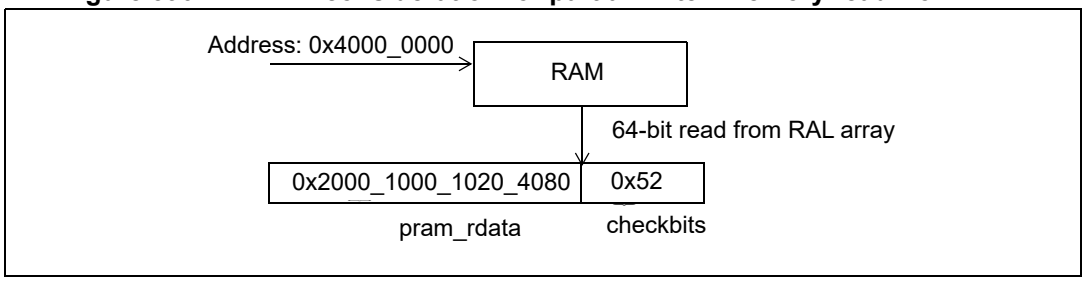

Figure 389. E2EECC consideration for partial write - 16-bit write request

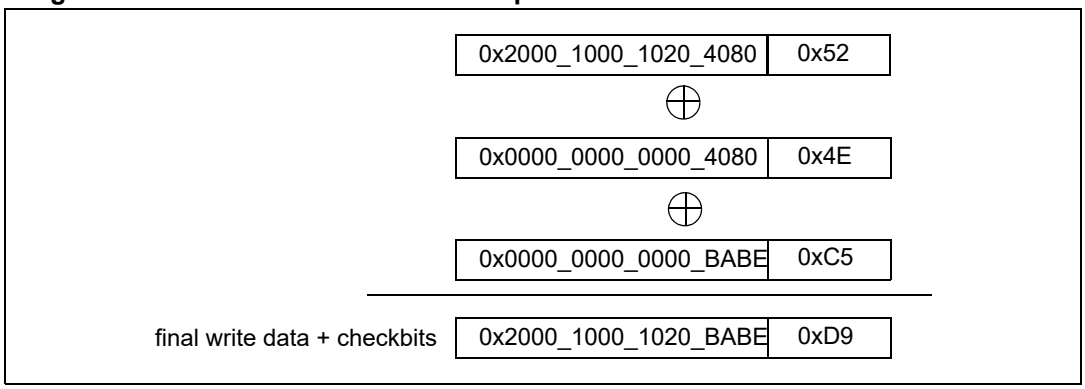
- The PRAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

  If a non correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

Figure 390. E2EECC consideration for partial write - memory read from RAM



- The PRAM controller isolates the pertinent byte lanes of the read data by zero-padding the non pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

Figure 391. E2EECC consideration for partial write - Separation of check-bits of targeted bit-lines

- The PRAM controller merges the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

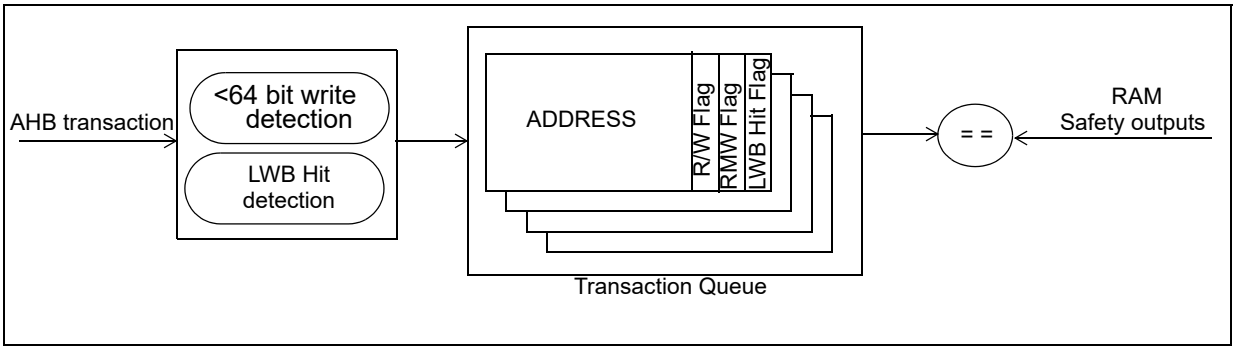
Figure 392. E2EECC consideration for partial write - calculation of final check-bits

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and PRAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The PRAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

35.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by an e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the PRAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions



- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, the safety feature compare outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

Figure 393. RAM controller transaction monitor block diagram

36 Flash memory controller

36.1 Introduction

This device implements two Flash memory controllers and two Flash arrays. The Flash memory controllers act as an interface between the system bus (AHB-Lite 2.v6) and the Flash memory arrays.

- Serve as the interface to the on-chip overlay RAM.
- Serve as the interface to on-chip System RAM that can be used as overlay RAM.
- Serve as the interface to the off-chip buddy device.

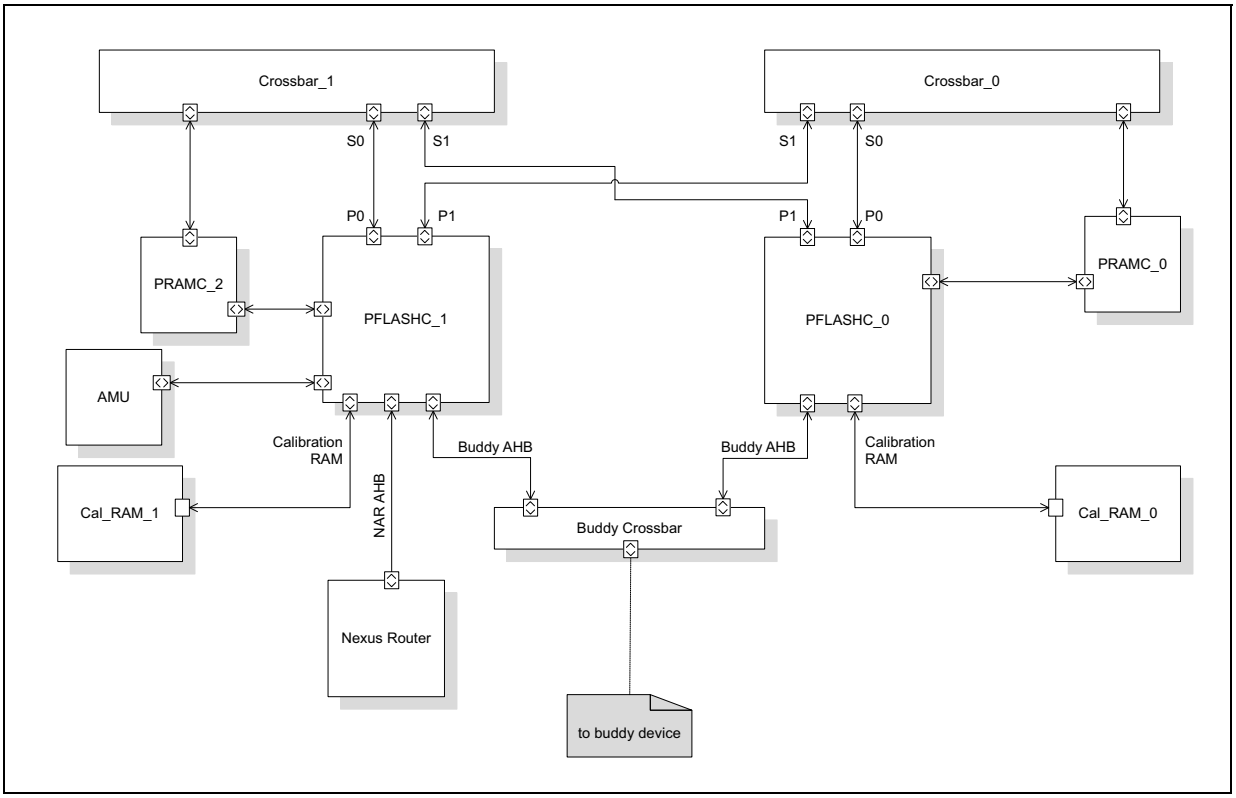
The Flash memory controllers support two 64-bit AHB buses and a 256-bit read data interface from each Flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the Flash arrays into the mini-cache. This buffer mechanism serves to deliver Flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed Flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the Flash array page size and providing 256 bytes of total buffered storage.

Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the Flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

36.2 Features

The following list summarizes the key features of the Flash memory controller:

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle “buffer hit” read response
- Configurable access control based on read/write and AHB master ID attributes
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets
- Optional address pipelining capability to maximize throughput
- Support for reporting of single-, double- and multi-bit Flash ECC events on a 64-bit doubleword boundary
- Configurable overlay remapping of logical Flash accesses to on-chip calibration RAM, extended off-chip calibration RAM, on-chip system RAM
- Nexus trace stream interface supports message dumping to the on-chip overlay RAM[15]



15. Available only on PFLASHC_1, as shown in *Figure 394*

36.3 Block diagrams

Figure 394 provides a block diagram showing the Flash memory controller and the attached Flash array.

Note: This module is also known as the Platform Flash controller, that is, PFlash.

Figure 394. Platform-centric simple block diagram with Flash memory controllers

36.4 Flash memory controller memory map

36.4.1 Overview

The Flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of Flash memory access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The Flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the Flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario.

There is no idle indicator for the Flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the Flash, code execution must be temporarily moved to system RAM.

16:18 APC	Address Pipeline Control This field controls the number of cycles that a subsequent Flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. 000 Pipelined access to the Flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 Reserved 011 Reserved 1xx Pipelined access to the Flash is disabled and one wait state is inserted before a subsequent access can be initiated

Table 506. PFCR1 field descriptions (continued)

Field	Description
19:23 RWSC	Read Wait State Control This field controls the number of wait-states to be added to the best-case Flash array access time for reads. The best-case Flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the Flash memory controller and the actual read access time of the Flash memory controller. The required settings are documented in the device data sheet. Higher operating frequencies require non-zero settings for this field for proper Flash operation. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added **Note:** Refer to the device data sheet for wait state configuration
25 P0_DPFEN	Port0 Data Prefetch Enable This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P0_IPFEN	Port0 Instruction Prefetch Enable This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
29:30 P0_PFLIM	Port0 PFlash Prefetch Limit This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 1x The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

36.4.1.2 Platform Flash configuration register 2 (PFCR2)

The PFlash configuration register 2 (PFCR2) specifies operation Port1 of the Flash memory controller.

Figure 397. Platform Flash configuration register 3 (PFCR3)

Table 508. PFCR3 field descriptions

Name	Description
0:1 P0_WCFG	Port0 Way Configuration This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the Flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the Flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any Flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved.
2:3 P1_WCFG	Port1 Line Buffer Configuration This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the Flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the Flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any Flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffer 0 allocated for instruction fetches and buffer 1 for data accesses. 11 Reserved

Table 508. PFCR3 field descriptions (continued)

Name	Description
11 BDRM	Buddy Device Read Mode This field controls the Flash memory controller bus response when the master presents a read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address. This field is ignored on production ECUs where the Buddy Device is not present. On production ECUs, this memory map region is provided for the “OLDA” (on-line data acquisition) function. Read requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are terminated with error on the system bus. This field is ignored on write requests targeting the extended overlay RAM using the direct, non-remapped address. Write requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address and terminate cleanly on the system bus. Write requests on engineering ECUs targeting the extended overlay RAM using the direct, non-remapped address are ignored are executed. This field is initialized by hardware reset. 0 Read requests targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are aborted, and the request is terminated with error on the system bus. 1 Read requests targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are allowed. The Flash memory controller returns the requested data from the extended overlay RAM, which resides on the BD. Any system bus errors returned by the BD are passed onto the master.
15 BAF_DIS	BAF Disable This field controls executable access to the BAF (Boot Assist Flash) region of the Flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF Flash region is allowed. 1 Executable access to the BAF Flash region is prohibited.
16:17 ARBM	Arbitration Mode This 2-bit field controls the arbitration of concurrent Flash access requests from the two AHB ports of the Flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 1x Round-robin arbitration

36.4.1.4 Platform Flash access protection register (PFAPR)

The PFlash access protection register (PFAPR) is used to control read and write accesses to the Flash array.

Table 510. PFCRCR field descriptions

Field	Description
23 SAFE_CAL	Safe Calibration This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the Flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 32 to 16. This field is initialized by hardware reset. 0 Established calibration overlay regions are not considered safety-critical. 1 Established calibration overlay regions are considered safety-critical.
27 IRMEN	Instruction Remap This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming Flash access requests - data and instruction fetches.
31 GRMEN	Global Remap Enable This bit globally enables or disables the calibration remap evaluation on system Flash accesses. Calibration remap evaluation is immediately available the next cycle following an update to enable PFCRCR[GRMEN] This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system Flash access requests. 1 Calibration remap evaluation is performed on all incoming system Flash access requests.

36.4.1.6 PFlash calibration remap descriptor enable register (PFCRDE)

The PFlash calibration remap descriptor enable register (PFCRDE) is used to enable or disable up to 32 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Table 511. PFCRDE field descriptions

Field	Description
0 CRD0EN	Calibration Remap Descriptor 0 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
1 CRD1EN	Calibration Remap Descriptor 1 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
2 CRD2EN	Calibration Remap Descriptor 2 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
3 CRD3EN	Calibration Remap Descriptor 3 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
4 CRD4EN	Calibration Remap Descriptor 4 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
5 CRD5EN	Calibration Remap Descriptor 5 Enable This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid

36.4.1.7 PFlash calibration region descriptor *n* (PFCRD*n*)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a Flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

36.4.1.7.1 PFlash calibration region descriptor *n*, Word0 (PFCRD*n*_Word0)

The first word of the Flash memory controller overlay region descriptor defines the 0-modulo-*size* logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

Offset 0x100 + *n**0x10 (n=0 to 31) Access: Supervisor Read/Write

Field	Description
0:28 LSTARTADDR	Logical Start Address This field defines the most significant bits of the 0-modulo-*size* logical start address of the overlay remap region. It corresponds to the logical system address which maps to the Flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.

36.4.1.7.2 PFlash calibration region descriptor *n*, Word1 (PFCRD*n*_Word1)

The second word of the Flash memory controller calibration region descriptor defines the 0-modulo-*size* byte physical start (byte) address of the calibration remap region. *The contents of this word define the targeted destination overlay memory*. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

36.5 Functional description

As shown in *Figure 394* the Flash memory controllers interface between:

- The AHB system bus ports
- Nexus trace
- Flash memory array
- Overlay RAM
- Off-chip Buddy Device
- System RAM

For accesses targeting the Flash array, the Flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the Flash array. The Flash memory controller captures read data from the Flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the Flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

36.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

36.5.2 Access protections

36.5.2.1 PFAPR - Platform Flash access protection register (PFAPR)

The Flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash access protection register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in *Section 36.4.1.4*. Detection of a protection violation results in an error response from the Flash memory controller on the AHB transfer.

36.5.2.2 BAF execution disable

The Flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash configuration register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on either Port0 or Port1 are evaluated. If the Flash memory controller detects an attempted instruction fetch access to the BAF region of the Flash, the Flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

36.5.3 Read cycles – buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. In the event of a buffer miss, a Flash access is initiated. If globally enabled, the calibration remap evaluation is also performed. If the access is to be remapped, the appropriate access is routed to the destination memory.

If the Flash access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as most-recently-used. If the Flash access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

36.5.4 Read cycles – buffer hit

Single cycle read responses to the AHB are possible with the Flash memory controller when the requested read access was previously loaded into one of the page buffers. In these “buffer hit” cases, read data is returned on the system bus with a zero wait-state response.

36.5.5 Error termination

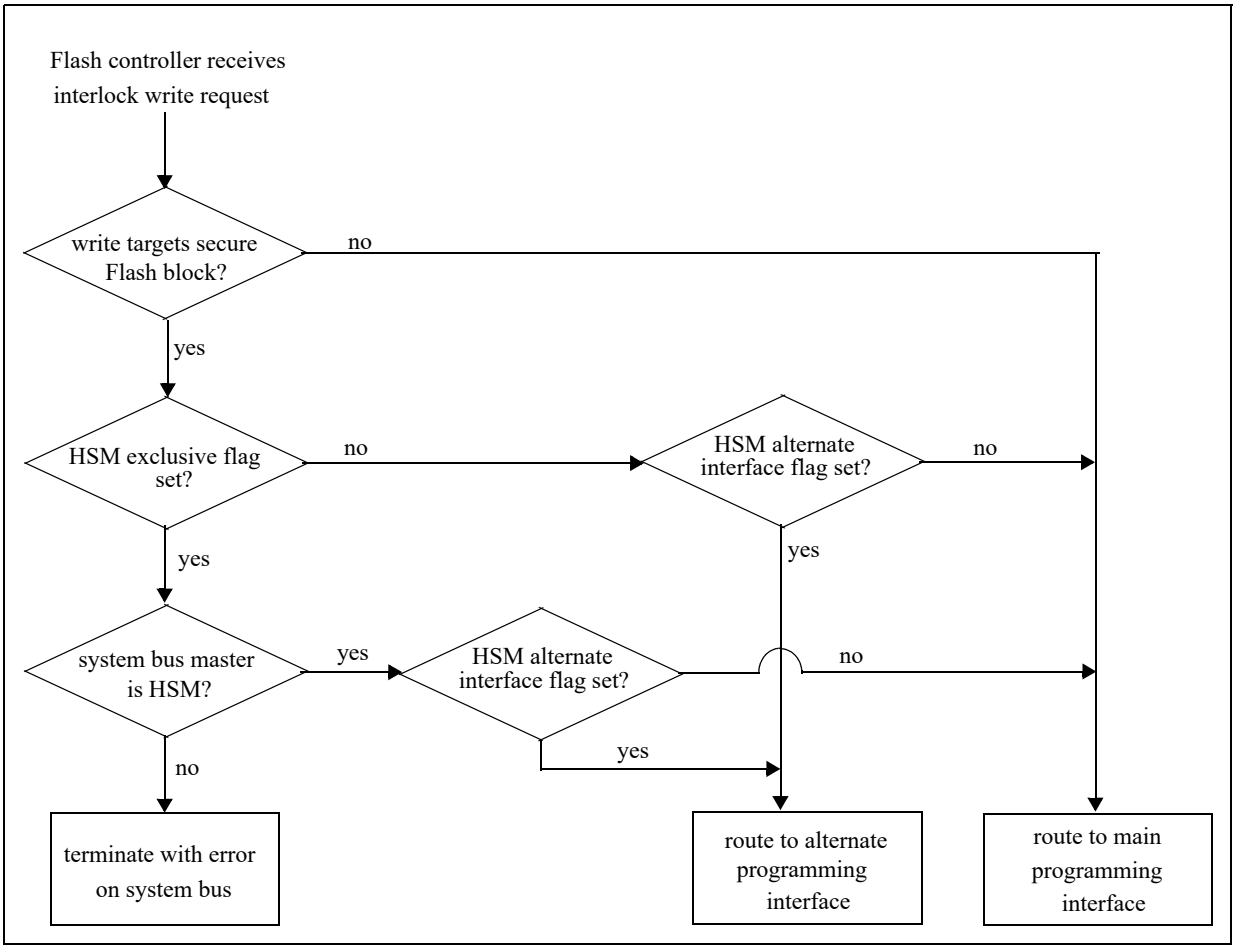
The Flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read access Control or Write access Control settings do not allow the access, thus causing a protection violation. See *Section 36.4.1.4* for more detail. In this case the Flash memory controller does not initiate a Flash array access.
- Attempted instruction fetch by an AHB master to the BAF Flash region when the PFCR3[BAF_DISABLE] field in Platform Flash configuration register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See *Section 36.4.1.3* for more detail. In this case, the Flash memory controller does not initiate a Flash array access.
- The Flash or overlay RAM returns an error response on an attempted access (see *Section 36.5.6*).
- Attempted access by an AHB master to a reserved region in the Flash memory map.

36.5.6 Flash error response operation

The Flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations, or improper sequencing during array integrity testing. When an error response is received, the Flash memory controller does not update or validate a page read buffer. An error response may be signaled on read or interlock write operation. For more information on the specifics related to signaling of Flash errors, including Flash ECC events, array integrity testing and read-while-write events, refer to the Flash memory chapter.

36.5.7 Security module exclusive control



During “Production at OEM” lifecycle state and beyond, the HSM can establish the secure Flash blocks to be exclusive to the HSM and route program or erasing of secure Flash blocks to the alternate programming interface.

The secure Flash space is independently controlled for each of the following regions:

- 16 KB secure code Flash block at address range 0x0060_C0000 - 0x0060_FFFF
- 64 KB secure code Flash blockA at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code Flash blockB at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data Flash blocks at address range 0x0068_0000 - 0x0068_7FFF

The HSM provides flags to individually control the HSM-exclusivity for each of the four secure Flash regions. When a given secure Flash block is marked as exclusive to the HSM, the HSM is the only system bus master granted access to that block and access attempts by non-HSM masters are terminated with error. Once HSM-exclusivity is established for a given secure Flash block, the HSM is guaranteed access to that block, regardless of the state of the censorship controls. Secure Flash exclusivity applies to read and write accesses.

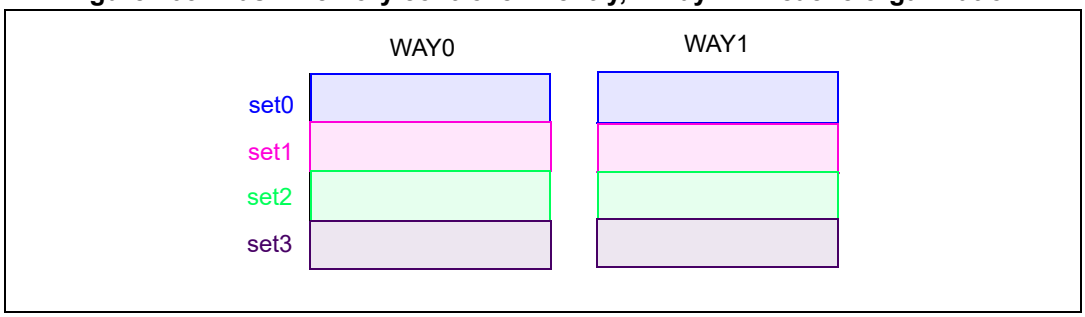
Figure 404. Interlock Write Alternate Programming Interface Routing Flowchart

36.5.8 Access pipelining

Accesses to the Flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the Flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by

the AHB master. Access pipelining may be applied only to read cycles targeting the Flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal Flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.



Note: Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

36.5.9 Line read buffers and prefetch operation

The AHB ports of the Flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the Flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see *Section 36.4.1.1*). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the Flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32 bytes, and a subsequent Flash access is initiated. A Flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 405. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the Flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of Flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted Flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in *Section 36.4.1.1*. More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to ‘1’,
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted

Refer to *Section 36.4.1.1* for a description of these controls.

36.5.10 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to *Section 36.4.1.1* for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to *Section 36.4.1.2* for a description of these controls. Prefetches are never triggered by write cycles.

36.5.11 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to *Section 36.4.1.1* for a description of these controls.

36.5.12 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to *Section 36.4.1.3*. The buffers can be organized as a “pool” of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

36.5.13 PFlash calibration remap support

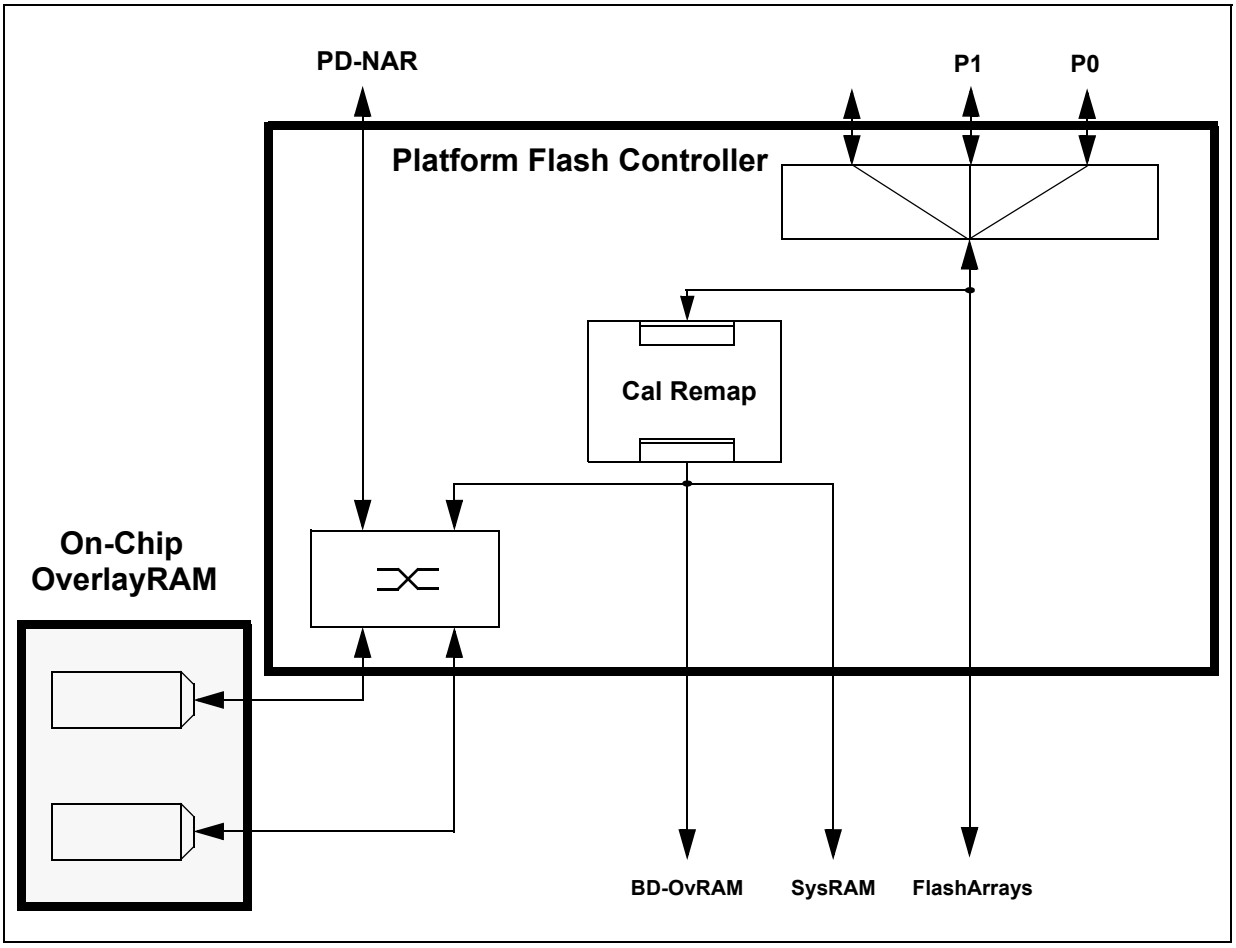
The Flash memory controller supports calibration development by providing a remapping function to route Flash accesses to overlay RAM on-chip system RAM that can be used as overlay RAM. Recall this family of devices includes a comprehensive set of features including dedicated overlay RAM arrays to aid calibration and debug.

The overlay function supports the following features:

- Can be mapped over internal Flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Can be used to hold device debug trace stream
  - Allows limited trace based debug without requirement for complex debug tool hardware and access to high speed trace port
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal Flash
  - Timing for calibration accesses to a particular overlay RAM is only guaranteed if it is not being used as a destination for trace streaming at the same time
  - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function:
  - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
  - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay RAM targets:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is only available on special ED devices.
- A portion of the system RAM can be used for overlay.



36.5.13.1 PFlash calibration remap to RAM

The *overlay RAM is selected based on the translated physical address*.

To better understand the functionality of the calibration remap, consider more detailed block diagrams, one showing the overall structure of the calibration remap function and another showing more detail on the actual remap logic. Recall the Flash memory controller implements a hardware interconnection matrix connecting the four input ports and four destination memories. See *Figure 406*.

The following figure illustrates the calibration remap connection matrix.

Figure 406. PFlash calibration remap connection matrix

Note the 64-bit on-chip overlay RAM is split into 2 equal-sized memories to allow concurrent accesses for calibration data from the P0, P1 (where these are the crossbar slave input ports) plus trace data writes from the Production Device Nexus Aurora Router (PD-NAR).

The translated physical address defines the destination memory. *Table 515* shows the base addresses for the calibration data memories as defined by the system memory map.

Table 515. Calibration data memory base addresses

Calibration memory	Base address(1)	Possible access sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1
On-chip Overlay RAM	0x0D00_----	P0, P1, PD-NAR
Buddy Device (Extended) Overlay RAM	0x0C{0,1}-_----	P0, P1

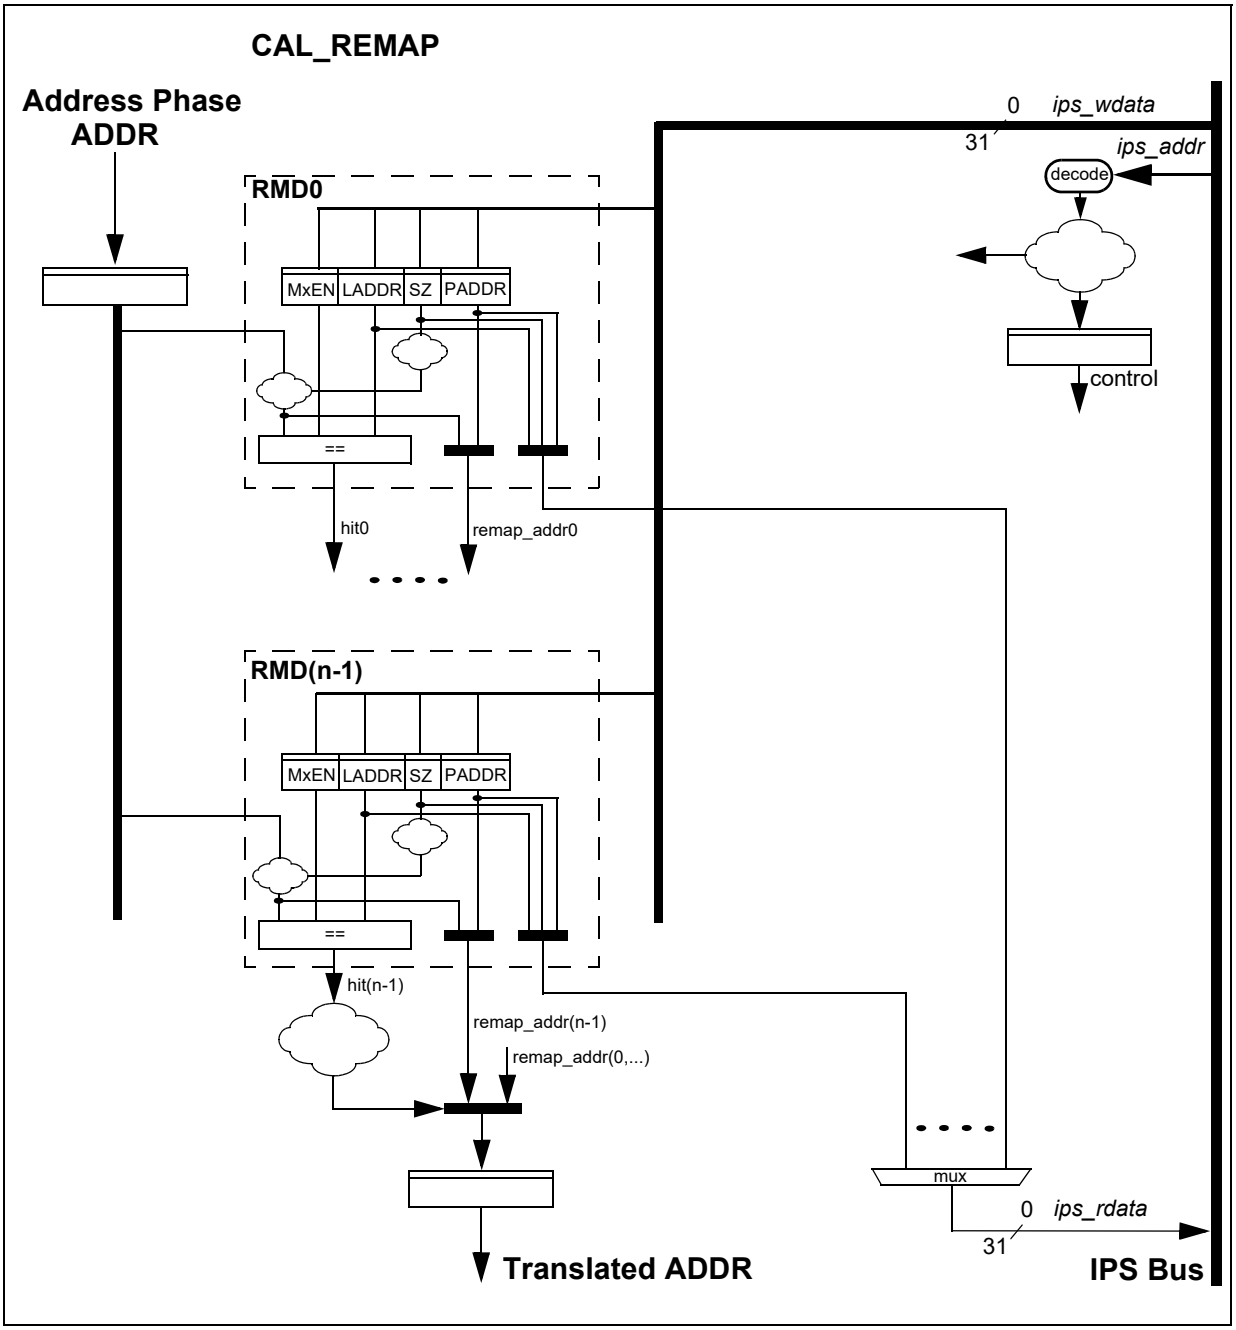
1. All memories are not implemented. Please refer to the *Table 505* for detailed information.

Note the trace data from the Nexus Aurora Router (PD-NAR) can only be routed to the on-chip overlay RAM; there is a different connection path in the Buddy Device from the BD-NAR into the extended overlay RAM.

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the Flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM, on-chip or buddy device (extended) overlay RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address. Byte-, halfword-, word- and doubleword-sized data store references to the on-chip overlay RAM are supported. Byte-, halfword-, word- and doubleword-sized store references to the buddy device (extended) overlay RAM are supported.

The read data interface of system RAM, on-chip overlay RAM and buddy (extended) device is 64 bits wide for each, whereas the Flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single Flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample Flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device. The access time when fetching data from the buddy device presents the longest latency. Therefore, in order for an initial, random calibration load access to mimic the Flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:



$$(\mathrm{RWSC}+2) \geq \left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right) \geq (\mathrm{OverlayRAMTranferBurstLatency})$$

Notice the overall latency on a random, initial Flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic Flash access time. This cycle accounts for pipeline stalls incurred by the Flash controller state machine. The formula above is based on specified intrinsic Flash access times of the array at 150C. Calibration data that is loaded in the Flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the Flash controller is presented with a Flash access request from any system bus master to a location in the mirrored Flash address space. Conversely, references using the associated non-mirrored Flash system address are not evaluated for calibration remapping. Generally, not all areas of the Flash memory map are available for calibration remapping. Secure Flash blocks, EEPROM, BAF and UTEST are usually not available for calibration remapping. Flash access requests which present an address targeting the secure Flash blocks, EEPROM, BAF or UTEST will bypass calibration remap evaluation and return Flash data.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries. See *Figure 407*.

Figure 407. PFlash calibration remap logic detail

Each instantiation of the basic calibration remap function {RMD0,..., RMD(*n*-1)} in *Figure 407* includes the three descriptor registers containing the logical start address (LADDR in the figure), the physical start address (PADDR), region size (SZ), and per-master enable bits (MxEN). The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical Flash address. An equality comparator then compares the adjusted logical Flash address against the logical address from the calibration remap descriptor to determine the region “hit”. The hit determination is further qualified based on the bus master number that initiated the Flash access. At the same time, the logical Flash address and the physical address defined in the calibration

remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region “hit” data is returned from the Flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical Flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x. This definition is selected as it minimizes the gate cost and timing impact of the calibration remap descriptor “hit” logic.

In general, the calibration remap logic operates only on Flash data accesses. However, Flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

36.5.13.2 PFlash calibration remap to Flash memory

Calibration remapping of a Flash access to another on-chip Flash address uses the same mechanism and controls as remapping to RAM addresses. The following should be noted:

- UTEST Flash, BAF, EEPROM, and secure Flash blocks cannot be remapped nor can accesses to other Flash blocks be rerouted to addresses in UTEST Flash, BAF, EEPROM, or secure Flash
- All other Flash blocks can be overlaid using the mirrored address range2.

36.5.14 Safety considerations

36.5.14.1 e2eECC (End-to-End ECC)

36.5.14.1.1 e2eECC and Flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with Flash memory. The basic issues involve: the default state of a Flash block that is erased (all ones) and the fact that programming an erased Flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the Flash memory in three ways.

First, the all ones codeword, since it reflects the state of an erased Flash location, is treated as a valid, error free encoding; in particular, it is required that the checkbits associated with the all ones data value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased Flash block generates an all ones data for all locations, the address field cannot be included in the ECC code used by the Flash. The Flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the Flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the Flash memory in multiple ways. The required ECC adjustments are handled by the platform Flash controller before data is written to the Flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a Flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all ones erased state.

On a Flash read operation, a similar but “reversed” set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the Flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following Flash ECC example. Let the Flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The Flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

```
addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)
```

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

```
addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3
```

Before performing the interlock write to the Flash array, the Flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the Flash array is:

```
fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8
```

3. Read address 0x00345678. The Flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The Flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

```
addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3
```

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The Flash memory controller performs EDC after ECC check on all Flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

36.5.14.2 Flash address generation check

Functional safety coverage of the address and data are handled by ECC performed within the Flash and e2eECC performed at the master. Functional safety coverage of the address path and control within the Flash memory controller rely on a feedback path between the Flash controller and Flash. Recall on a requested access to Flash, the Flash memory controller must decode the system AHB bus signals to generate the corresponding Flash interface signals to invoke a Flash lookup. In addition to providing the requested read data, the Flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.In the event of EDC after ECC errors detected on accesses to data and secure data flash, the event is not reported.

This sideband information is used by the Flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or

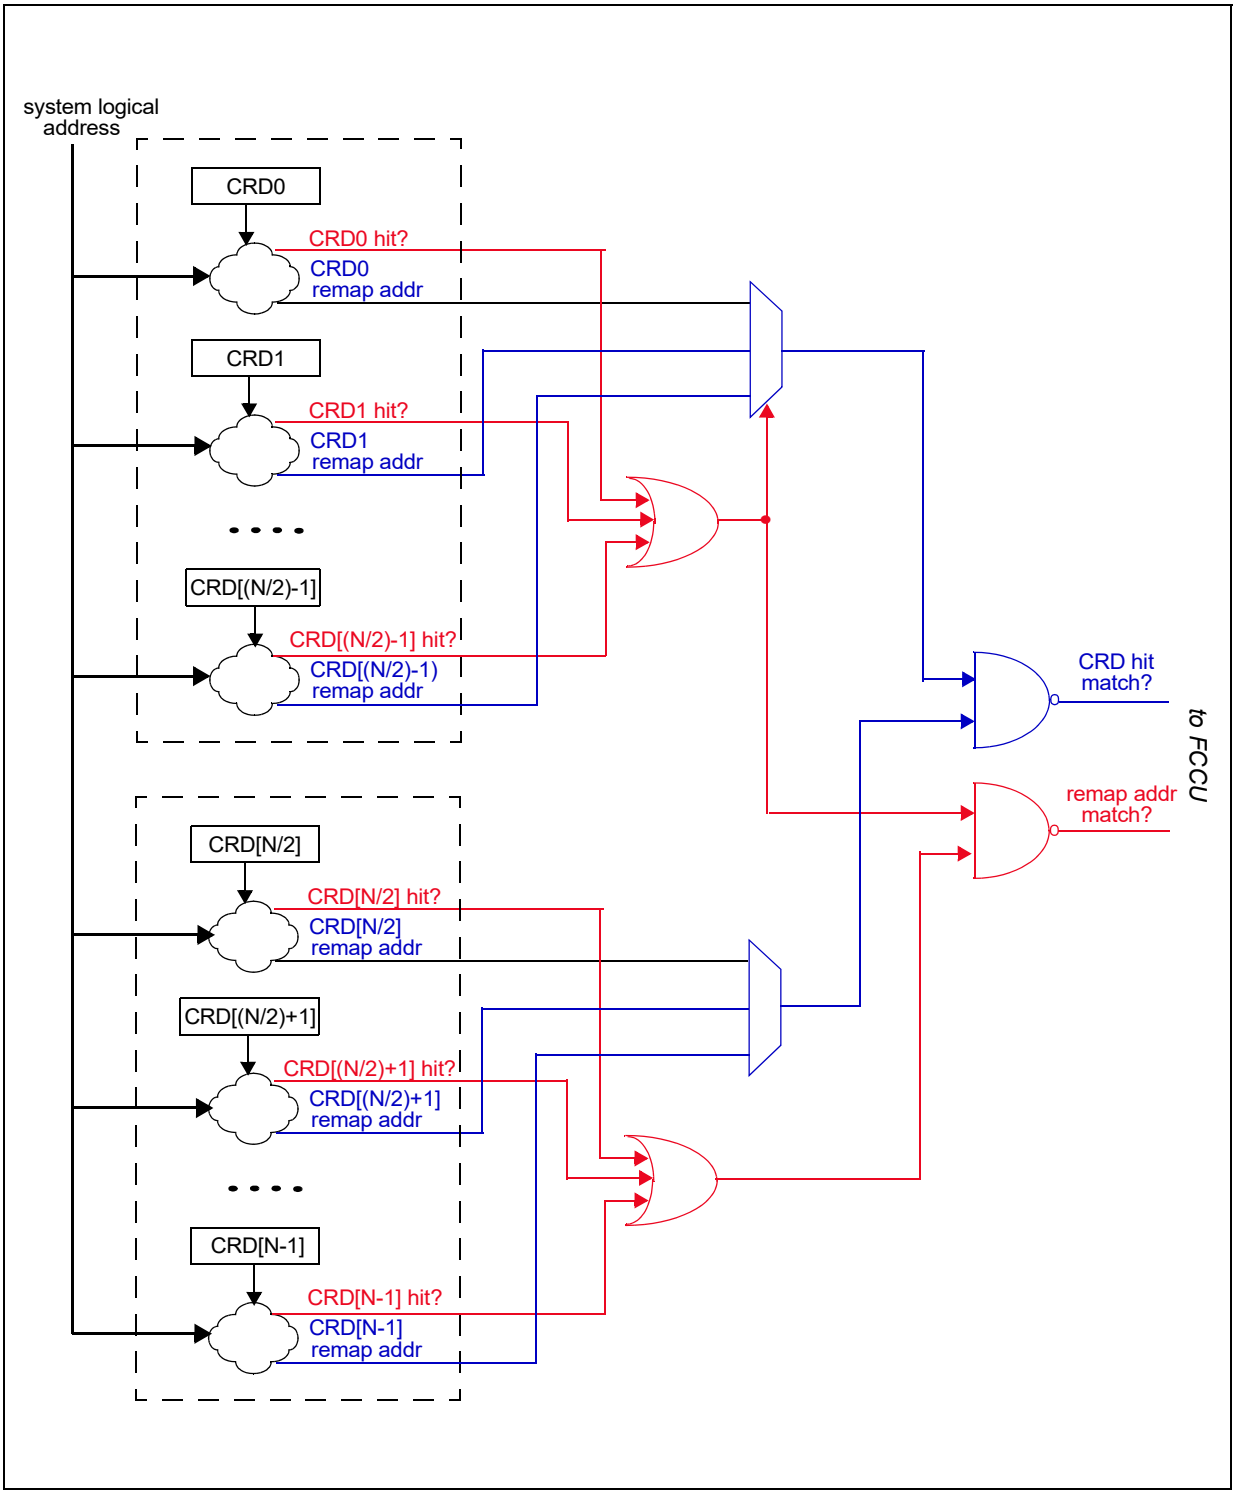
control logic within the Flash memory controller or the transmission path between the Flash memory controller and Flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

36.5.14.2.1 On-Chip Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the Flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the Flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the Flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the Flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the Flash memory controller or the transmission path between the Flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

36.5.14.2.2 Safety considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical Flash address contribution. This is required to satisfy the e2eECC check at the originating master.



In addition, the Flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the Flash memory controller treats the 32 total number of available calibration region descriptors (CRD0-CRD31) as a replicated group of 16 region descriptors that is half the size of the total number. More specifically, when N is the total number of region descriptors:

- The contents of CRD0 are expected to be redundantly defined in CRD[N/2]
- The contents of CRD1 are expected to be redundantly defined in CRD[(N/2)+1]
- The contents of CRD2 are expected to be redundantly defined in CRD[(N/2)+2]
- ...and so on
- The contents of CRD[(N/2)-1] are expected to be redundantly defined in CRD[N-1]

Note: It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming Flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2-1)] and the calibration regions defined in CRD[N/2] to CRD[N-1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the Flash.

Figure 408. Safety-critical calibration remap datapath with redundancy

36.5.15 e2eECC on data Flash accesses

ECC events detected on accesses to the EEPROM Flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit or double-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU. In the event of EDC after ECC errors detected on accesses to data and secure data flash, generation of the fault is suppressed. The related bit in MCR is not set and the event is not forwarded to the FCCU.

36.5.16 Array integrity considerations

During an array integrity sequence, the Flash memory array ignores any incoming read requests. When a Flash array integrity check is in progress, the Flash memory controller terminates all Flash access requests with an error.

37 Embedded Flash Memory

37.1 Introduction

The Flash Memory module serves as electrically programmable and erasable nonvolatile memory, for instructions and data storage.

The Flash Memory module is a nonvolatile, solid-state silicon memory device consisting of blocks of single transistor storage elements, an electrical means for selectively adding (programming) and removing (erasing) charge from these elements, and a means of selectively sensing (reading) the charge stored in these elements.

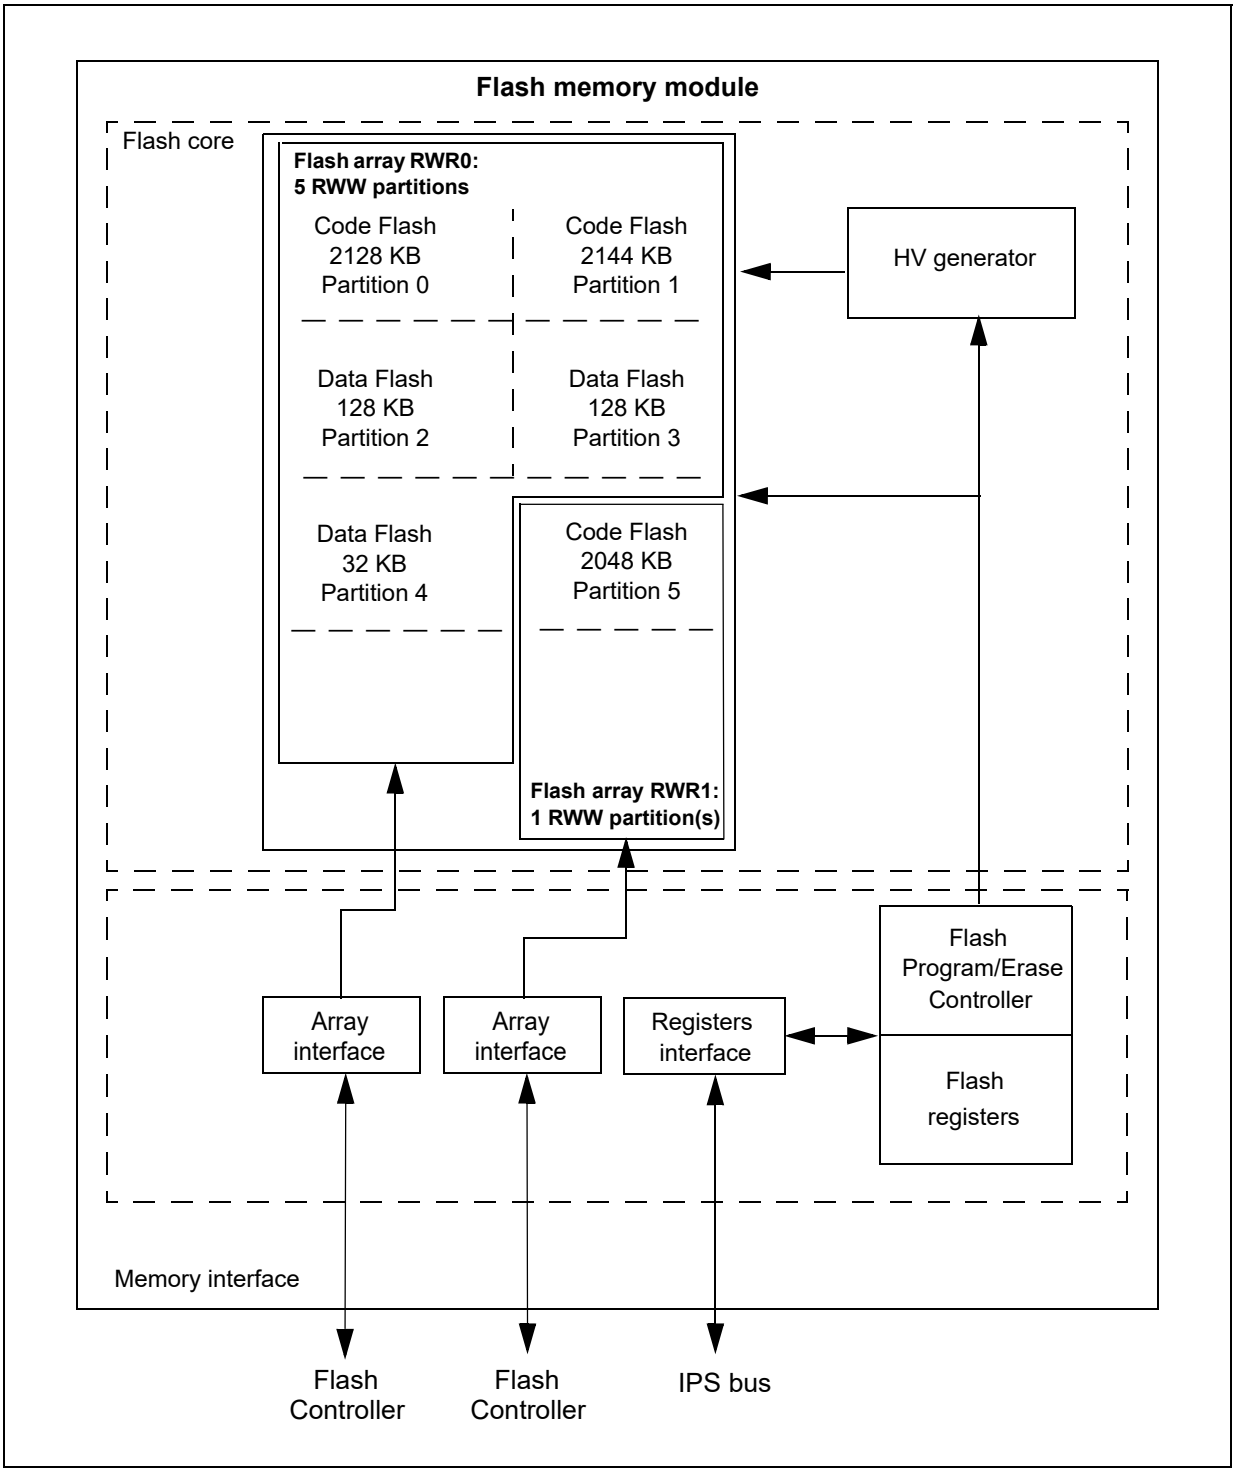
The Flash Memory module has two functional units:

- The Flash core: it is composed of a common high voltage HV block and a Flash array which can contain one or more Flash partitions. Each Flash partition is composed of arrayed nonvolatile storage elements, sense amplifiers, row decoders and column decoders. The arrayed storage elements in the Flash partitions are subdivided into physically separate units referred to as blocks.
- The Memory interface: it contains the registers and logic which control the operation of the Flash core and contains two main ports: the Array Interface and the Registers Interface. The memory interface is also the interface between the Flash Memory module and a Bus Interface Unit (BIU) and contains the ECC and redundancy logic.

37.1.1 Overview

The 6608 KB Flash Memory module contains six array partitions. Read-While-Write operations are only possible for separate partitions, meaning fetching/reading from one (or more) partition(s) while a program/erase operation is active on another partition. Each module counts as an RWW partition.

EEPROM emulation is managed as 4 × 64 KB blocks in two partitions, referred to as Data Flash.



HSM EEPROM emulation is managed as 2 × 16 KB blocks in two partition, referred to as HSM Data Flash.

The Modify operations are managed by an embedded Flash Program/Erase Controller (FPEC). Commands to the FPEC are delivered through a User Registers interface.

The Read Data bus is 256-wide, while the Flash registers are on a separate, 32-bit bus.

The high voltages needed for Program and Erase operations are internally generated and are common for the six partitions.

Figure 409. Flash memory module structure

The Flash Memory module is designed for use in embedded applications which require high density non-volatile memories with high-speed Read access.

The Flash array is addressable:

- For programs in data partition: by word (32 bits) or doubleword (64 bits). ECC granularity is 64 bits.
- For programs in code partition: by word (32 bits) or doubleword (64 bits). ECC granularity is 128 bits.
- For reading code partitions – by page (256 bits).
- For reading data partitions – by half-page (128 bits).

Multiple-word or doubleword writes to the Flash memory may be performed to fill the program page buffer (256 bits), enabling page programming (256 bits – requiring 4 doubleword writes) and quad-page programming (1024 bits – requiring 16 doubleword writes). Code Flash memory reads always return 256, although Read buffering may be performed by the Bus Interface Unit (BIU). The address for each word retrieved within a page differs from the other addresses in the page by address bits (4:2).

Data Flash memory reads always return 128 bits, or two consecutive doublewords of information. The address for each word retrieved within a doubleword differs from the other addresses by address bits (3:2).

The Flash Memory module supports fault tolerance through Error Correction Code (ECC) and error detection. The ECC implemented within the Flash Memory module corrects double bit failures and detects triple bit failures.

The Flash Memory module uses an embedded hardware algorithm implemented in the Flash Program/Erase Controller to program and erase the Flash partitions.

Control logic that works with the software block-enables and software lock mechanisms are included in the embedded hardware algorithm to guard against accidental program/erase. The hardware algorithm performs the necessary steps to ensure that the storage elements are programmed and erased with sufficient margin to guarantee data integrity and reliability.

A programmed bit in the Flash array reads as logic level ‘0’ (or low). An erased bit in the Flash array reads as logic level ‘1’ (or high).

Programming and Erasing of the Flash array requires multiple system clock cycles to complete.

The Program and Erase sequences may be suspended or aborted.

37.1.2 Features

- 30 ns code/data array access time
- Code Partition High Read parallelism: 256 bits
- Data Partition Read parallelism: 128 bits
- Error Correction Code (Double Error Correction-Triple Error Detection) to enhance data integrity
- Data Partition Doubleword program granularity: 64 bits
- Erase with fast erase time at factory
- Blocks one time programmable (OTP) marking
- Read-While-Modify capability when the accesses are to different partitions
- Erase/Program Suspend
- Programming during Erase-Suspend
- Software programmable program/erase protection to avoid unwanted writings
- Temperature range (-40 °C to 165 junction)
- UTEST mode (user-accessible Test modes)
- Alternate interface provided for program and erase operations to dedicated master as private access to blocks
- Independent and Parallel Read access to specific Code Flash Partitions, namely Read-While-Read supported.
- Critical flops, which may affect Flash content, are triple-voted for safety application.

37.1.3 Modes of operation

The Flash Memory module supports the following modes of operation:

- Reset: the Flash Memory module initializes when the reset is deasserted.
- Power-down (Disable mode): the Flash Memory module removes all static consumption. The embedded Flash memory (array and registers) is not accessible to Read, Program or Erase once disabled. The wake-up time from Disable mode is longer than the wake-up time from Sleep mode.
- Low-power mode (Sleep mode): the Flash Memory module removes most of the static consumption. It is not accessible to Read, Program or Erase once disabled, however it does maintain a faster exit to Read mode with respect to Power-Down.
- Read mode: the Flash Memory module accepts Read accesses to the array.
- Modify mode: it is possible to read and write registers, Interlock Write the memory array, program the memory array, and erase the memory array. Program and Erase operations are initiated by performing array and register writes, and controlled by an internal state machine. Program/Erase operations or User Test modes (Margin Read or Array Integrity Check) are considered Main Modify modes.
- Read-While-Write: The Flash Memory module accepts Read accesses to array partitions that are not in Modify mode.
- Read-While-Read: The Flash Memory module accepts parallel Read accesses in separate Read-While-Read partitions.
- Alternate Modify mode: blocks in LOW and MID space could be assigned to Alternate interface, though which it is possible to read and write registers, Interlock Write the assigned memory array, program the assigned memory array, and erase the assigned memory array. Program and Erase operations are initiated by performing array and

alternate register writes, and are controlled by the same internal state machine as in Main. Alternate Program/Erase operations are considered Alternate Modify modes. Alternate Modify modes operates concurrently to Main ones and, although functionally independent, timing can be mutually influenced.

Such modes of operation are described in detail in *Section 37.4: Functional description*.

37.2 Flash memory map and description

The Flash Memory module block subdivision also facilitates independent Erase and Program protection. A software mechanism is provided to independently lock and unlock each block in Low, Mid, High and Data address spaces against program and erase.

37.2.1 Flash array memory map

37.2.1.1 Code Flash

Partition 0 accounts for 2128 KB of the total Flash Memory and is divided in 14 user blocks for code storage.

The sectorization of partition 0 of the Flash Memory is shown in *Table 516*.

Table 516. Flash memory partition 0 memory map

Block	Addresses	Size	Address space	LOCK	SEL
B0F0	0x00FC_4000 to 0x00FC_7FFF	16 KB	Low	LOWLOCK[1]	LOWSEL[1]
B0F1	0x00FC_C000 to 0x00FC_FFFF	16 KB	Low	LOWLOCK[2]	LOWSEL[2]

37.2.1.2 Data Flash

Data Flash is allocated in partition 2 and 3 of the Flash Memory as 4 × 64 KB blocks destined for data storage.

The Data Flash sectorization of the Flash Memory module is listed below.

Table 519. Flash Memory EEPROM DATA Partition 2 memory map

Block	Addresses	Size	Address Space	LOCK	SEL
D0_00	0x0080_0000 to 0x0080_FFFF	64 KB	High	HIGHLOCK[0]	HIGHSEL[0]
D0_01	0x0081_0000 to 0x0081_FFFF	64 KB	High	HIGHLOCK[1]	HIGHSEL[1]
—	—	—	—	—	—
—	—	—	—	—	—

Table 520. Flash Memory EEPROM DATA Partition 3 memory map

Block	Addresses	Size	Address Space	LOCK	SEL
D1_00	0x0082_0000 to 0x0082_FFFF	64 KB	High	HIGHLOCK[2]	HIGHSEL[2]
D1_01	0x0083_0000 to 0x0083_FFFF	64 KB	High	HIGHLOCK[3]	HIGHSEL[3]
—	—	—	—	—	—
—	—	—	—	—	—

HSM Data Flash is allocated in partition 4 and is composed by 2 x 16 KB blocks. The HSM Data Flash sectorization is listed below.

Table 521. Flash Memory HSM EEPROM Data Partition 4 memory map

Block	Addresses	Size	Address Space	LOCK	SEL
H0_00	0x0068_0000 to 0x0068_3FFF	16 KB	Mid	MIDLOCK[0]	MIDSEL[0]
H0_01	0x0068_4000 to 0x0068_7FFF	16 KB	Mid	MIDLOCK[1]	MIDSEL[1]

37.2.1.3 UTEST block memory map

The UTEST block is programmed and read independently of the other blocks. UTEST is included to support systems which require nonvolatile memory for security and to store system initialization information.

The usage of reserved UTEST block is detailed in *Table 522*.

Table 522. UTEST block memory map

Address Offset	Description	Size	Access
UTEST (Base Address 0x0040_0000 to 0x0040_3FFF)			
0x0000	Reserved	32 bytes	R
0x0020	Factory Erase Diary Location	16 bytes	R/P
0x0030	Test Mode Disable Override Passcode	16 bytes	R/P
0x0040	Test Mode Disable Seal	16 bytes	R/P
0x0050	Test Mode Disable Group A	16 bytes	R/P

Table 522. UTEST block memory map (continued)

Address Offset	Description	Size	Access
0x0060	Test Mode Disable Group B	16 bytes	R/P
0x00A0	UID	32 bytes	R
0x00C0	SW-DCF Start address	16 bytes	R
0x00D0	Reserved	48 bytes	R
0x0100	Password to enable the Flash Test Mode when in FA	32 bytes	R
0x0120	JTAG Password	32 bytes	R/P
0x0140(1)	PASS password - Group 0	32 bytes	R/P
0x0160	PASS password - Group 1	32 bytes	R/P
0x0180	PASS password - Group 2	32 bytes	R/P
0x01A0	PASS password - Group 3	32 bytes	R/P
0x01C0	Reserved	32 bytes	R/P
0x01E0	Life Cycle slot 0 - ST Production	32 bytes	R/P
0x0200	Life Cycle slot 1 - Customer Delivery	32 bytes	R/P
0x0220	Life Cycle slot 2 - OEM Production	32 bytes	R/P
0x0240	Life Cycle slot 3 - In Field	32 bytes	R/P
0x0260	Life Cycle slot 4 - Failure Analysis	32 bytes	R/P
0x0280	Customer Single Bit Correction area	32 bytes	R
0x02A0	Customer Double Bit Correction area	32 bytes	R
0x02C0	Customer Triple Bit Detection area	32 bytes	R
0x02E0	Customer Programmable Detection Area	32 bytes	R
0x0300	DCF Records	3328 bytes	R/P
0x1000	Customer OTP data	12288 bytes	R/P

1. The offset 0x140 contains the least significant 32-bit of the PASS password - Group 0. The offset 0x15C contains the most significant 32-bit of the PASS password - Group 0. The same endianess also applies to the other groups of the PASS password.

UTEST block supports RWW, and is grouped with the Code Flash in partition 0.

Programming of any section of the UTEST block is subject to similar restrictions as the array in terms of how ECC is calculated. Only one program is allowed per 128-bit ECC segment.

The UTEST Nonvolatile Memory section is OTP and erase is not allowed. User mode programming of the UTEST section is enabled only when MCR.PEAS is high. The UTEST section is divided into a *Flexible* area where content is managed at System level, and a *Reserved* area where addresses are pre-allocated for storing certain content. The UTEST section may be locked and unlocked against programming via LOCK0.TSLOCK in conjunction with the relative sideband (System specific). For locking purposes, UTEST is treated as a stand-alone block. UTEST access (both Read and Modify) is disabled in Test mode once the Test Mode Disable Seal password is written. Test Flash logical block gets also protected by the Test Mode Disable Seal.

The UTEST section is also set as OPP once the Test Mode Disable Seal password is written, thus programming is only allowed on virgin 128-bit locations.

37.2.1.4 RWR1_UTEST virtual block memory map

RWR1_UTEST virtual block is an area allocated for the purpose of injecting safety relevant error and to test the reaction path. This task is accomplished in the primary Read-While-Read partition 0 directly within UTEST memory map. RWR1_UTEST virtual block is assigned for the second, parallel, Read-While-Read partition 1 (see *Section 37.4.4.1: Read While Read*).

Warning: Customer Programmable Detection Area for RWR1_UTEST virtual block is qualified by UT0.CPA and UT0.CPE. UT0.CPR has no effect.

Table 523. RWR1_UTEST virtual block memory map

Address Offset	Description	Size	Access
RWR1_UTEST (Base Address 0x08FBC000)			
0x0000	Reserved	640 bytes	
0x0280	Customer Single Bit Correction area	32 bytes	R
0x02A0	Customer Double Bit Correction area	32 bytes	R
0x02C0	Customer Triple Bit Detection area	32 bytes	R
0x02E0	Customer Programmable Detection Area	32 bytes	R

37.3 Register memory maps and descriptions

In this section some nonvolatile registers are described as well as the usual volatile registers. Note that such entities are not Flip-Flops, but Test Flash block locations with a specific purpose.

During the Flash Initialization phase, the FPEC reads these nonvolatile registers and updates their corresponding volatile registers. When the FPEC detects ECC double errors in these special locations, it behaves in the following way:

- In the case of failing system locations (configurations, redundancy, EmbAlgo firmware), the initialization phase is interrupted and a Fatal Error is flagged.
- In the case of failing coherency checks, the volatile registers are filled with ‘1’s and the Flash Initialization ends setting MCR.RE.

37.3.1 Register memory maps

This section presents the memory mapping of all the Flash memory registers.

37.3.1.1 User register memory maps

The Flash User registers represent the communication interface between the host CPU and the FPEC.

Some register bits (command bits) are Read/Write for the CPU and read only for the FPEC. Other register bits (status bits) are Read/Write for the FPEC and read only for the CPU.

The Flash User Registers mapping is shown in *Table 524*.

37.3.2 User register descriptions

This section consists of user register descriptions in address order.

37.3.2.1 Module Configuration Register (MCR)

The Module Configuration Register is used to enable and monitor all the Modify operations of the Flash Memory module and to monitor the Read operations of Read-While-Read Interface 0.

Address: 0x0000 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 410. Module Configuration Register (MCR)

Table 525. MCR field descriptions

Field	Description
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the analog Read references. If the current and voltage Read references are out of range, this bit is set to signify that previous reads requested may have been corrupted. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A Read Reference Error occurred during a previous Read.
2 AEE	Address Encode Error On every Read request to the Flash, the incoming address is compared to an encoded address (row, column, and block) from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error is recorded. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An Address Encode Error occurred during a previous Read.
3 EEE	EDC after ECC Error EEE provides information on previous reads monitoring the EDC after ECC feature. On every Read request to the Flash, ECC parity is recomputed (encoding) just after ECC decoding, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error is reported. The EEE flag indicates this event when data is legal or containing up to 3 bit errors. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A previous Read may have been decoded by an ECC logic corrupted.
4:7 DWEE	Double Word Uncorrectable ECC Error DWEE identifies which Double Word is involved in ECC Uncorrectable Error Event. In Code Flash 4 Double Words are read in parallel and ECC is evaluated on a couple of Double Words basis. Therefore DWEE value could be: 1111 if an ECC Uncorrectable Error is found in both couples of Double Words 1100 if an ECC Uncorrectable Error is found in the couple of Double Words at high address 0011 if an ECC Uncorrectable Error is found in the couple of Double Words at low address 0000 if no ECC Uncorrectable Error is found In Data Flash 2 Double Words are read in parallel and ECC is evaluated on a single Double Word basis. Therefore DWEE value could be: 1111 if an ECC Uncorrectable Error is found in both Double Words 1010 if an ECC Uncorrectable Error is found in Double Word at high address 0101 if an ECC Uncorrectable Error is found in Double Word at low address 0000 if no ECC Uncorrectable Error is found DWEE is a read only. Flags bits get cleared when EER is cleared.

Table 525. MCR field descriptions (continued)

Field	Description
11 SBC1	Single Bit Correction 1 SBC1 provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection or ECC Double Error correction, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE1). 0 Reads are occurring normally. 1 An ECC Single Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.
12 SAK	Suspend Acknowledge SAK provides information about the Acknowledge of a suspend request at the setting of DONE: SAK qualifies if the suspend has been accepted (initiated by PSUS or ESUS setting) or if the running command has been completed, since very close to natural end. The aim of this bit is for monitor. The sequence to resume normal functionality (PSUS or ESUS clearing) is the same both is suspend has been acknowledged or not. SAK is read Only 0 Operation has been completed prior that Suspend got processed 1 Suspend Acknowledged
13 LSW	Lock-Sel Write Error LSW provides information about Lock and Sel write denied during the program and erase sequence. If LSW is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Lock and Sel write successful 1 Lock and Sel write not succeeded
14 PEP	Program and Erase Protection Error PEP provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a Locked block, or if an erase is selected to a locked block. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations will not be attempted for this request. If PEP is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program and Erase protection errors do not exist 1 Previous program or erase protection error encountered

Table 525. MCR field descriptions (continued)

Field	Description
15 PES	Program Erase Sequence Error PES provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an out-of-order event is detected, PES will assert, and the remainder of the sequence will not be accepted. Sequence errors are checked from the time the PGM or ERS are set (or remains set from previous operation) until EHV is set. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program or Erase phase accepted 1 Program or Erase command encountered an error
16 EER	ECC uncorrectable Event Error EER provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. EER may not be set to ‘1’ by the user. EER is not set for a ECC correctable Error detection and related correction event. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An ECC uncorrectable Error occurred during a previous Read. In Code Flash, with 128b ECC coding, ECC error is evaluated on couple of Double word basis. In Data Flash for EEE, ECC error is evaluated on each Double word.
17 RWE	Read-while-Write event Error RWE provides information on previous Reads during a Modify operation. Read-While-Write Error means that a Read access to the Flash Array partition has occurred while the FPEC was performing a Program or Erase operation or an Array Integrity Check on the same partition. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A RWW Error occurred during a previous Read.
18 SBC	double Bit Correction SBC provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE). 0 Reads are occurring normally. 1 An ECC Double Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.

Table 525. MCR field descriptions (continued)

Field	Description
19 RE	Reset Error This bit provides information on previous resets. Checks are done within the Flash, and if a coherency issue or ECC error is detected during the reset reads used for trimming on the Flash, this status flag will assert. This bit is status only, and is not writable. 0 Flash Boot phase has occurred normally. 1 A reset error has been encountered.
20 PEAS	Program/Erase Access Space PEAS is used to indicate which space is valid for Program and Erase operations: main array space or UTEST section within Test Flash block. – PEAS is captured and held with the first Interlock Write done for Modify operations. – PEAS is retained between sampling events (that is subsequent to first interlock writes). – PEAS is changed during erase-suspended program (when program is in UTEST) and reverts back to its original state (related to erase suspended operation) once the erase-suspended program is completed (at MCR.PGM 1-0 transition). 0 UTEST address space is disabled for program and main address space enabled. 1 UTEST address space is enabled for program and main address space disabled.
21 DONE	Modify operation DONE DONE indicates if the Flash Memory module is performing a high voltage operation. DONE is set to ‘1’: – On termination of the Flash Memory module reset. – At the end of program and Erase High Voltage sequences. – After “1-0” transition of EHV, which aborts a high voltage Program/Erase operation (within t_{PABT} or t_{EABT}, equal to the P/E Abort Latency). – After “0-1” transition of ESUS/PSUS which suspends an Erase/Program operation (within t_{ESUS}/t_{PSUS} time equal to the Erase/Program Suspend Latency). DONE is cleared to ‘0’: – just after “0-1” transition of EHV, which initiates a high voltage operation, or after resuming a suspended operation. 0 Flash is executing a high voltage operation. 1 Flash is not executing a high voltage operation.

Table 525. MCR field descriptions (continued)

Field	Description
22 PEG	Program/Erase Good PEG is automatically updated to show the completion status of the last Flash Program or Erase sequence involving high voltage operations. PEG is evaluated on the completion status of only the interlocked doubleword during page program or quad-page programming where some doubleword addresses are not interlocked (already programmed or intended to remain virgin). PEG is set to ‘0’ after Aborting a Program/Erase high voltage operation, indicating sequence failure. PEG is set to ‘1’ when the Flash Memory module is reset, unless a Flash Initialization error has been detected. **Note:** PEG is valid only when PGM=1 or ERS=1, or both, and after DONE 0-1 transitions due to an Abort or the completion of a Program/Erase operation. PEG remains valid until PGM/ERS 1-0 transitions or EHV 0-1 transitions. PEG is not valid after DONE 0-1 transitions when ESUS/PSUS is set to logic ‘1’. If Program or Erase is attempted on blocks that are locked, PEG=1 indicating that the content of the block were properly protected from the Program or Erase operation. Blocks can be locked through LOCK0/1/2/3 registers OR with flh_plock0/1/2/3 sideband signals. If a Program operation tries to write ‘1’ to bits that are ‘0’, the program operation is correctly executed on the new bits to be programmed at ‘0’, but PEG is cleared indicating that the requested operation has failed. If Programming during an Erase-Suspend a location that was under suspended erase, program is not executed and PEG is set to ‘0’. With end2end ECC scheme, during an Interlock Write also ECC parity bits are input. After setting EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, in the page program or in the quad-page program, contains an inconsistency between data and parity, the whole operation is rejected and a PEG=0 is set. PEG behavior with blocks marked as OPP (though flh_otpen0/1/2/3 sideband signals) is the following: PEG=0 if the location to be programmed is not virgin, and thus would not be over programmed. In Array Integrity Check or Margin Read PEG is not altered when the operation is completed, regardless of the occurrence of any error, abort, break point or suspend. The presence of errors can only be detected by comparing the checksum value stored in UM0-9 and by checking the MCR flags. 0 Program, Erase operation failed or Program, Erase aborted. 1 Program or Erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag. 0 An interrupt request is not generated when the DONE flag is set. 1 An interrupt request is generated when the DONE flag is set.

Table 525. MCR field descriptions (continued)

Field	Description
24 FERS	Factory Mode FERS is used for Erase and Program operations to enable a faster operation. Factory Mode must adhere to *Initial maximum (All Temperatures)* conditions, with respect to voltage conditions and Write/Erase cycling. The temperature can range from -40 °C to 150 °C. Factory Mode does not support Read and RWW operations. – FERS may be set to enable a Factory Erase or Program after setting ERS or PGM but prior to setting EHV. – FERS can be cleared only when EHV is low and DONE is high. – FERS is cleared on reset **Note:** Factory Mode may be permanently disabled by writing a location in the UTEST Nonvolatile Memory space. Offset 0x0020 in the UTEST Nonvolatile Memory space is checked at reset, and if programmed with data that contains at least one zero, a Factory Mode is not allowed, and FERS is locked. Writes attempted that violate the above cases result in FERS remaining cleared. 0 Factory Mode is disabled. 1 Factory Mode is enabled.
27 PGM	Program PGM is used to setup the Flash Memory module for a Program operation. – “0-1” transition of PGM initiates a program sequence. – “1-0” transition of PGM ends the program sequence. PGM can only be set in the following conditions: – User Mode Read (ERS is low and UT0.UTE is low); – Erase Suspend (ERS and ESUS high) with EHV low. PGM can only be cleared by the user when PSUS and EHV are low and DONE is high. PGM is cleared on reset. **Note:** In an erase-suspended program, programming Flash memory locations in blocks which were being operated on in the Erase is forbidden. Command is not accepted and PEG is set to ‘0’ 0 Flash is not executing a program sequence. 1 Flash is executing a program sequence.

Table 525. MCR field descriptions (continued)

Field	Description
28 PSUS	Program Suspend PSUS is used to indicate that the Flash Memory module is in Program Suspend or in the process of entering a Suspend state. The Flash Memory module is in Program Suspend when PSUS=1 and DONE=1. – PSUS can be set high only when PGM and EHV are high. – “0-1” transition of PSUS starts the sequence which sets DONE and places the Flash in Program Suspend. The Flash Memory module enters Suspend within t_{PSUS} of this transition. – PSUS can be cleared only when DONE and EHV are high. – “1-0” transition of PSUS with EHV=1 starts the sequence which clears DONE and returns the module to Program. The Flash Memory module cannot exit Program Suspend and clear DONE while EHV is low. In the case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), PSUS has to be cleared first in order to resume currently higher level suspended operation that is program. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERS	Erase ERS is used to setup the Flash Memory module for an Erase operation. – “0-1” transition of ERS initiates an Erase sequence. – “1-0” transition of ERS ends the Erase sequence. ERS can be set only under User Mode Read (PGM is low and UT0.UTE is low). ERS can be cleared by the user only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash is not executing an Erase sequence. 1 Flash is executing an Erase sequence.

Table 525. MCR field descriptions (continued)

Field	Description
30 ESUS	Erase Suspend ESUS is used to indicate that the Flash Memory module is in Erase Suspend or in the process of entering a Suspend state. The Flash Memory module is in Erase Suspend when ESUS = 1 and DONE=1. – ESUS can be set high only when ERS and EHV are high and PGM is low. – “0-1” transition of ESUS starts the sequence which sets DONE and places the Flash in Erase Suspend. The Flash Memory module enters Suspend within t_{ESUS} of this transition. – ESUS can be cleared only when DONE and EHV are high and PGM is low. – “1-0” transition of ESUS with EHV=1 starts the sequence which clears DONE and returns the module to Erase. The Flash Memory module cannot exit Erase Suspend and clear DONE while EHV is low. In case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), ESUS cannot be cleared first. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.

Table 525. MCR field descriptions (continued)

Field	Description
31 EHV	Enable High Voltage The EHV bit enables the Flash Memory module for a high voltage Program/Erase operation. EHV is cleared on reset. EHV must be set after an Interlock Write to start a Program/Erase sequence. EHV may be set under one of the following conditions: – Erase (ERS=1, ESUS=0, UT0.AIE=0) – Program (ERS=0, ESUS=0, PGM=1, UT0.AIE=0) – Erase-suspended program (ERS=1, ESUS=1, PGM=1, PSUS=0, UT0.AIE=0). For a program operation to initiate while an Erase is suspended, EHV must be cleared while in Erase-Suspend (after DONE transitions to 1) before setting PGM. In normal operation, a “1-0” transition of EHV with DONE high, PSUS low and ESUS low terminates the current Program/Erase high voltage operation. In an erase-suspended program operation, a “1-0” transition of EHV with DONE, ESUS, PGM and ERS high and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a “1-0” transition of EHV with DONE low and the eventual Suspend bit for the current program/erase operation low. An Abort causes the value of PEG to be cleared, indicating failed Program/Erase. Address locations being operated on by the aborted operation contain indeterminate data after an Abort. EHV cannot be set to ‘1’ after an Abort request (EHV being cleared) until the Abort sequence is completed (DONE transitions to 1). Once the Abort sequence is completed (DONE=1) a new operation of the kind aborted can start provided that a new interlock is given and then EHV is set to ‘1’ again. A suspended operation cannot be aborted. Aborting a high voltage operation leaves the Flash Memory module addresses in an indeterminate data state. This may be recovered by executing an Erase on the affected blocks. EHV may be written during Suspend. EHV must be high to exit Suspend, resuming previously suspended command. EHV cannot not be written during transition into Suspend state (after Suspend bit (ESUS or PSUS) is set high) until DONE transitions to ‘1’. EHV may not be written after ESUS is set and before DONE transitions high. EHV may not be cleared after ESUS is cleared and before DONE transitions low. 0 Flash is not enabled to perform a high voltage operation. 1 Flash is enabled to perform a high voltage operation.

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

The Flash Memory module does not allow the user to write bits simultaneously (which puts the device into an illegal state). This is implemented through a priority mechanism among the bits shown in *Table 526*.

Table 526. MCR Bits Set/Clear Priority Levels

Priority level	MCR bits
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If the user attempts to write two or more MCR bits simultaneously then only the bit with the lowest priority level is written.

37.3.2.2 Alternate Module Configuration Register (MCRA)

The Alternate Module Configuration Register is used to enable and monitor all the Modify operations of the Flash Memory module managed through Alternate interface.

Address: 0x0004 Access: User Read/Write

Figure 411. Alternate Module Configuration Register (MCRA)

Table 527. MCRA field descriptions

Field	Description
12 SAKA	Alternate Suspend Acknowledge SAKA provides information about the Acknowledge of a suspend request at the setting of DONEa: SAKA qualifies if the suspend has been accepted (initiated by PSUSa or ESUSa setting) or if the running command has been completed, since very close to natural end. The aim of this bit is for monitor. The sequence to resume normal functionality (PSUSa or ESUSa clearing) is the same both is suspend has been acknowledged or not. SAKA is read Only 0 Operation has been completed prior that Suspend got processed. 1 Suspend Acknowledged
13 LSWA	Alternate Lock Write Error LSWA provides information about Lock write denied during the program and erase sequence. If LSWA is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Lock and Sel write successful. 1 Lock and Sel write not succeeded.
14 PEPA	Alternate Program and Erase Protection Error PEPA provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a Locked block, or if an erase is selected to a locked block. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations will not be attempted for this request. If PEPA is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program and Erase protection errors do not exist. 1 Previous program or erase protection error encountered.
15 PESA	Alternate Program Erase Sequence Error PESA provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an out-of-order event is detected, PESA will assert, and the remainder of the sequence will not be accepted. Sequence errors are checked from the time the PGMA or ERSA are set (or remains set from previous operation) until EHVA is set. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program or Erase phase accepted 1 Program or Erase command encountered an error
20 PEASA	Program/Erase Access Space PEASA is used to indicate which space is valid for Program and Erase operations: main array space or UTEST block. It should be noted that erase is not allowed to the UTest NVM space, therefore If an interlock write is done to the UTest NVM space with ERSA set, PEASA will remain 0. See PEAS definition in the MCR register for more information(*Table 525*).
21 DONEA	Modify operation DONE DONEA indicates if the embedded Flash memory is performing a high-voltage operation for the Alternate program and erase interface. See DONE definition in the MCR register for more information (*Table 525*).

Table 527. MCRA field descriptions (continued)

Field	Description
22 PEGA	Program/Erase Good The PEGA bit indicates the completion status of the last Flash memory program or erase sequence for which high-voltage operations were initiated for the Alternate program and erase interface. See PEG definition in the MCR register for more information (*Table 525*). It should be noted that in the event of a error on the alternate interface PEGA will clear, but the ADR register will not be updated with the failing location. The ADR register is only valid for main interface program or erase fails, and other fails noted in the ADR register.
27 PGMA	Program PGMA is used to set up embedded Flash memory for a program operation for the Alternate program and erase interface. See PGM definition in the MCR register for more information (*Table 525*).
28 PSUSA	Program Suspend PSUSA is used to indicate the embedded Flash memory is in program suspend or in the process of entering a suspend state for the Alternate program and erase interface. See PSUS definition in the MCR register for more information (*Table 525*).
29 ERSA	Erase ERSA is used to set up embedded Flash memory for an erase operation for the Alternate program and erase interface. See ERS definition in the MCR register for more information (*Table 525*).
30 ESUSA	Erase Suspend ESUSA is used to indicate that the embedded Flash memory is in erase suspend or in the process of entering a suspend state for the Alternate program and erase interface. See ESUS definition in the MCR register for more information (*Table 525*).
31 EHVA	Enable High Voltage The EHVA bit enables the embedded Flash memory for a high-voltage program/erase operation for the Alternate program and erase interface. See EHV definition in the MCR register for more information (*Table 525*).

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

37.3.2.3 Extended Module Configuration Register (MCRE)

The Extended Module Configuration Register value is based on the size, blocks and address space configuration of the Flash Memory module.

Address: 0x0008 Access: User Read

21:23 N16KM	Number of 16 KB blocks in mid space N16KM is read only. 000 Zero 16 KB blocks. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Eight 16 KB blocks. 101 Reserved. 110 Reserved. 111 Reserved.

Table 528. MCRE field descriptions (continued)

Field	Description
24:26 N64KL	Number of 64 KB blocks in low space N64KL is read only. 000 Zero 64 KB blocks. 001 Two 64 KB blocks. 010 Four 64 KB blocks. 011 Six 64 KB blocks. 100 Eight 64 KB blocks. 101 Three 64 KB blocks + One 96KB block. 110 Reserved. 111 Reserved.
27:28 N32KL	Number of 32 KB blocks in low space N32KL is read only. 00 Zero 32 KB blocks. 01 Two 32 KB blocks. 10 Four 32 KB blocks. 11 Three 32 KB blocks.
29:31 N16KL	Number of 16 KB blocks in low space N16KL is read only. 000 Zero 16 KB blocks. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Eight 16 KB blocks. 101 Three 16 KB blocks. 110 Five 16 KB blocks. 111 Reserved.

37.3.2.4 Lock 0 register (LOCK0)

The LOCK0 (Low/Mid Address Space Block Locking) register provides a means of protecting blocks from being modified. LOWLOCK and MIDLOCK bits corresponding to non existent blocks are read as ‘1’.

To determine the effective status of the Low/Mid Address Space, combine (Or) LOCK0 with sidebands:

- flh_plock0 – in order to evaluate protection against programming.
- flh_elock0 – in order to evaluate protection against erase.

The effect of programming or erasing a block protected with LOCK0 is that no modification occurs and PEG is set to ‘1’.

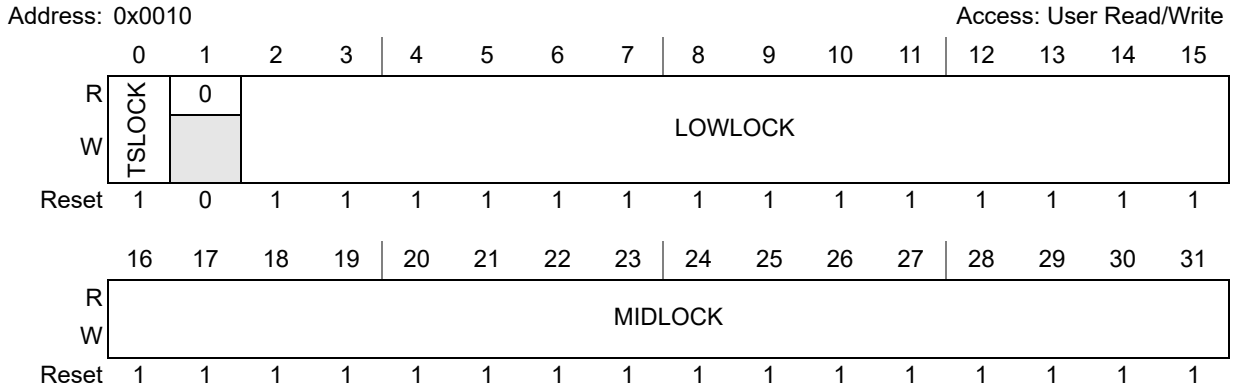

Figure 413. Lock 0 register (LOCK0)

Table 529. LOCK0 field descriptions

Field	Description
0 TSLOCK	UTEST NVM block lock This bit is used to lock the UTEST NVM from programming (UTEST NVM is not erasable). The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0.TSLOCK with sidebands *flh_plock0.31* in order to evaluate protection against program. 0 Test Address Space Block is unlocked and can be modified. 1 Test Address Space Block is locked and cannot be modified.

Table 529. LOCK0 field descriptions (continued)

Field	Description
2:15 LOWLOCK	Low address space block lock These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the LOWLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the LOWLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Low Address Space Block is unlocked and can be modified. 1 Low Address Space Block is locked and cannot be modified.
16:31 MIDLOCK	Mid address space block lock These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the MIDLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the MIDLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Mid Address Space Block is unlocked and can be modified. 1 Mid Address Space Block is locked and cannot be modified.

37.3.2.5 Lock 1 register (LOCK1)

The LOCK1 (High/Data Address Space Block Locking) register provides a means of protecting blocks from being modified. HIGHLOCK bits corresponding to nonexistent blocks on are read as ‘1’.

- To determine the effective status of the High Address Space, combine (Or) LOCK1 with sidebandsflh_plock1 – in order to evaluate protection against program
- flh_elock1 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK1 is that no modification occurs and PEG is set to ‘1’.

Figure 414. Lock 1 register (LOCK1)

Table 530. LOCK1 field descriptions

Field	Description
16:31 HIGHLOCK	High address space block lock These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the HIGHLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

37.3.2.6 Lock 2 Register (LOCK2)

The LOCK2 (256K Address Space Block Locking) register provides a means of protecting blocks from being modified. The A256KLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the A256KLOCK Address Space, combine (Or) LOCK2 with sidebands:

- flh_plock2 – in order to evaluate protection against program
- flh_elock2 – in order to evaluate protection against erase

The effect of programming/erasing a block protected with LOCK2 is that no modification occurs and PEG is set to ‘1’.

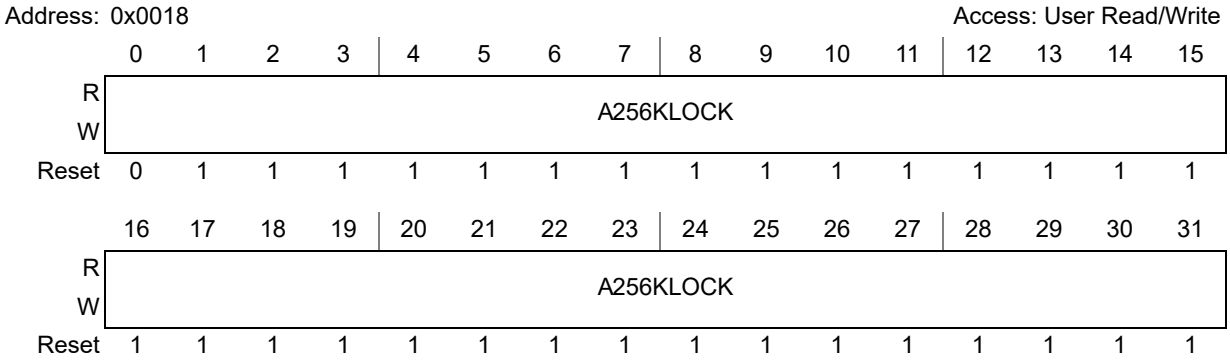

Figure 415. Lock 2 Register (LOCK2)

Table 531. LOCK2 field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the 256 KB blocks starts with A256KLOCK[0] and continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the A256KLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the A256KLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 A256K Address Space Block is unlocked and can be modified. 1 A256K Address Space Block is locked and cannot be modified.

37.3.2.7 Lock 3 Register (LOCK3)

The LOCK3 (256K Address Space Block Locking) register provides a means of protecting blocks from being modified. The A256KLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the A256KLOCK Address Space, combine (Or) LOCK3 with sidebands:

- flh_plock3 – in order to evaluate protection against program
- flh_elock3 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK3 is that no modification occurs and PEG is set to ‘1’.

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[63:32] These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the 256 KB blocks starts with A256KLOCK[32] and continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the A256KLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the A256KLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 A256K Address Space Block is unlocked and can be modified. 1 A256K Address Space Block is locked and cannot be modified.

37.3.2.8 Alternate Lock 0 register (LOCK0A)

The Alternate LOCK0A (Low/Mid Address Space Block Locking) register provides a means of protecting blocks from being modified on the alternate program and erase interface. LOWLOCKA and MIDLOCKA bits corresponding to non existent blocks are read as ‘1’.

The effective status of the Alternate Low Address Space is not affected by sidebands as in the Main Interface

The effect of programming/erasing a block protected with LOCK1A is that no modification occurs and PEGA is set to ‘1’.

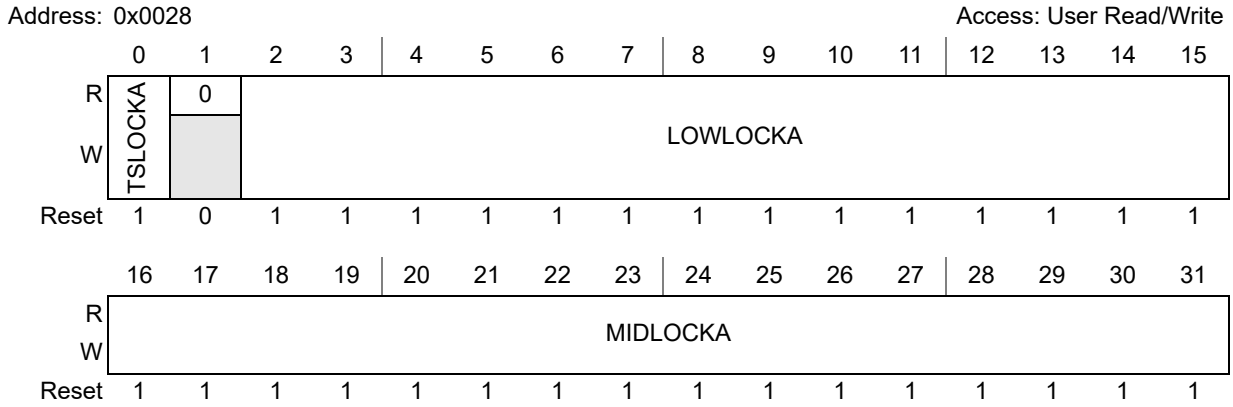

Figure 417. Alternate Lock 0 register (LOCK0A)

The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0A.TSLOCKA with sidebands *flh_aplock_utest* in order to evaluate protection against program. 0 The UTEST Block is unlocked and can be modified on the alternate interface. 1 The UTEST Block is locked and cannot be modified on the alternate interface.

Table 533. LOCK0A field descriptions (continued)

Field	Description
2:15 LOWLOCKA	Alternate Low address space block lock These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the LOWLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the LOWLOCKA bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Alternate Low Address Space Block is unlocked and can be modified. 1 Alternate Low Address Space Block is locked and cannot be modified.
16:31 MIDLOCKA	Alternate Mid address space block lock These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the MIDLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the MIDLOCKA bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Alternate Mid Address Space Block is unlocked and can be modified. 1 Alternate Mid Address Space Block is locked and cannot be modified.

37.3.2.9 Alternate Lock 1 register (LOCK1A)

The Alternate LOCK1A (Alternate High Address Space Block Locking) register provides a means of protecting blocks from being modified on the alternate program and erase interface. HIGHLOCK bits corresponding to nonexistent blocks on are read as ‘1’.

The effect of programming/erasing a block protected with LOCK1a is that no modification occurs and PEGa is set to ‘1’.

Table 534. Alternate LOCK1A field descriptions

Field	Description
16:31 HIGHLOCKA	Alternate High address space block lock These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the HIGHLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

37.3.2.10 Select 0 register (SEL0)

The SEL0 (Low/Mid Address Space Block Select 0) register provides a means to select blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL0 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 37.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL0 at the start of the Erase operation) while writing has no effect.

Figure 419. Select 0 register (SEL0)

Table 535. SEL0 field descriptions

Field	Description
2:15 LOWSEL	Low address space block Select The block numbering for the Low Blocks starts at LOWSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared. – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size) the corresponding LOWSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 Low Address Space Block is unselected for Erase. 1 Low Address Space Block is selected for Erase.

Table 535. SEL0 field descriptions (continued)

Field	Description
16:31 MIDSEL	Mid address space block Select The block numbering for the Mid Blocks starts at MIDLSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared. – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size), the corresponding MIDSEL bits default to unselected and are not writable.The reset value is always ‘0’, and register writes have no effect. 0 Mid Address Space Block is unselected for Erase. 1 Mid Address Space Block is selected for Erase.

37.3.2.11 Select 1 register (SEL1)

The SEL1 (High Address Space Block Select Register 1) provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL1 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 37.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL1 at the start of the Erase operation) while writing has no effect.

Figure 420. Select 1 register (SEL1)

Table 536. SEL1 field descriptions

Field	Description
16:31 HIGHSEL	High/Data address space block Select 1 The block numbering for the High Blocks starts at HIGHSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared. – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size) the corresponding HIGHSEL bits default to unselected and are not writable. The reset value is always '0' and register writes have no effect. 0 High Address Space Block is unselected for Erase. 1 High Address Space Block is selected for Erase.

37.3.2.12 Select 2 register (SEL2)

The SEL2 (256K Address Space Block Select 2) register provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL2 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 37.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL2 at the start of the Erase operation) while writing has no effect.

Figure 423. Module Configuration Register 2 (MCR2)

Table 539. MCR2 field descriptions

Field	Description
2 PAEE	Parallel Address Encode Error On every Read request to the Flash, the incoming address is compared to an encoded address (row, column, and block) from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error is recorded. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally 1 An Address Encode Error occurred during a previous Read.
3 PEEE	Parallel EDC after ECC Error PEEE provides information on previous reads monitoring the EDC after ECC feature. On every Read request to the Flash, ECC parity is recomputed (encoding) just after ECC decoding, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error is reported. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally 1 A previous Read may have been corrupted.
4:7 PDWEE	Parallel Double Word Uncorrectable ECC Error PDWEE identifies which Double Word is involved in ECC Uncorrectable Error Event. In Code Flash 4 Double Words are read in parallel and ECC is evaluated on a couple of Double Words basis. Therefore PDWEE value could be: 1111 if an ECC Uncorrectable Error is found in both couples of Double Words 1100 if an ECC Uncorrectable Error is found in the couple of Double Words at high address 0011 if an ECC Uncorrectable Error is found in the couple of Double Words at low address 0000 if no ECC Uncorrectable Error is found PDWEE is a read only. Flags bits get cleared when EER is cleared.
11 PSBC1	Parallel Single Bit Correction 1 PSBC1 provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection or ECC Double Error correction, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE1). 0 Reads are occurring normally. 1 An ECC Single Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.

Table 539. MCR2 field descriptions (continued)

Field	Description
16 PEER	Parallel ECC Event Error PEER provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. PEER may not be set to ‘1’ by the user. PEER is not set for a ECC correctable Error detection and related correction event. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An ECC uncorrectable Error occurred during a previous Read. In Code Flash, with 128b ECC coding, ECC error is evaluated on couple of Double word basis. In Data Flash for EEE, ECC error is evaluated on each Double word.
17 PRWE	Parallel Read-while-Write event Error PRWE provides information on previous Reads during a Modify operation. Read-While-Write Error means that a Read access to the Flash Array partition has occurred while the FPEC was performing a Program or Erase operation or an Array Integrity Check on the same partition. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A RWW Error occurred during a previous Read.
18 PSBC	Parallel double Bit Correction PSBC provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE). 0 Reads are occurring normally. 1 An ECC Double Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.

37.3.2.15 Program Address register (PAR)

The Program Address register provides the last successful address programmed. A successful program is defined as a program operation of data that is not all 1s, to an

unlocked block and the operation results in MCR.PEG returning a ‘1’. This value is held until the next successful address program event.

Address: 0x004C Access: User Read

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 424. Program Address register (PAR)

Table 540. PAR field descriptions

Field	Description
8:28 PAR	Address The Address Register provides the last successful address programmed through the Main Interface. Address given is in Flash format and has to be intended as in the Flash memory Map: offset respect to absolute address. Mapping can be found in *Section 37.3.2.16: Address register (ADR)*

37.3.2.16 Address register (ADR)

The Address register provides the first failing address in the event of module failures (ECC, RWW or FPEC). ADR captures the first failing address for the modes listed in *Table 542* according to the priority rules in *Table 543*.

In case of Array Integrity Check or Margin Read with Break Point enabled (UT0.AIBPE=1), the ADR value matches the address where the Break Point was triggered only when the current run (first start or re-start after a breakpoint (NAIBP cleared)) starts with MCR.ERR and MCR.SBC flags cleared, otherwise the ADR priority rule overrides Break Point.

Address: 0x0050 Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 425. Address register (ADR)

Table 541. ADR field descriptions

Field	Description
0 SAD	Test Address When this bit is high, the address indicated by ADDR[23:3] belongs to the Test Block.
8:28 ADDR	Address The Address Register provides the first failing address in the event of ECC Uncorrectable error (MCR.EER set) or the first failing address in the event of RWW error (MCR.RWE set), or the address of a failure that may have occurred in a FPEC operation (MCR.PEG cleared). The Address Register also provides the first address at which a ECC correction occurs (MCR.SBC or MCR.SBC1, or both are set) if the SoC is configured to show this feature through UT0.SBCE or UT0.SBCE1, or both. The ECC uncorrectable error detection takes the highest priority, followed by the RWW error, the FPEC error and the ECC error corrections. When accessed, ADR provides the address related to the first event occurred with the highest priority. In case of a simultaneous ECC Events Detection, bits ADDR[4] and ADDR[3] output ‘0’. In User mode the Address Register is read only. In Modify Mode ADDR can be updated on FPEC Error on the whole Flash Memory address space. In User Test Mode ADDR can be updated on Error events on the whole Flash Memory address space. In Read and RWW Modes ADDR can be updated on Error belonging to the address space of the primary Read-While-Read Partition 0. Address given is in Flash format and has to be intended as in the Flash memory Map.

Table 542. ADR update mode list

Mode	Update on error	Note
Read	ECC Triple Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	—
Modify	FPEC error	—
RWW	Read-While-Write error	In RWW all Read and Modify cause of update on error may also occur
User Test	ECC Triple Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	With Break Point enabled (UT0.AIBPE=1), ADR requires MCR.ERR and MCR.SBC to be cleared

Table 543. ADR content: priority list

Priority level	Error flag	ADR content
1	MCR.EER = 1	Address of first ECC Uncorrectable Error
2	MCR.RWE = 1	Address of first RWW Error

Table 543. ADR content: priority list (continued)

Priority level	Error flag	ADR content
3	MCR.PEG = 0	Address of first FPEC Error
4	MCR.SBC = 1	Address of first ECC Double Error Correction
5	MCR.SBC1 = 1	Address of first ECC Single Error Correction

37.3.2.17 User Test 0 register (UT0)

The User Test 0 register feature gives the user of the Flash Memory module the ability to perform test features on the Flash.

The User Test 0 register allows control of the way the Flash content check is performed. Bits MRE, MRV and AIS of the User Test 0 register are not accessible when MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

Figure 426. User Test 0 register (UT0)

Table 550. UT0 field descriptions

Field	Description
0 UTE	User Test Enable This status bit gives indication when User Test is enabled. All bits in UT0 and UM0–UM9 are locked when this bit is ‘0’. This bit is not writable to a ‘1’, but may be cleared. The reset value is ‘0’. To set UTE, write the password 0xF9F99999 to the UT0 register. The UTE password is only accepted if PGM=0 and ERS=0 (Program and Erase are not being requested). UTE can only be cleared if AID=1, MRE=0 and AIE=0. While clearing UTE, writes to set AIE or MRE are ignored.
1 SBCE	Double Bit Correction Enable This bit, when high, enables to flag the information about any eventual ECC Double Bit Correction in the Flash array (MCR.SBC and ADR). This is true in read mode and in Array Integrity Check. SBCE is also used as an Enable for interrupt signals created by the embedded Flash memory. ECC corrections that occur when SBCE is cleared are not logged.

Table 550. UT0 field descriptions (continued)

Field	Description
8 SBCE1	Single Bit Correction Enable This bit, when high, enables to flag the information about any eventual ECC Single Bit Correction in the Flash array (MCR.SBC1 and ADR). This is true in read mode and in Array Integrity Check. SBCE1 is also used as an Enable for interrupt signals created by the embedded Flash memory. ECC corrections that occur when SBCE1 is cleared are not logged.
13 CPR	Customer Programmable Read Voltage and Reference Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block when reading Read-While-Read partition 0. This bit is used to control the error generation for the Customer Programmable Detection area in the RWR1_UTEST block when reading Read-While-Read partition 1. If this bit is set and the Customer Programmable Detection location in UTEST is read, a Read Voltage and Reference Error detection is set. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled.
14 CPA	Customer Programmable Address Encode Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block when reading Read-While-Read partition 0. This bit is used to control the error generation for the Customer Programmable Detection area in the RWR1_UTEST block when reading Read-While-Read partition 1. If this bit is set, and the Customer Programmable Detection location in UTEST is read an Address Encode Error detection is set. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block when reading Read-While-Read partition 0. This bit is used to control the error generation for the Customer Programmable Detection area in the RWR1_UTEST block when reading Read-While-Read partition 1. If this bit is set, and the Customer Programmable Detection location in UTEST is read a EDC after ECC Error detection is set. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
19 VTD	Vth Distribution To enable Vth Distribution, VTD may be set. Effective setting of this bit is allowed when SoC has been brought into Failure Analysis Mode. When Vth Distribution is enabled, multiple run are needed to assess the Vth status of the cells belonging to selected blocks. At the end of each run NAIPB has to be checked and if equals to ‘1’ it has to be cleared to start an increased voltage step run. See NAIBP description for more information. 0 Vth Distribution is not enabled. 1 Vth Distribution is enabled.

Table 550. UT0 field descriptions (continued)

Field	Description
22 NAIBP	Next Array Integrity Break Point If AIBPE is set, NAIBP is set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to ‘1’ but may be cleared to ‘0’. Clearing NAIBP to ‘0’ enables the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID is set with NAIBP remaining ‘0’. If VTD is set, NAIBP is set once a voltage step run has been completed during the voltage sweep in Vth Distribution. NAIBP is not writable to ‘1’ but may be cleared to ‘0’. Clearing NAIBP to ‘0’ enables the Vth Distribution run yo be re-started with an increased voltage step. If the Vth Distribution completes the last voltage step run, AID is set with NAIBP remaining ‘0’. 0 Array Integrity-Vth Distribution is not currently at a break point. 1 Array Integrity-Vth Distribution is at a break point.
23 AIBPE	Array Integrity Break Point Enable To enable breakpoints during an Array Integrity test, AIBPE may be set. When breakpoints are enabled, if the run has been started with MCR.ERR (and MCR.SBC when UT0.SBCE=1) flag cleared, on the eventual occurrence of a breakpoint condition, MCR flags and ADR value may be updated. See NAIBP description for more information about Array Integrity breakpoints. 0 Array Integrity breakpoints are not enabled. 1 Array Integrity breakpoints are enabled during Array Integrity Checks.
25 AISUS	Array Integrity Suspend AISUS toggles Suspend of an Array Integrity - Margin Read Operation. AISUS can be written to ‘1’ only when AID is low AISUS can be written to ‘0’ only when AID is high. Attempting to Write AISUS and AIE on the same clock cycle results in only AIE being written. 0 Array Integrity sequence not suspended. 1 Array Integrity sequence is suspended.
26 MRE	Margin Read Enable MRE enables margin reads to be done. MRE combined with MRV enables User Margin mode reads to be done. Margin reads run on a block-by-block basis in linear address sequence selected by SEL0, SEL1 and SEL2. This bit is not accessible when MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Margin Read is not enabled. 1 Margin Read is enabled.
27 MRV	Margin Read Value If MRE is high, MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). This bit is not accessible whenever MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Zero’s (programmed) margin reads are requested (if MRE=1). 1 One’s (erased) margin reads are requested (if MRE=1).

Table 550. UT0 field descriptions (continued)

Field	Description
29 AIS	Array Integrity Sequence AIS determines the address sequence to be used during Array Integrity checks. The default AIS=0 checks the read propagation paths along proprietary sequences followed by user code. The sequential run sequence time is significantly shorter than the proprietary sequence. AIS is not writable if AIE is high. This bit is not accessible whenever MCR.DONE or UT0.AID are low: reading returns indeterminate data while writing has no effect. 0 Array Integrity sequence is proprietary sequence. 1 Array Integrity sequence is sequential.
30 AIE	Array Integrity Enable Setting AIE to '1' starts the Array Integrity Check and the Margin Read on all selected blocks. The sequence is selected by AIS and the MISR (UM0–UM9) is checked on completion to determine if a correct signature is obtained. AIE can be set only if MCR.ERS, MCR.PGM and MCR.EHV are all low. AIE is not simultaneously writable to '1' while UTE is being cleared to '0'. Clearing AIE terminates the check when an Array Integrity operation finishes (AID=1) and aborts the check when and Array Integrity operation is ongoing (AID=0). AIE remains '1' when the Array Integrity Check - Margin read are suspended or are in breakpoint and cannot be cleared. (AIE can be cleared if NAIBP=0 and AISU=0) 0 Array Integrity Check and Margin Read and are not enabled. 1 Array Integrity Check and Margin Read are enabled.
31 AID	Array Integrity Done AID is set to indicate that the Array Integrity Check - Margin Read is complete and the MISR (UM0–9) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set) and the breakpoint condition is met. AID may also assert if Suspend is set (AISUS 0–1). AID can not be written, and is status only. 0 Array Integrity Check is on-going. 1 Array Integrity Check is done.

37.3.2.18 User Multiple Input Signature registers

The Multiple Input Signature registers allow evaluation of the Array Integrity or Margin Read run on a block-by-block basis by accumulating signatures from data bit fields.

These registers are not accessible whenever MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

The registers can be written in order to seed signatures before starting an AIC or MR operation.

Note: Do not write to the MISR registers during an Array Integrity operation (including Suspend or Breakpoint) as it may alter the final signature in an unpredictable way.

If reads extend into an invalid address location during address sequencing (that is greater than the maximum address for a given array size), reads are still executed to the array but

the results are not deterministic: MISR registers are not recalculated and the previous value is retained.

37.3.2.18.1 User Multiple Input Signature 0 register (UM0)

UM0 represents bits 31–0 of the whole 288-bit word (4 doublewords including ECC).

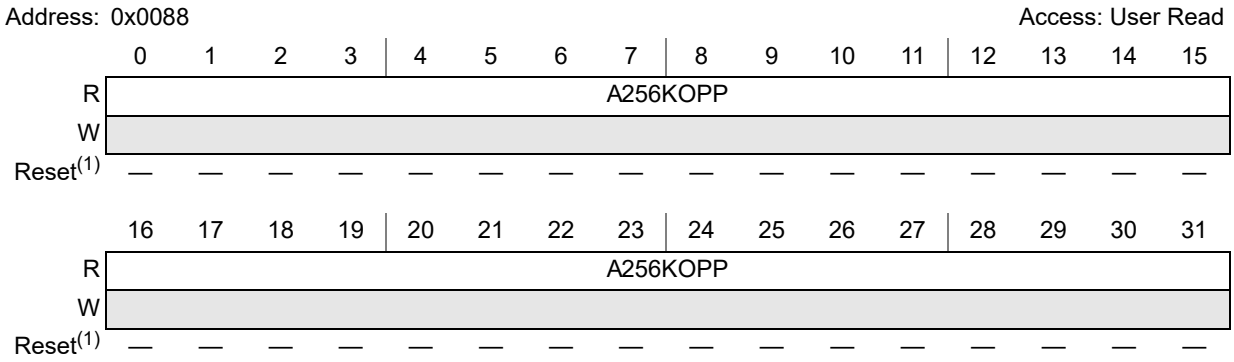

Figure 438. Over-program protection 1 register (OPP1)

Table 562. OPP1 field descriptions

Field	Description
16:31 HIGHOPP	High address space Over Program Protection The block numbering for the High Blocks starts at HIGHOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The HIGHOPP field is not writable, and is status only. The default value of the HIGHOPP bits is not over-programming protected. When blocks are not present (due to configuration or total memory size), the HIGHOPP bits default to not over-programming protected and will remain 0. 0 High Address Space Block is unprotected from over-programming. 1 High Address Space Block is protected from over-programming.

37.3.2.19.3 Over-program protection 2 register (OPP2)

The A256K Address Space Block is covered by the Over Program Protection 2 (OPP2) register.

1. A reset value of "—" indicates that the value is set at the factory and can vary among different applications

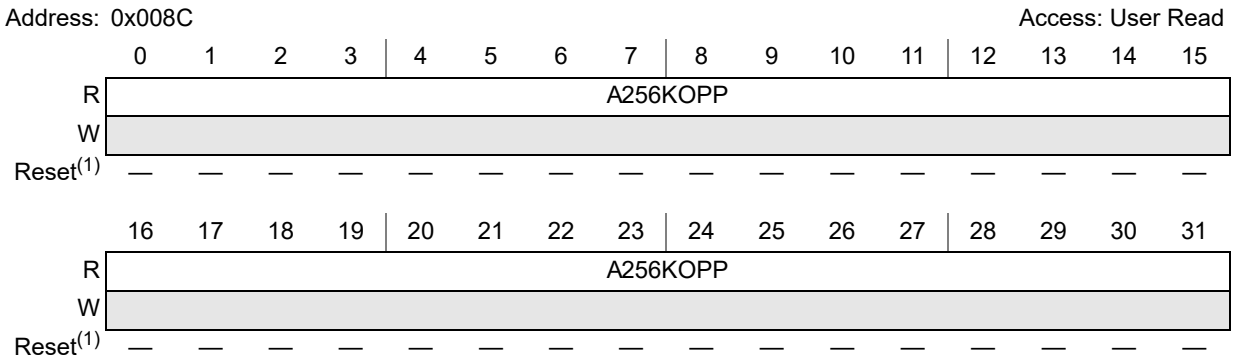

Figure 439. Over-program protection 2 register (OPP2)

Table 563. OPP2 field descriptions

Field	Description
0:31 A256KOPP	256K Address Space Block Over Program Protection A256KOPP[31:0] The block numbering for the 256 KB Blocks starts at A256KOPP[0] and continues until all blocks are accounted for. The A256KOPP field is not writable, and is status only. The default value of the A256KOPP bits is not over-programming protected. When blocks are not present (due to configuration or total memory size), the A256KOPP bits default to not over-programming protected and will remain 0. 0 A256K Address Space Block is unprotected from over-programming. 1 A256K Address Space Block is protected from over-programming.

37.3.2.19.4 Over-program protection 3 register (OPP3)

The 256K high Address Space is covered by the Over Program Protection 3 (OPP3) register.

1. A reset value of "—" indicates that the value is set at the factory and can vary among different applications

Figure 440. Over-program protection 3 register (OPP3)

Table 564. OPP3 field descriptions

Field	Description
0:31 A256KOPP	256K Address space Over Program Protection A256KOPP[63:32] The block numbering for the 256 KB Blocks starts at A256KOPP[32] and continues until all blocks are accounted for. The A256KOPP field is not writable, and is status only. The default value of the A256KOPP bits is not over-programming protected. When blocks are not present (due to configuration or total memory size), the A256KOPP bits default to not over-programming protected and will remain 0. 0 A256K Address Space Block is unprotected from over-programming. 1 A256K Address Space Block is protected from over-programming.

37.3.2.20 Test Mode Disable Password Check register (TMD)

The Test Mode Disable Password Check (TMD) register provides a means of entering the password to be matched with the one stored in UTEST location in order to allow manufacturer access to protected Test Mode blocks by writing 0x5A4B_3C2D in the Test Mode Disable Seal location.

Address: 0x0090 Access: User Write

Figure 441. Test Mode Disable Password Check register (TMD)

Table 565. TMD field descriptions

Field	Description
0:31 PWD	The Test Mode Disable Check register is used as a location to provide a password challenge to unlock blocks selected to be sealed as part of the Test Mode Disable seal mechanism. Please see *Section 37.4.8.2: Test Mode Disable* for more information. Writes to the register have no effect except for a password challenge. Reads to this register will always return 0. The register's reset value is 0. **Note:** PWD bit field is byte-reversed compared to UTEST TMD password: for instance, if UTEST TMD password is written 0x01020304, the PWD bit field must be written 0x04030201

37.3.2.21 HSM Alternate selector registers

HSM Alternate selectors assign blocks from default to ALTERNATE Program & Erase interface. These registers show the HSM Alternate assignment status. See *Section 37.4.6: Alternate program and erase interface*.

37.3.2.21.1 HSM ALT-SEL register 0 (ALTSEL0)

The Low/Mid Address Space is assigned between MAIN and ALT Interface. Through the HSM ALT-SEL register it is possible to read the actual status of the assignment.

Address: 0x0094 Access: User Read

37.3.2.24 Parallel Address register (ADR2)

The Parallel Address register provides the first failing address in the event of module failures (ECC) or the first address at which ECC single error correction occurs, when Reads are performed from Read While Read 1 interface. ADR2 captures the first failing address for the modes listed in *Table 542* according to the priority rules in *Table 543*.

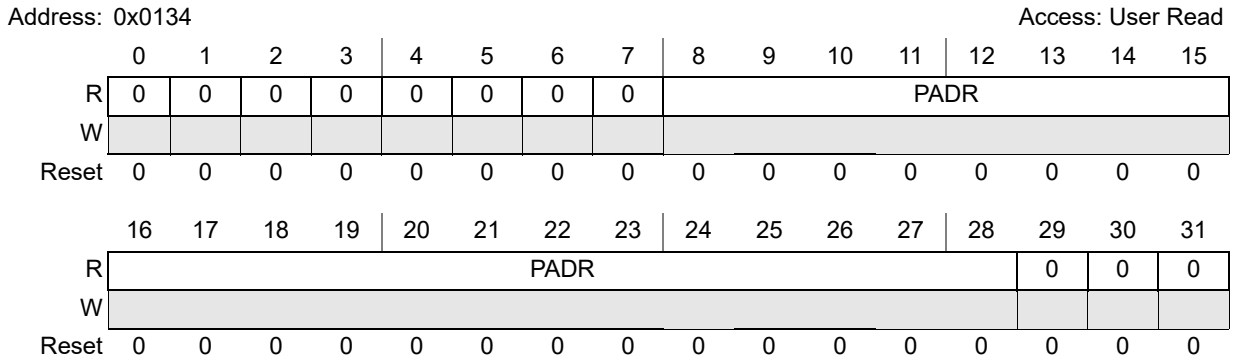

Figure 452. Parallel Address register (ADR2)

Table 576. ADR2 field descriptions

Field	Description
8:28 PADR	Parallel Address The Address Register provides the first failing address in the event of ECC Uncorrectable error (MCR2.PEER set) or the first failing address in the event of RWW error (MCR2.PRWE set). The Address Register also provides the first address at which a ECC correction occurs (MCR2.PSBC or MCR2.PSBC1, or both are set) if the SoC is configured to show this feature through UT0.SBCE or UT0.SBCE1, or both. The ECC uncorrectable error detection takes the highest priority, followed by the RWW error, and the ECC error corrections. When accessed, PADR provides the address related to the first event occurred with the highest priority. In case of a simultaneous ECC Events Detection, bits PADR[4] and PADR[3] output '0'. In Read and RWW Modes PADR can be updated on Error belonging to the address space of the primary Read-While-Read Partition 1. Address given is in Flash format and has to be intended as in the Flash memory Map.

Table 577. ADR2 update mode list

Mode	Update on error	Note
Read	ECC Triple Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	—
RWW	Read-While-Write error	In RWW all Read and Modify cause of update on error may also occur
User Test	ECC Triple Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	With Break Point enabled (UT0.AIBPE=1), ADR requires MCR.ERR and MCR.SBC to be cleared

Table 578. ADR2 content: priority list

Priority level	Error flag	ADR2 content
1	MCR2.PEER = 1	Address of first ECC Uncorrectable Error
2	MCR2.PRWE = 1	Address of first RWW Error
3	MCR2.PSBC = 1	Address of first ECC Double Error Correction
4	MCR2.PSBC1 = 1	Address of first ECC Single Error Correction

For the address mapping, refer to *Section 37.3.2.16: Address register (ADR)* description.

37.4 Functional description

This chapter describes the details of all the modes of operation available to the Flash Memory module.

37.4.1 Reset

A reset is the highest priority operation for the Flash Memory module and terminates all other operations.

The Flash Memory module uses reset to initialize register and status bits to their default reset values. If the Flash Memory module is executing a Program or Erase operation (MCR.PGM=1 or MCR.ERS=1) and a reset is issued, the operation is immediately terminated and the module disables the high voltage circuits.Reset terminates all operations and forces the Flash Memory module into Read mode ready to receive Read/Write accesses.

Warning: Reset and Power-Off must not be used as a systematic way to terminate a Program or Erase operation.

After reset is negated Read register access may be performed, although registers that require updating from shadow information or other inputs may not read updated values until MCR.DONE transforms. MCR.DONE may be polled to determine if the Flash Memory module has transitioned out of reset. Note that the registers cannot be written until MCR.DONE is high.

37.4.2 Power-down mode (Disable mode)

The Power-down (or Disable) mode allows the turning-off of all Flash DC current sources. All power dissipation in this mode is due solely to leakage.

In Power-down mode no Read from or Write to the Flash array is possible. Every Flash array Read access executed when the Power-down mode is active outputs invalid data,.

The user may not read some registers (UM0–UM9 and part of UT0) until the Power-down mode is exited.On the contrary, Write access is locked on all the registers in Power-Down mode.

When enabled the Flash Memory module returns to its predisable state in all cases unless in the process of executing an Erase or a Program High Voltage operation at the time of disable. If the Flash Memory module is disabled during an Erase operation, the operation is suspended and MCR.ESUS bits are set to ‘1’. The user may resume the Erase operation at the time the module is enabled by clearing MCR.ESUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is disabled during a program operation, the operation is suspended and MCR.PSUS bit is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR.PSUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is disabled during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled PSUS must be cleared first to resume the program. Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

If the Flash Memory module is put in Power-down mode and the Vector Table remains mapped in the Flash Address space, the user must be mindful that the Flash Memory module significantly increases the interrupt response time by adding several Wait States.

Note: Do not enter Low-power mode when the Power-down mode is active.

37.4.3 Low-power mode (Sleep mode)

The Low-power (or Sleep) mode turns-off most of the DC current sources within the Flash Memory module. Wake-up time from Low-power mode is faster than wake-up time from Power-down mode.

In Low-power mode no Read from or Write to the Flash array is possible. Every Read access executed when the Low-power mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the Low-power mode is exited. Write access is locked on all the registers in Low-power mode.

When exiting from Low-power mode the Flash Memory module returns to its presleep state in all cases unless in the process of executing an Erase High Voltage operation at the time of entering sleep mode. If the Flash Memory module is put in sleep mode during an Erase operation, MCR.ESUS is set to ‘1’. The user may resume the Erase operation at the time the module exits from sleep by clearing MCR.ESUS. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during a program operation, the operation is suspended and MCR.PSUS is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR.PSUS. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled, PSUS must first be cleared for the program to resume. The Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

Note: Do not enter Power-down mode when the Low-power mode is active.

37.4.4 Read mode

Read mode is the active mode of operation of the Flash Memory module in which the Flash array can be read or ‘written’ (the so-called Interlock Write), or the Flash registers can be read or written.

The Flash Memory module enters Read mode when exiting from reset. The default state of the Flash Memory module is Read mode.

The main spaces (Low, Mid, High, and 256K) and UTEST address space of Flash array can only be read in Read mode.

Flash registers can even be read when the module is in Power-down or Low-power mode (except a few documented registers) as well as in Read mode. However, Flash registers can only be written while in Read mode.

Flash memory module is in Read mode, granting the same access time, under the following conditions:

- The Read state is active when the module is enabled (User Mode Read)
- The Read state is active when MCR.ERS and MCR.ESUS are high and MCR.PGM is low (Erase Suspend)
- The Read state is active when MCR.PGM and MCR.PSUS are high (Program Suspend)
- The Read state is active when MCR.PGM or MCR.ERS are high and High Voltage operation is ongoing on one partition, thus MCR.EHV is high (condition referred as Read-While-Write). In this case reads done on the other partitions are allowed, while reads done to the partition being operated on (either Erase or Program) result in an error with MCR.RWE set and the data read back possibly being random including the possibility of ECC errors.
- The Read state is active when MCRA.ERSA and MCRA.ESUSA are high and MCRA.PGMA is low (Alternate Erase Suspend)
- The Read state is active when MCRA.PGMA and MCRA.PSUSA are high (Alternate Program Suspend)
- The Read state is active when MCRA.PGMA or MCRA.ERSA are high and High Voltage operation is ongoing on one partition, thus MCRA.EHVa is high (condition referred as Alternate Read-While-Write). In this case reads done on the other partitions are allowed, while reads done to the partition being operated on (either Alternate Erase or Alternate Program) result in an error with MCRA.RWEA set and the data read back possibly being random including the possibility of ECC errors.

37.4.4.1 Read While Read

Flash Memory Module is organized in Two independent Read Interfaces. Each Read interface is associated exclusively to a specific group of Read While Write Partitions. Flash Memory Module supports independent and Parallel Read access through the Two interfaces, namely Read-While-Read. Read interface assignment to Read While Write Partition is described in the following table:

Table 579. Read Interface Assignment

Read-While-Read Interface 0	Read-While Read Interface 1
RWW P0	—
RWW P1	—
RWW P2	—
RWW P3	—
RWW P4	—
—	RWW P5

Code Flash partitions reads return 256 bits (1 page = 4 doublewords). Data Flash partition reads return 128 bits. Register reads return 32 bits (1 word).

Flash array reads are performed through the Bus Interface Unit. In many cases the BIU applies “Read Page Buffering” to allow sequential reads to be executed with higher performance. This can provide data coherency issues that must be handled by software.

Data coherency may be an issue after a program or an Erase operation, as well as Test block operations.

Flash array reads to invalid locations result in indeterminate data. Invalid locations occur when addressing points to blocks that are not included in the Flash memory Map of any partition. Interlock writes to invalid locations result in an interlock occurring, but attempts to program these blocks do not eventuate since they are forced into a locked state. Erase occurs to selected and unlocked blocks even if the Interlock Write is to an invalid location.

Register reads to unmapped register address spaces return all 0's. Registers writes to unmapped register address spaces have no effect.

Simultaneous Read cycles on the Flash array and Read/Write cycles on the registers are possible, but not simultaneous register Read/Write accesses with Flash Array Interlock Writes are forbidden.

37.4.4.2 Error correction code

The Flash Memory module implements a strategy for improving the reliability of the data stored in Flash via the use of Error Correction Code.
In Code Memory the ECC size is 128 bits with 17 ECC bits associated. In Data Memory the ECC size is 64 bits with 15 ECC bits associated.
ECC function is implemented in such a way to guarantee Double Error Correction and Triple Error Detection (DEC-TED).
ECC coding has all 0's (intended as data and parity) as an invalid word and all 1's as a valid word.

In addition to providing the requested Read data, the Flash also provides output sidebands reflecting the status of the single and double error corrections and triple error detections performed at the end of each Read.

For functional safety coverage, Flash performs an EDC post ECC operation at every Read to detect mismatches in the ECC logic detection and correction. The result is output as sideband. Also active is a monitor circuit that checks the reference current in the sense amplifiers, including control of the internally regulated Read voltage, to prevent anomalous Read operation.

ECC circuitry provides single-bit fault correction used to achieve automotive reliability targets. Some units experience single-bit corrections throughout the life of the product with no impact on product reliability.

37.4.4.2.1 Multi-bits error management (more than 3 bits error >=4)

In this case, we can't predict the behavior without knowing the original data and the position of the bit flips. The hardware can react in multiple ways:

1. do nothing (that is, not signaling of any flag)
2. assert either SBC, SBC1, or EER without EEE
3. assert either SBC, SBC1, or EER with EEE
4. assert EEE only.

Note: SBC and SBC1 reporting have to be activated in UT0.

It is worth highlighting that by design the purpose of the ECC logic is not to detect multi-bit errors but cope with errors in the data and parity containing maximum 3 bit flips. In this condition, the EDC after ECC monitors the integrity of the ECC logic.

Other mechanisms must detect multi-bit errors or avoid their occurrence.

For example running the Array Integrity Check once after the boot before the safety application starts to protect the Data with an application level checksum.

An example of a mechanism that decreases the possibility of multi-bit errors in the array is the multiplexing. The bits of the same word are not one next to each other, but they are spaced of a fixed number of bits.

37.4.4.2.2 EEPROM emulation

The chosen ECC allows some bit manipulation so that a doubleword can be re-written several times without needing an erase of the block. This allows the use of a doubleword to store flags useful for the EEPROM emulation.

The sequence provided in *Table 580: Bits Manipulation: doublewords preserving ECC integrity* is related to Data Memory (therefore would not apply on Code Memory). The ECC coding allows, starting from an all 1's doubleword value, to rewrite subsequent predefined code values changing only 0s into 1s and preserving the ECC integrity.

Caution: Predefined code values have to be applied following the exact Byte order, as reported in the table.

Table 580. Bits Manipulation: doublewords preserving ECC integrity

Doubleword	ECC parity bits	Sequence
B7-B6-B5-B4-B3-B2_B1-B0		
0xFFFF_FFFF_FFFF_FFFF	0x7FFF	erase
0xFFFF_FFFF_FFFF_FFFE	0x3C88	write1
0xFFFF_FFFF_FEFE_FC80	0x3C88	write2
0xFFFF_FFFC_FEFC_FC80	0x1880	write3
0xFCFC_FFFC_FCFC_F880	0x1880	write4
0xFCF8_F8F0_FCE0_E080	0x1800	write5
0xF8F8_E080_F0E0_E000	0x1000	write6
0xE0E0_E080_E0E0_C000	0x1000	write7
0xE000_8000_00C0_0000	0x1000	write8

37.4.4.3 Flash address generation check

For functional safety coverage, Flash provides output sidebands reflecting the re-encoded address used to perform the actual Read operation. In the re-encoding process both word line and column within the selected block are evaluated. For the completion of the re-encoding operation, the addresses related to block selections are also computed. Re-encoding circuitry is able to detect both no-selection as well as multi-selection. Flash provides a self-check of address consistency comparing at each Read the sampling of the current Read address with the re-encoded one, and in case of mismatch an error sideband is set.

37.4.5 Modify mode

All the Modify operations of the Flash Memory module are managed through the Flash User Registers interface. This interface is referred as MAIN.

When a Modify operation is active on some blocks, no Read access is possible on any other block of the same Flash Partition. The Read-While-Modify is supported only among different Flash partitions.

During a Flash Modify operation any attempt to read any Flash location in the same Flash partition outputs invalid data and MCR.RWE is automatically set.

If a reset occurs during a Modify operation, the operation is immediately terminated and the module is reset to Read mode. The data integrity of the Flash section where the Modify operation was terminated is not guaranteed: the interrupted Flash Modify operation must be repeated.

In general each Modify operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in MCR.PGM or MCR.ERS or UT0.MRE.
2. The second step is the definition of the operands: the address and the data for Programming, or the blocks for Array Integrity Check or Margin Read.
3. The third instruction is used to start the Modify operation by setting MCR.EHV or UT0.AIE.

Once selected, but not yet initiated, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Modify operations are shown in *Table 581*.

Table 581. Flash Modify operations

Operation	Select bit	Operands	Start bit
Doubleword Program	MCR.PGM	Address and Data by Interlock Writes	MCR.EHV
Block Erase	MCR.ERS	SEL0, SEL1, SEL2 and SEL3	MCR.EHV
Array Integrity Check	None	SEL0, SEL1, SEL2 and SEL3	UT0.AIE
Margin Read	UT0.MRE	UT0.MRV + SEL0, SEL1, SEL2 and SEL3	UT0.AIE

Once MCR.EHV (or UT0.AIE) is set, all the operands can no longer be modified until MCR.DONE (or UT0.AID) is high.

In general each Modify operation is completed through a sequence of 4 steps:

1. Wait for operation completion: wait for MCR.DONE (or UT0.AID) to go high.
2. Check operation result: check bit MCR.PEG (or compare UM0–UM9 with expected value).
3. Switch-Off FPEC by resetting MCR.EHV (or UT0.AIE).
4. Deselect current operation by clearing MCR.PGM/ERS (or UT0.MRE).

Note: Do not initiate a Modify operation on a Flash Memory module while another Modify operation is in progress on a separate module.

In the following sections, all the possible Modify operations are described with accompanying examples of the sequences needed to activate them.

37.4.5.1 Program

A Flash Program sequence operates on any doubleword within the Flash core. Up to two words within the doubleword may be altered in a single doubleword program operation. A single program operation can also alter one page (4 doublewords, 32 bytes), or 4 pages max (128 bytes in total). It is possible to program only certain doublewords in the page or the quad-page, leaving the others with their original content. Whenever the array is programmed, the ECC bits are also programmed.

ECC is handled on a 64-bit boundary in Data Flash and 128b boundary in Code Flash. Whenever you program, ECC bits are also programmed. Thus, if only one word in any given ECC segment is programmed, the adjoining word/s (in that segment) should not be programmed later on, since ECC calculation has already completed for that segment. Attempts to program the adjoining word will probably result in an operation failure. All programming operations should be from 64 bits to 1024 bits, should be 64-bit aligned for Data Flash and 128-bit aligned for Code Flash. The programming operation should completely fill selected ECC segments.

Due to the fact that Flash functions in a System with an end2end ECC scheme, ECC parity bit are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, the page program or the quad-page program contains an inconsistency between data and parity, the whole operation is rejected and a MCR.PEG=0 is set. The doublewords without data and with parity inconsistency are thus not programmed.

Programming changes the value stored in an array bit from logic ‘1’ to logic ‘0’ only. Programming cannot change a stored logic ‘0’ to a logic ‘1’. If a logic ‘0’ is attempted to be over programmed by a logic ‘1’, the resulting operation fails (MCR.PEG=0), and the 0s that are interlocked are merged (ORed) with 0s that are already present in the 64-bit ECC segment. Extreme care has to be taken when doing such an operation due to the high risk of producing ECC errors.

Addresses in locked blocks cannot be programmed. Register locked blocks cannot be programmed. Hardware locking is also available which only affects the program operation. Hardware locking is enabled by sideband signals, and if enabled, programs are prevented from accessing hardware locked blocks in the same way as program software locking.

The user may program the values in any or all of eight the words in a page with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. Only certain doublewords may be programmed within the page or the quad-page, without altering the content of the ones unselected via interlock.

The Program operation consists of the following sequence of events:

1. Change the value of MCR.PGM from ‘0’ to ‘1’.
2. Ensure the block that contains the address to be programmed is unlocked. Write the first address to be programmed with the program data. The Flash Memory module latches address bits (23:7) at this time, as well as written data. This Write is referred to as a Program Data Interlock Write. An Interlock Write may be as large as 64 bits, and as small as 32 bits (depending on the CPU bus).
3. If more than 1 word is to be programmed, write the additional address in the doubleword with data to be programmed. This is referred to as a Program Data Write.

The Flash Memory modules ignore address bits (23:7) for program data writes. The eventual unwritten data word defaults to 0xFFFFFFFF.

4. Write a logic ‘1’ to the MCR.EHV to start the internal program sequence or terminate via step 9.
5. Wait until the MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to the MCR.EHV.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic ‘0’ to the MCR.PGM to terminate the program operation.

Programs may be initiated with the 0–1 transition of MCR.PGM or by clearing MCR.EHV at the end of a previous program. The first Write after a program is initiated determines the page address to be programmed. This first Write is referred to as an Interlock Write. The Interlock Write determines if the UTEST or normal array space will be programmed via MCR.PEAS.

In the case of an erase-suspended program, the values in MCR.PEAS may be modified via the Program Interlock Write, enabling erase-suspended programs to UTEST Nonvolatile Memory space and revert back to their original state (related to erase-suspended operation) once the erase-suspended program is completed.

An Interlock Write must be performed before setting MCR.EHV. An Interlock Write performed after setting MCR.EHV is forbidden and data and address passed through interlock is lost.The user may terminate a program sequence by clearing MCR.PGM prior to setting MCR.EHV.

After the Interlock Write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024 bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are performed on the same location, the data for the last Write is used in programming.

While MCR.DONE is low and MCR.EHV is high, the user may clear EHV, resulting in a Program Abort.

A Program Abort forces the module to step 8 of the program sequence.

An aborted program results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The data space being operated on before the Abort contains indeterminate data. This may be recovered by repeating the same program instruction or executing an Erase of the affected blocks.

The user may not abort a program sequence while in Program Suspend.

Figure 453. Doubleword program of data 0x55AA_55AA at address 0x00_AAA8 and data 0xAA55_AA55 at address 0x00_AAAC

```
MCR = 0x0000_0010;           /* Set PGM in MCR: Select Operation */
(0x00_AAA8) = 0x55AA_55AA;   /* Latch Address and 32 LSB data */
(0x00_AAAC) = 0xAA55_AA55;   /* Latch 32 MSB data */
MCR = 0x0000_0011;           /* Set EHV in MCR: Operation Start */
do                           /* Loop to wait for DONE=1 */
{ tmp = MCR;                 /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;  /* Check PEG flag */
MCR = 0x0000_0010;           /* Reset EHV in MCR: Operation End */
MCR = 0x0000_0000;           /* Reset PGM: Deselect Operation */
```

37.4.5.1.1 Program Suspend/Resume

The program sequence may be suspended to allow Read access to the Flash array. It is not possible to program or to erase during a Program Suspend. Read-While-Write operations may also be used to read the array during a program sequence providing the Read is to a different partition.

During Program Suspend, all reads to the doubleword targeted for program return indeterminate data.

A Program Suspend can be initiated by changing the value of MCR.PSUS from ‘0’ to ‘1’. MCR.PSUS can be set to ‘1’ at any time when MCR.PGM and MCR.EHV are high and MCR.ERS is low. 0–1 transition of MCR.PSUS causes the module to start the sequence which places it in Program Suspend.

It is possible to suspend a program performed during an Erase Suspend. The user must wait until MCR.DONE=1 before the module is suspended and further actions are attempted. MCR.DONE takes no more time than t_{PSUS} to go high after MCR.PSUS is set to ‘1’.

Once suspended, the array may be read. Flash memory reads while MCR.PSUS=1 from the doubleword being programmed return indeterminate data.

Figure 454. Doubleword Program Suspend

```
MCR = 0x0000_0019; /* Set PSUS in MCR: Program Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.PGM in order to perform reads during program suspend.

The Program sequence is resumed by writing a logic ‘0’ to MCR.PSUS.

MCR.EHV must be set to ‘1’ before MCR.PSUS can be cleared to resume the operation.

The module continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

Figure 455. Doubleword Program Resume

```
MCR = 0x0000_0011;/* Reset PSUS in MCR: Program Resume */
```

Repeated suspends at a high frequency may result in the operation timing out, and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Program Suspends to ensure this does not occur is t_{PSRT}.

37.4.5.1.2 Over-programming protection (OPP) enable

Over Programming Protection can be enabled on a block-by-block basis. In an OPP enabled block of code Flash, any quad-word which has already been programmed cannot be programmed again. The OPP enable does not affect the Erase operation. It is possible to independently set OPP and (hardware) erase protection in order to avoid any kind of overwrite. Using these protection mechanisms in conjunction with the Test mode disable feature gives even greater overwrite protection. Attempts to over-program result in MCR.PEG being cleared.

OPP can be enabled for 16 KB, 32 KB, 64 KB and 256 KB blocks.

OPP is enabled by sideband signals and, if enabled, the program operation is modified to check for programmed bits prior to undertaking a high voltage program event.

37.4.5.1.3 Successful program address

To enable the System to create logic to authenticate operations with a program (like in a diary operation), the Flash Memory module provides the last successful address programmed as a sideband signal. This value is held until the next successful program. A successful program is defined as a program operation of data that is not all 1s, to an unlocked block and the operation results in MCR.PEG returning a ‘1’. An all 1’s value is the default (and invalid) address after reset.

In case of page programming, the last successful address returned is the beginning of the page itself regardless of whether that specific address has not been passed through interlock. In case of quad-page programming, the last successful address returned is the beginning of the quad-page itself regardless of whether that specific address has not been passed through interlock.

37.4.5.2 Erase

Erase changes the value stored in all bits of the selected block(s) to logic ‘1’. An Erase sequence operates on any combination of blocks in the low, mid, high or 256K address space. The Test block cannot be erased.

The Erase sequence is fully automated within the Flash. The user only needs to select the blocks to be erased and initiate the Erase sequence.

Register locked blocks cannot be erased. Hardware locking, which only affects the Erase operation is also available. Hardware locking is enabled by sideband signals and, if enabled, erases are prohibited on hardware locked blocks in the same way as erase software locking. If multiple blocks are selected for erase during an Erase sequence, no specific operation order can be assumed.

The Erase operation consists of the following sequence of events:

1. Change the value in the MCR.ERS bit from ‘0’ to ‘1’.
2. Select the block(s) to be erased by writing 1’s to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers. Note that Lock and Select are independent. If a block is selected and locked, no erase occurs.
3. Write to any address in Flash. This is referred to as an Erase Interlock Write.
4. Write a logic ‘1’ to MCR.EHV to start the internal Erase sequence or skip to step 9 to terminate.
5. Wait until MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to MCR.EHV.
8. If more blocks are to be erased, return to step 2.
9. Write a logic ‘0’ to the MCR.ERS bit to terminate the Erase operation.

After setting MCR.ERS, one Write (referred to as an Interlock Write) must be performed before MCR.EHV can be set to ‘1’.

Data words written during Erase sequence Interlock Writes are ignored. As Flash functions in an System with an end2end ECC scheme, ECC parity bits are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC even if the value of the data is not meaningful for the Erase operation. If an inconsistency between data and parity is found, the whole operation is rejected and MCR.PEG=0 is set.

The user may terminate the Erase sequence by clearing ERS before setting EHV.

An Erase operation may be aborted by clearing MCR.EHV assuming MCR.DONE is low, MCR.EHV is high and MCR.ESUS is low. An Erase Abort forces the module to step 8 of the Erase sequence. An aborted Erase results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The block(s) being operated on before the Abort contain indeterminate data. This may be recovered by executing an Erase on the affected blocks. The user may not abort an Erase sequence while in Erase-Suspend.

Figure 456. Erase of blocks B0F1 and B0F2

```
MCR = 0x0000_0004;           /* Set ERS in MCR: Select Operation */
SEL0 = 0x0006_0000;          /* Set LSL2-1 in SEL0: Select Blocks */
(0x00_0000) = 0xFFFF_FFFF;   /* Latch a Flash Address */
MCR = 0x0000_0005;           /* Set EHV in MCR: Operation Start */
do                           /* Loop to wait for DONE=1 */
{ tmp = MCR;                 /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;  /* Check PEG flag */
MCR = 0x0000_0004;           /* Reset EHV in MCR: Operation End */
MCR = 0x0000_0000;           /* Reset ERS: Deselect Operation */
```

37.4.5.2.1 Erase Suspend/Resume

The Erase sequence may be suspended to allow Read access to the Flash array. It is possible to program another block in any Flash Memory module during Erase-Suspend.

Programming a location subject to suspended Erase results in the program not being executed and PEG being set to 0.

It is not possible to erase any block during an Erase-Suspend.

During Erase-Suspend, all reads to blocks targeted for Erase return indeterminate data.

An Erase-Suspend can be initiated by changing the value of MCR.ESUS from ‘0’ to ‘1’. MCR.ESUS can be set to 1 at any time when MCR.ERS and MCR.EHV are high and MCR.PGM is low. A 0–1 transition of MCR.ESUS causes the module to start the sequence which places it in Erase-Suspend. The User must wait until MCR.DONE=1 before the module is suspended and further actions are attempted.

MCR.DONE takes no longer than t_{ESUS} to go high after MCR.ESUS is set to ‘1’.

Once suspended, it is not possible to alter the content of SEL0, SEL1, SEL2 and SEL3 registers. Once suspended, the array may be read. Flash memory reads while MCR.ESUS=1 from the block(s) being erased return indeterminate data.

Figure 457. Block Erase Suspend

```
MCR = 0x0000_0007; /* Set ESUS in MCR: Erase Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.ERS in order to perform reads during Erase-Suspend.

The Erase sequence is resumed by writing a logic ‘0’ to MCR.ESUS.

MCR.EHV must be set to ‘1’ before MCR.ESUS can be cleared to resume the operation. The module continues the Erase sequence from one of a set of predefined points and this may extend the time required for the Erase operation.

Figure 458. Block Erase Resume

```
MCR= 0x0000_0005;/* Reset ESUS in MCR: Erase Resume */
```

Repeated suspends at a high frequency may result in the operation timing out and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Erase suspends to ensure this does not occur is t_{ESRT}.

37.4.5.3 Factory Mode

The Factory Mode feature can be used to improve Program and Erse Times and it is managed through a diary location mechanism. If location UTEST at offset +0x0020 is found virgin at the moment of the reset, MCR.FERS can be set, after rising MCR.ERS and before MCR.EHV. After setting MCR.EHV the FPEC recognizes the value of FERS and allows a fast Program and Erase Operation. Under those conditions a factory Mode can start and no Read-While-Write is allowed (all the flh_busy sideband signals are set high). If the diary location has been programmed by the user (having changed from being virgin at reset), the Factory Mode gets permanently disabled.

37.4.6 Alternate program and erase interface

A second Modify interface is provided on the Flash for program and erase operations. The intent is that a dedicated master can have private access to blocks through this interface.

The alternate interface includes an alternate MCR register and alternate lock registers. Any block in low, mid, or high address space may be accessible through the alternate interface. The UTest NVM Block is also accessible for program through the alternate interface. Blocks in 256K Address Space are not accessible through this interface.

The alternate interface supports programming of data sizes from one doubleword (64 bits) to four doublewords within a single page (256 bits). Within a page, up to eight words may be altered in a single program operation. It is recommended that programming operations through the alternate interface be from 64 bits to 256 bits, and be 64-bit aligned. Programming has the same constraints as for the Main interface concerning ECC boundaries: 64b for Data Flash and 128b for Code Flash.

The alternate interface supports erasing a single block at a time with each erase operation.

As with the main interface, erase suspend, program suspend, and erase-suspended programs are supported.

Program and Erase times for the alternate interface are the same as the main interface when programs and erases are done in isolation. If main interface and alternate interface are being utilized simultaneously, bandwidth sharing is utilized.

Note: It is possible for the UTest NVM block to exist in both the main program interface and alternate program interface. In the event of a conflict the first interface to do the program to an address will get priority, and all other attempts after this will result in an OTP over-program failure (MCR[PEG] or MCRA[PEGa] being set to 0).

37.4.6.1 Alternate program interface

The programming procedure follows exactly the same flow as the main interface, except that only page programming is allowed.

The alternate interface program is done at lower priority compared to the main interface. Based on the size of programming allowed, the main interface has a 4:1 ratio advantage over the alternate interface. Program operations are allowed to finish on the active interface prior to allowing the inactive interface to execute its operation. Suspends done on the active interface enable the inactive interface to begin its operation.

For alternate program while erase, there could be a latency of up to 5 ms in the program operation.

For more information on interaction between the alternate program interface and the main interface, see *Section 37.4.6.3: Alternate interface performance*.

If the alternate interface is the only interface active, then normal program times may be expected.

37.4.6.2 Alternate erase interface

For erases done through the alternate interface, the single block to be erased is selected based on the address that is received during the erase interlock write. Thus the Select registers are not valid for the alternate interface (step 2 of the erase flow in *Section 37.4.5.2: Erase*), and the interlock write address is used (step 3 of the erase flow in *Section 37.4.5.2: Erase*). All other features of the main interface apply to the alternate erase interface. The

erase procedure is exactly the same as for the main interface. See *Section 37.4.5.2: Erase* for more information on erase.

The alternate interface erase is done at lower priority compared to the main interface. The time-slice ratio between the two interfaces is 10:1, with 50 ms of time given to the main erase for every 5 ms of alternate interface. Suspends done on the active interface enable the inactive interface to begin its operation.

For alternate erase while program, there can be a latency of up to 5 ms in the main program time. Once the alternate erase is interrupted, it will remain interrupted for main programs for a fixed time of 50 ms, at which time the alternate erase will restart. It should be noted that multiple interruptions of the alternate erase will significantly increase the total erase time.

For alternate erase while erase, the main erase has priority and receives 50 ms of erase for every 5 ms of alternate erase. This may result in a significant increase in the erase time for the alternate interface, and a minor increase in erase time for the main interface.

For more information on interaction between the alternate erase interface and the main interface, see *Section 37.4.6.3: Alternate interface performance*.

If the alternate interface is the only interface active, then normal erase times may be expected.

37.4.6.3 Alternate interface performance

Table 582 highlights the interactions between the alternate interface and the main interface for program, erase, suspend, and idle conditions.

Table 582. Alternate Program and Erase Characteristics

Alt PGM/ERS interface request	Main PGM/ERS interface request	Alt interface result on memory array	Main interface result on memory array
Idle	Idle	Idle	Idle
Idle/SUSP	PGM/ERS	Idle/SUSP	PGM/ERS
PGM/ERS	Idle/SUSP	PGM/ERS	Idle/SUSP
PGM	PGM	PGM	Priority PGM (4:1 ratio)
PGM	ERS	PGM with 5ms latency	ERS (possible minimal increase to total ERS time)
ERS	PGM	ERS (significant increase in total ERS time expected)	Priority PGM (possible latency of 5 ms) Once PGM is granted, 50 ms time slice available for more programs
ERS	ERS	ERS (significant increase in total ERS time expected)	Priority ERS (10:1 ratio) (possible minimal increase to total ERS time) 50 ms Main ERS for every 5 ms alternate ERS

37.4.7 User Test mode

Customers can put the Flash Memory module in User Test mode to perform specific tests for the integrity of the Flash array.

Three kinds of test can be performed:

- Array Integrity Self Check
- Margin Read
- Vth Distribution

User Test mode is an exclusive operation—it cannot be run in conjunction with any other Flash mode (Read, Write, Low-Power and Power-Down), and Read-While-Write functionality is inapplicable. Read accesses attempted by the user during User Test mode generates a Read-While-Write Error (RWE of MCR set). Vth Distribution mode is conditioned by SoC Life Status (mode allowed only as Failure analysis)

It is not permitted to perform User Test operations on the Test blocks (including the UTEST section).

37.4.7.1 Array Integrity Self Check

Array integrity is checked using a predefined address sequence (proprietary), and this operation is executed on selected (SEL0, SEL1, SEL2 and SEL3) blocks. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Any random or non-random code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value (stored in UM0–UM9), to determine if an incorrect Read, or ECC detection was noted. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the frequency being used.

The internal MISR calculator is a 64 + 8 + 1-bit register.

The 256-bit data, the respective ECC parity data, and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location.

The whole check is done through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction and the double error flag is set after any ECC detection. Single-bit correction is always active and logging may be enabled (UT0.SBCE), resulting in the MCR.SBC flag and related address to be captured in ADR register, but this does not change the final signature in the UM0–UM9.

Only data from existing locations are captured by the MISR. The MISR can be seeded to any value by writing the UM0–UM9 registers.

The Array Integrity Self Check consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1’s to the appropriate field(s) in SEL0, SEL1, SEL2 and SEL3 registers. Blocks selected for Array Integrity Check do not need

to be unlocked. It is not possible to perform Array Integrity operations on the UTEST Nonvolatile Memory block.

3. If desired, UT0.AIS can be set for sequential addressing only.
4. Seed the MISR UM0–UM9 with desired values.
5. If breakpoints are desired, set UT0.AIBPE to ‘1’, and ensure that MCR.EER and MCR.SBC are cleared. If breaking on single-bit correction is required, ensure that UT0.SBCE is set.
6. Write a logic ‘1’ to UT0.AIE to start the Array Integrity Check. Array integrity operations may be aborted prior to UT0.AID going high. This may be done by clearing UT0.AIE. It should be noted that in the event of an aborted Array Integrity check, the MISR registers contain a signature for the portion of the operation that was completed prior to the Abort, and is not definitive. Prior to performing further Array Integrity operations, the UM0–UM9 registers may require initialization to the desired seed value by performing register writes. Array Integrity operations may be suspended while UT0.AID is low. UT0.AISUS may be set to request an Array Integrity Suspend. Once UT0.AID has been set high, UT0.AISUS may be cleared to resume the Array Integrity sequence.
7. Wait until UT0.AID goes high.
8. Check that UT0.NAIBP is set to ‘1’ if breakpoints were previously enabled so that the MCR.EER, MCR.SBC and ADR registers may be checked to determine the cause and address of the break. Prior to resuming the operation, it necessary to clear MCR.SBC or MCR.EER in order to preserve coherency of MCR.SBC, MCR.EER and ADR updates with respect to any subsequent breakpoints. Operation may then be resumed by clearing UT0.NAIBP. Continue waiting until the UT0.AID bit goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
9. Compare UM0–UM9 content with the expected result.
10. Write a logic ‘0’ to the UT0.AIE bit.

Use sequential addressing for normal integrity checks of the Flash memory. If a more detailed check of the Read path is required (in diagnostic mode), leave UT0.AIS at ‘0’ and use the proprietary address sequence that checks the Read path more completely, however this sequence takes more time.

Caution: Do not modify the content of Block Select (SEL0, SEL1, SEL2 and SEL3) and Lock (LOCK0, LOCK1, LOCK2 and LOCK3) registers during execution of the Array Integrity Check operation or the MISR value may vary unpredictably.

User mode array reads requested during the Array Integrity test are ignored to ensure that the Array Integrity operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may clear AIE, resulting in an Array Integrity Check Abort. UT0.AID must be checked to know when the aborting command has completed.

Array Integrity Check can be suspended by setting UT0.AISUS while Array Integrity Check is running (UT0.AID=0). Once suspended (UT0.AID=1) Array Integrity Check cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 459. Array Integrity Check of blocks B0F1 and B0F2

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set LSL2-1 in SEL0: Select Blocks */
SEL2 = 0x0000_0006;  /* Set A256KSL2-1 in SEL2: Select Blocks */
UT0 = 0x8000_0002;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9 = UM0/9;     /* Read UM0/9 content*/
UT0 = 0x0000_0000;   /* Reset UTE, AIE: Operation End */
```

37.4.7.2 Margin Read

User Margin Read may be achieved using the Array Integrity interface and has all the associated features of the Array Integrity interface (MISR calculation, suspend capability and Breakpoints).

Margin Read procedure (either Margin 0 or Margin 1) can be run on selected blocks in order to unbalance the Sense Amplifiers with respect to standard Read conditions, so that all the Read accesses reduce the margin vs ‘0’ (UT0.MRV=0) or vs ‘1’ (UT0.MRV=1).

User Margin Read is a self timed event and is independent of system clocks or wait states selected. Margin Read can be run on selected (SEL0, SEL1, SEL2 and SEL3) blocks, generating checksum calculations on MISR and ECC flagging. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Once the operations are completed, the results of the Margin Reads can be checked, comparing checksum values in UM0–UM9 and reading MCR.EER and MCR.SBC to determine if zero, one or two bits are being detected by the Margin Read.

The MISR can be seeded to any value by writing the UM0–UM9 registers.

As with Array Integrity Check, the internal MISR calculator is a 64 + 8 + 1-bit register. The 256-bit data, the corresponding ECC parity data and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location. The whole check is accomplished through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction, and the double error flags are set after any ECC detection. Single-bit logging is always enabled regardless of the value of UT0.SBCE, resulting in the MCR.SBC flag and related address to be captured in ADR register, but this does not alter the final signature in the UM0–UM9.

In any case, the charge losses detected through the Margin Read cannot be considered device failures and no Failure Analysis is initiated on them.

The Margin Read Setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers. Blocks selected for Margin Read do not need to be unlocked. It is not possible to do Margin Read operations on the UTEST Nonvolatile Memory block.
3. Seed the MISR UM0–UM9 with desired values.
4. Ensure that MCR.EER and MCR.SBC are cleared.
5. Set UT0.SBCE to '1' to detect single bits during Margin Read.
6. Change the value of UT0.MRE from '0' to '1'.
7. Select the Margin level: UT0.MRV=0 for 0's margin, UT0.MRV=1 for 1's margin.
8. Write a logic '1' to UT0.AIE to start the Margin Read.
9. Wait until UT0.AID goes high.
10. Check that UT0.NAIBP is set to '1' if breakpoints were previously enabled so that MCR.EER, MCR.SBC and ADR.ADDR may be checked to determine the cause and address of the break. Prior to resuming operation, clear MCR.SBC or MCR.EER. Operation may then be resumed by clearing UT0.NAIBP. Continue to wait until UT0.AID goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
11. Compare UM0–UM9 content with the expected results.
12. Check MCR.EER and MCR.SBC.
13. Write a logic '0' to UT0.AIE, UT0.MRE and UT0.MRV.
14. If more blocks are to be checked, return to step 2.

The linear address sequence is used regardless of the value of UT0.AIS.

Caution: Do not modify the content of Block Select (SEL0, SEL1, SEL2 and SEL3) and Lock (LOCK0, LOCK1, LOCK2 and LOCK3) registers during execution of the Margin Read operation, otherwise the MISR value may vary unpredictably.

User mode array reads requested during the Margin Read are ignored to ensure that the Margin Read operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may abort Margin Read by clearing AIE. UT0.AID must be checked to know when the aborting command has completed. Margin Read can be suspended by setting UT0.AISUS while Margin Read is running (UT0.AID=0). Once suspended (UT0.AID=1), Margin Read cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 460. Margin Read Check versus 1's

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set LSL2-1 in SEL0: Select Blocks */
UT0 = 0x8000_0020;   /* Set MRE in UT0: Select Operation */
UT0 = 0x8000_0030;   /* Set MRV: Select Margin versus 1's */
UT0 = 0x8000_0032;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9 = UM0/9;     /* Read UM0/9 content*/
UT0 = 0x8000_0030;   /* Reset AIE in UT0: Operation End */
UT0 = 0x0000_0000;   /* Reset UTE, MRE, MRV, AIS in UT0:
                        Deselect Operation */
```

37.4.7.3 Vth Distribution

Vth Distribution functionality can be used in case of Failure Analysis for quick assessment of cells status in terms of Vth. The functionality has bit register UTO.VTD as initiator. Writing of this bit is enabled by the Life Cycle state of the device. Life Cycles has to be in Failure Analysis (FA) condition to allow Vth Distribution mode.

Vth Distribution functionality works on selected blocks on the base of multi internal runs. Each run corresponds to an internal voltage step, where cells read as '1' (Vth lower than internal voltage level) are counted: the completion of each run provides on UMISR0 the count of these cells. Clearing UTO.NAIBP starts next voltage step run, till completion of the intended voltage range. Number of internal voltage step is fixed. Aim of the test is to sweep the range from the erased cells with the highest Vth to the programmed cells with the lowest Vth, therefore to provide an assessment of the effective distribution of the cells in the selected blocks.
Once all the cell counts, one per run, have been collected, distribution can be obtained as difference between counts collected through subsequent steps.
In every run, all the cell, including the ECC parity ones, are counted for the block selected.
Vth Distribution results are expected to be collected at room temperature (25C).

Vth Distribution Setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers.
3. Unlock blocks Blocks o be checked by writing 0's to the appropriate register(s) in LOCK0, LOCK1, LOCK2 and LOCK3 registers. Blocks selected for Vth Distribution need to be unlocked. It is not possible to do Vth Distribution operations on the UTEST

Nonvolatile Memory block, neither on blocks protected through TMD SEAL Block Select.

4. Set UT0.VTD to ‘1’ to select Vth Distribution mode.
5. Write a logic ‘1’ to UT0.AIE to start the first internal run.
6. Wait until UT0.AID goes high.
7. Check that UT0.NAIBP is set to ‘1’. If NAIBP is at ‘1’ it means current internal run has been completed and device is ready to increase voltage step. If NAIBP is at ‘0’ the overall sweep has been completed.
8. Collect UM0 content for the current voltage step (run).
9. Clear UT0.NAIBP to increase voltage step and return to 6)

Caution: Voltage levels used during Vth distribution sweep may alter the intended reliability of the Cells as data retention. For this reason Vth distribution can be used no more than 10 times.

37.4.8 Protection strategy

Two kinds of protection are available: Modify Protection to avoid unwanted program/erase in Flash blocks and Test Mode Disable to avoid piracy.

37.4.8.1 Modify Protection

The Flash Modify Protection information is stored in nonvolatile Flash cells located in the UTEST region. This information is read once during the Flash Initialization phase following exit from reset and is stored in volatile registers that act as actuators at SoC level. The information is passed to the Flash Memory module through erase_lock and program_lock sidebands, and allows independent protection of each block of Low, Mid, High and 256K Address Space Block.

There are also Address Space Block Locking registers provided to independently lock/unlock each block of Low, Mid, High and 256K Address Space Block against program and erase. Locking is done through the LOCK0, LOCK1, LOCK2 and LOCK3 registers. These registers do not have a nonvolatile image stored in the UTEST area of TestFlash, so the locking information is kept on reset: volatile content is all 1’s, meaning all blocks are locked.

All the volatile registers can be written to ‘0’ or ‘1’ at any time, therefore the user application can lock and unlock blocks when desired. Note, however, that overall protection is achieved by the combination of sidebands with Low, Mid, High and 256K Address Space Block Locking registers in such a way that a block can be programmed/erased only if both (sidebands and Locking registers) indicate an unlocked state. Sidebands independently control program protection, erase protection and over-programming protection (OPP) on a block-by-block basis.

37.4.8.2 Test Mode Disable

In the TestFlash area a mechanism is also available to disable entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected for protection in this way cannot be analyzed for possible failures by manufacture failure analysts.

Protection of this sort prevents all high voltage operations to the Flash executed by the internal FPEC as well as reads from FPEC, including Array Integrity Check or Margin Read,

when using Test mode interfaces. Protection through other interfaces is managed through normal User mode protection mechanisms, that are System specific.

To disable manufacturer entry into Test mode, first program the Test Mode Disable Seal location to 0x5A4B_3C2D and once the next reset is asserted, Test mode is disabled.

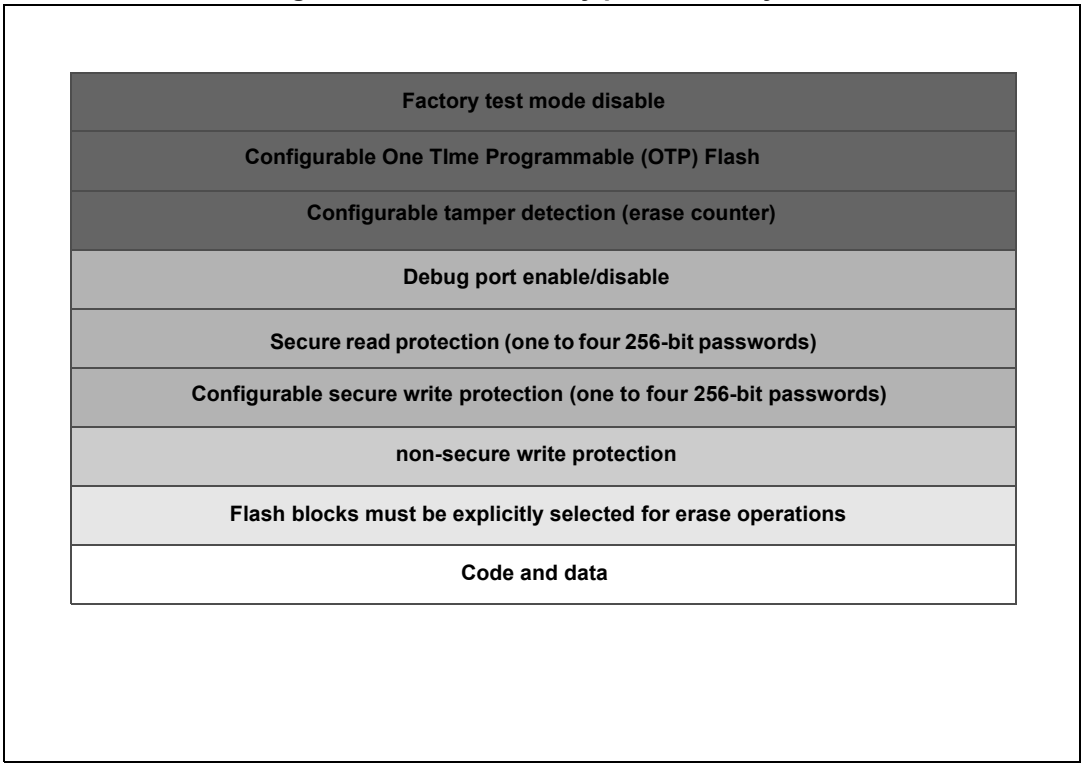
It is possible to create a password to enable manufacturer entry into Test mode. This can be programmed into the Test Mode Disable Override Passcode. It is safest to do this prior to censoring the part to avoid unintended lockout. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and are not accepted for override. If the customer desires that override never be possible, one of the three invalid passcodes should be put into this location. Passcodes may be entered to authenticate entry (if enabled) by performing a register Write to offset address 0x90.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus is it possible for customers to select blocks for this type of protection, and render them ineligible for manufacturer failure analysis. Bits programmed to ‘0’ in the Test Mode Disable Block Select field designate blocks that are controlled by Test Mode Disable feature. The TestFlash block, and thus the UTEST and BAF sections, is always protected once the Test Mode Disable Seal password is written. In order to permit two opportunities to select blocks for Test Mode disable, two regions are available, both in UTEST: one at offset 0x50, and the other at offset 0x60; both are 128-bit sized (only some may be effective, depending on actual sectorization). The bits of these two regions are logically ANDed in order to define which blocks are effectively selected for the Test Mode Disable feature.

The bit Block Select field is organized as follows, and aligned in the way blocks are defined in the LOCKx/SELx registers:

Table 583. Test Mode Disable block select

Block	Block selection bits
Blocks in Mid space	Data[16:31]
Blocks in Low space	Data[2:15]
Blocks in High space	Data[48:63]
Blocks in 256K space	Data[64:127]



38 Flash Memory Programming and Configuration

This chapter provides basic guidance on activities related to configuring and programming the embedded Flash memory in the SPC58xEx/SPC58xGx microcontroller.

Multiple layers of protection are available to prevent unintended updates to Flash contents and unauthorized reads and writes to Flash contents. The protection mechanisms range from simple write-protect bits for individual Flash blocks to four levels of 256-bit password read/write protection and configuration of Flash memory blocks as One Time Programmable (OTP).

Additionally, the SPC58xEx/SPC58xGx microcontroller includes a tamper detection feature, debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

Figure 461. Flash memory protection layers

At the lowest layer of protection, all Flash erase operations require the explicit selection of one or more blocks of Flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual Flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual Flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of Flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The SPC58xEx/SPC58xGx microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected Flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection region if desired.

Another protection feature related to tamper detection is the ability to configure any Flash block as one-time programmable (OTP).

Finally, the microcontroller includes a feature that allows the customer to disable the ability to place the device in factory test mode.

The remainder of the chapter provides details regarding these protection mechanisms and gives a brief overview of security configuration planning.

Note: Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the Flash protection features work and relate to each other, please read the chapter in sequence from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection and tamper detection applied to groups of Flash memory blocks), which means that a custom level of access protection can be provided for each Flash memory block. This is accomplished through the use of registers containing bits that are mapped to individual Flash blocks. Understanding the mapping is key to understanding the implementation and use of the SPC58xEx/SPC58xGx microcontroller's Flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in *Section 38.1: Selection of Flash memory blocks for erase*. It is important to understand the topic before proceeding to other sections.

38.1 Selection of Flash memory blocks for erase

The registers used for selecting Flash blocks for erase operations are the Flash control registers named LOCK0, LOCK1, LOCK2 and LOCK3.

The LOCK0–2 registers are 32-bit registers containing fields associated with specific address spaces: low, mid, high, and 256 KB. Each non-reserved bit in the fields is mapped to a specific Flash block.

For example, *Section 37.3.2.10: Select 0 register (SEL0)* shows the Select 0 (SEL0) register for the Flash module. This register provides a way of selecting blocks in the low and mid address spaces for erase operations.

Table 516: Flash memory partition 0 memory map shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual Flash blocks. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–11 (register bits 15–4) and MIDSEL bits 0–2 are mapped. Before any mapped block can be erased, it must be

selected by writing a ‘1’ to its corresponding bit in one of the SEL*n* registers. Refer to the device configuration chapter for the complete mapping.

Note: Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 419: Select 0 register (SEL0), all bits are reset to ‘0’. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Example 1 Selecting blocks for erase

Writing the value 0x0005_0000 to the SEL0 register (*Figure 419: Select 0 register (SEL0)*) selects the blocks in *Table 535: SEL0 field descriptions* for erase.

38.2 Non-secure write protection

Non-secure write protection refers to the chip’s ability to lock individual Flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip’s modules. The non-secure write protection feature detailed here applies only to embedded Flash memory.

Implementing non-secure write protection is almost identical to selecting specific Flash blocks for an erase operation—the only difference is the register used. To provide non-secure write protection for a block, write a ‘1’ to the corresponding mapped bit found in one of the LOCK0–3 Flash control registers.

Note: As indicated by the reset values shown in Section 37.3.2.4: Lock 0 register (LOCK0), after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

Example 2 Selecting blocks for write protection

Writing the value 0x0005_0000 (same value used in *Example 1*) to the LOCK0 register (*Section 37.3.2.4: Lock 0 register (LOCK0)*) locks the blocks in *Table 516* (same blocks selected in *Example 1*) so they cannot be programmed or erased, even if selected for erase.

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in *Section 38.3: Secure write protection*). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to ‘0’.

38.3 Secure write protection

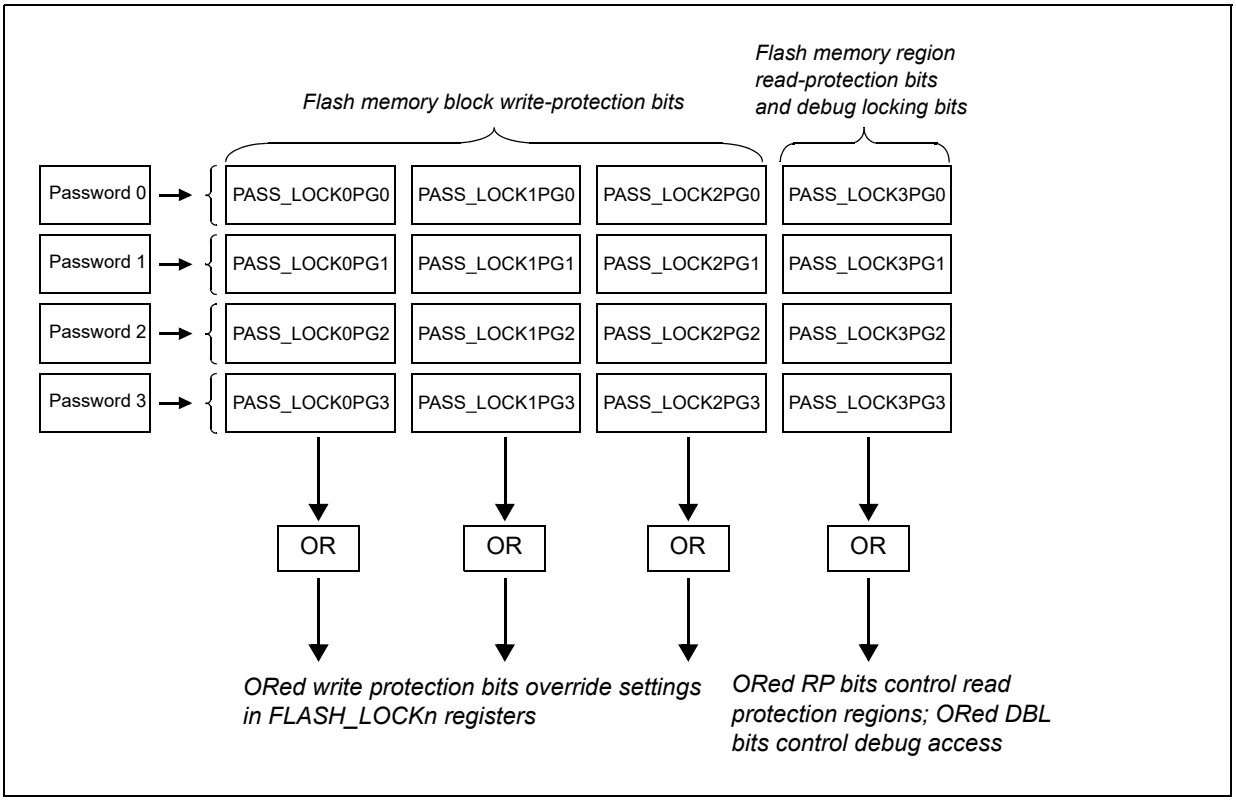
Secure write protection refers to the chip’s ability to implement up to four levels of 256-bit password-secured *write* protection for individual Flash blocks. Use of this feature is optional but the default behavior of the SPC58xEx/SPC58xGx microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records. For details, please refer to *Section 92.5.2.1: JTAG Password Challenge* in the PASS chapter.

Note that the *secure* write protection settings override the non-secure write protection detailed in *Section 38.2: Non-secure write protection*.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each Flash block. The DCF records use a bit mapping scheme identical to the mapping in the Flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module—they distinguished by the PG*n* suffix. The PG*n* (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.



The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each Flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding Flash block.

Each set of registers contains the same mapping of bits to Flash blocks as the Flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a Flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the Flash block is available for programming or erase.

Figure 462 shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

Figure 462. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

38.3.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers[16]. The DCF records have a structure that includes the same mapping of bits to Flash memory blocks as the Flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers.

Refer to *Chapter 9: Device Configuration Format (DCF) Records* for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to Flash memory blocks is identical to the mapping used for selecting Flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring Flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during

16. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

OEM production activities. The selection becomes a permanent part of the device configuration.

2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

Caution: Careful planning is required before writing DCF records. They are created in a write-once area of Flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table (*Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*). Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST Flash memory. The structure of a DCF Record is shown in *Figure 463*.

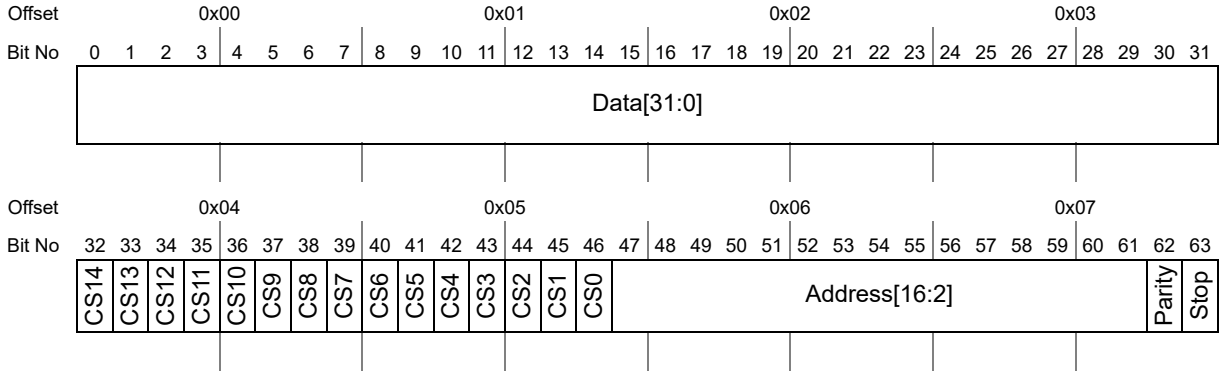


Figure 463. DCF record structure

Note: The values in the PASS_LOCKxPGn registers should mirror the settings in the Flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated Flash block to be locked against programming or erase.

The PASS_LOCKxPGn bits take effect when the life cycle is matured to "OEM Production" or older.

Example 3 Implementing secure write protection

Implementation of secure write protection is done during initial Flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device Flash called UTEST Flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to Flash blocks as the Flash module's SEL0–3 registers and LOCK0–3 registers.
2. DCF records must be created to define which Flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2., determine the reset values of the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group: refer to *Table 516*.

From the PASS section of *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*:

Table 584. DCF client list of PASS

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to *Figure 463*, the values for the DCF record are:

- Data[31:0] is 0x0005_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (refer to footnotes in *Figure 464*).

The following DCF record provides secure write protection for the blocks by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	X (1)	X (2)

Figure 464. Sample DCF record for secure write protection

1. Bit 62 indicates parity strategy, which is not used in the PASS DCF records so it is a “don’t care”.
2. Bit 63 indicates whether the current record is the last DCF. Generally, this should be written as ‘0’ so the first unprogrammed (all 1’s) DCF record acts as the stop record.

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to Flash blocks 4 and 5 set to ‘1’.

Caution: The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

Refer to the PASS section of DCF client list table (*Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details on the DCF records.

38.3.2 Overriding secure write protection

The “PG*n*” (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock

PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the Flash module's SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to '1', locking a Flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCK*x*PG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the Flash block is available for programming or erase.

Figure 465 shows the PASS_LOCK0_PG*n* register. It has the same structure as the Flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCK*x*_PG*n* registers and the Flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding Flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

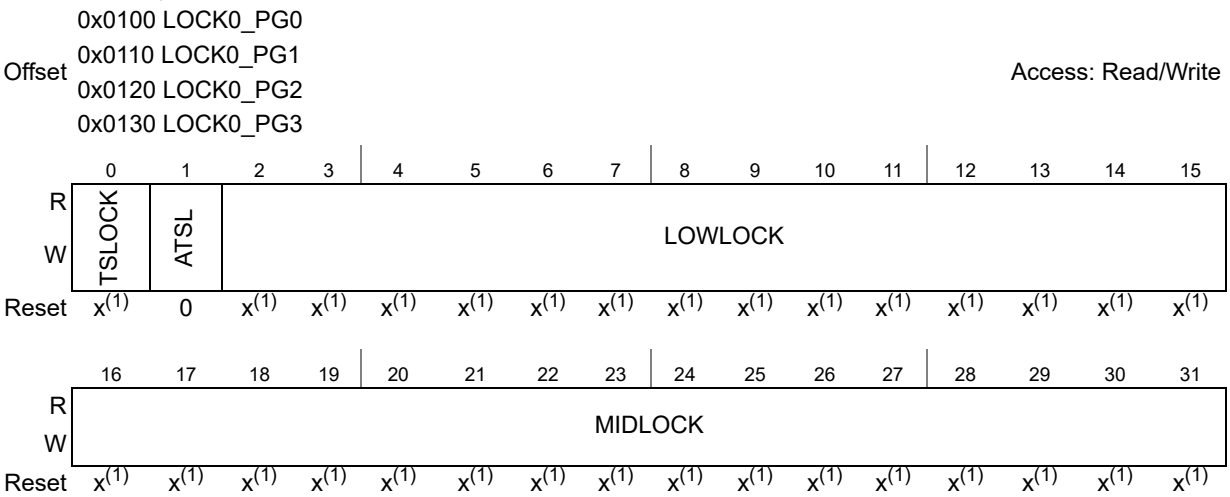

Figure 465. LOCK0_PG*n* register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'

Note: The values in the PASS_LOCKxPGn registers should mirror the settings in the Flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated Flash block to be

locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.

The PASS_LOCKxPGn bits take effect after the life cycle is matured to "OEM Production" or older.

Example 4 Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the Flash module's LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired Flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant 32 bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

As in the previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

38.4 Secure read protection

Read Protection is ability of the Flash controller to block read accesses to the Flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- SIPI reads
- All other types of bus master reads

When secure read protection is active, the affected Flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a Flash read protected region terminates with a bus error.

Most instances of Flash memory read protection in the SPC58xEx/SPC58xGx microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTEST Flash memory. Password-based read protection *is* customer-configurable(17) and is similar to the password-based write protection mechanism detailed in *Section 38.3: Secure write protection*.

There are two significant differences between password-based read protection and password-based write protection in the SPC58xEx/SPC58xGx microcontroller.

1. Read protection can only be applied to pre-defined groups of Flash memory blocks. These groups, called “Read Lock groups”, cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to “Failure Analysis”.

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

Note: The mappings of PASS_LOCK3_PGn register bits to Flash blocks vary with different microcontrollers. Refer to the Flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC58xEx/SPC58xGx microcontroller.

The next sections discuss implementing secure read protection and overriding secure write protection.

38.4.1 Implementing secure read protection

Implementation of secure read protection is done during initial Flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device Flash named UTEST Flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to Flash blocks as the Flash module’s SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which Flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers.

   Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.
   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in *Figure 466*. The fields relevant to implementing secure read protection are RL4–RL0.

17. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

Offset
0x010C LOCK3_PG0
0x011C LOCK3_PG1
0x012C LOCK3_PG2
0x013C LOCK3_PG3

Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 466. PASS_LOCK3_PG*n* Register

1. Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
2. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Example 5 Implementing secure read protection

Assume four passwords have been previously implemented.

Following is an example of a mapping of Flash blocks to Read Locking groups.

To provide two levels of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL*n* bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 585. DCF client list of PASS

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to *Figure 463*, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG2
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG3
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.

38.4.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG*n* registers (refer to *Figure 466*) contain five read protection fields, RP0–RP4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to ‘1’, causing the blocks associated with each read group to be read locked.

Example 6 Overriding secure read protection

Building on *Example 5: Implementing secure read protection*, where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to ‘0’ in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

38.5 Debug port enable/disable

The mechanism for temporarily enabling the SPC58xEx/SPC58xGx debug port after it has been locked by its life cycle state is similar to the Flash memory read protection mechanism detailed in *Section 38.4: Secure read protection*. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RP0–RP4 fields.

38.6 Tamper detection

The Tamper Detection Module (TDM) provides a type of Flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual Flash memory blocks to be selected for tamper detection.

Refer to *Chapter 93: Tamper Detection Module (TDM)*, for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, such as a Flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of DCF client list table (*Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) gives the CS and Address value combinations that correspond to groups of LOCK0–LOCK3 registers, similar to the Flash module's LOCK0–LOCK3 registers.

The mapping of individual Flash blocks to TDM DCF record data field bits is shown included in the detailed Flash block map in the Flash section of the Device Configuration chapter.

38.6.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections.

38.6.2 Creating the tamper detect diary

Tamper detection in the SPC58xEx/SPC58xGx microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called “tamper detect regions”, or TDRs, within the Flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the Flash module’s SEL*n* and LOCK*n* registers, which contain bits matched to specific Flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a “diary” that tracks Flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector.

Note: The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for SPC58xEx/SPC58xGx) multiplied by 4 KB, the portion of the diary allotted to records associated with each TDR.

The diary can be placed within any Flash block in the Flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section).
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be ‘0’.

Caution: The tamper detect diary base address DCF record is a “write once” record. All subsequent tamper detect diary base address DCF records created are ignored.

Example 7 Creating the tamper detect diary

If the total space required for a diary is 24 KB (as in the case of 6 TDRs), any Flash block in the SPC58xEx/SPC58xGx microcontroller but B0F0 and B0F1 whose size is not enough to allocate the diary total space can be used. Since the diary base address must be on a 4 KB, boundary, though, if the diary base address is within a 32 KB Flash block, it can be assigned to the base address of the block or the address given by the base address plus 4 KB or the address given by the base address plus 8 KB.

If the base address of the 32 KB block is 0x00FD000, the base address of the diary is given by:

32’b0000_0000_1111_1101_0000_0000_0000_0000 (32 KB base address)

or

32’b0000_0000_1111_1101_0001_0000_0000_0000 (32 KB base address + 4 KB)

or

32’b0000_0000_1111_1101_0010_0000_0000_0000 (32 KB base address + 8 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 16'b0000_0000_0000_0000
- TDR1 = Diary_Base_Address + 16'b0001_0000_0000_0000
- TDR2 = Diary_Base_Address + 16'b0010_0000_0000_0000
- TDR3 = Diary_Base_Address + 16'b0011_0000_0000_0000
- TDR4 = Diary_Base_Address + 16'b0100_0000_0000_0000
- TDR5 = Diary_Base_Address + 16'b0101_0000_0000_0000
- End of the diary = Diary_Base_Address + 16'b0110_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 586. DCF client list of Tamper Detect

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to *Figure 463*, the values for the DCF record are:

- For LOCK0_PG0
  - Data[31:0] is 0x00FC4000 (the base address).
  - CS[14:0] is 0b000_0000_0001_0000 (bits 32–46).
  - Address[16:2] is 0b000_0000_0000_0000 (bits 47–61).
  - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62).
  - Preferred Stop value is 0.

Refer to the Tamper Detect section of DCF client list table (*Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details.

Note: User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in Section 38.6.4: Overriding tamper detection.

38.6.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDR*x*_LOCK*n* DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDR*x*LOCK*n* DCF records mapped in exactly the same way as the Flash module's SEL*n* and LOCK*n* registers (refer to the detailed Flash block map in the Flash section of the Device Configuration chapter for the mapping).

In the TDR*x*LOCK*n* DCF records:

- A bit set to '1' means the corresponding Flash block is assigned to this TDR.
- A bit set to '0' means the corresponding Flash block is NOT assigned to this TDR.

The default state (no TDRs defined) is defined as "Block NOT assigned to the TDR".

38.6.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in *Figure 467*.

Caution: Bits in this DCF record are writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

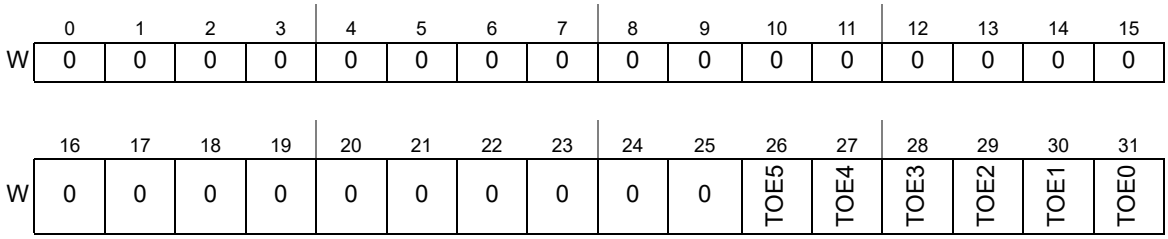

Figure 467. Data portion of Tamper Region Override (TO) DCF record

Example 8 Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full.

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 587. DCF client list of Tamper Detect

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to *Figure 463*, the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3).
- CS[14:0] is 0b000_0000_0001_0000 (bits 32–46).
- Address[16:2] is 0b000_0000_0000_0001 (bits 47–61).
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

Refer to the Tamper Detect section of DCF client list table (*Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details.

38.7 Implementing OTP

Any Flash block within the Flash array can be assigned, at any time, to be OTP. OTP means that Flash erase of the entire block is disabled and only 128-bit quad-words that are already erased (Flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

Caution: After a Flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*. Refer to the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

38.8 Implementing test mode disable

The SPC58xEx/SPC58xGx Flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the Flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

38.8.1 Unconditional test mode disable seal

Warning: This process is not reversible. After completing these steps the SPC58xEx/SPC58xGx microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual Flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST Flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTEST Flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST Flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

Note: The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

38.8.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual Flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST Flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTEST Flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST Flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

Note: The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

38.8.3 Selecting Flash memory blocks for test mode disable seal

Selecting Flash memory blocks for test mode disable seal protection is similar to selecting blocks for tamper detection in that it involves writing to non-register Flash locations. In the case of the test mode disable seal function, there are two areas of UTEST Flash memory that have identical mapping to Flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

The mapping of bits to blocks for this function is identical to the mapping used for other functions. Refer to *Chapter 37: Embedded Flash Memory* for the map.

Note: Selecting a block for test mode disable requires a '0' in the mapped bit—not a '1' as with other functions.

38.9 Security configuration planning

At minimum, designing the Flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

In devices containing a Hardware Security Module (HSM), significant planning must go into the implementation of HSM functions. The HSM is an independent software platform within the microcontroller. It is intended to be used to implement advanced security functions that are defined by customer software.

Note: Details of advanced security features, including the advanced security architecture is and the Hardware Security Module (HSM) are contained in the SPC58xEx/SPC58xGx Microcontroller Security Reference Manual. Distribution of the document is restricted to qualified customers.

The basic security features available in the SPC58xEx/SPC58xGx microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) Flash memory block assignment
- Factory test mode disable

38.9.1 Hardware Security Module (HSM)

Details of the HSM are included in the *SPC58xEx/SPC58xGx Microcontroller Security Reference Manual*. It is mentioned here because the Flash memory module includes blocks that can be configured for exclusive access by the HSM. If the HSM is to be used in an application it is advisable to protect HSM code by configuring it for exclusive access by the HSM. The blocks configurable for exclusive access by the HSM appear in *Figure 7* in *Chapter 3: Embedded memories*. They are labeled as secure code Flash or secure EEPROM emulation blocks. They are not configured for HSM-exclusive access by default, though—they are available to act as secure Flash areas but must be explicitly configured for that purpose. Refer to *SPC58xEx/SPC58xGx Microcontroller Security Reference Manual* for details.

38.9.2 Creating password groups

Most basic security features in the SPC58xEx/SPC58xGx microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTEST memory map (refer to the Memory Map chapter).

The UTEST memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Passwords must not be one of the following, which are considered insecure and therefore invalid:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

Caution: The password fields are in OTP UTEST Flash, so they can only be written once.

38.9.3 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user Flash are write protected, so this could be more accurately viewed as planning which blocks of user Flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the Flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in *Section 38.3.1: Implementing secure write protection* and *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

38.9.4 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to Flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user Flash are read protected, so this could be more accurately viewed as planning which blocks of user Flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the Flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in *Section 38.4.1: Implementing secure read protection* and *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

38.9.5 Planning debug port enable/disable

Refer to *Section 38.5: Debug port enable/disable* and *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

38.9.6 Planning OTP Flash memory block assignment

Any block of user Flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a Flash block as OTP is not reversible.

Before creating DCF records to implemented OTP Flash blocks, please thoroughly review the implementation steps detailed in *Section 38.7: Implementing OTP* and *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

38.9.7 Planning factory test mode disable

Refer to *Section 38.8: Implementing test mode disable* and *Table 129: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

39 Decorated Storage Memory Controller (DSMC)

39.1 Introduction

This section details hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called “*decorated storage*”. It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A “decoration” is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rA,rB` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rA,rB` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `“x”` mnemonic suffix, signaling an “indexed” addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in *Figure 468*.

Figure 468. Power Architecture Decorated Load and Store Instruction Formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

lwdcbx	0	1	1	1	1	1	**r**T						**r**A				**r**B				1	0	0	1	0	0	0	0	1	0	/
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
stbdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	0	0	0	0	1	1	/
sthdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	1	0	0	0	1	1	/
stwdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	1	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	1	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	1	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit “decoration”. The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and operand data for the command or both.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

39.2 Decorated Stores: st[b,h,w]d{cb}x rS,rB,rA

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a <command>.<size> syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

39.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container

Figure 469. Decoration Format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory “container” defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read

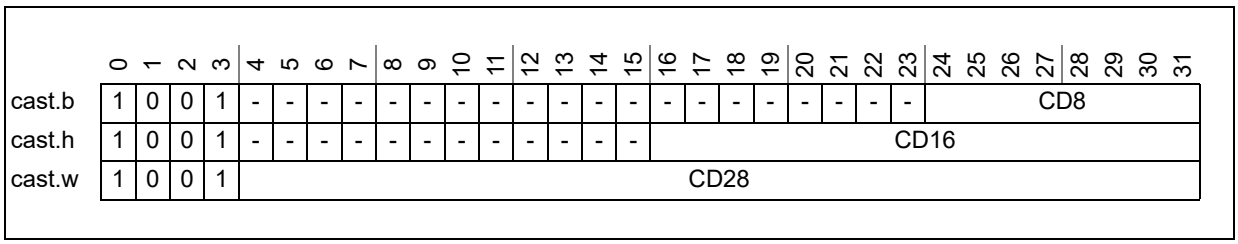
if bfw == 0
   then bfw = container

if ((srtbit + bfw) <= container)// generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp   & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp// memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.



To illustrate, consider the following example of the insertion of the 3-bit field “xyz” into an 8-bit memory container, initially set to “abcd_efgh”. For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

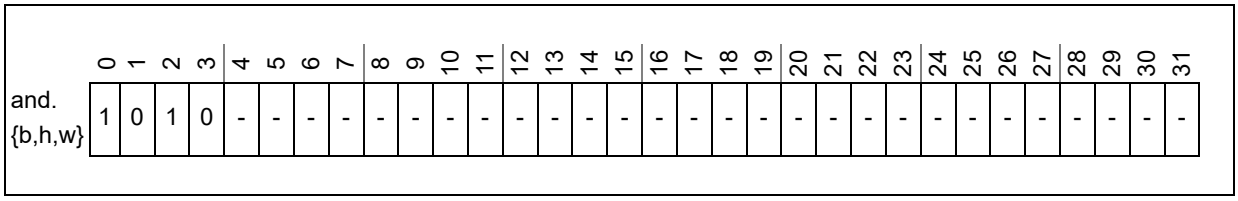
If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

39.2.2 Compare-and-Store (CAST)

Figure 470. Decoration Format: CAST

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read



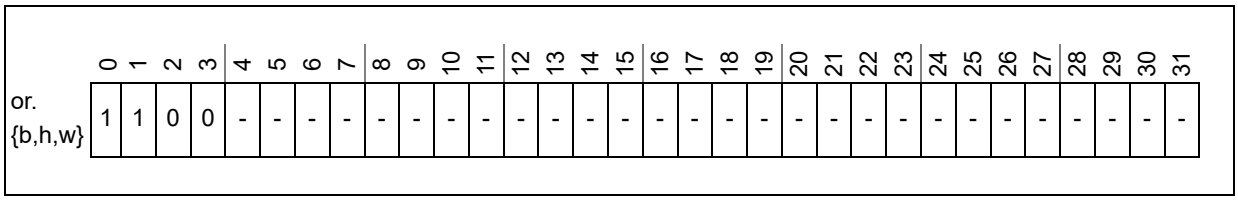
if (size == 8)// define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand)// compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

39.2.3 Logical AND (AND)

Figure 471. Decoration Format: AND

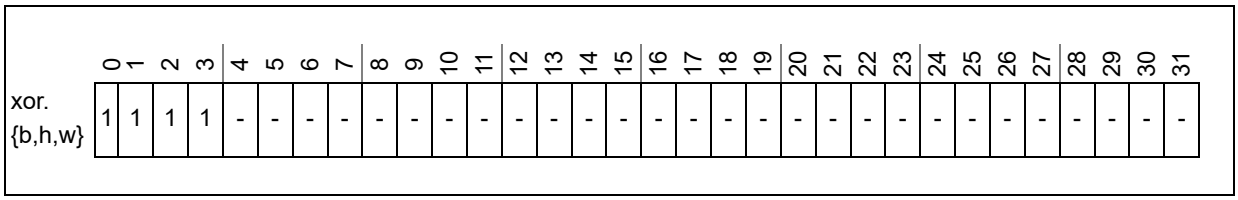


This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata// modify
mem[accessAddress, size] = tmp// memory write
```

39.2.4 Logical OR (OR)

Figure 472. Decoration Format: OR



This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata// modify
mem[accessAddress, size] = tmp// memory write
```

39.2.5 Logical Exclusive-OR (XOR)

Figure 473. Decoration Format: XOR

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata// modify
mem[accessAddress, size] = tmp// memory write
```

39.3 Decorated Loads: `l[b,h,w]d{cb}x rT,rB,rA`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an “extract”) operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

39.3.1 Simple Load (SLD)

Figure 474. Decoration Format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld. {b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

39.3.2 Registers-and-Memory Exchange (SWAP)

Figure 475. Decoration Format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
cast.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	WD16															
cast.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)// store_operand - "modify"
    store_operand = WD8
else if (size == 16)
          store_operand = WD16
     else store_operand = {0x0, WD28}// zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32-bit store operand.

39.3.3 Load-and-Set-1(Bit) (LAS1)

Figure 476. Decoration Format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp
mask  = 1 << (container - bit - 1)// generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

39.4 DSMC Instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the data port of the cores and the master ports of the crossbar.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the targeted slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

40 Analog-to-Digital Converters (ADC) Configuration

This chapter is organized as follows:

- *Section 40.1: ADC overview*
  - *Section 40.1.1: ADC subsystem block diagram*
  - *Section 40.1.2: Analog input pin multiplexing*
- *Section 40.2: Configuration of ADC modules*
  - *Section 40.2.1: Sigma-Delta Analog-to-Digital Converter (SDADC)*
  - *Section 40.2.2: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*

40.1 ADC overview

SPC58xEx/SPC58xGx contains the following analog-to-digital converters (ADCs):

- five independent 12-bit and three independent 10-bit Successive Approximation Register Analog-to-Digital Converters (SARADCs)
- six independent 16-bit Sigma-Delta Analog-to-Digital Converters (Sigma-Delta, or SDADCs)

Table 588. ADC implementation

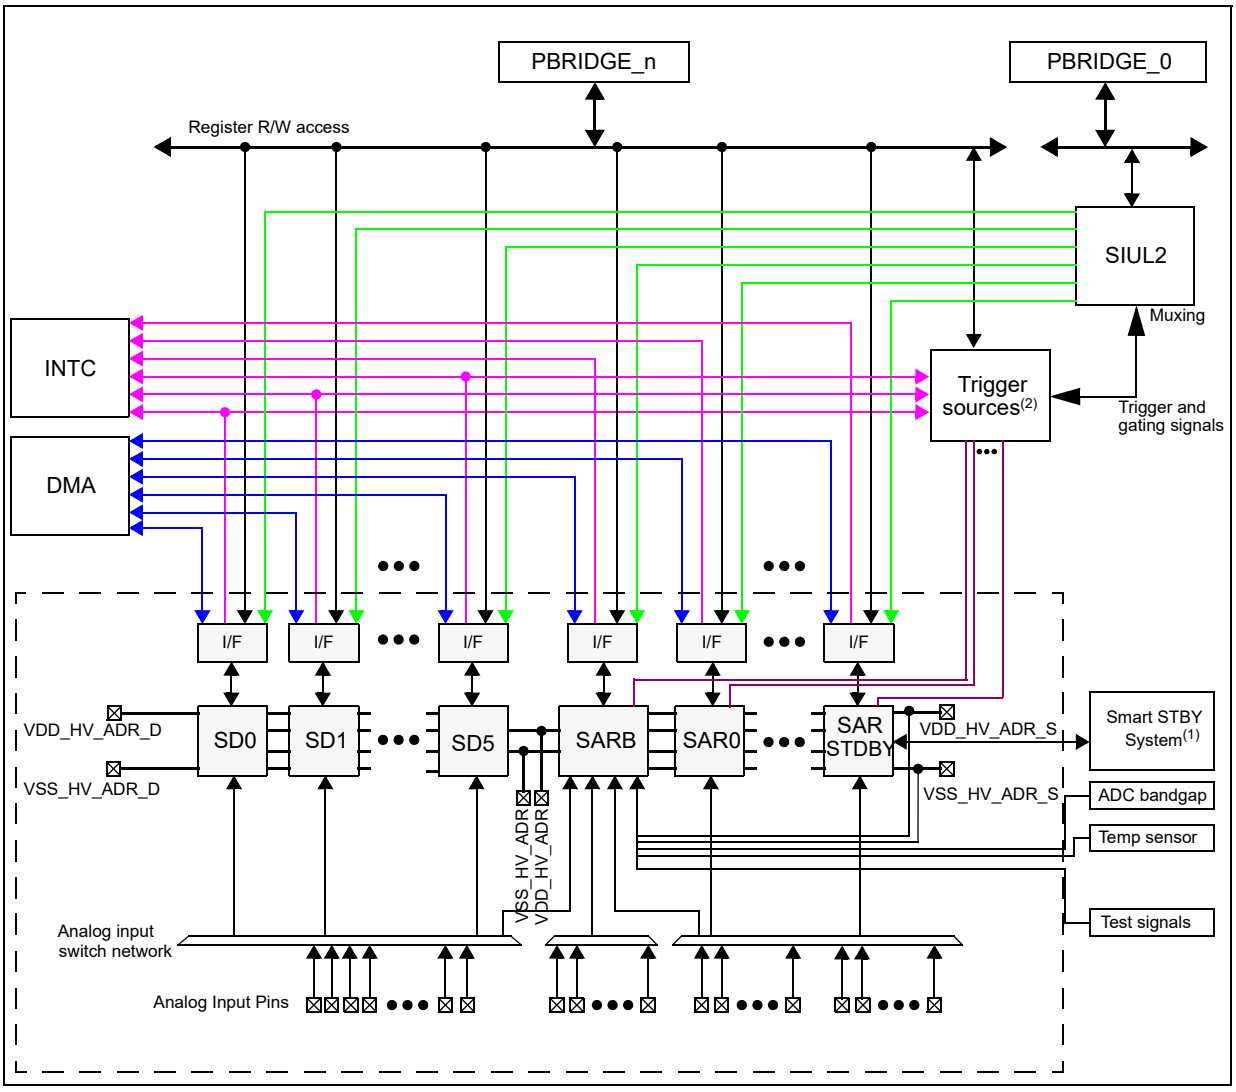
Converter Type	12-bit SAR ADC					10-bit SAR ADC			16-bit SD ADC					
Special Function	Supervisor SAR ADC	Fast SAR ADC				Fast Comparator		STDBY & Fast Comparator	Sigma-Delta					
Name	SAR_ADC_12bit_SUPERVISOR (SAR_ADC_12bit_B0)	SAR_ADC_12bit_0	SAR_ADC_12bit_1	SAR_ADC_12bit_2	SAR_ADC_12bit_3	SAR_ADC_10bit_0	SAR_ADC_10bit_1	SAR_ADC_10bit_STDBY	SD_ADC_0	SD_ADC_1	SD_ADC_2	SD_ADC_3	SD_ADC_4	SD_ADC_5
Number of internal channels(1)	82	8	8	15	15	4	4	8	2	2	4	8	2	2

1. This is the maximum number of available channels per dedicated silicon but the available number of channels per package might be different (see the IO_Definition document)

Note: SDADC and SARADC instances naming in some figures of this chapter may differ from the naming provided in Table 588 in order to simplify these figures.

The internal channels of each ADC are connected to analog input pads. The analog pads include programmable pull-up / pull-down resistors.

These ADCs interface to external analog input pins. The number of external analog input pins for each package is available in the IO_Definition.xls file attached to the IO_Definition document.



Each ADC instance, whether SAR or Sigma-Delta, has independent analog input , register interface, trigger and clock inputs, independent interrupt, and DMA capability. Each SAR and Sigma-Delta ADC has a dedicated peripheral bridge (PBRIDGE) interface for CPU access to the registers.

All SAR and Sigma-Delta ADCs share the same supply pins (VDD_HV_ADV/VSS_HV_ADV) and ground, but have separate reference pins. This is true for all packages.

40.1.1 ADC subsystem block diagram

Figure 477 gives the block diagram for the high-level integration of the ADC sub-system for SPC58xEx/SPC58xGx. The primary intent of the diagram is to show that each ADC, whether SAR or Sigma-Delta, has independent register interfaces, interrupt/DMA requests, and trigger source selection.

Figure 477. SPC58xEx/SPC58xGx ADC subsystem

1. SAR_ADC_10bit_STDBY interactions with the Smart STBY System are described in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*
2. The different trigger sources are detailed in the *Section 40.2.2.5: SAR ADC triggering*.

40.1.2 Analog input pin multiplexing

For analog input pin multiplexing please refer to the IO_Definition.xls file attached to the IO_Definition document.

40.2 Configuration of ADC modules

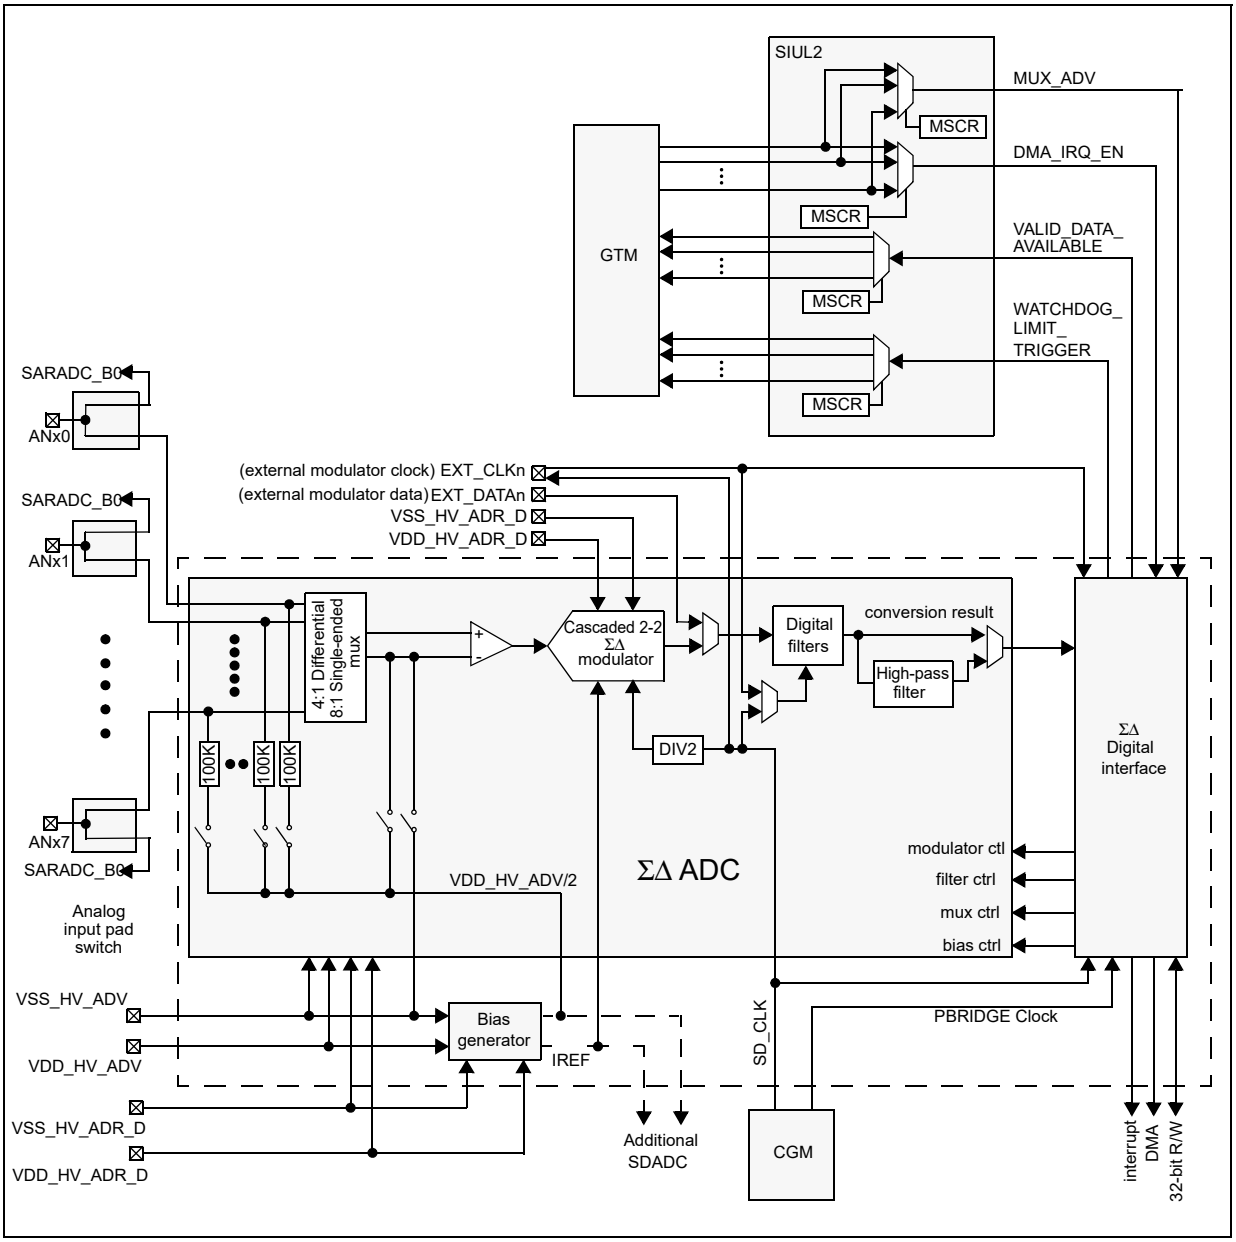
The following sections describe device-specific details for the following modules:

- *Section 40.2.1: Sigma-Delta Analog-to-Digital Converter (SDADC)*
- *Section 40.2.2: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*

40.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC)

There are six independent Sigma-Delta ADCs on SPC58xEx/SPC58xGx. Refer to *Figure 477* for the ADC subsystem block diagram.

The following sections describe configuration details:



- *Section 40.2.1.1: Sigma-Delta ADC integration diagram*
- *Section 40.2.1.2: Sigma-Delta ADC analog input multiplexing*
- *Section 40.2.1.3: Sigma-Delta ADC clock sources*
- *Section 40.2.1.4: Sigma-Delta ADC starting/triggering*
- *Section 40.2.1.5: Sigma-Delta ADC external modulator*
- *Section 40.2.1.6: Conversion result interrupt/DMA*
- *Section 40.2.1.9: Sigma-Delta ADC analog input channel selection*

For detailed module information, refer to the Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface chapter.

40.2.1.1 Sigma-Delta ADC integration diagram

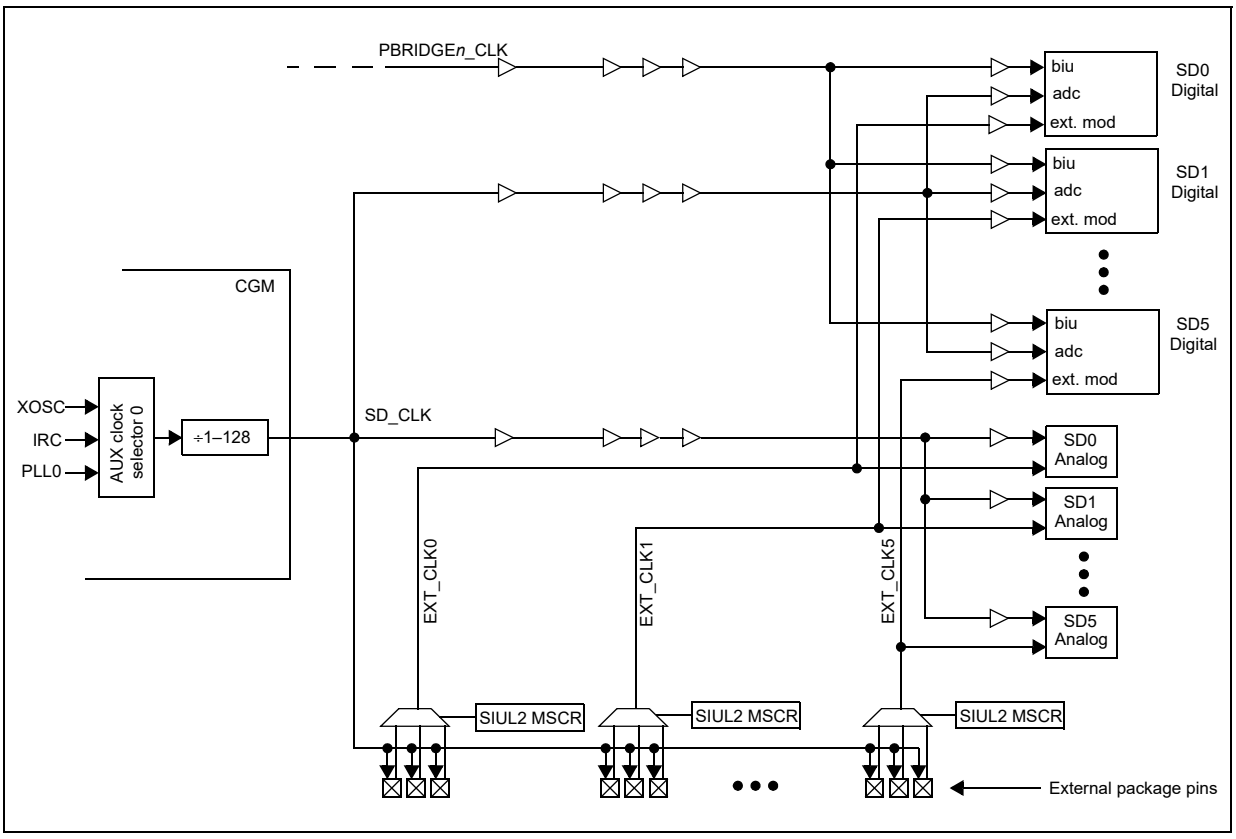
Figure 478 shows the block diagram of the Sigma-Delta ADC integration on SPC58xEx/SPC58xGx. Note that in the diagram any unused Sigma-Delta ADC input can be read by SAR_ADC_12bit_B0. This is true for the unused input in single-ended operation.

Figure 478. Sigma-Delta ADC integration diagram

40.2.1.2 Sigma-Delta ADC analog input multiplexing

The analog input multiplexing switches are contained within the Sigma-Delta ADCs and within the SAR_ADC_B. The connection to the Sigma-Delta ADC inputs is made to the pad pin through the analog pad cell, shown in *Figure 478*, and is controlled as follows:

- SAR_ADC_12bit_B0 analog inputs have no SIUL2_MSCRn[APC] bit-control, but are directly connected to the pad.
- SDADC analog inputs have no SIUL2_MSCRn[APC] bit control, but are directly connected to the pad.



The mapping of analog input pins to the Sigma-Delta converters is given in *Section 40.2.1.9: Sigma-Delta ADC analog input channel selection*.

40.2.1.3 Sigma-Delta ADC clock sources

Each Sigma-Delta ADC digital interface on the SPC58xEx/SPC58xGx has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE*n*_CLK. The module clock is sourced by the modulator clock (SD_CLK). The input clock for the Sigma-Delta modulator is the SD_CLK. *Figure 479* gives a block diagram of the required Sigma-Delta ADC clock architecture. See the *Section 27.6.7: Sigma-Delta ADC clocking* in the *Chapter 27: Clocking*, for more detail on the clock sources.

Both the analog and digital blocks of the ADC contain an internal clock mux for external modulator mode. The external modulator clock (EXT_CLK) can be input to the device, or generated from SD_CLK from the CGM. The pad input/output settings in the corresponding SIUL2 MSCR pad control registers determine the external modulator clock source to the ADC blocks. The EXT_CLK pins are multiplexed on multiple external pins on the device. Selection of the EXT_CLK pin to use for the external modulator clock for each ADC is done in the SIUL2 MSCR input multiplexing registers. Each Sigma-Delta ADC has three external pins to select from for an external modulator clock.

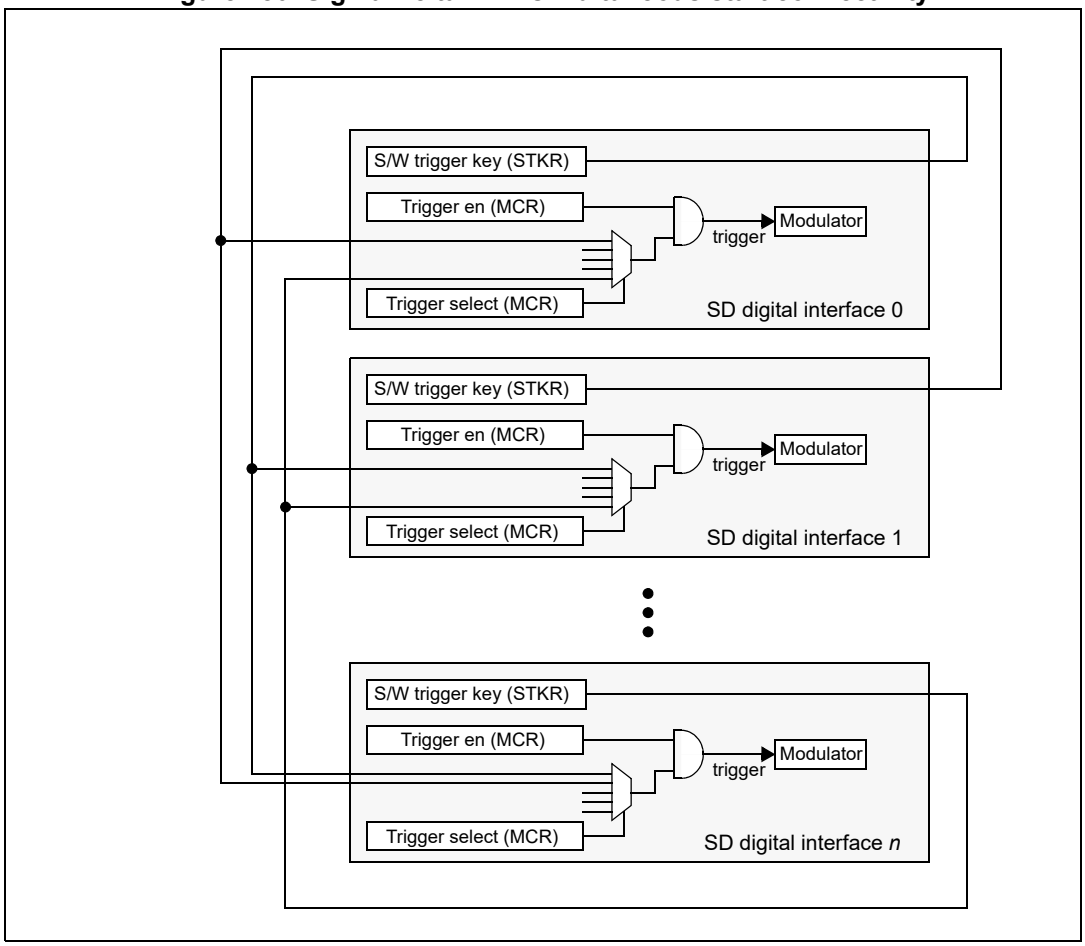
Figure 479. Sigma-Delta ADC clock diagram

40.2.1.3.1 Clock Skew

To avoid crosstalk issues, all Sigma-Delta ADCs run at the same clock frequency. Independent programmable oversampling rates are provided to support the varying bandwidths of interest on each ADC in the application. Therefore, all Sigma-Delta analog blocks are clocked from the output of a single divider of the peripheral clock at the chip level.

40.2.1.4 Sigma-Delta ADC starting/triggering

Each Sigma-Delta ADC on SPC58xEx/SPC58xGx supports starting the converter with a software write to an enable bit in a register in the digital interface.



40.2.1.4.1 Simultaneous start of multiple Sigma-Delta converters

A method to start multiple Sigma-Delta converters simultaneously by a single software write to a control register is available on the device. Simultaneously in this case means that all selected converters start sampling their inputs on the same SD_CLK clock edge.

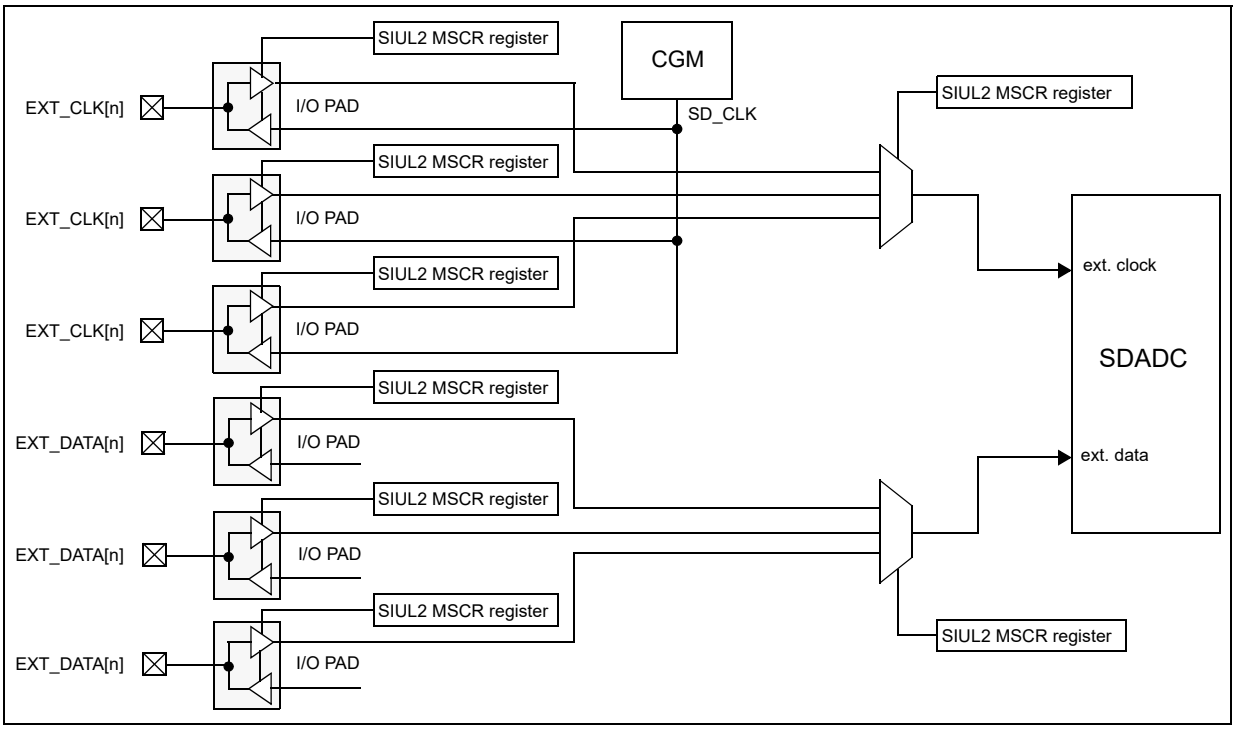
The digital interface of the Sigma-Delta ADC contains the control register for simultaneous start of the ADCs. When the register is written to start multiple converters, an output from the digital interface is asserted. The hardware trigger input of each Sigma-Delta ADC is connected to this simultaneous start output. This way the user controls which ADCs are selected by enabling the hardware trigger of desired ADCs before writing to the starting simultaneous converters.

The connections for the simultaneous start of the converters is given in *Figure 480*.

Figure 480. Sigma-Delta ADC simultaneous start connectivity

40.2.1.4.2 Sigma-Delta mux input advance and wraparound

The mux wraparound feature is enabled and controlled in the digital interface of the Sigma-Delta ADC. The advancing of the mux can be controlled in the interface by software or by external GTM channels. The mapping of GTM output channels to the mux advance input for each Sigma-Delta ADC for each device is given in the SIUL2 MSCR registers.



40.2.1.5 Sigma-Delta ADC external modulator

40.2.1.5.1 External modulators

The Sigma-Delta ADC supports an interface to external Sigma-Delta modulators. In this mode, the Sigma-Delta ADC internal modulator is disabled, and a serial bit stream from an external modulator is clocked into the back-end digital filters of the on-chip Sigma-Delta ADC. Currently, the AMC1203 external modulator is supported by the Sigma-Delta ADC. It is possible that other external 2nd order modulators with clock rates less than 10 MHz and a compatible electrical interface (see SPC58xEx/SPC58xGx Data Sheet) could be supported.

The external modulator interface for each Sigma-Delta ADC on SPC58xEx/SPC58xGx is shown in *Figure 481*.

Figure 481. Sigma-Delta ADC external modulator interface

40.2.1.5.2 External modulator clock/data inputs

Two external pins are required for each Sigma-Delta ADC to support an external modulator, an input data pin EXT_DATA (bitstream data), and an input/output clock pin EXT_CLK (bitstream clock). When the external modulator is used, the clock and data inputs to the Sigma-Delta ADC digital filters come from the EXT_CLK and EXT_DATA pins, instead of the internal modulator as shown in *Figure 481*. External modulator operation is enabled in the ADC digital interface registers. The internal modulator is disabled. The EXT_CLK and

EXT_DATA inputs are multiplexed on port input pins. For each Sigma-Delta ADC, there are three sets of EXT_CLK/EXT_DATA pins, and selection of those pins for each ADC is done in the SIUL2 MSCR registers.

40.2.1.5.3 External modulator clock output

SPC58xEx/SPC58xGx provides an option for an output clock from the device to the external modulator. When providing an output clock, the SD_CLK from the CGM is connected to the EXT_CLK output pin. Both the input and output buffer of the EXT_CLK pin must be enabled in the corresponding SIUL2 MSCR register, in order for both the external modulator and internal filters to be clocked from the SD_CLK. This is shown in *Figure 481*.

40.2.1.6 Conversion result interrupt/DMA

A DMA or interrupt can be generated for each conversion for each ADC. The Sigma-Delta ADC has an 8-deep result FIFO.

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input signal is connected to outputs from the GTM timer block. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the signal from the GTM is asserted, no interrupt or DMA request is generated for any conversion results. The polarity of the gating signal is such that when the signal is high, interrupt and DMA requests are passed. When the gating signal is low, interrupt and DMA requests are blocked.

The gating signal for each ADC is driven by several GTM channels. See *Chapter 17: System Integration Unit Lite2 (SIUL2)* for the specific mapping of GTM channels to Sigma-Delta interrupt/DMA gating signals.

40.2.1.7 Conversion Limit Watchdog Output to GTM

Each Sigma-Delta ADC provides an optional conversion limit check for upper and lower bounds. The enable bit and the two 16-bit limit registers for the feature are included in the SDADC wrapper. If a conversion result exceeds one of the limits, a flag bit is asserted in a status register in the SDADC wrapper. The flag bit is output to the GTM for each SDADC. The mapping of conversion limit watchdog outputs to GTM channels is defined in the SIUL2 MSCR registers.

40.2.1.8 SDADC_MCR[TRIGSEL] definitions

For this chip, the following input triggers apply.

Table 589. Input triggers

TRIGSEL	Trigger input selection(1)
0000	SD_ADC_0
0001	SD_ADC_1
0010	SD_ADC_2
0011	SD_ADC_3
0100	SD_ADC_4
0101	SD_ADC_5
0110	MUX_ADV
0110–1111	Reserved

1. This field selects which input will be used for hardware-triggered conversions.

Note: Selecting the input trigger source to be from the output trigger of the same SDADC is not prohibited by hardware, but is not supported, and will result in the SDADC never responding to the input trigger.

40.2.1.9 Sigma-Delta ADC analog input channel selection

For the Sigma-Delta mux inputs AN[x], the positive and negative input terminals are selected in the Sigma-Delta ADC digitial interface Channel Selection Register (CSR).

This section shows analog channel selections for each combination of Module Configuration Register (MCR) field values MCR_MODE and MCR_VCOMSEL. The following table provides a quick reference key to the MCR fields used in the SD ADC analog input selection tables that follow it.

Table 590. Register fields for SD ADC analog input channel selection

Field	Description
MCR_VCOMSEL	Common Voltage Bias Selection This bit selects the common voltage bias for the negative input terminal of SDADC during single-ended mode (MODE=1). 0 Negative input terminal is biased with VREFN. 1 Negative input terminal is biased with VREFP/2 (half scale bias).
MCR_MODE	Mode selection 0 Differential input mode is selected. 1 Single-ended input mode is selected.
CSR_ANCHSEL	Analog Channel Selection Based on single-ended or differential mode of operation (MODE bit of MCR), common mode voltage selection (VCOMSEL bit of MCR), this bit-field defines the connectivity of analog inputs to either positive or negative polarity terminals of Sigma-Delta ADC, as shown in the following tables: – *Table 591* for SD_ADC_0 – *Table 592* for SD_ADC_1 – *Table 593* for SD_ADC_2 – *Table 594* for SD_ADC_3 – *Table 595* for SD_ADC_4 – *Table 596* for SD_ADC_5

40.2.2 Successive Approximation Register Analog-to-Digital Converter (SAR ADC)

There are five independent 12-bit and three independent 10-bit SAR ADCs on SPC58xEx/SPC58xGx. Refer to *Figure 477* for the ADC sub-system block diagram.

The following sections describe configuration details:

- *Section 40.2.2.1: SAR ADC configuration overview*
- *Section 40.2.2.2: SAR ADC integration diagram*
- *Section 40.2.2.3: SAR ADC analog input*
- *Section 40.2.2.4: SAR ADC clock sources*
- *Section 40.2.2.5: SAR ADC triggering*
- *Section 40.2.2.6: SAR ADC fast comparator*
- *Section 40.2.2.7: SAR ADC Standby*
- *Section 40.2.2.8: SAR absolute voltage reference*
- *Section 40.2.2.9: SAR ADC diagnostic*
- *Section 40.2.2.10: SAR ADC channel assignment*

For detailed module information, refer to the Successive Approximation Register Analog-to-Digital Converter (SAR ADC) Digital Interface chapter.

40.2.2.1 SAR ADC configuration overview

40.2.2.1.1 12-bit Fast SAR ADC

Four 12-bit Fast SAR ADC instances are implemented with:

- 12-bit and 10-bit conversion mode selectable by software on a per conversion basis
  - 8 analog input channels for each SAR_ADC_12bit_0 and SAR_ADC_12bit_1
  - 15 analog input channels for each SAR_ADC_12bit_2 and SAR_ADC_12bit_3
- 4 internal test channels (called "test channels") to be used for self-diagnosis of the converter and diagnosis of the analog signal path up to the external circuitry. This includes:
  - four internal voltage references with 20 kOhm source impedance
- 4 watchdogs

40.2.2.1.2 12-bit SAR ADC B0

One 12-bit SARADC B0 (SAR_ADC_12BIT_B0) instance with diagnosis is implemented with:

- 12-bit and 10-bit conversion mode selectable by software on a per conversion basis
- 82 analog input channels (called internal channels)
- 64 external multiplexed channels (called external channels)
- All analog internal channels from other ADCs are also connected to SAR_ADC_12bit_B0
- 9 internal test channels (called "test channels") to be used for self-diagnosis of the converter and diagnosis of the analog signal path up to the external circuitry. This includes:
  - an internal bandgap reference from temperature sensor
  - an internal analog ground signal for software offset cancellation
  - four internal voltage references with 20 kOhm source impedance
- 8 watchdogs
- Body Cross Triggering Unit (BCTU) support to trigger ADC conversion

40.2.2.1.3 10-bit Fast SAR ADC

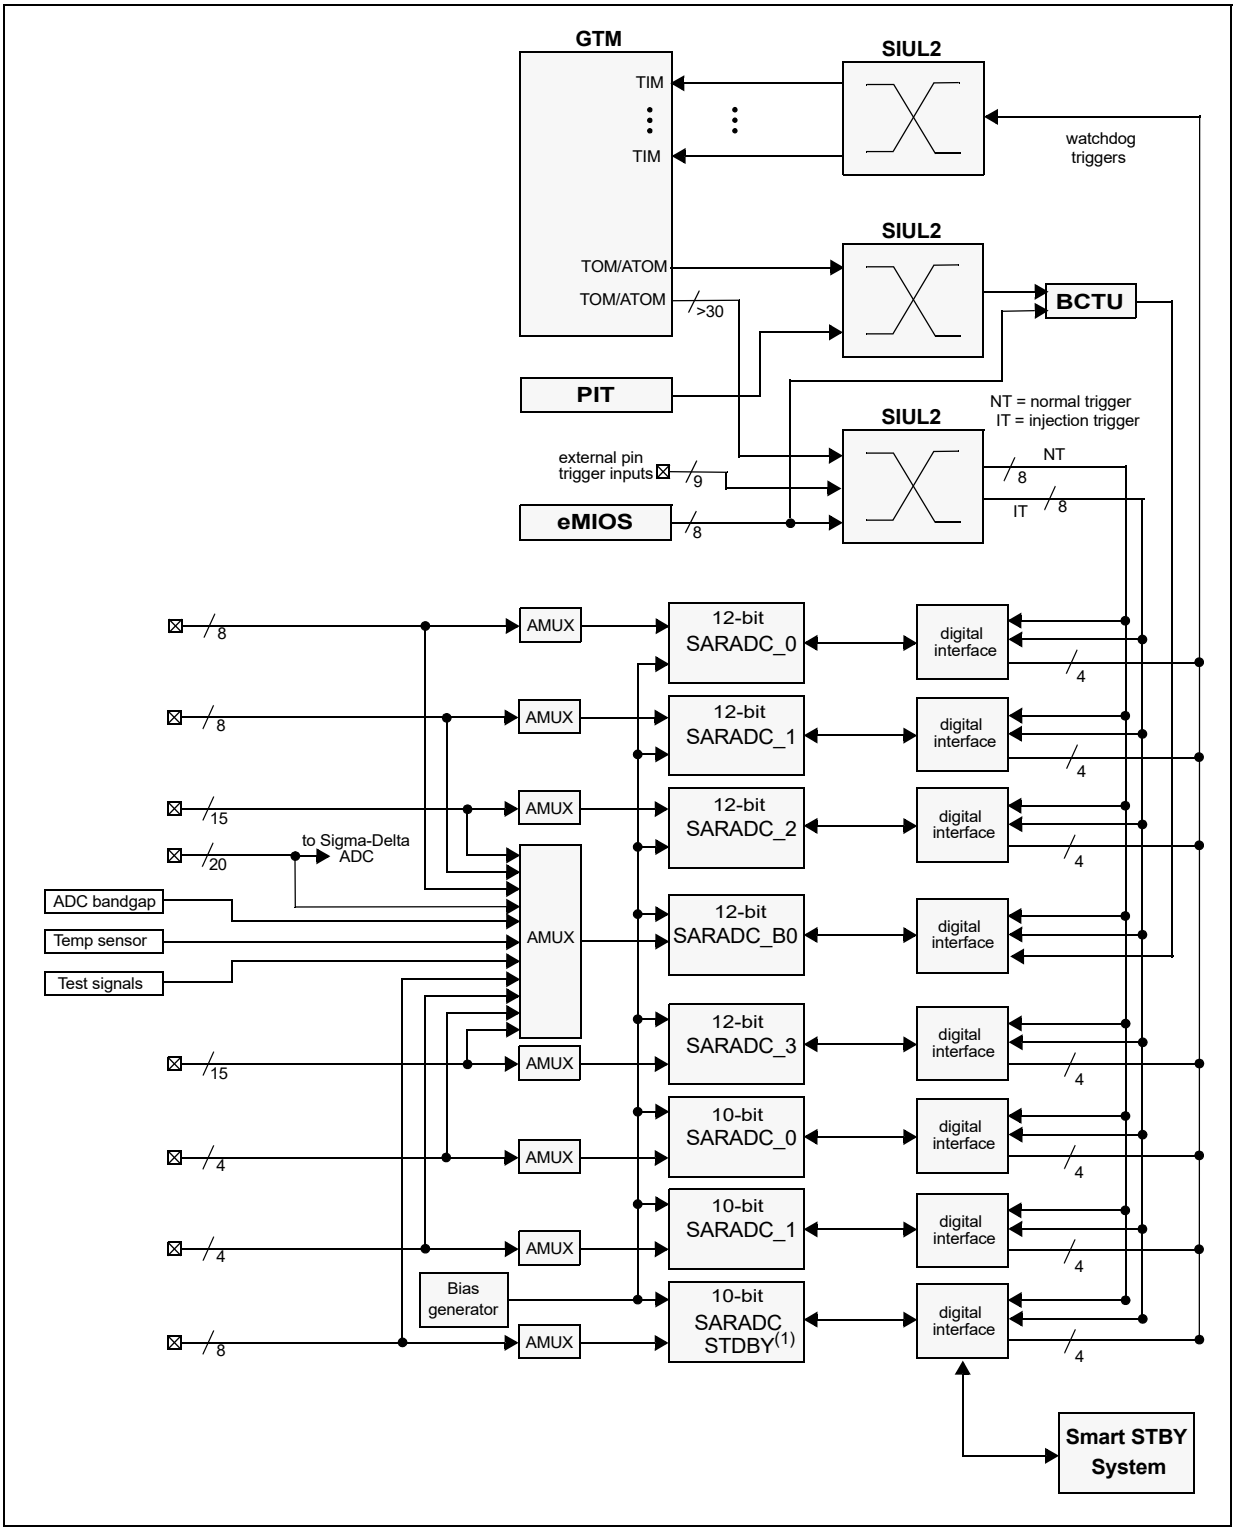
Two fast 10-bit SAR ADC instances with four internal channels and fast comparator capability are implemented with:

- 10-bit and 8-bit conversion mode selectable by software on a per conversion basis
- Very fast detection of analog threshold violations
- 4 internal test channels (called "test channels") to be used for self-diagnosis of the converter and diagnosis of the analog signal path up to the external circuitry. This includes:
  - four internal voltage references with 20 kOhm source impedance
- 4 watchdogs
- Comparator mode:
  - the detection is done against two programmable 10-bit thresholds
  - two violation events (against upper and lower thresholds) are available. These events are combined in one signal connected to the GTM.

40.2.2.1.4 10-bit Fast SAR ADC STDBY

One fast 10-bit SAR ADC STDBY instance with 8 internal channels with fast comparator capability and supporting STAND-BY feature is implemented with:

- 10-bit and 8-bit conversion mode selectable by software on a per conversion basis (all standard SAR ADC functionalities are present)
- 8 external channels needed for data register and watchdog functionality
- 4 analog watchdogs
- Cross Triggering Unit (STBY eCTU) support. In Standby mode, ADC operation is controlled by STBY eCTU. Refer to the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* for details on STAND-BY feature
- In RUNTIME, 10-bit Fast ADC STDBY can be used as the other 10-bit Fast SAR ADC instances



Note: Refer to SPC58xEx/SPC58xGx datasheet for SAR ADC analog performances.

40.2.2.2 SAR ADC integration diagram

Figure 482 shows the block diagram of the integration of the five 12-bit and three 10-bit SAR ADCs on SPC58xEx/SPC58xGx.

The bias generator provides 4 reference points (VDD_HV_ADR_S, 1/3 VDD_HV_ADR_S, 2/3 VDD_HV_ADR_S, and VSS_HV_ADR_S) which are provided to SAR_ADC_12bit_B0 via an internal 20 kΩ impedance. See the SAR ADC block diagram in the *Chapter 42: Successive Approximation Register Analog-to-Digital Converter (SARADC)*.

Figure 482. SAR ADC integration diagram(1)

1. SAR_ADC_10bit_STDBY instance is implemented on a special low-power domain. Further information is provided in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*

40.2.2.3 SAR ADC analog input

All analog input pins are routed to SAR_ADC_12bit_B0 and another fast SAR ADC. Analog input (AMUX) is implemented in the SAR ADC subsystem.

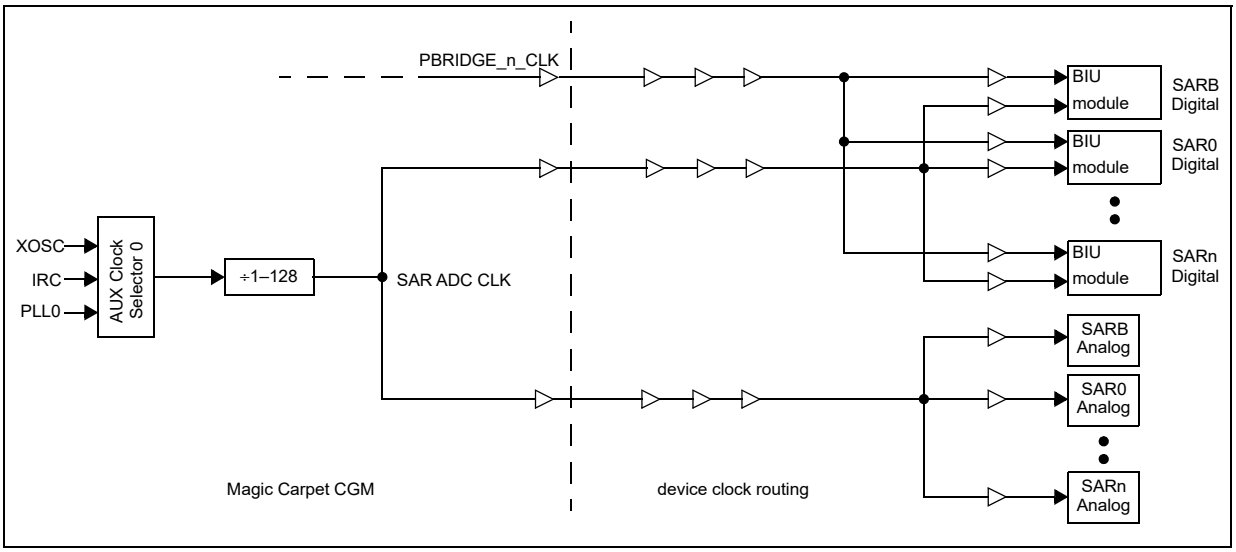
Note: Simultaneous sampling of two SAR ADCs on the same analog channel is possible under certain conditions:

- both ADCs need synchronized start of sampling (both ADCs have to be triggered by the same trigger signal)

- both ADCs need synchronized end of sampling (both ADCs have to be configured with the same sampling time)

- external circuitry on the analog input has to be chosen accordingly (effective internal capacity on analog signal path during sampling time is doubled versus single conversion as given in the device data sheet)

The mapping of analog input pins to the SAR converters is given in *Section 40.1.2: Analog input pin multiplexing*.



40.2.2.4 SAR ADC clock sources

Each SAR ADC digital interface on SPC58xEx/SPC58xGx has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE*n*_CLK. The module clock is sourced by the ADC clock (SAR ADC CLK). See *Chapter 27: Clocking* for more detail on the clock sources.

The input clock for the SAR ADC analog blocks is clocked by the SAR ADC CLK. *Figure 483* shows a block diagram of the SAR ADC clock architecture.

To avoid crosstalk issues, all SAR ADCs run at the same clock frequency. The SAR digital interface is clocked from the PBRIDGE*n*_CLK clock. All SAR analog blocks are clocked from the output of a single divider of the SAR ADC CLK at the device level.

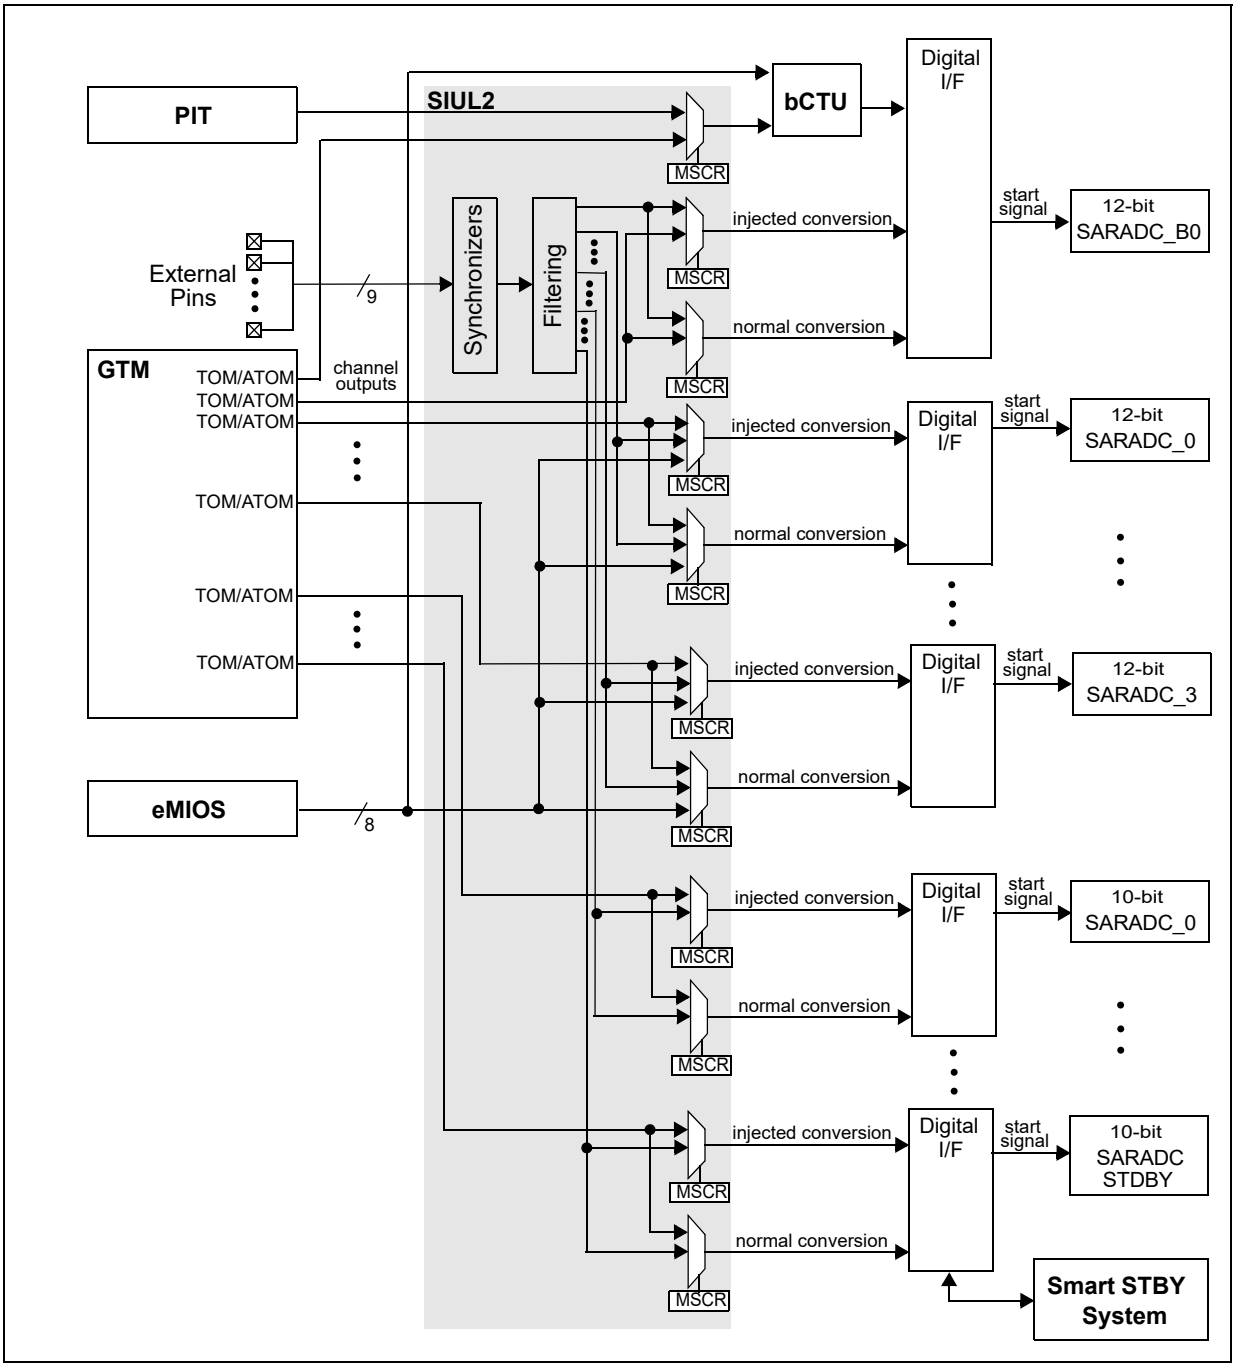
Figure 483. SAR ADC clock diagram

40.2.2.5 SAR ADC triggering

Each SAR ADC has 2 independent trigger inputs for starting normal conversion or injected conversion on an analog input. One trigger source can be selected among a list of available signals and connected to the trigger inputs independently for each SAR ADC.

The trigger sources for each SAR ADC on the device are either external input pins, eMIOS or GTM channels. Each external input can selectively trigger any of the SAR ADCs on the device. The synchronization to the PBRIDGE clock and digital filtering of the external input pin triggers is done in the system integration logic.

Each trigger input supports software selectable options for rising edge, falling edge, rising and falling edge, or level-based trigger assertion. The trigger selection for each SAR ADC and edge/level selection is located in the SIUL2.



The BCTU module is connected to SAR_ADC_12bit_B0 (SAR_ADC parameter CTSEN = 0). This module receives trigger requests from the timer module (PIT_RTI), from the generic timer module (GTM-TOM) or from EMIOS. It translates those trigger requests into ADC measurement commands.

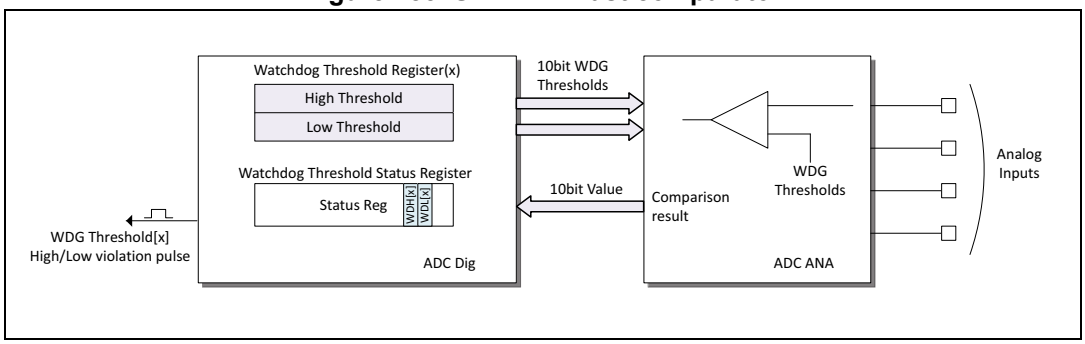
The STBY eCTU module is connected to SAR_ADC_10bit_STDBY (SAR_ADC parameter CTSEN = 2). It receives trigger requests from the real time clock module (RTC) and translates them into ADC commands. The STBY eCTU is used for the Smart Standby feature. Please refer to the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* for more data about this feature.

The SPC58xEx/SPC58xGx SoC diagram for the SAR ADC trigger inputs is given in *Figure 484*.

Note: Please refer to the MS Excel file attached to SPC58xEx/SPC58xGx IO_Definition document (I/O signal table) to get the exhaustive list of signals source able to trigger ADC conversion.

Figure 484. SAR ADC input trigger diagram

Trigger source selection for each SAR ADC is given in the *Chapter 17: System Integration Unit Lite2 (SIUL2)*.



Each SAR ADC digital interface, except SAR_ADC_12bit_B0, provides 4 watchdog Threshold Crossover event trigger signals. These signals can be routed to the GTM module (TIM interface) via SIUL2. Selection of watchdog trigger event for each GTM TIM interface is provided in the *Chapter 17: System Integration Unit Lite2 (SIUL2)*.

40.2.2.6 SAR ADC fast comparator

The fast comparator mode feature is only available with the 10-bit SAR ADCs.

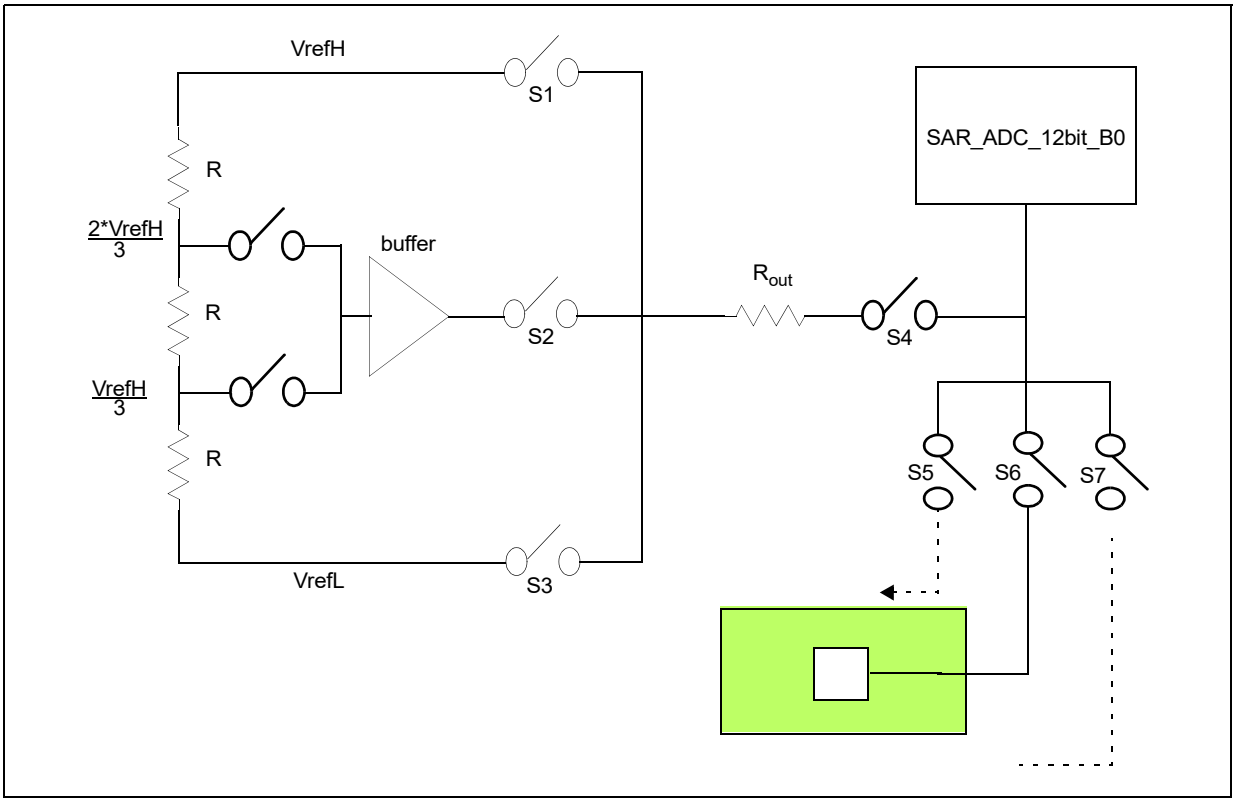
The fast comparator mode provides fast signal evaluation with respect to two thresholds configurable by the user. The result of the comparison is reflected by two status bits in the Watchdog Threshold Status Register and a watchdog pulse that is generated out of the ADC and forwarded to the GTM. SAR ADC fast comparator scheme is shown below.

Figure 485. SAR ADC fast comparator

40.2.2.7 SAR ADC Standby

SAR_ADC_10bit_STDBY interactions with the Smart STBY System are described in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*

40.2.2.8 SAR absolute voltage reference



SPC58xEx/SPC58xGx provides an internal, absolute voltage reference that can be calculated from two digital temperature sensor signal values. The temperature sensor signal values can be read by SAR_ADC_12bit_B0. For further information refer to *Chapter 43: Temperature Sensor*. The ADC conversion channel numbers for the temperature sensor signals are given in *Table 598*.

40.2.2.9 SAR ADC diagnostic

40.2.2.9.1 Self Test features

- The ADCBIAS provides four different voltage levels defined as GND, $V_{ref}/3$, $2*V_{ref}/3$ and V_{ref}. The self test internal reference voltage precision is provided in the SAR ADC electrical specification table of the device datasheet.
- For the impedance requirements please refer to SPC58xEx/SPC58xGx datasheet.
- The impedance of the switches that are connecting the different references to the ADC input has not been considered in the impedance calculation.
- The impedance of the switches from the reference generation to the ADC input has been matched with the one of the switches that are connecting the device pin to the ADC input.
- The sampling time of SAR_ADC_12bit_B0 needs to be extended due to long settling time induced by the high impedance of the source. For sampling time adjustment, please refer to SPC58xEx/SPC58xGx datasheet.
- The SAR ADC Digital Interface provides the necessary control to select the required switches S1–S7 (shown in *Figure 486*) to perform the Self Test.

Figure 486. Self Test implementation

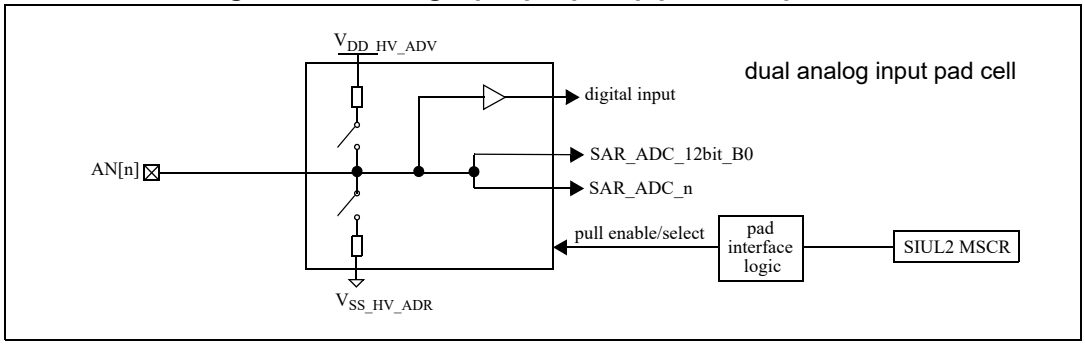
40.2.2.9.2 Internal reference

SAR_ADC_12bit_B0 provides the ability to sample and convert four internal voltages through a 20 kΩ source impedance. These voltages are as follows:

- $V_{DD_HV_ADR_S}$
- 1/3 $V_{DD_HV_ADR_S}$
- 2/3 $V_{DD_HV_ADR_S}$
- $V_{SS_HV_ADR_S}$

Conversion of an internal reference voltage works the same as that for a normal conversion, with the exception of the conversion time. Due to the 20 kΩ source impedance, the sampling time is much higher than the normal time.

Enabling the sampling and selection of an internal reference is independent of input channel selection for SAR_ADC_12bit_B0.



40.2.2.9.3 Analog input pin programmable pullup/pulldown

An open or short circuit condition is detectable within the device for analog input pins. There is a programmable pullup/pulldown pad cell at the input pad. This allows for application testing of the mux input logic. The analog input pin diagram with the pullup/pulldown is shown in *Figure 487*. The pullup/pulldown is included inside the analog input pad cell.

Control of the pullup/pulldown is independently done in the SIUL2 MSCR registers for each analog input pin.

Only the analog input pins specified in *Section 40.1.2: Analog input pin multiplexing* have the pullup/pulldown feature.

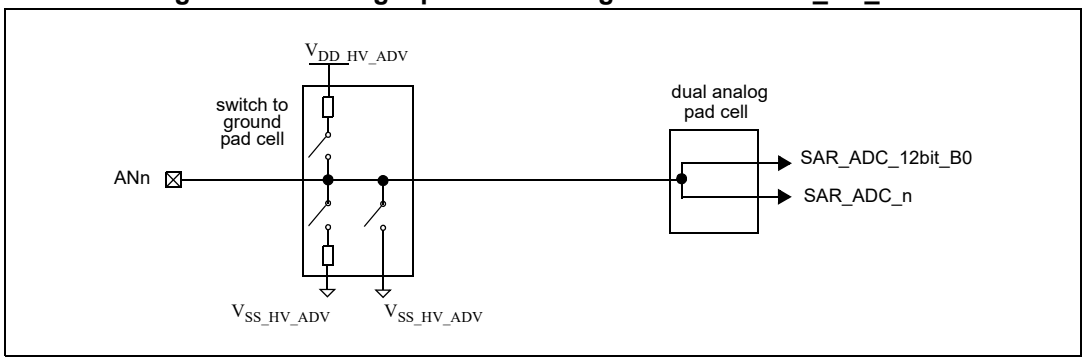


Figure 487. Analog input pin pullup/pulldown pad cell

40.2.2.9.4 Analog input pin switch to $V_{SS_HV_ADV}$

All analog input-only pins on SPC58xEx/SPC58xGx have in addition to the weak pullup/pulldown a programmable switch to $V_{SS_HV_ADV}$ to discharge the input. The analog input diagram is given in *Figure 488*. The default state of the switch for both inputs is OFF.

Figure 488. Analog input — discharge switch to VSS_HV_ADV

The ground switches are controlled independently from the input switch to the ADC. The ground switch is controlled in input multiplexing MSCR registers (MSCR[WPDE], MSCR[WPUE]) in the SIUL2. The MSCR register provides selection between open or closed switch, with open being the default state.

The ground switches can be used to periodically discharge the associated channels.

40.2.2.10 SAR ADC channel assignment

40.2.2.10.1 Internal channel assignment

The input multiplexer channel assignments for the SAR ADCs is provided in *Table 597*.

Table 597. SAR analog input channel assignment

Analog input pin	SAR_ADC_12bit_B0 input channel	Fast SAR	Fast SAR channel	Description

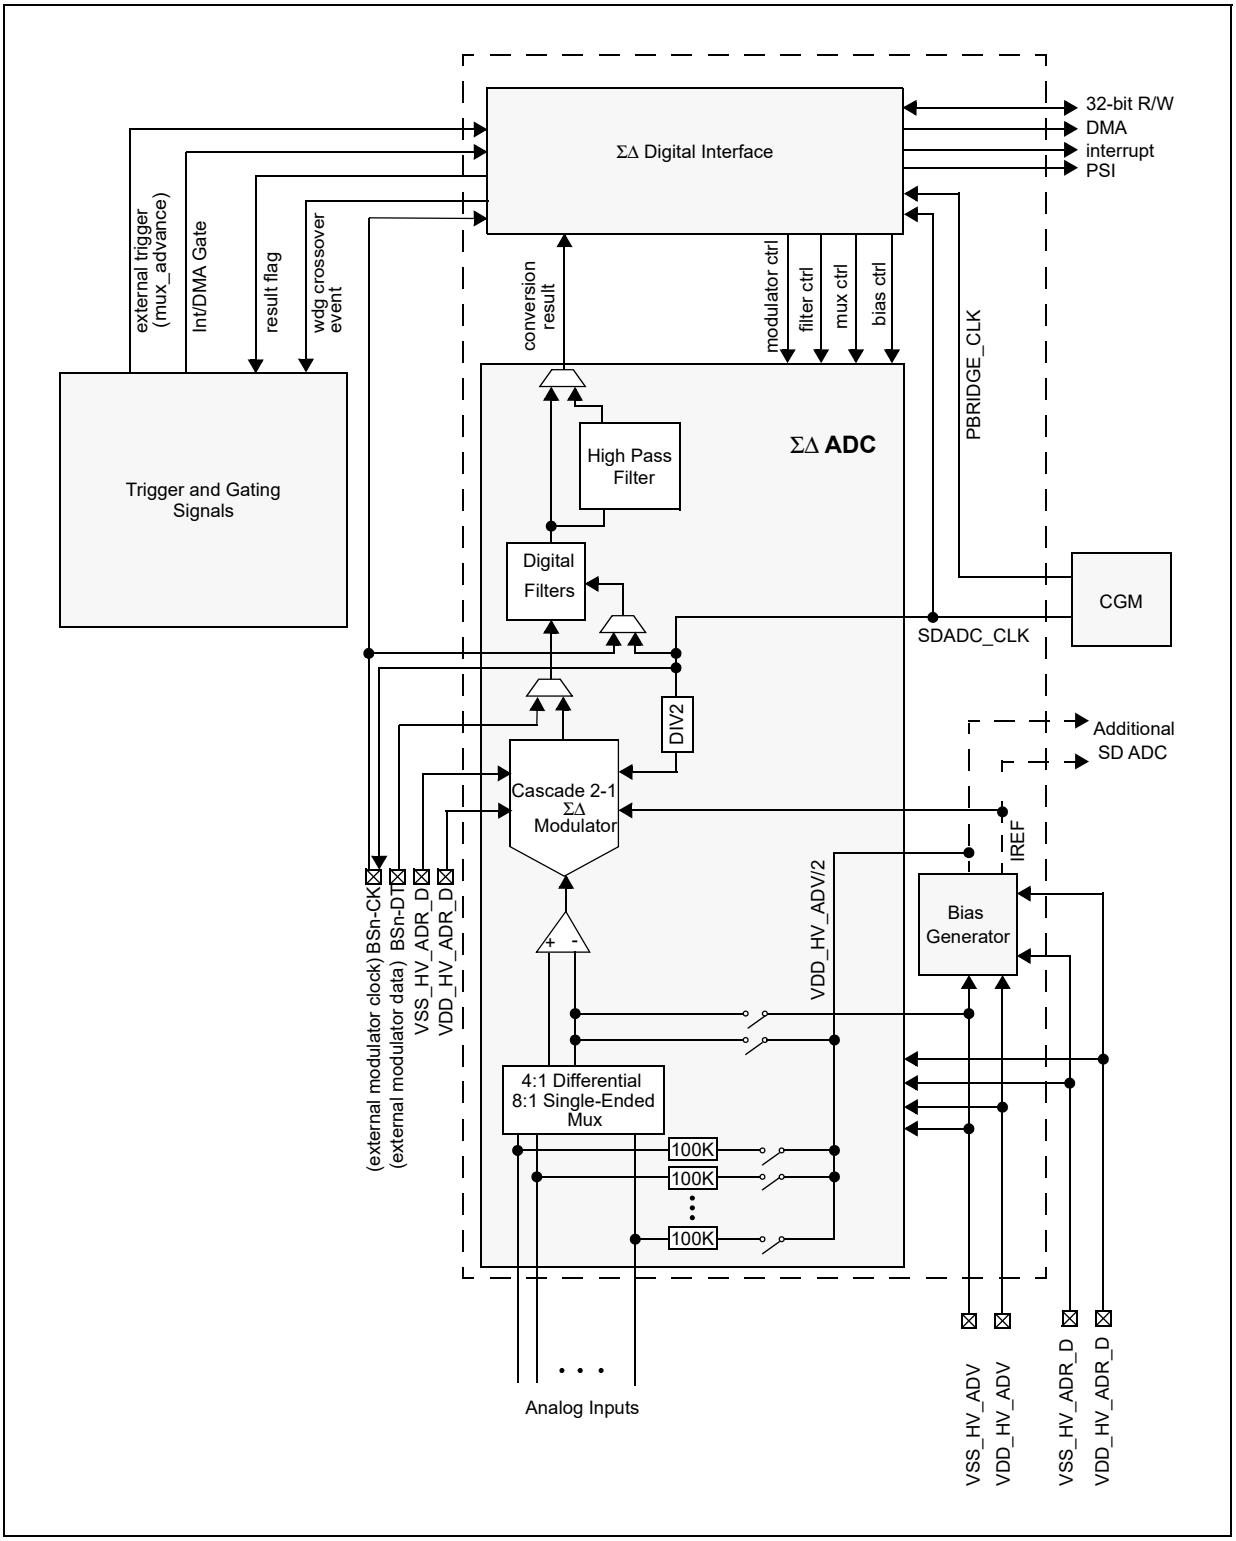
41 Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface



41.1 Introduction

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides accurate conversion data for a wide range of applications.

41.2 Overview

Figure 489 depicts the block diagram of an SDADC and its digital control block. The SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, high-pass filter enable, and so on. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. It also provides external modulator support and keeps the internal modulator in low consumption mode. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

Figure 489. SDADC block diagram

41.3 Features

- 16-bit data resolution output
- Single-ended input or differential input mode of operation
- Programmable wraparound mechanism for both modes of operation
  - Configurable trigger sources: hardware or software
  - Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single-ended mode
- Gain and offset calibration support using fixed bias for input terminals
- Programmable decimation rate
- Cascaded COMB + FIR decimation filter with an optional FIR filter for the SD ADC data path
- Programmable gain for analog inputs
- Optional external modulator support
- Optional high-pass filter for pure AC application
- Hardware trigger support for synchronous operation of multiple SDADC blocks
- Trigger event output generation by software
- Programmable FIFO structure for storing 16-bit converted data
- Left/right data alignment
- Signed/unsigned format of converted data output
- Interrupt/DMA request generation based on various conditions:
  - Data buffer at or above threshold
  - Data buffer overrun
  - WDG crossover event
- Programmable threshold range WDG support
- Low consumption mode
- Optional conversion process halt mechanism on SoC debug request

41.4 Modes of operation

This section describes the different operation modes of the SDADC. When exiting reset, the mode of operation is determined by the Module Configuration Register (MCR).

41.4.1 Differential input mode

This mode is entered by negating the MCR[MODE] bit. In this mode, a pair of analog inputs are connected to positive and negative terminals of ADC modulator. In order to support gain and offset calibration for diagnostics, it is possible in this mode to select fixed bias voltages to both input terminals.

41.4.2 Single-ended input mode

This mode is entered by asserting the MCR[MODE] bit. In this mode, the negative input terminal is biased with a fixed voltage based on selection information in MCR, and the other analog input is connected to the selected external analog channel.

41.4.3 External modulator mode

This mode is entered by asserting the MCR[EMSEL] bit. In this mode, the data stream and clock outputs from the external modulator available on BSEXT/CLKEXT input pins are routed directly to the SDADC block. The internal modulator is bypassed in this mode. Only the digital filters of the SDADC will be used for result calculation. The source for the external modulator clock can be the internal on-chip clock source or the direct clock output coming from the external modulator. The external pin function control for these pins must be configured in the integration logic on a device, and is not included in the SDADC digital interface.

41.5 External signal description

Table 599 shows the list of signals driven by external pins. At the chip integration level, some of the digital and analog signals might share pins or may not be available external to the chip.

Table 599. Signal properties

Name[1]	Function	I/O	Reset	Pull-up
AIN[0:7]	Single-ended analog inputs or Differential pairs of analog inputs	I	—	—
BSEXT	External modulator data input	I	0	—
CLKEXT	External modulator clock input	I	0	—
VREFP = VDD_HV_ADR_D	Voltage reference for SDADC	I	—	—
VREFN = VSS_HV_ADR_D	Ground reference for SDADC	I	—	—
VDD_HV_ADV	Analog voltage supply for SDADC	I	—	—
VSS_HV_ADV	Analog ground supply for SDADC	I	—	—
VDD_LV	Digital voltage supply for SDADC	I	—	—
VSS_LV	Digital ground supply for SDADC	I	—	—

1. See *Section 40.2.1.1: Sigma-Delta ADC integration diagram*.

41.5.1 Detailed signal descriptions

Table 600 provides a detailed description of the external signals.

Table 600. Detailed signal descriptions

Signal	I/O	Description	
AIN[0:7]	I	Each analog input can be used as a single-ended analog input or one of a differential pair of analog inputs which is connected to either positive or negative terminals of the SDADC, depending on the mode of operation and polarity selection.	
		State meaning	Analog input
		Timing	Can be sampled at any time by the ADC.
BSEXT	I	Data stream input provided by external modulator.	
		State meaning	Asserted—Data input is 1 Negated—Data input is 0
		Timing	Assertion—May occur at any time, but data stream is valid only when external modulator is selected by MCR[MODSEL] = 1. Negation—Ignored when external modulator is not selected.
CLKEXT	I	Clock input provided by external modulator.	
		State meaning	Asserted—clock high level Negated—clock low level
		Timing	Assertion—May occur at any time, but clock is valid only when external modulator is selected by MCR[MODSEL] = 1. Negation—Ignored when external modulator is not selected.

41.6 Memory map and register descriptions

41.6.1 Memory map

This section provides the memory map for the SDADC block.

Table 601. SDADC memory map

Address Offset	Register name	Width (in bits)	Access	Reset value	Section

Table 602. SDADC_MCR field descriptions

Field	Description
3:7 PDR	Programmable Decimation Rate This field selects the over-sampling ratio to be applied to support different pass-bands with a fixed input sampling clock. The output data rate f_d is equal to f_s / (2×OSR), where f_s is the input sampling clock frequency. When external modulator is selected, the output data rate is independent of this field and is fixed to f_s / 256. 00000 OSR = 24 00001 OSR = 28 00010 OSR = 32 00011 OSR = 36 00100 OSR = 40 00101 OSR = 44 00110 OSR = 48 00111 OSR = 56 01000 OSR = 64 01001 OSR = 72 01010 OSR = 75 01011 OSR = 80 01100 OSR = 88 01101 OSR = 96 01110 OSR = 112 01111 OSR = 128 10000 OSR = 144 10001 OSR = 160 10010 OSR = 176 10011 OSR = 192 10100 OSR = 224 10101 OSR = 256 10110 OSR = 512 10111 OSR = 1024 11000-11111 Reserved
9:11 PGAN	Programmable Gain This field selects the gain to be applied to the analog input stage of the SDADC. The effective analog input becomes the input voltage level multiplied by the gain factor. **Note:** When SDADC_MCR[PGAN]=111b (programmable gain is 16), the least significant bit of the conversion data in SDADC_CDR[CDATA] is always 0. 000 Gain = 1 001 Gain = 2 010 Gain = 4 011 Gain = 8 100 Reserved 101 Reserved 110 Reserved 111 Gain = 16
12 ODF	Output Data Format ODF selects the representation for digital part. 0 Output data is unsigned. 1 Output data is signed and sign extended to 16 bits.

Table 602. SDADC_MCR field descriptions (continued)

Field	Description
13 ODA	Output Data Alignment 0 Output data is right-aligned. 1 Output data is left-aligned.
14 EMSEL	External Modulator Selection 0 External modulator data and clock inputs are ignored. 1 External modulator data stream and clock inputs are provided to SDADC.
15 HPFEN	High Pass Filter Enable 0 High-pass (DC removal) filter is disabled. 1 High-pass (DC removal) filter is enabled.
16 WDGEN	Watchdog Enable This bit enables the WDG monitor. 0 WDG disabled 1 WDG is enabled
17:18 TRIGEDSEL	Trigger Edge Selection 00 Falling edge of trigger input is selected. 01 Rising edge of trigger input is selected. 10 Both edges of trigger input are selected. 11 Both edges of trigger input are selected.
19 TRIGEN	Trigger Enable This field enables the hardware trigger input to initiate a fresh conversion. Upon receiving a trigger event, SDADC reset input is asserted and deasserted synchronously with respect to the peripheral clock. The reset pulse width is fixed to four peripheral clock cycles. The trigger event is ignored if the SDADC internal modulator is not enabled (MCR[EN] = 0) or the external modulator is selected (MCR[EMSEL] = 1). 0 Trigger input is disabled 1 Trigger input is enabled

Table 602. SDADC_MCR field descriptions (continued)

Field	Description
20:23 TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware-triggered conversions. 0000 Input trigger 0 is selected. See chip-specific information for trigger source. 0001 Input trigger 1 is selected. See chip-specific information for trigger source. 0010 Input trigger 2 is selected. See chip-specific information for trigger source. 0011 Input trigger 3 is selected. See chip-specific information for trigger source. 0100 Input trigger 4 is selected. See chip-specific information for trigger source. 0101 Input trigger 5 is selected. See chip-specific information for trigger source. 0110 MUX_ADV 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved **Note:** MUX_ADV is GTM trigger selectable vie SIUL MCR. Refer to the SPC58xEx/SPC58xGx pinout Microsoft Excel file attached to the IO_Definition document, for more details.
24 FRZ	Freeze This field enables stopping the SDADC conversions at the end of the current channel conversion when the SoC enters debug mode. When the SoC enters debug mode, further conversions by the SDADC analog block will be stopped, and converted data output from the SDADC analog block are ignored. The ongoing channel conversion will be completed and the converted data is stored. When the SoC exits debug mode, SDADC resumes the job that was left before halting the conversions. 0 Conversions are not stopped 1 Conversions are stopped
27 VCOMSEL	Common Voltage Bias Selection VCOMSEL selects the reference for analog part. This field selects the common voltage bias for the negative input terminal of the SDADC during single-ended mode (MODE = 1). 0 Negative input terminal is biased with VREFN. 1 Negative input terminal is biased with VREFP/2 (half-scale bias).
28 WRMODE	Wrap-Around Mode This bit selects the wraparound mechanism for conversion of programmed sequence of channels. 0 Wraparound mechanism disabled (in this case the default software control mechanism will be enabled) 1 Wraparound mechanism enabled

Table 602. SDADC_MCR field descriptions (continued)

Field	Description
29 GECEN	Accurate Gain Error Mode Enable This bit selects the accurate gain error mode, and must be set during gain error calibration as well as during conversions requiring accurate gain error mode. It can be kept '0' if gain error calibration mode is not needed. 0 Gain error calibration mode disabled 1 Gain error calibration mode enabled
30 MODE	Mode selection 0 Differential input mode selected 1 Single-ended input mode selected
31 EN	Enable for SDADC block Refer to *Section 41.8: Initialization information* for details on configuration sequence. 0 SDADC internal modulator placed in low consumption mode 1 SDADC internal modulator enabled

41.6.3 Channel Selection Register (SDADC_CSR)

The Channel Selection Register (CSR) selects analog inputs AIN[0:7] to be connected to positive and negative terminals of the SDADC and controls the biasing of analog inputs to half-scale bias through 100 Kohm resistance.

Offset 0x0004 Access: User Read/Write

Table 603. SDADC_CSR field descriptions

Field	Description
8:15 BIASEN	Bias enable If BIASEN[i] = 1, analog input AIN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 KΩ resistor.

Table 603. SDADC_CSR field descriptions (continued)

Field	Description
21:23 ANCHSEL_WRAP	Analog Channel Selection Wraparound Value (ANCHSEL_WRAP) When in wraparound mode, this field indicates the maximum value of the wraparound counter, after which it will wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1).
29:31 ANCHSEL	Analog Channel Selection (ANCHSEL) Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of the SDADC according to *Table 604*. Wraparound Mode: – This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter will start incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[WRMODE] = 1)). – If this field is written any time during wraparound mode (when MCR[WRMODE] = 1), the present value of the wraparound counter will be updated with the value of ANCHSEL — the next trigger will act on the updated channel, and the next increment will be on the updated channel. Here, the value of ANCHSEL chosen should be < ANCHSEL_WRAP; otherwise it will be ignored by hardware. – Wraparound will always be from initial counter value 000.

Figure 492. Reset Key Register (SDADC_RKR)

Table 605. SDADC_RKR field descriptions

Field	Description
16:31 RESET_KEY	Reset Key This field, when written with 0x5AF0, is used to generate the reset for the SDADC block and to reload the internal counter with the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access will always return the inverted key.

41.6.5 Status Flag Register (SDADC_SFR)

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing ‘1’ to those bits. Writing a ‘0’ to a flag has no effect.

Figure 493. Status Flag Register (SDADC_SFR)

Table 606. SDADC_SFR field descriptions

Field	Description
13:15 ANCHSEL_CNT	Analog Channel Selection Counter (ANCHSEL_CNT) This field reflects the current value of the internal Analog Channel Selection Counter. It indicates the present number of the channel selected through the analog multiplexer.
23 DFEF	Data FIFO Empty Flag This field is asserted when there is no data word in the FIFO. 0 Data FIFO is not empty. 1 Data FIFO is empty.
27 WTHH	Watchdog Upper Threshold Cross Over Event This field is set when Converted Data crosses Upper Threshold of WDG. This bit automatically gets cleared on arrival of ipd_done when current ongoing DMA transfer completes, It can also be cleared by software writing ‘1’ to clear. 0 Watchdog Upper Threshold Cross Over Event did not occur. 1 Watchdog Upper Threshold Cross Over Event occurred.
28 WTHL	Watchdog Lower Threshold Cross Over Event This field is set when Converted Data crosses Lower Threshold of WDG. This bit automatically gets cleared on arrival of ipd_done when current ongoing DMA transfer completes. It can be cleared by software writing ‘1’ to clear. 0 Watchdog Lower Threshold Cross Over Event did not occur. 1 Watchdog Lower Threshold Cross Over Event occurred.
29 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the SDADC block. The converted data is not valid or becomes corrupted whenever there is a change in configuration settings determined by MCR, channel selection programmed in CSR. Any write access to the registers MCR and CSR will reset this flag. This flag is set automatically after generating SDADC reset and internal timer counts OSD cycles of output clock f_d. 0 Data output from SDADC is not valid. 1 Data output from SDADC is valid.

Table 606. SDADC_SFR field descriptions (continued)

Field	Description
30 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted data words. Software can clear this bit by writing ‘1’ to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0 No overrun has occurred since the last time the flag was cleared. 1 Overrun has occurred or the DFORF has not been cleared since the last overrun occurred.
31 DFFF	Data FIFO Full Flag This bit is set when the number of converted data words in the FIFO is equal to o greater than the number of data words indicated by FCR[FTHLD] value. Software can clear this bit by writing ‘1’ to it. This bit is also cleared by an acknowledgment from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, data words will continue to be received until an overrun condition occurs. Data words will not be received if the converted data is not valid (CDVF = 0). 0 The number of data words in FIFO is less than or equal to the number indicated by FCR[FTHLD]. 1 The number of data words in FIFO is greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared. **Note:** Whenever MCR[EN] is cleared in order to stop the SDADC or change the channel configuration, it is necessary to clear the RSER[DFFDIRE] bit as well. Similarly if DMA or software is too slow in not reading the FIFO data words resulting in DFFF condition it is advisable to stop the SDADC by clearing the MCR[EN] followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation.

41.6.6 Request Select and Enable Register (SDADC_RSER)

The Request Select and Enable Register (RSER) serves two purposes:

- Enables the flag bits in SFR to generate DMA requests or interrupt requests.
- Selects the type of request to generate.

Refer to the field descriptions for the type of requests that are supported.

Figure 494. Request Select and Enable Register (SDADC_RSER)

Table 607. SDADC_RSER field descriptions

Field	Description
14 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When SFR[WTHH/WTHL] and RSER[WTHDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected. 1 DMA request is selected.
15 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When the SFR[DFFF] and RSER[DFFDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected. 1 DMA request is selected.
16 GDIGE	Global DMA/Interrupt Gating Enable This field determines whether all module interrupts and DMA requests need to be gated by an external gating signal or not. 0 No impact of external gating signal on module DMA/interrupt requests. 1 All module DMA/interrupt requests are qualified only when external gating signal is asserted.
28 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable This field enables the SFR[WTHH/WTHL] field to generate a request. The WTHDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GGE and DIRFWGS fields. 0 Interrupt/DMA request is disabled on WDG Threshold Cross Over Event. 1 Interrupt/DMA request is enabled on WDG Threshold Cross Over Event.
29 CDVEE	Conversion Data Valid Event Enable The status of SFR[CDVF] gated with RSER[CDVEE] is passed on as an event on “conversion_flag" output port, which can be used at SoC level for indication of valid data conversion window. Once enabled, the event output will remain asserted as long as valid data conversions are ongoing. 0 Event output disabled 1 Event output assertion/deassertion based on the SFR[CDVF] field

Table 607. SDADC_RSER field descriptions (continued)

Field	Description
30 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the SFR[DFORF] field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GGE and DIRFWGS fields. 0 Interrupt request is disabled when data FIFO overrun condition occurs. 1 Interrupt request is enabled when data FIFO overrun condition occurs.
31 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the SFR[DFFF] field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GGE and DIRFWGS fields. To have safe operation this bit should not be set when MCR[EN]=0. Whenever MCR[EN] is cleared this bit should also be cleared if already set and FCR[FRST] can be set to clear the previous FIFO content. 0 Interrupt/DMA request is disabled when data FIFO full condition occurs. 1 Interrupt/DMA request is enabled when data FIFO full condition occurs.

41.6.7 Output Settling Delay Register (SDADC_OSDR)

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the SDADC.

Figure 495. Output Settling Delay Register (SDADC_OSDR)

Table 608. SDADC_OSDR field descriptions

Field	Description
24:31 OSD	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output clock f_d until it reaches zero, and then it generates a flag which qualifies the converted data. The output clock f_d is equal to f_s / (2 x OSR), where f_s is the input sampling clock frequency. When external modulator is selected, the output clock is fixed to f_s / 256. See the electrical specifications for the settling delays.

41.6.8 FIFO Control Register (SDADC_FCR)

The FIFO Control Register (FCR) provides the ability to enable or disable FIFO functionality, and to control the amount of available FIFO depth to be used.

Note: It is important to note that the FIFO depth is set at the factory and cannot be changed but the amount of available FIFO space actually used can be set by specifying the value in the FTHLD field. The FSIZE field indicates the amount of FIFO space available. By setting the value of FTHLD to be less than the FIFO depth indicated by FSIZE, the FIFO is considered to be full when the number of data words in the FIFO is equal or greater than FTHLD.

This register may be read at any time, but should only be written when SDADC is disabled (MCR[EN] = 0).

Offset 0x0018 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Figure 496. FIFO Control Register (SDADC_FCR)

Table 609. SDADC_FCR field descriptions

Field	Description
15 FRST	FIFO Flush Reset This is functional soft reset to flush the current FIFO content and initialize the internal FIFO pointers. This is W1S (write one shot) bit which can be written as ‘1’ but always read as ‘0’. Use this option only after disabling the ADC that is MCR[EN]=’0’. 0 No effect 1 Generate a single cycle reset event to flush the FIFO
20:23 FTHLD	FIFO Threshold It sets the threshold to generate DMA/Interrupt event. For example: FTHLD = "0000" indicates 1 data word, FTHLD = "0011" indicates 4 data words and so on. When the number of data words in the data FIFO is greater than or equal to the number of data words indicated by the FTHLD field, the FIFO full event is flagged. An interrupt or a DMA request will be generated as determined by DFFDIRE and DFFDIRS fields of RSER. For proper operation, number of data words indicated by the FTHLD field must be set less than or equal to the FIFO size as indicated by FSIZE.

Table 609. SDADC_FCR field descriptions (continued)

Field	Description
28 FOWEN	FIFO Over Write Enable When set the built-in FIFO structure allows the overwriting of new converted data over older converted data after the FIFO has number of entries equal to the FSIZE. In this case overrun will not be seen. 0 Data FIFO OW option disabled. 1 Data FIFO OW option enabled.
29:30 FSIZE	FIFO Size The maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define the FIFO size. 00 FIFO depth = 1 data word 01 FIFO depth = 4 data words 10 FIFO depth = 8 data words 11 FIFO depth = 16 data words
31 FE	FIFO Enable When this field is set the built-in FIFO structure is enabled. The size of the FIFO structure is indicated by the FSIZE field. If this field is not set then the FIFO depth is set to one data word regardless of the value in the FSIZE field. 0 Data FIFO is not enabled for multiple data words; FIFO depth is one data word. 1 Data FIFO is enabled; FIFO depth is indicated by FSIZE.

41.6.9 Software Trigger Key Register (SDADC_STKR)

The Software Trigger Key Register (STKR) allows generating the trigger event output by a software write operation.

Figure 498. Converted Data Register (SDADC_CDR)

If the output data format is right-aligned (ODA is reset), then the register bit map will be as follows.

Table 611. SDADC_CDR field descriptions

Field	Description
16:31 CDATA	Converted Data Register The converted data words can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 16 up to 31) coming from ADC. If the data width is less than 16 (for example: 14) and if ODF is set, then: – If bit 18 is ‘1’, then the result is negative and bits 16 and 17 will also return ‘1’. – If bit 18 is ‘0’, then the result is positive and bits 16 and 17 will return ‘0’. If ODF is reset, then bits 16 and 17 will always return ‘0’.

Note: If the output data format is left-aligned (ODA is set), then the register bit map will be as follows.

Table 612. SDADC_CDR field descriptions

Field	Description
16:31 CDATA	Converted Data Register The converted data words can be read from FIFO by reading this register. If the actual data width is less than 16 bits (for example: 14), then bits 16 up to 29 will store the data coming from SDADC and bits 30 and 31 will always return ‘0’.

41.6.11 WDG Threshold Register (SDADC_WTHHLR)

This is the Converted Data Range WDG Threshold register.

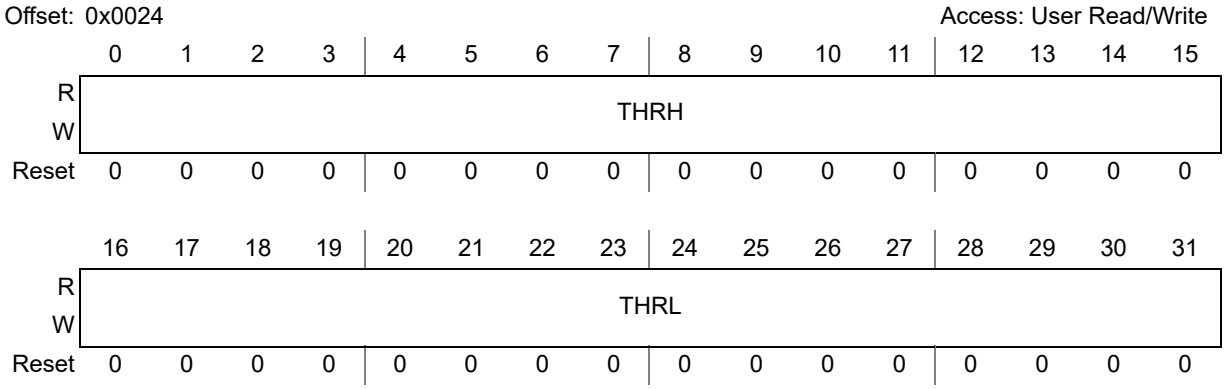

Figure 499. WDG Threshold Register (SDADC_WTHHLR)

Note: A single WDG monitor will check for lower and upper threshold crossover events.

Table 613. SDADC_WTHHLR field descriptions

Field	Description
0:15 THRH	WDG Upper Threshold Value This indicates the upper threshold for the converted data on any channel, above which threshold a crossover event wold be flagged through SFR[WTHH].
16:31 THRL	WDG Lower Threshold Value This indicates the lower threshold for the converted data on any channel, below which threshold cross over event wold be flagged through SFR[WTHL].

41.7 Functional description

The SDADC has four distinct available modes determined by fields in MCR.

- Differential input mode
- Single-ended input mode
- External modulator mode
- Low consumption mode

41.7.1 Differential input mode

After system reset exit, this is the default mode of operation if SDADC is enabled by asserting MCR[EN]. This mode is entered by negating MCR[MODE]. In differential input mode, a pair of analog inputs among AIN[0:7] is connected to the input terminals of the SDADC modulator block. The module supports four differential pairs: AIN[0,1], AIN[2,3], AIN[4,5], and AIN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on the ANCHSEL field of CSR. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative terminal, is determined according to *Table 604*.

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

41.7.2 Single-ended input mode

Single-ended input mode is entered by asserting MCR[MODE]. In this mode, one of the analog inputs among AIN[0:7] is selected by the ANCHSEL field of CSR, and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are two internal bias voltages available: reference ground (VREFN) and half-scale bias (VREFP/2). The selection of this common mode voltage is controlled by MCR[VCOMSEL].

41.7.3 External modulator mode

This mode is selected by asserting the MCR[EMSEL] field. When external modulator is selected, the internal modulator can be put in low consumption mode by deasserting the MCR[EN] field. In this mode, the data stream and clock outputs from the external modulator available on BSEXT/CLKEXT input pins are multiplexed with internal modulator data output and input sampling clock (f_s). External modulator data must be synchronized with respect to the falling edge of CLKEXT. In this mode, hardware trigger input is ignored even if it is enabled by asserting the MCR[TRIGEN] field. All other configuration settings (such as gain, decimation rate, filter) programmed in MCR have no effect on the conversion.

41.7.4 Low consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting the MCR[EN] field to enable the SDADC block. When data conversion is not required, the SDADC internal modulator can be put in low consumption mode to reduce power consumption.

41.7.5 Analog input multiplexing and bias support

The complete selection and connectivity of analog inputs AIN[0:7] is based on the ANCHSEL field of CSR and the MODE and VCOMSEL bits of MCR, according to *Table 604*. Each analog input can be biased to half scale (VDD_HV_ADV/2) via on-chip 100 kΩ resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not.

41.7.6 Programmable gain and decimation rate

All analog inputs can be configured to have a selectable input gain as defined in the PGAN field description in MCR. This means the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

The SDADC module is provided with a fixed input sampling clock f_s. The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different pass-bands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by the field PDR in MCR.

41.7.7 High-pass filter support

For pure AC applications, it is useful to remove any DC component in the input signal. An optional high-pass filter is implemented which can be enabled by asserting the MCR[HPFEN] field. The –3 dB frequency of the filter is fixed (not programmable) and is available in the device data sheet. This high-pass filter is implemented in the decimation filter logic of the SDADC and is applicable only to internal modulator mode.

41.7.8 Data conversion

Software Control Mechanism: The SDADC block will be in continuous conversion mode as soon as it is enabled. The conversion data is not accurate enough for some time, depending on the latency and output settling time specifications. This is true even when there is any change in the configuration settings provided by MCR, change in the analog channel selection due to mux switching time. To account for these delays, an internal timer is implemented which counts down from a start value determined by the OSD field of OSDR. This timer is reloaded whenever the RESET_KEY of RKR is written with 0x5AF0, which is required to start SDADC conversion from a fresh state with a changed configuration. The timer is stalled on reaching count ‘0’ and asserts the SFR[CDVF] field. Once this flag is asserted, converted data is loaded into data FIFO on every rising edge of the output clock (f_d).

Any write access to the MCR and CSR registers will deassert the CDVF flag bit to indicate that data coming from SDADC is not valid or corrupted. If the CDVF flag is reset, the flags DFFF and DFORF are blocked from becoming asserted, that is transitioning from inactive state to active state. If DFFF bit is already set, this means the data FIFO is already full before CVDF deassertion.

The DFF flag bit (which not conditioned by the interrupt or DMA selection) is provided outside which can be routed to timer module at SoC level.

Wraparound Control Mechanism: Here a wrap-around logic shall include all analog channels of the input multiplexer from Ain(“000“) to Ain(CSR[ANCHSEL_WRAP]) in both Single ended and Differential ended mode in wraparound sequence triggered by Hardware or software source:

- MCR[WRMODE] bit would enable or disable the wraparound mechanism. Clearing the WRMODE bit automatically switches FSM back to Software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- Wraparound Counter: An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value “000“. Maximum value of the counter

(wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode, definition of ANCHSEL and ANCHSEL_WRAP is provided in *Table 604*.

- Upon entering or during wraparound mode user should take care to program ANCHSEL value < ANCHSEL_WRAP value, otherwise hardware would reject the new ANCHSEL value.
- Possible trigger sources:
  – SOURCE1 (Software Bit): writing to STKR.ST_KEY at any time during the wraparound mode (irrespective of MCR[TRIGEN or TRIGSEL] setting) generates a trigger pulse, each such trigger initiates a fresh conversion and advances the wraparound counter by one.

Note: Care should be taken while programming the TRIGEN/TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

  – SOURCE2 (Hardware Trigger): Here external trigger output (for example mux_advance of GTM) enabled by MCR[TRIGEN or TRIGEDSEL or TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger, each such valid trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.
- Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution, this can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value (wraparound counter would increment from the updated value).
- Current wraparound counter value can be read from SFR[ANCHSEL_CNT] bit field.

41.7.9 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. The field TRIGSEL of MCR selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously for four cycles. This will ensure that SDADC starts from a fresh state when reacting to the input trigger event. The SDADC internal modulator must be enabled before enabling the trigger event — otherwise the trigger event will be ignored. A hardware trigger event is also ignored when external modulator is selected (MCR[EMSEL] = 1).

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (TRIGEN bit MCR) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSDR[OSD].

It is also possible to generate a software trigger event output by a write access of STKR with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, the skew/jitter will be less than 100 ns. It will be more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

Wraparound Control Mechanism: In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

41.7.10 Interrupt/DMA request support

The SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted data words stored in data FIFO is equal to or greater than the number of data words indicated by FCR[FTHLD] value. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted data words cannot be received and data is lost when FIFO overwrite functionality is disabled. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

If RSER[GDIGE] is set, all module interrupt/DMA requests are qualified only when an external global gating signal is asserted.

41.7.11 Gain calibration support

To perform gain calibration, the following sequence needs to be applied.

1. Select differential mode of operation by writing MCR[MODE] to ‘0’.
2. Enable gain error calibration mode by writing MCR[GECEN] to ‘1’.
3. Configure the mux selection ANCHSEL field of CSR to ‘110’. This configuration will apply VREFP on positive terminal and VREFN on negative terminal.
4. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 0x00.
5. Disable the high-pass filter by deasserting MCR[HPFEN].
6. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
7. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. The measurement should be repeated to reduce contribution of noise during calibration process. D_p is the average value of attenuated positive full scale given by D_p = AVERAGE(CDR[CDATA]).
8. Change the mux selection ANCHSEL field of CSR to ‘111’. This configuration will apply VREFN on positive terminal and VREFP on negative terminal.
9. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
10. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. The measurement should be repeated to reduce contribution of noise during calibration process. Dn is the average value of attenuated negative full scale given by Dn = AVERAGE(CDR[CDATA]).
11. The SDADC calibrated gain can be calculated as:
    $$\text{Gain} = (D_p - D_n) / 2^{16}$$
12. The measured gain value can be used to nullify the gain errors in the digital output. For calibrated conversion, the data CDR[CDATA] provided by the SDADC should be

normalized using the calculated gain: $CDATA_{norm}$ is given by $CDATA_{norm}$ = CDR[CDATA]/Gain.

Note: The gain error calibration should only be done with gain equal to '1' (in other words, PGAN = 000). Nevertheless, the calculated gain can be applied to normalized data also for conversion with GAIN > 1.

MCR[GECEN] = 1 ensures the accurate gain error mode is enabled. This bit should be set both during calibration process and after calibration, for application data conversion. Application data conversion must then be normalized using the measured gain.

The higher the number of full-scale conversion (D_p, D_n) done, the higher the rejection of noise during the calibration. The number of conversion is dependent on application noise. It is recommended to run at least 16 conversions when calculating an average value.

Gain calibration should be done using the same OSR configuration as the target application, since full-scale values may vary slightly with these settings .

Refer to Digital output codes in full scale table in the SPC58xEx/SPC58xGx microcontroller Datasheet for Full-Scale values (with MCR[GECEN] = 1) with different OSR settings.

41.7.12 Offset calibration support

To perform offset calibration, the following sequence must be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Configure the mux selection ANCHSEL field of CSR to '100' or '101' as required.
   a) CSR = '100' in case of data conversion after calibration in "single ended mode with negative input = $V_{SS_HV_ADR_D}$"
   b) CSR = '101' in case of data conversion after calibration in "differential mode" and "single ended mode with negative input = ($V_{DD_HV_ADR_D}$–$V_{SS_HV_ADR_D}$)/2"
3. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 0x00.
4. Disable the high pass filter by deasserting MCR[HPFEN].
5. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
6. Read the digital output stored in FIFO after the output settling time.
7. The measured offset can be used to nullify the offset error in the digital output. Expected output is 0b00_0000_0000_0000. The SDADC offset can be calculated as:

   Offset = Expected Output – Actual Output

Note: The offset must be calculated for each PGAN field setting since it is expected to vary with gain configuration of SDADC.

41.8 Initialization information
