8 MTX_IF	**Media Access Test Symbol Received Interrupt Flag** This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event 1 MTS symbol received
9 LTXB_IF	*pLatestTx* **Violation on Channel B Interrupt Flag** This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation, as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel B
10 LTXA_IF	*pLatestTx* **Violation on Channel A Interrupt Flag** This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel A
11 TBVB_IF	**Transmission across boundary on channel B Interrupt Flag** This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel B
12 TBVA_IF	**Transmission across boundary on channel A Interrupt Flag** This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel A
13 TI2_IF	**Timer 2 Expired Interrupt Flag** This flag is set whenever timer 2 expires. 0 No such event 1 Timer 2 has reached its time limit

Table 1307. FR_PIFR0 field descriptions (continued)

Field	Description
14 TI1_IF	**Timer 1 Expired Interrupt Flag** This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	**Cycle Start Interrupt Flag** This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started

Figure 1227. Protocol Interrupt Flag Register 1 (FR_PIFR1)

The register holds one set of the protocol-related individual interrupt flags.

Table 1308. FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	**Error Mode Changed Interrupt Flag** This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event 1 ERRMODE field changed
1 IPC_IF	**Illegal Protocol Control Command Interrupt Flag** This flag is set when the PE tries to execute a protocol control command that was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case, the command is not executed. For more details, refer to *Section 53.7.6: Protocol control command execution*. 0 No such event 1 Illegal protocol control command detected
2 PECF_IF	**Protocol Engine Communication Failure Interrupt Flag** This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event 1 Protocol Engine Communication Failure detected

Table 1308. FR_PIFR1 field descriptions (continued)

Field	Description
3 PSC_IF	**Protocol State Changed Interrupt Flag** This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event 1 Protocol state changed
4 SSI3_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR3) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
5 SSI2_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR2) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
6 SSI1_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR1) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
7 SSI0_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR0) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
10 EVT_IF	**Even Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the even cycle. 0 No such event 1 Sync frame measurement table written
11 ODT_IF	**Odd Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the odd cycle. 0 No such event 1 Sync frame measurement table written

Figure 1230. CHI Error Flag Register (FR_CHIERFR)

This register holds the CHI-related error flags. The interrupt generation for each of these error flags is controlled by the CHI interrupt enable bit, CHIE, in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 1311. FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	**Frame Lost Channel B Error Flag** This flag is set if a complete frame was received on channel B but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	**Frame Lost Channel A Error Flag** This flag is set if a complete frame was received on channel A but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected

Table 1311. FR_CHIERFR field descriptions (continued)

Field	Description
2 PCMI_EF	**Protocol Command Ignored Error Flag** This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case, the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	**Receive FIFO Overrun Channel B Error Flag** This flag is set when an overrun of the FIFO for channel B has occurred. This error occurs if a semantically valid frame was received on channel B and matches all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information are lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	**Receive FIFO Overrun Channel A Error Flag** This flag is set when an overrun of the FIFO for channel A has occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information are lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	**Message Buffer Search Error Flag** This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 131 is detected in the FR_MBIDXR[MBIDX] field of a found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to *Section 53.6.7.4: Message buffer search error* for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
6 MBU_EF	**Message Buffer Utilization Error Flag** This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	**Lock Error Flag** This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected

Table 1311. FR_CHIERFR field descriptions (continued)

Field	Description
9 SBCF_EF	**System Bus Communication Failure Error Flag** This flag is set if a system bus access was not finished within the required amount of time (refer to *Section 53.6.19.1.2: System bus access timeout*). 0 No such event 1 System bus access not finished in time
10 FID_EF	**Frame ID Error Flag** This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register. 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	**Dynamic Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	**Static Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	**Network Management Length Error Flag** This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case, the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
14 NMF_EF	**Network Management Frame Error Flag** This flag is set if a received message in the static segment with a Preamble Indicator flag (PP) asserted has its Null Frame indicator flag (NF) asserted as well. In this case, the Global Network Management Registers (refer to *Section 53.5.2.40: Network Management Vector Registers (FR_NMVRn)*) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	**Illegal System Bus Address Error Flag** This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (refer to *Section 53.6.19.1.1: System bus illegal address access*). 0 No such event 1 Illegal system bus address accessed

53.5.2.19 Message Buffer Interrupt Vector Register (FR_MBIVEC)

Figure 1231. Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their MBIF interrupt status flag and MBIE interrupt enable bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Table 1312. FR_MBIVEC field descriptions

Field	Description
1:7 TBIVEC	**Transmit Buffer Interrupt Vector** This field provides the number of the lowest numbered enabled transmit message buffer that has its MBIF interrupt status flag and its MBIE interrupt enable bit set. If there is no transmit message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.
9:15 RBIVEC	**Receive Buffer Interrupt Vector** This field provides the message buffer number of the lowest numbered receive message buffer that has its MBIF interrupt flag and its MBIE interrupt enable bit asserted. If there is no receive message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.

53.5.2.20 Channel A Status Error Counter Register (FR_CASERCR)

1. **A**dditional Reset: RUN Command

Figure 1232. Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits *vSS!SyntaxError, vSS!ContentError, vSS!BViolation*, and *vSS!TxConflict*. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, refer to *Section 53.6.18: Slot status monitoring*.

Table 1313. FR_CASERCR field descriptions

Field	Description
0:15 CHAERSCNT	**Channel Status Error Counter** This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

1. Additional Reset: CSAA, CSP, CPN: RUN Command

Figure 1235. Protocol Status Register 1 (FR_PSR1)

Table 1316. FR_PSR1 field descriptions

Field	Description
0 CSAA	**Cold Start Attempt Aborted Flag** protocol-related event: 'set coldstart abort indicator in CHI.' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	**Leading Cold Start Path** This status bit is set when the CC has reached the *POC:normal active* state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 *POC:normal active* reached from *POC:startup* state via leading cold start path
3:7 REMCSAT	**Remaining Coldstart Attempts** protocol-related variable: *vRemainingColdstartAttempts.* This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	**Leading Cold Start Path Noise**—protocol-related variable: *vPOC!ColdstartNoise.* This status bit is set if the CC has reached the *POC:normal active* state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 *POC:normal active* state was reached from *POC:startup* state via noisy leading cold start path
9 HHR	**Host Halt Request Pending** protocol related variable: *vPOC!CHIHaltRequest.* This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 HALT command received
10 FRZ	**Freeze Occurred** protocol related variable: *vPOC!Freeze.* This status bit is set when the CC has reached the *POC:halt* state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11:15 APTAC	**Allow Passive to Active Counter** protocol-related variable: *vPOC!vAllowPassivetoActive.* This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the *POC:normal passive* state due to an application-configured delay to enter *POC:normal active* state. This delay is defined by the allow_passive_to_active field in Protocol Configuration Register 12 (FR_PCR12).

53.5.2.24 Protocol Status Register 2 (FR_PSR2)

1. Additional Reset: RUN Command

Figure 1236. Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the network idle time (NIT), the symbol window, and the clock synchronization. The NIT-related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The symbol-window-related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol-window-related status bits remain in their reset state. The clock synchronization-related CKCORFCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Table 1317. FR_PSR2 field descriptions

Field	Description
0 NBVB	**NIT Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for NIT on channel B. This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	**NIT Syntax Error on Channel B** protocol-related variable: *vSS!SyntaxError* for NIT on channel B. This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	**Symbol Window Transmit Conflict on Channel B** protocol-related variable: *vSS!TxConflict* for symbol window on channel B. This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	**Symbol Window Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for symbol window on channel B. This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected

Table 1317. FR_PSR2 field descriptions (continued)

Field	Description
4 SSEB	**Symbol Window Syntax Error on Channel B** protocol related variable: *vSS!SyntaxError* for symbol window on channel B. This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	**Media Access Test Symbol MTS Received on Channel B** protocol-related variable: *vSS!ValidMTS* for Symbol Window on channel B. This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	**NIT Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for NIT on channel A. This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	**NIT Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected
8 STCA	**Symbol Window Transmit Conflict on Channel A** protocol related variable: *vSS!TxConflict* for symbol window on channel A. This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	**Symbol Window Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for symbol window on channel A. This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	**Symbol Window Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for symbol window on channel A. This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected

Table 1317. FR_PSR2 field descriptions (continued)

Field	Description
11 MTA	**Media Access Test Symbol MTS Received on Channel A** protocol-related variable: *vSS!ValidMTS* for symbol window on channel A. This status bit is set if the Media Access Test Symbol (MTS) was received in the symbol window on channel A. 0 No such event 1 MTS symbol received
12:15 CKCORFCNT	**Clock Correction Failed Counter** protocol -elated variable: *vClockCorrectionFailed.* This field provides the number of consecutive even/odd communication cycle pairs that have passed without a clock synchronization offset or rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the *POC:normal active* state, or when both the rate and offset correction terms have been calculated successfully.

53.5.2.25 Protocol Status Register 3 (FR_PSR3)

Offset: 0x002E

Access: Read/Write
Write: Normal mode

Figure 1237. Protocol Status Register 3 (FR_PSR3)

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Table 1318. FR_PSR3 field descriptions

Field	Description
2 WUB	**Wakeup Symbol Received on Channel B** This flag is set when a wakeup symbol was received on channel B. 0 No wakeup symbol received 1 Wakeup symbol received
3 ABVB	**Aggregated Boundary Violation on Channel B** This flag is set when a boundary violation was detected on channel B. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected

Table 1318. FR_PSR3 field descriptions (continued)

Field	Description
4 AACB	**Aggregated Additional Communication on Channel B** This flag is set when at least one valid frame was received on channel B in a slot that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
5 ACEB	**Aggregated Content Error on Channel B** This flag is set when a content error was detected on channel B. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
6 ASEB	**Aggregated Syntax Error on Channel B** This flag is set when a syntax error was detected on channel B. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
7 AVFB	**Aggregated Valid Frame on Channel B** This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel B. 0 No syntactically valid frames received 1 At least one syntactically valid frame received
10 WUA	**Wakeup Symbol Received on Channel A** This flag is set when a wakeup symbol was received on channel A. 0 No wakeup symbol received 1 Wakeup symbol received
11 ABVA	**Aggregated Boundary Violation on Channel A** This flag is set when a boundary violation was detected on channel A. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
12 AACA	**Aggregated Additional Communication on Channel A** This flag is set when a valid frame was received in a slot on channel A that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
13 ACEA	**Aggregated Content Error on Channel A** This flag is set when a content error has been detected on channel A. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected

Table 1318. FR_PSR3 field descriptions (continued)

Field	Description
14 ASEA	**Aggregated Syntax Error on Channel A** This flag is set when a syntax error has been detected on channel A. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
15 AVFA	**Aggregated Valid Frame on Channel A** This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel A. 0 No syntactically valid frames received 1 At least one syntactically valid frame received

1. Additional Reset: RUN Command

Figure 1242. Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Table 1323. FR_RTCORVR field descriptions

Field	Description
0:15 RATECORR	**Rate Correction Value** protocol-related variable: *vRateCorrection* (before value limitation and external rate correction). This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag (CCL_IF) is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

53.5.2.31 Offset Correction Value Register (FR_OFCORVR)

Offset: 0x003A Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: RUN Command

Figure 1243. Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Table 1324. FR_OFCORVR field descriptions

Field	Description
0:15 OFFSETCORR	**Offset Correction Value** protocol-related variable: *vOffsetCorrection* (before value limitation and external offset correction). This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

53.5.2.32 Combined Interrupt Flag Register (FR_CIFR)

Offset: 0x003C Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1244. Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in *Figure 1375*. The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

Note: The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 1325. FR_CIFR field descriptions

Field	Description
8 MIF	**Module Interrupt Flag** This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	**Protocol Interrupt Flag** This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	**CHI Interrupt Flag** This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1. 0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	**Wakeup Interrupt Flag** Provides the same value as FR_GIFER[WUPIF].
12 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFBIF].
13 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFAIF].
14 RBIF	**Receive Message Buffer Interrupt Flag** This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted 1 At least one individual receive message buffers has the MBIF flag asserted
15 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted 1 At least one individual transmit message buffers has the MBIF flag asserted

53.5.2.33 System Memory Access Timeout Register (FR_SYMATOR)

Offset: 0x003E

Access: Read/Write
Write: Disabled mode

Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: RUN Command

Figure 1246. Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 macroticks after offset correction start.

Note: If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the SFODB and SFODA values.

Table 1327. FR_SFCNTR field descriptions

Field	Description
0:3 SFEVB	Sync Frames Channel B, even cycle protocol-related variable: size of (*vsSyncIdListB* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4:7 SFEVA	Sync Frames Channel A, even cycle protocol related variable: size of (*vsSyncIdListA* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8:11 SFODB	Sync Frames Channel B, odd cycle protocol-related variable: size of (*vsSyncIdListB* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
12:15 SFODA	Sync Frames Channel A, odd cycle protocol-related variable: size of (*vsSyncIdListA* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.

53.5.2.35 Sync Frame Table Offset Register (FR_SFTOR)

Offset: 0x0042

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SFT_OFFSET															0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1247. Sync Frame Table Offset Register (FR_SFTOR)

This register defines the FlexRay memory area related offset for sync frame tables. For more details, refer to *Section 53.6.12: Sync frame ID and sync frame deviation tables*.

Table 1328. FR_SFTOR field descriptions

Field	Description
0:14 SFT_OFFSET	**Sync Frame Table Offset** The offset of the sync frame tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus, STF_OFFSET[0] is always 0.

53.5.2.36 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Offset: 0x0044

Access: Read/Write
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	CYCNUM						ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
W	ELKT	OLKT												OPT		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1248. Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, refer to *Section 53.6.12: Sync frame ID and sync frame deviation tables*.

Table 1329. FR_SFTCCSR field descriptions

Field	Description
0 ELKT	**Even Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables
1 OLKT	**Odd Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables

Table 1329. FR_SFTCCSR field descriptions (continued)

Field	Description
2:7 CYCNUM	**Cycle Number** This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	**Even Cycle Tables Lock Status** This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables 1 Application has locked the even cycle tables
9 OLKS	**Odd Cycle Tables Lock Status** This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables 1 Application has locked the odd cycle tables
10 EVAL	**Even Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
11 OVAL	**Odd Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
13 OPT	**One Pair Trigger** This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.

Table 1329. FR_SFTCCSR field descriptions (continued)

Field	Description
14 SDVEN	**Sync Frame Deviation Table Enable** This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area **Note:** If SDVEN is set to 1, then SIDEN must also be set to 1.
15 SIDEN	**Sync Frame ID Table Enable** This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

Table 1332. FR_SFIDAFMR field descriptions

Field	Description
6:15 FMSK	**Filter Mask** This field defines the mask for the sync frame acceptance filtering.

53.5.2.40 Network Management Vector Registers (FR_NMVR*n*)

Offset: 0x004C +*n**0x2 (*n*=0 to 5)

Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	NMVP															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1252. Network Management Vector Registers (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0–FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Table 1333. FR_NMVR*n* field descriptions

Field	Description
0:15 NMVP	**Network Management Vector Part** The mapping between the Network Management Vector Registers (FR_NMVR0–FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in *Table 1334*.

Table 1334. Mapping of FR_NMVRn to the received payload bytes NMV*x*

R	T2_MTCNT[31:16]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. It is read as 0. Application must not write 1 to this bit.

Figure 1257. Timer 2 Configuration Register 0 (FR_TI2CR0)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to *Section 53.6.17.2: Absolute/relative timer T2*.

Table 1339. FR_TI2CR0 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
2:7 T2_CYC_VAL	**Timer T2 Cycle Filter Value** This field defines the cycle filter value for timer T2.
10:15 T2_CYC_MSK	**Timer T2 Cycle Filter Mask** This field defines the cycle filter mask for timer T2.
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
0:15 T2_MTCNT[31:16]	**Timer T2 Macrotick High Word** This field defines the high word of the macrotick count for timer T2.

Note: If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

53.5.2.46 Timer 2 Configuration Register 1 (FR_TI2CR1)

Offset: 0x0062

Access: Read/Write
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved(1)				T2_MTOFFSET											
R W	T2_MTCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. It is read as 0. Application must not write 1 to this bit.

Figure 1258. Timer 2 Configuration Register 1 (FR_TI2CR1)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to *Section 53.6.17.2: Absolute/relative timer T2*.

Table 1340. FR_TI2CR1 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
2:15 T2_MTOFFSET	**Timer T2 Macrotick Offset** This field holds the macrotick offset value for timer T2.

Table 1340. FR_TI2CR1 field descriptions (continued)

Field	Description
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
0:15 T2_MTCNT	**Timer T2 Macrotick Low Word** This field defines the low word of the macrotick value for timer T2.

Note: If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

53.5.2.47 Slot Status Selection Register (FR_SSSR)

Offset: 0x0064

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1259. Slot Status Selection Register (FR_SSSR)

This register is used to access the four internal non-memory-mapped Slot Status Selection Registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR_SSR0–FR_SSR7) according to *Table 1342*. For a detailed description of slot status monitoring, refer to *Section 53.6.18: Slot status monitoring*.

Table 1341. FR_SSSR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL field only on write access

Table 1341. FR_SSSR field descriptions (continued)

Field	Description
2:3 SEL	**Selector** This field selects one of the four internal slot status selection registers for access. 00 Select FR_SSSR0 01 Select FR_SSSR1 10 Select FR_SSSR2 11 Select FR_SSSR3
5:15 SLOTNUMBER	**Slot Number** This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. **Note:** If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.

Table 1342. Mapping between FR_SSSRn and FR_SSRn

Internal slot status selection register	Write the slot status of the slot selected by FR_SSSRn for each			
	Even communication cycle		Odd communication cycle	
	For channel B to	For channel A to	For channel B to	For channel A to
FR_SSSR0	FR_SSR0[0:7]	FR_SSR0[8:15]	FR_SSR1[0:7]	FR_SSR1[8:15]
FR_SSSR1	FR_SSR2[0:7]	FR_SSR2[8:15]	FR_SSR3[0:7]	FR_SSR3[8:15]
FR_SSSR2	FR_SSR4[0:7]	FR_SSR4[8:15]	FR_SSR5[0:7]	FR_SSR5[8:15]
FR_SSSR3	FR_SSR6[0:7]	FR_SSR6[8:15]	FR_SSR7[0:7]	FR_SSR7[8:15]

53.5.2.48 Slot Status Counter Condition Register (FR_SSCCR)

Offset: 0x0066

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	SEL		0	CNTCFG		MCY	VFR	SYF	NUF	SUF	STATUSMASK			
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1260. Slot Status Counter Condition Register (FR_SSCCR)

This register is used to access and program the four internal non-memory-mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal Slot Status Counter Condition Registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). The correspondence is given in *Table 1344*. For a detailed description of slot status counters, refer to *Section 53.6.18.4: Slot status counter registers*.

Table 1343. FR_SSCCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
2:3 SEL	**Selector** This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0 01 select FR_SSCCR1 10 select FR_SSCCR2 11 select FR_SSCCR3
5:6 CNTCFG	**Counter Configuration** This bit field controls the channel related incrementing of the slot status counter. 00 Increment by 1 if condition is fulfilled on channel A 01 Increment by 1 if condition is fulfilled on channel B 10 Increment by 1 if condition is fulfilled on at least one channel 11 Increment by 2 if condition is fulfilled on both channels Increment by 1 if condition is fulfilled on only one channel.
7 MCY	**Multi Cycle Selection** This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	**Valid Frame Restriction** This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	**Sync Frame Restriction** This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	**Null Frame Restriction** This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.

Table 1343. FR_SSCCR field descriptions (continued)

Field	Description
11 SUF	**Startup Frame Restriction** This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12:15 STATUSMASK	**Slot Status Mask** This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3]: This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2]: This bit enables the counting for slots with the content error indicator bit set to 1. STATUSMASK[1]: This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0]: This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

Table 1344. Mapping between internal FR_SSCCR*n* and FR_SSCR*n*

R	SLOTSTATUSCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1262. Slot Status Counter Registers (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal Slot Status Counter Condition Register (FR_SSCCRn), which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, refer to *Section 53.6.18.4: Slot status counter registers*.

Note: If the counter has reached its maximum value 0xFFFF and is in Multicycle mode (that is, FR_SSCCRn[MCY] = 1), the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be put into Multicycle mode again.

Field	Description
0:7 WM_A/WM_B	**Watermark** This field defines the watermark value for the selected FIFO. This value is used to control the generation of the almost full interrupt flags.
15 SEL	**Select** This control bit selects the receiver FIFO for subsequent programming. 0 Receiver FIFO for channel A selected 1 Receiver FIFO for channel B selected

This register is used to:

- Select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in *Table 1351*.
- Define the watermark for the selected FIFO.

Table 1351. SEL-controlled receiver FIFO registers

Register
Receive FIFO Start Index Register (FR_RFSIR)
Receive FIFO Depth and Size Register (FR_RFDSR)
Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)
Receive FIFO Range Filter Control Register (FR_RFRFCTR)

53.5.2.55 Receive FIFO Start Index Register (FR_RFSIR)

Offset: 0x0088

Access: Read/Write
Write: *POC:config*

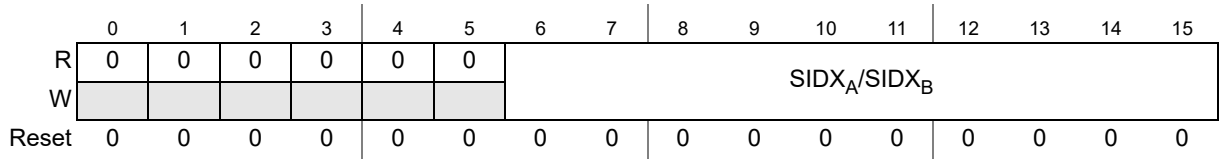

Figure 1267. Receive FIFO Start Index Register (FR_RFSIR)

This register defines the message buffer header index of the first message buffer of the selected FIFO.

Table 1352. FR_RFSIR field descriptions

Field	Description
6:15 SIDX$_A$/SIDX$_B$	**Start Index** This field defines the number of the message buffer header field of the selected FIFO's first message buffer. The CC uses the value of the SIDX field to determine the physical location of the receiver FIFO's first message buffer header field.

53.5.2.56 Receive FIFO Depth and Size Register (FR_RFDSR)

Offset: 0x008A

Access: Read/Write
Write: *POC:config*

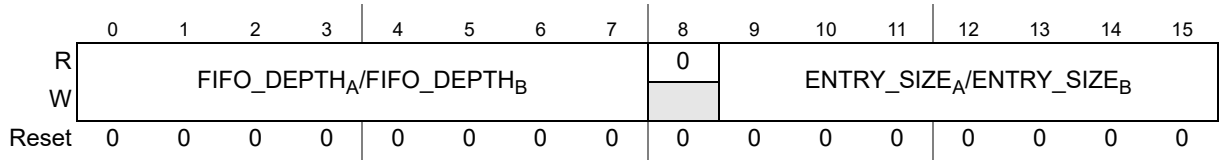

Figure 1268. Receive FIFO Depth and Size Register (FR_RFDSR)

This register defines the structure of the selected FIFO, that is the number of entries and the size of each entry.

Table 1353. FR_RFDSR field descriptions

Field	Description
0:7 $FIFO_DEPTH_A$/ $FIFO_DEPTH_B$	**FIFO Depth** This field defines the depth (the number of entries) of the selected FIFO. **Note:** If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 as well to ensure that no frames are received into the FIFO.
9:15 $ENTRY_SIZE_A$/ $ENTRY_SIZE_B$	**Entry Size** This field defines the size of the frame data sections for the selected FIFO in two-byte entities.

53.5.2.57 Receive FIFO A Read Index Register (FR_RFARIR)

Offset: 0x008C Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	RDIDX									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1269. Receive FIFO A Read Index Register (FR_RFARIR)

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

Table 1354. FR_RFARIR field descriptions

Field	Description
6:15 RDIDX	**Read Index** This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

Note: If the FIFO is empty, the RDIDX field points to a physical message buffer with invalid content.

53.5.2.58 Receive FIFO B Read Index Register (FR_RFBRIR)

Offset: 0x008E Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	RDIDX									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1270. Receive FIFO B Read Index Register (FR_RFBRIR)

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

Table 1355. FR_RFBRIR field descriptions

Field	Description
6:15 RDIDX	**Read Index** This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

Note: If the FIFO is empty, the RDIDX field points to a physical message buffer with invalid content.

53.5.2.59 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Offset: 0x0090

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	$MIDAFVAL_A$/$MIDAFVAL_B$															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1271. Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

This register defines the filter value for the message ID acceptance filter of the selected FIFO. For details on message ID filtering, refer to *Section 53.6.9.9: FIFO filtering*.

Table 1356. FR_RFMIDAFVR field descriptions

Field	Description
0:15 $MIDAFVAL_A$/ $MIDAFVAL_B$	**Message ID Acceptance Filter Value** Filter value for the message ID acceptance filter.

53.5.2.60 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

Offset: 0x0092

Access: Read/Write
Write: *POC:config*

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1275. Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter, refer to *Section 53.6.9.9: FIFO filtering*.

Table 1360. FR_RFRFCFR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL and IBD field only on write access
1 IBD	**Interval Boundary** This control bit selects the interval boundary to be programmed with the SID value. 0 Program lower interval boundary 1 Program upper interval boundary
2:3 SEL	**Filter Selector** This control field selects the frame ID range filter to be accessed. 00 Select frame ID range filter 0 01 Select frame ID range filter 1 10 Select frame ID range filter 2 11 Select frame ID range filter 3
5:15 SID_A/SID_B	**Slot ID** Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

53.5.2.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Offset: 0x009A

Access: Read/Write
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1278. Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Table 1363. FR_LDTXSLBR field descriptions

Field	Description
5:15 LDYNTXSLOTB	**Last Dynamic Transmission Slot Channel B** Protocol-related variable: *zLastDynTxSlot* channel B. Number of the last transmission slot in the dynamic segment for channel B. If no frame was transmitted during the dynamic segment on channel B the value of this field is set to 0.

53.5.2.67 Protocol configuration registers

The following configuration registers provide the necessary configuration information to the protocol engine. The individual values in the registers are described in *Table 1364*. For more

details about the FlexRay related configuration parameters and the allowed parameter ranges, refer to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

Table 1364. Protocol configuration register fields

Name	Description(1)	Min	Max	Unit	FR_PCR
coldstart_attempts	gColdstartAttempts	—	—	number	3
action_point_offset	gdActionPointOffset - 1	—	—	MT	0
cas_rx_low_max	gdCASRxLowMax - 1	—	—	gdBit	4
dynamic_slot_idle_phase	gdDynamicSlotIdlePhase	—	—	minislot	28
minislot_action_point_offset	gdMinislotActionPointOffset - 1	—	—	MT	3
minislot_after_action_point	gdMinislot - gdMinislotActionPointOffset - 1	—	—	MT	2
static_slot_length	gdStaticSlot	—	—	MT	0
static_slot_after_action_point	gdStaticSlot - gdActionPointOffset - 1	—	—	MT	13
symbol_window_exists	gdSymbolWindow!=0	0	1	bool	9
symbol_window_after_action_point	gdSymbolWindow - gdActionPointOffset - 1	—	—	MT	6
tss_transmitter	gdTSSTransmitter	—	—	gdBit	5
wakeup_symbol_rx_idle	gdWakeupSymbolRxIdle	—	—	gdBit	5
wakeup_symbol_rx_low	gdWakeupSymbolRxLow	—	—	gdBit	3
wakeup_symbol_rx_window	gdWakeupSymbolRxWindow	—	—	gdBit	4
wakeup_symbol_tx_idle	gdWakeupSymbolTxIdle	—	—	gdBit	8
wakeup_symbol_tx_low	gdWakeupSymbolTxLow	—	—	gdBit	5
noise_listen_timeout	(gListenNoise * pdListenTimeout) - 1	—	—	µT	16/17
macro_initial_offset_a	pMacroInitialOffset[A]	—	—	MT	6
macro_initial_offset_b	pMacroInitialOffset[B]	—	—	MT	16
macro_per_cycle	gMacroPerCycle	—	—	MT	10
macro_after_first_static_slot	gMacroPerCycle - gdStaticSlot	—	—	MT	1
macro_after_offset_correction	gMacroPerCycle - gOffsetCorrectionStart	—	—	MT	28
max_without_clock_correction_fatal	gMaxWithoutClockCorrectionFatal	—	—	cyclepairs	8
max_without_clock_correction_passive	gMaxWithoutClockCorrectionPassive	—	—	cyclepairs	8
minislot_exists	gNumberOfMinislots!=0	0	1	bool	9
minislots_max	gNumberOfMinislots - 1	—	—	minislot	29
number_of_static_slots	gNumberOfStaticSlots	—	—	static slot	2
offset_correction_start	gOffsetCorrectionStart	—	—	MT	11
payload_length_static	gPayloadLengthStatic	—	—	2 bytes	19

Table 1364. Protocol configuration register fields (continued)

Name	Description[1]	Min	Max	Unit	FR_PCR
max_payload_length_dynamic	pPayloadLengthDynMax	—	—	2 bytes	24
first_minislot_action_point_offset	max(gdActionPointOffset, gdMinislotActionPointOffset) - 1	—	—	MT	13
allow_halt_due_to_clock	pAllowHaltDueToClock	—	—	bool	26
allow_passive_to_active	pAllowPassiveToActive	—	—	cyclepairs	12
cluster_drift_damping	pClusterDriftDamping	—	—	µT	24
comp_accepted_startup_range_a	pdAcceptedStartupRange - pDelayCompensation[A]	—	—	µT	22
comp_accepted_startup_range_b	pdAcceptedStartupRange - pDelayCompensation[B]	—	—	µT	26
listen_timeout	pdListenTimeout - 1	—	—	µT	14/15
key_slot_id	pKeySlotId	—	—	number	18
key_slot_used_for_startup	pKeySlotUsedForStartup	—	—	bool	11
key_slot_used_for_sync	pKeySlotUsedForSync	—	—	bool	11
latest_tx	gNumberOfMinislots - pLatestTx	—	—	minislot	21
sync_node_max	gSyncNodeMax	—	—	number	30
micro_initial_offset_a	pMicroInitialOffset[A]	—	—	µT	20
micro_initial_offset_b	pMicroInitialOffset[B]	—	—	µT	20
micro_per_cycle	pMicroPerCycle	—	—	µT	22/23
micro_per_cycle_min	pMicroPerCycle - pdMaxDrift	—	—	µT	24/25
micro_per_cycle_max	pMicroPerCycle + pdMaxDrift	—	—	µT	26/27
micro_per_macro_nom_half	round(pMicroPerMacroNom / 2)	—	—	µT	7
offset_correction_out	pOffsetCorrectionOut	—	—	µT	9
rate_correction_out	pRateCorrectionOut	—	—	µT	14
single_slot_enabled	pSingleSlotEnabled	—	—	bool	10
wakeup_channel	pWakeupChannel	Refer to *Table 1365*			10
wakeup_pattern	pWakeupPattern	—	—	number	18
decoding_correction_a	pDecodingCorrection + pDelayCompensation[A] + 2	—	—	µT	19
decoding_correction_b	pDecodingCorrection + pDelayCompensation[B] + 2	—	—	µT	7
key_slot_header_crc	header CRC for key slot	0x000	0x7FF	number	12
extern_offset_correction	pExternOffsetCorrection	—	—	µT	29
extern_rate_correction	pExternRateCorrection	—	—	µT	21

Table 1366. FR_STPWR field descriptions

Field	Description
0:15 STPW	Stop Watch Count Register This is the value of the stop watch counter running on system clock. This starts on cycle start even and stops on an external event “OS_tick”. For details, refer to *Section 53.6.26*. This is a read reset type register, which means that when all the 32 bits are read, it automatically clears.

53.5.2.69 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Figure 1313. Receive FIFO Start Data Offset Register (FR_RFSDOR)

Table 1368. FR_RFSDOR field descriptions

Field	Description
0:15 SDO_A/SDO_B	Start Data Field Offset This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO’s first message buffer header field. For configuration constraints, refer to *Section 53.7.1.2: Configure data field offsets*.

Note: Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses, the content of the FR_RFSDOR register corresponds to the start address of the payload area of the selected FIFO.

53.5.2.71 Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)

Figure 1315. Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Table 1369. FR_RFSYMBADR field descriptions

Field	Description
SMBA	System Memory Base Address This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defined as a byte address.

53.5.2.72 Receive FIFO Periodic Timer Register (FR_RFPTR)

Offset: 0x00EC

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	PTD													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1316. Receive FIFO Periodic Timer Register (FR_RFPTR)

This register holds the periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (refer to *Section 53.6.9.3: FIFO periodic timer*).

Table 1370. FR_RFPTR field descriptions

Field	Description
2:15 PTD	Periodic Timer Duration This value defines the periodic timer duration in terms of macroticks. 0000 Timer stays expired 3FFF Timer never expires other Timer expires after specified number of macroticks, expires and is restarted at each cycle start

53.5.2.73 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

Offset: 0x00EE Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	FLB_PCB								FLA_PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1317. Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs.

Table 1371. FR_RFFLPCR field descriptions

Field	Description
0:7 FLB_PCB	Fill Level FIFO B (FLB) This field provides the current number of entries in the FIFO B. Pop Count FIFO B (PCB) This field defines the number of entries to be removed from FIFO B.
8:15 FLA_PCA	Fill Level FIFO A (FLA) This field provides the current number of entries in the FIFO A. Pop Count FIFO A (PCA) This field defines the number of entries to be removed from FIFO A.

Note: If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, then the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

53.5.2.74 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1318. ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC-related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description, refer to *Section 53.6.24.2*.

Table 1372. FR_EEIFER field descriptions

Field	Description
Error overflow flags	
0 LRNE_OF	LRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *but not corrected* on CHI LRAM and interrupt flag LRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of CHI LRAM. 0 No such event 1 Non-Corrected Error overflow detected on CHI LRAM
1 LRCE_OF	LRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *and corrected* on CHI LRAM and interrupt flag LRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of CHI LRAM. 0 No such event 1 Corrected Error overflow detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
2 DRNE_OF	DRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *but not corrected* on PE DRAM and interrupt flag DRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of the PE DRAM. 0 No such event 1 Non-Corrected Error overflow detected on PE DRAM
3 DRCE_OF	DRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *and corrected* on PE DRAM and interrupt flag DRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of PE DRAM. 0 No such event 1 Corrected Error overflow detected on PE DRAM

Table 1372. FR_EEIFER field descriptions (continued)

Field	Description
Error interrupt flags	
4 LRNE_IF	LRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on the CHI LRAM. 0 No such event 1 Non-Corrected Error detected on CHI LRAM
5 LRCE_IF	LRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on the CHI LRAM. 0 No such event 1 Corrected Error detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
6 DRNE_IF	DRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on PE DRAM. 0 No such event 1 Non-Corrected Error detected on PE DRAM
7 DRCE_IF	DRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on PE DRAM. 0 No such event 1 Corrected Error detected on PE DRAM
Error interrupt enables	
12 LRNE_IE	**LRAM Non-Corrected Error Interrupt Enable** This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 LRCE_IE	**LRAM Corrected Error Interrupt Enable** This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 DRNE_IE	**DRAM Non-Corrected Error Interrupt Enable** This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 DRCE_IE	**DRAM Corrected Error Interrupt Enable** This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

53.5.2.75 ECC Error Report and Injection Control Register (FR_EERICR)

Offset: 0x00F2

Access: Read/Write

1. Additional Reset: CMT, DUP, DVAL, MBIF: Message Buffer Disable

Figure 1326. Message Buffer Configuration, Control and Status Register *n* (FR_MBCCSR*n*)

The content of these registers comprises message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in *Section 53.6.6: Individual message buffer functional description*.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Table 1382. FR_MBCCSR*n* field descriptions

Field	Description
Message buffer configuration	
3 MTD	Message Buffer Transfer Direction This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
Message buffer control	
4 CMT	Commit for Transmission This bit indicates if the transmit message buffer data are ready for transmission. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
Message buffer status	
11 DUP	Data Updated This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and message buffer data field not updated 1 Frame Header and message buffer data field updated
12 DVAL	Data Valid For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers, the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 Receive message buffer contains no valid frame data / message is transmitted for the first time. 1 Receive message buffer contains valid frame data / message will be transferred again.
13 EDS	Enable/Disable Status This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled 1 Message buffer is enabled

Table 1382. FR_MBCCSR*n* field descriptions (continued)

Field	Description
14 LCKS	Lock Status This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application 1 Message buffer is locked by the application
15 MBIF	Message Buffer Interrupt Flag This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled

53.5.2.83 Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

Offset: 0x0802 +*n**0x8 (*n* = 0 to 127)

Access: Read/Write(1)
Write: *POC:config* or MB_DIS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. 16-bit write access required

Figure 1327. Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to *Section 53.6.7.1: Message buffer cycle counter filtering*.

Table 1383. FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event Transmission mode 1 State Transmission mode
1 CHA	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 1384*.
2 CHB	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 1384*.
3 CCFE	Cycle Counter Filtering Enable This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled

Table 1383. FR_MBCCFR*n* field descriptions (continued)

Field	Description
4:9 CCFMSK	Cycle Counter Filtering Mask This field defines the filter mask for the cycle counter filtering.
10:15 CCFVAL	Cycle Counter Filtering Value This field defines the filter value for the cycle counter filtering.

Table 1384. Channel assignment description

CHA	CHB	Transmit message buffer		Receive message buffer	
		Static segment	Dynamic segment	Static segment	Dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Note: If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.

53.5.2.84 Message Buffer Frame ID Registers (FR_MBFIDR*n*)

Offset: 0x0804 +*n**0x8 (*n* = 0 to 127)

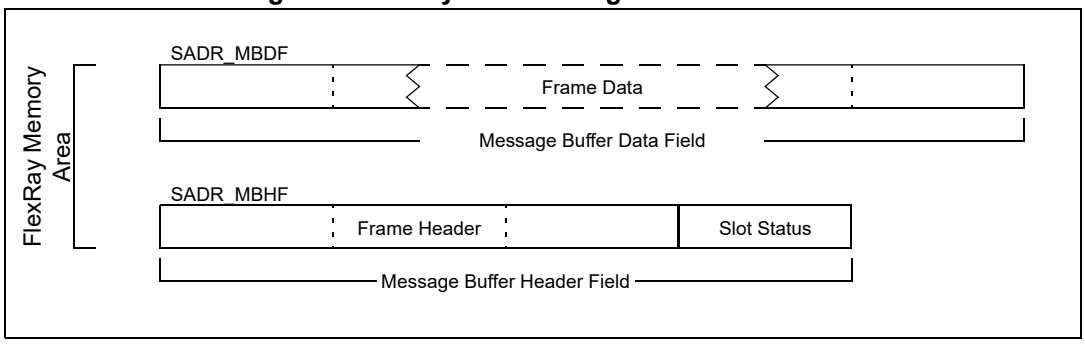
53.6 Functional description

This section provides a detailed description of the functionality implemented in the CC.

53.6.1 Message buffer concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts: the *message buffer control data* and the *physical message buffer.* The message buffer control data is located in dedicated registers. The structure of the message buffer control data depends on the message buffer type, described in *Section 53.6.3: Message buffer types*. The physical message buffer is located in the FlexRay memory area and is described in *Section 53.6.2: Physical message buffer*.



53.6.2 Physical message buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area.The structure of a physical message buffer is depicted in *Figure 1332*.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

Figure 1332. Physical message buffer structure

53.6.2.1 Message buffer header field

The message buffer header field is a contiguous region in the FlexRay memory area that occupies eight bytes. It contains the frame header and the slot status. Its structure is shown in *Figure 1332*. The physical start address SADR_MBHF of the message buffer header field must be 16-bit aligned.

53.6.2.1.1 Frame header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the usage and the content of the frame header is provided in *Section 53.6.5.2.1: Frame header description*.

53.6.2.1.2 Slot status

The slot status occupies the last 2 bytes of the message buffer header field. It provides the slot and frame status-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in *Section 53.6.5.2.2: Slot status description*.

53.6.2.2 Message buffer data field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in *Section 53.6.3: Message buffer types*.

53.6.3 Message buffer types

The CC provides three different types of message buffers.

- Individual Message Buffers
- Receive Shadow Buffers
- Receive FIFO Buffers

For each message buffer type, the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

53.6.3.1 Individual message buffers

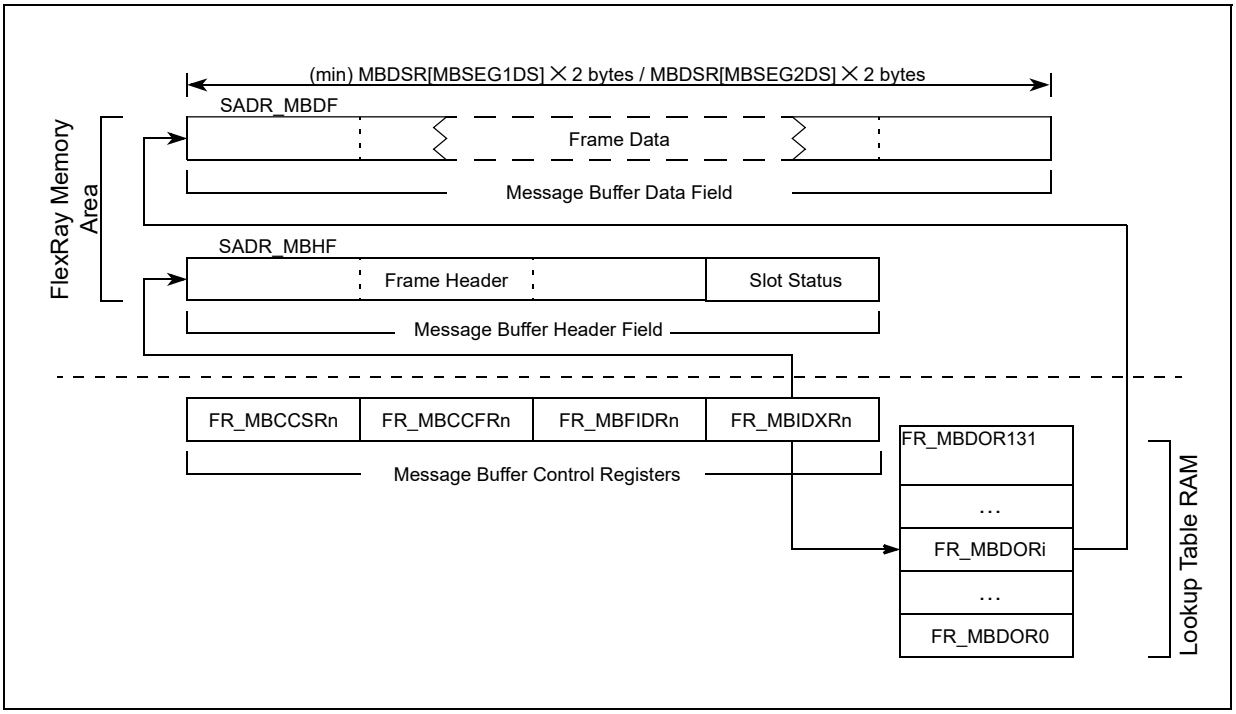
The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in *Section 53.6.6: Individual message buffer functional description*.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in *Figure 1333*.

Each individual message buffer has a message buffer number *n* assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n* and FR_MBIDXR*n*.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field, MBIDX, in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 37*.

Equation 37 **SADR_MBHF = (FR_MBIDXR*n*[MBIDX] × 8) + SMBA**



The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i, the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to *Equation 38*.

Equation 38 **SADR_MBDF = [Data Field Offset] + SMBA**

The FR_MBDOR*n* are stored in the module internal memory LRAM. Refer to *Section 53.7.2.3: CHI LRAM initialization* for the setup of the data field offset values.

Figure 1333. Individual message buffer structure

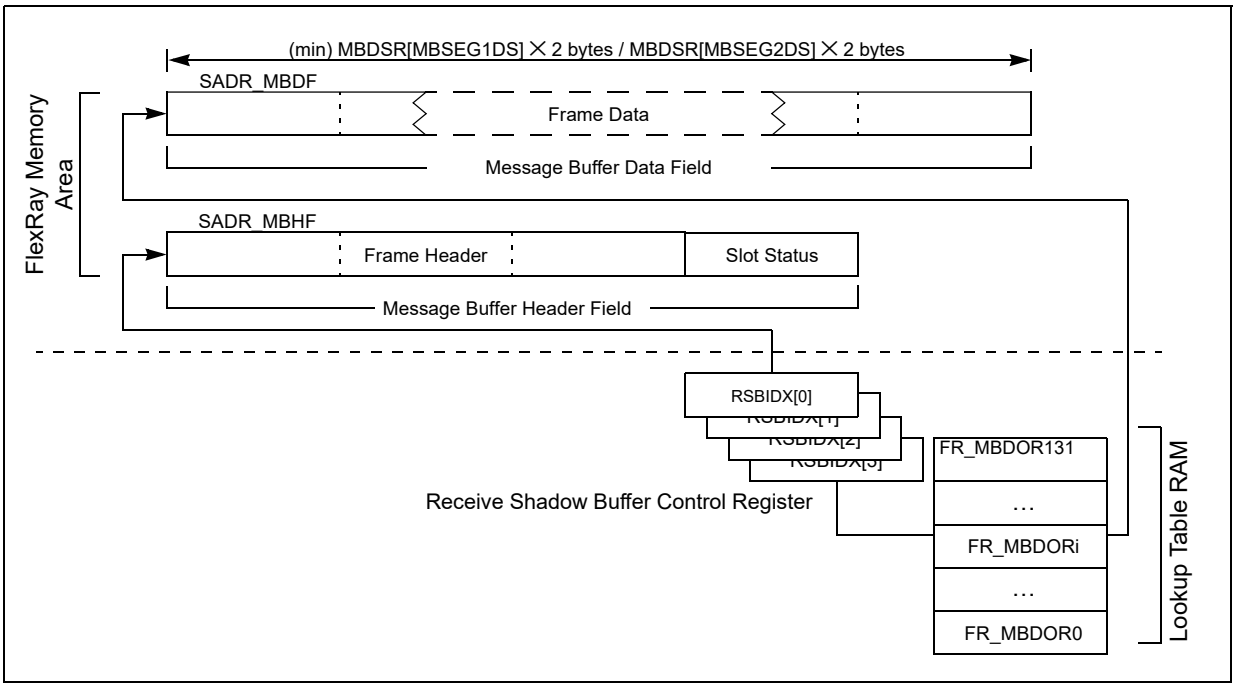
53.6.3.1.1 Individual message buffer segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- All physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length.
- The minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes.
- The minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.

53.6.3.2 Receive shadow buffers

The receive shadow buffers are required for the individual message buffers' frame reception process. The CC provides four receive shadow buffers: one receive shadow buffer per channel and per message buffer segment.



Each receive shadow buffer consists of two parts: the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in *Figure 1334*. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 39*.

Equation 39 $\quad SADR_MBHF = (FR_RSBIR[RSBIDX] \times 8) + SMBA$

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

Figure 1334. Receive shadow buffer structure

53.6.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in *Figure 1335*.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR)/Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM], refer to *Section 53.5.2.4: Module Configuration Register (FR_MCR)*.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to *Equation 40*.

Equation 40 SADR_MBHF[1] = (8 × FR_RFSIR[SIDX]) + SMBA

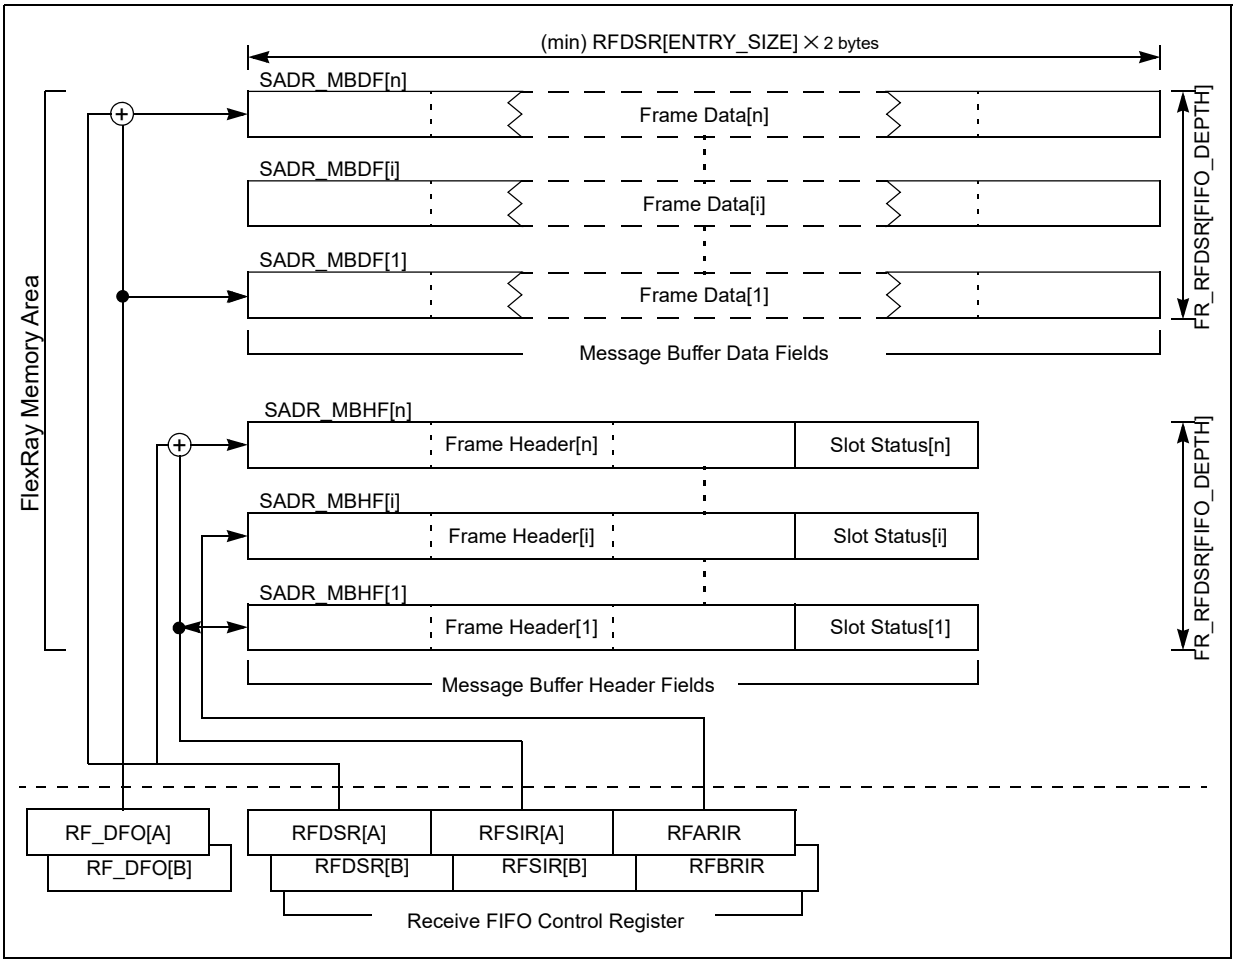
The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according to *Equation 41*.

Equation 41 SADR_MBHF[n] =
(8 × (FR_RFSIR[SIDX] + FR_RFDSR[FIFO_DEPTH])) + SMBA

The required information to access the current entry of the FIFO is given in the following registers:

- The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.
- The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

Equation 42 RF_DFO[X] =
FR_RFSDOR[X] + (FR_RFDSR[X][ENTRY_SIZE] × 2) × (i - R_RFSIR[SIDX])



Note: The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to Section 53.6.9.8: FIFO update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

Figure 1335. Receive FIFO structure

Note: The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 42. They are not stored in a register.

53.6.3.4 Message buffer configuration and control data

This section describes the configuration and control data for each message buffer type.

53.6.3.4.1 Individual message buffer configuration data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

53.6.3.4.2 Common configuration data

The set of common configuration data for individual message buffers is located in the following registers:

- Message Buffer Data Size Register (FR_MBDSR)
  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.
- Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)
  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, refer to *Section 53.6.3.1.1: Individual message buffer segments*.

53.6.3.4.3 Specific configuration data

The set of message buffer specific configuration data for individual message buffers is located in the following registers:

- Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
  The MTD bit configures the message buffer type.
- Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)
  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.
- Message Buffer Frame ID Registers (FR_MBFIDRn)
  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.
- Message Buffer Index Registers (FR_MBIDXRn)
  This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.

53.6.3.5 Individual message buffer control data

During normal operation, each individual message buffer can be controlled by the CMT, LCKT, EDT, and MBIE control and trigger bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn).

53.6.3.6 Receive shadow buffer configuration data

Before the individual message buffers can receive frames, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

53.6.3.7 Receive FIFO control and configuration data

This section describes the configuration and control data for the two receive FIFOs.

53.6.3.7.1 Receive FIFO configuration data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- Receive FIFO Periodic Timer Register (FR_RFPTR)

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- Receive FIFO Watermark and Selection Register (FR_RFWMSR)
- Receive FIFO Start Index Register (FR_RFSIR)
- Receive FIFO Start Data Offset Register (FR_RFSDOR)
- Receive FIFO Depth and Size Register (FR_RFDSR)
- Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
- Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
- Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
- Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
- Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

53.6.3.7.2 Receive FIFO control data

The application can access the FIFOs at any time using the control bits in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

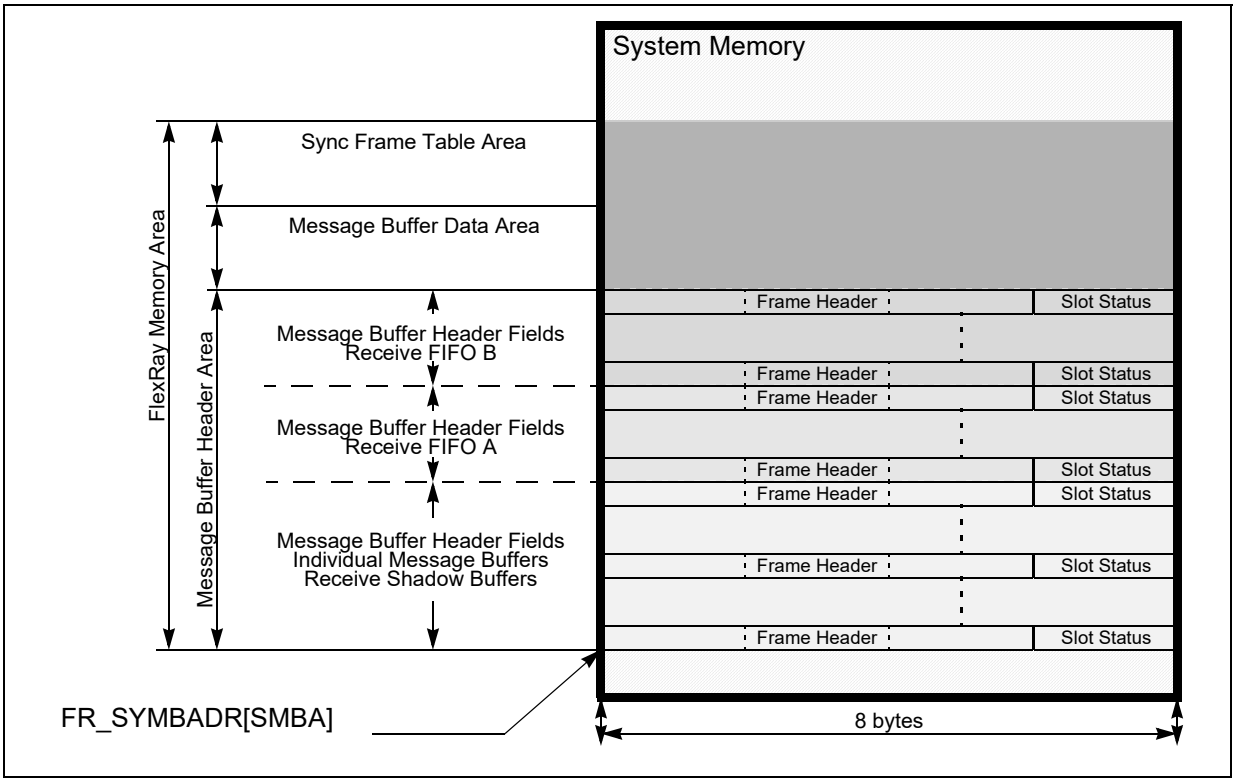
53.6.3.7.3 Receive FIFO status data

The current status of the receive FIFO is provided in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO A Read Index Register (FR_RFARIR)
- Receive FIFO B Read Index Register (FR_RFBRIR)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

53.6.4 FlexRay memory area layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].



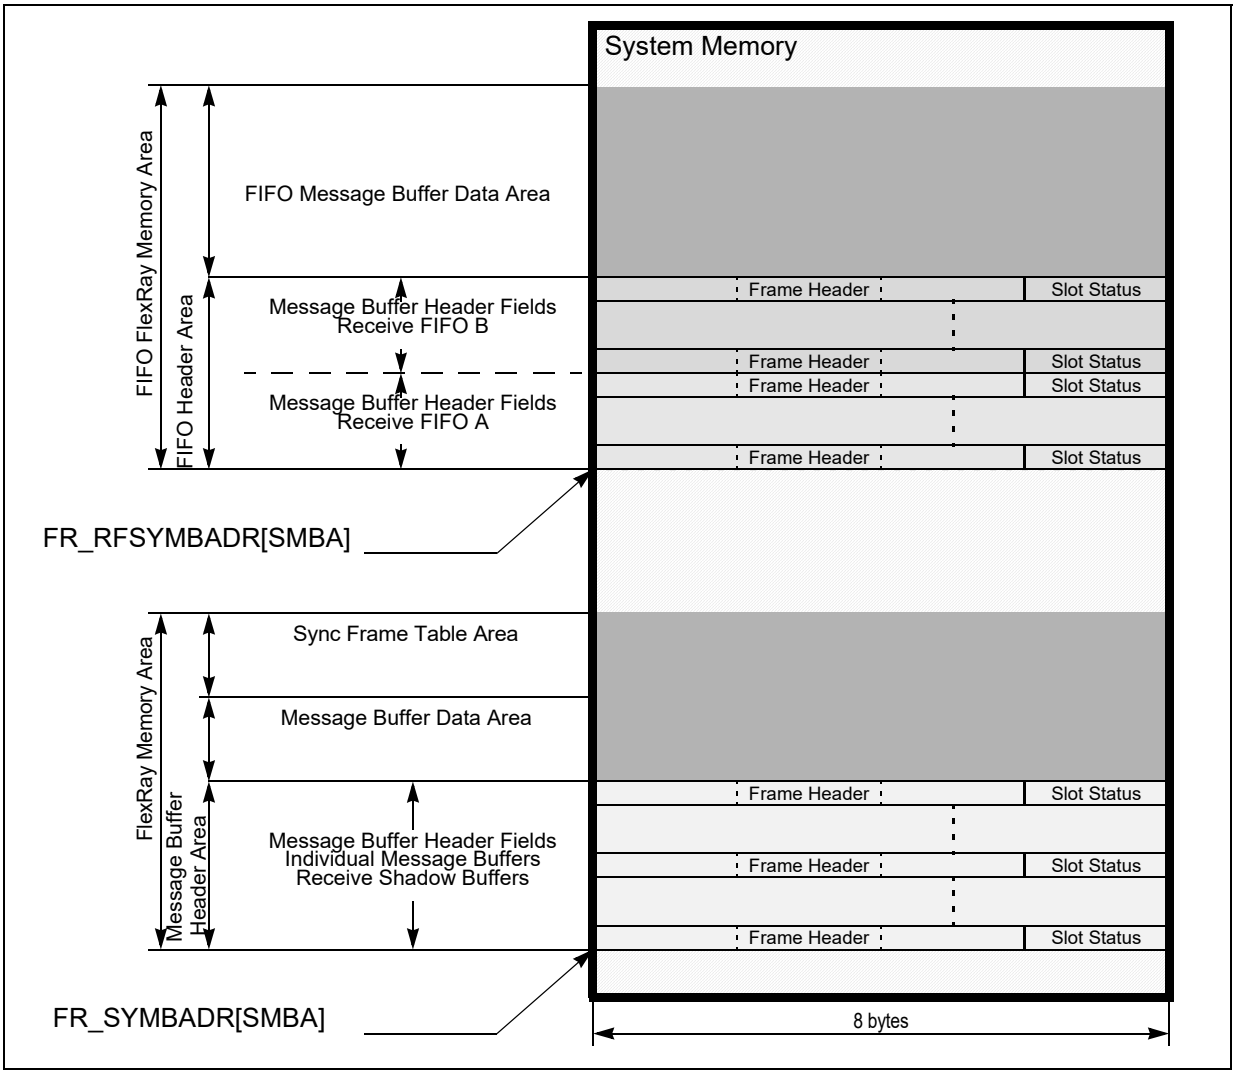
53.6.4.1 FlexRay memory area layout (FR_MCR[FAM] = 0)

Figure 1336 shows an example layout for the FIFO address mode FR_MCR[FAM] = 0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is a maximum of 64 KB.
- The FlexRay memory area starts at a 16 byte boundary.

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

Figure 1336. Example of FlexRay memory area layout (FR_MCR[FAM] = 0)



53.6.4.2 FlexRay memory area layout (FR_MCR[FAM] = 1)

Figure 1337 shows an example layout for the FIFO address mode FR_MCR[FAM] = 1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

Figure 1337. Area example of FlexRay memory area layout (FR_MCR[FAM] = 1)

53.6.4.3 Message buffer header area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rule applies to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 43*.

Equation 43 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 131)$$

2. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill *Equation 44*.

Equation 44 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 1023)$$

3. The message buffer header fields for each FIFO must be a contiguous area.

53.6.4.4 Message buffer header area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 45*.

Equation 45 $\mathbf{SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 131)}$

53.6.4.5 FIFO message buffer header area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill *Equation 46*.

Equation 46 $\mathbf{SADR_MBHF = (i \times 8) + FR_RFSYMBADR[SMBA];\ (0 \leq i \leq 1023)}$

2. The message buffer header fields for each FIFO have to be a contiguous area.

53.6.4.6 Message buffer data area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

53.6.4.7 Sync frame table area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to *Section 53.6.12: Sync frame ID and sync frame deviation tables* for the description of the sync frame table area.

53.6.5 Physical message buffer description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer: the message buffer header field and the message buffer data field.

53.6.5.1 Message buffer protection and data consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

53.6.5.2 Message buffer header field description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in *Section 53.6.2.1: Message buffer header field*. Each message buffer header field consists of two sections: the frame header section and the slot status section.

53.6.5.2.1 Frame header description

53.6.5.2.1.1 Frame header content

The semantic and content of the frame header section depend on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in *Figure 1338*. A detailed description is given in *Table 1390*.

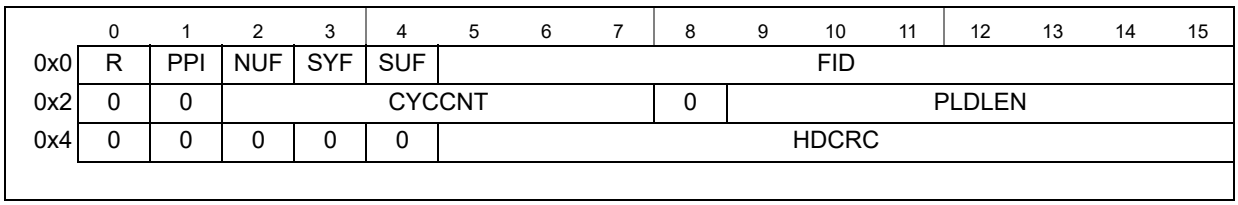


Figure 1338. Frame header structure (receive message buffer and receive FIFO)

The structure of the frame header in the message buffer header field for transmit message buffers is given in *Figure 1339*. A detailed description is given in *Table 1391*. The checks that will be performed are described in Frame Header Checks.

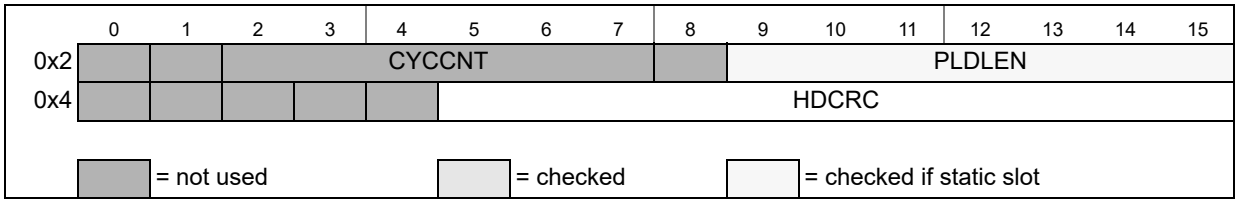

Figure 1339. Frame header structure (transmit message buffer)

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in *Figure 1340*.

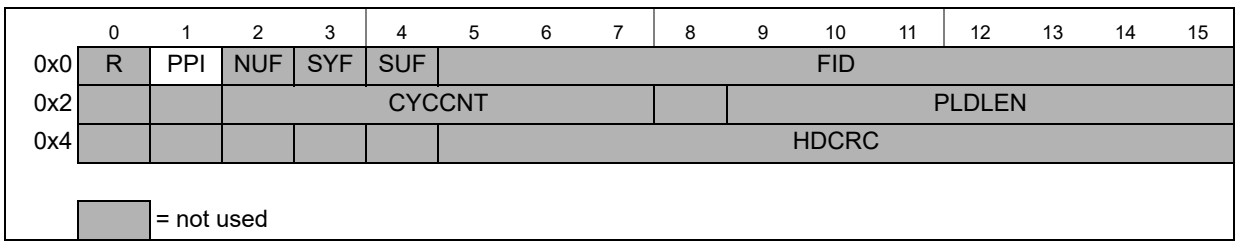

Figure 1340. Frame header structure (transmit message buffer for key slot)

53.6.5.2.1.2 Frame header access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 1389*. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 1389. Frame header write access constraints (transmit message buffer)

Field	Static segment	Dynamic segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	
		MB_LCK

53.6.5.2.1.3 Frame header checks

As shown in *Figure 1339* and *Figure 1340*, not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag, FID_EF, in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDRn).

For transmit message buffers assigned to the static segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 1390. Frame header field descriptions (receive message buffer and receive FIFO)

Field	Description
R	Reserved Bit This is the value of the *Reserved bit* of the received frame stored in the message buffer.
PPI	Payload Preamble Indicator This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	Null Frame Indicator This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	Sync Frame Indicator This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	Startup Frame Indicator This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	Frame ID This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	Cycle Count This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	Payload Length This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	Header CRC This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 1391. Frame header field descriptions (transmit message buffer)

Field	Description
R	Reserved Bit This bit is not used. The value of the Reserved bit is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
PPI	Payload Preamble Indicator This bit provides the value of the Payload Preamble Indicator for the frame transmitted from the message buffer.
NUF	Null Frame Indicator This bit is not used, the value of the Null Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

Table 1391. Frame header field descriptions (transmit message buffer) (continued)

Field	Description
SYF	Sync Frame Indicator This bit is not used. The value of the Sync Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
SUF	Startup Frame Indicator This bit is not used. The value of the Startup Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
FID	Frame ID This field is checked as described in Frame Header Checks.
CYCCNT	Cycle Count This field is not used, the value of the transmitted Cycle Count field is taken from the internal communication cycle counter.
PLDLEN	Payload Length This field is checked and used as described in Frame Header Checks.
HDCRC	Header CRC This field provides the value of the Header CRC field for the frame transmitted from the message buffer.

53.6.5.2.2 Slot status description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depend on the message buffer type.

53.6.5.2.2.1 Receive message buffer and receive FIFO slot status description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given by *Table 1392*.

Table 1392. Receive message buffer slot status content

Receive message buffer type	Slot status content
Individual Receive Message Buffer assigned to both channels FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 1	Refer to *Figure 1341*
Individual Receive Message Buffer assigned to channel A FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 0	Refer to *Figure 1342*
Individual Receive Message Buffer assigned to channel B FR_MBCCFR*n*[CHA] = 0 and FR_MBCCFR*n*[CHB] = 1	Refer to *Figure 1343*
Receive FIFO Channel A Message Buffer	Refer to *Figure 1342*
Receive FIFO Channel B Message Buffer	Refer to *Figure 1343*

The meaning of the bits in the slot status structure is explained in *Table 1393*.

53.6.5.2.2.2 Transmit message buffer slot status description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given by *Table 1394*.

Table 1394. Transmit message buffer slot status content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=1	Refer to *Figure 1344*
Individual Transmit Message Buffer assigned to channel A FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=0	Refer to *Figure 1345*
Individual Transmit Message Buffer assigned to channel B FR_MBCCFR*n*[CHA]=0 and FR_MBCCFR*n*[CHB]=1	Refer to *Figure 1346*

The meaning of the bits in the slot status structure is described in *Table 1395*.

53.6.5.3 Message buffer data field description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in *Table 1396*. The structure of the message buffer data field is given in *Figure 1347*.

Table 1396. Message buffer data field minimum length

Physical message buffer assigned to	Minimum length defined by
Individual message buffer in segment 1	FR_MBDSR[MBSEG1DS]
Receive shadow buffer in segment 1	FR_MBDSR[MBSEG1DS]
Individual message buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive shadow buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note: The CC will not access any locations outside the message buffer data field boundaries given by Table 1396.

	0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15
0x0	DATA0 / MID0 / NMV0		DATA1 / MID1 / NMV1	
0x2	DATA2 / NMV2		DATA3 / NMV3	
…	…		…	
0xN-2	DATA N-2		DATA N-1	

Figure 1347. Message buffer data field structure

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

53.6.5.3.1 Message buffer data field read access

For transmit message buffers, the CC will not modify the content of the message buffer data field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXRn). While the message buffer is locked, the CC will not update the message buffer data field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

53.6.5.3.2 Message buffer data field write access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 1397*.

Table 1397. Frame data write access constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 1398. Frame data field descriptions

Field	Description
DATA 0, DATA 1, … DATA N–1	Message Data Provides the message data received or to be transmitted. For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	Message Identifier If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0, NMV 1, … NMV 11	Network Management Vector If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

53.6.6 Individual message buffer functional description

The CC provides the following basic types of individual message buffers:

- Transmit message buffers
- Receive message buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in *Section 53.6.3.4.1: Individual message buffer configuration data*.

53.6.6.1 Individual message buffer configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

53.6.6.1.1 Common configuration data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. This data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

53.6.6.1.2 Specific configuration data

The second part of the message buffer configuration data is specific for each message buffer.

This data can be changed only when either

- The protocol is in the POC:config state, or
- The message buffer is disabled (that is, FR_MBCCSR*n*[EDS] = 0)

The individual message buffer type is defined by the MTD bit in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) as given in *Table 1399*.

Table 1399. Individual message buffer types

FR_MBCCSRn[MTD]	Individual message buffer description
0	Receive message buffer
1	Transmit message buffer

The message-buffer-specific configuration data includes the following:

1. MTD bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
2. All fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)
3. All fields in the Message Buffer Frame ID Registers (FR_MBFIDRn)
4. All fields in the Message Buffer Index Registers (FR_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions. Refer to *Section 53.6.6.2: Transmit message buffers* and *Section 53.6.6.3: Receive message buffers* for further information.

53.6.6.2 Transmit message buffers

The section provides a detailed description of the functionality of single-buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number *n* is configured to be a transmit message buffer by the following setting:

- FR_MBCCSR*n*[MTD] = 1 (transmit message buffer)

53.6.6.2.1 Access regions

For certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in *Figure 1348*. A description of the regions is given in *Table 1401*. If a region is active as indicated in *Table 1402*, the access scheme given for that region applies to the message buffer.

Figure 1348. Transmit message buffer access regions

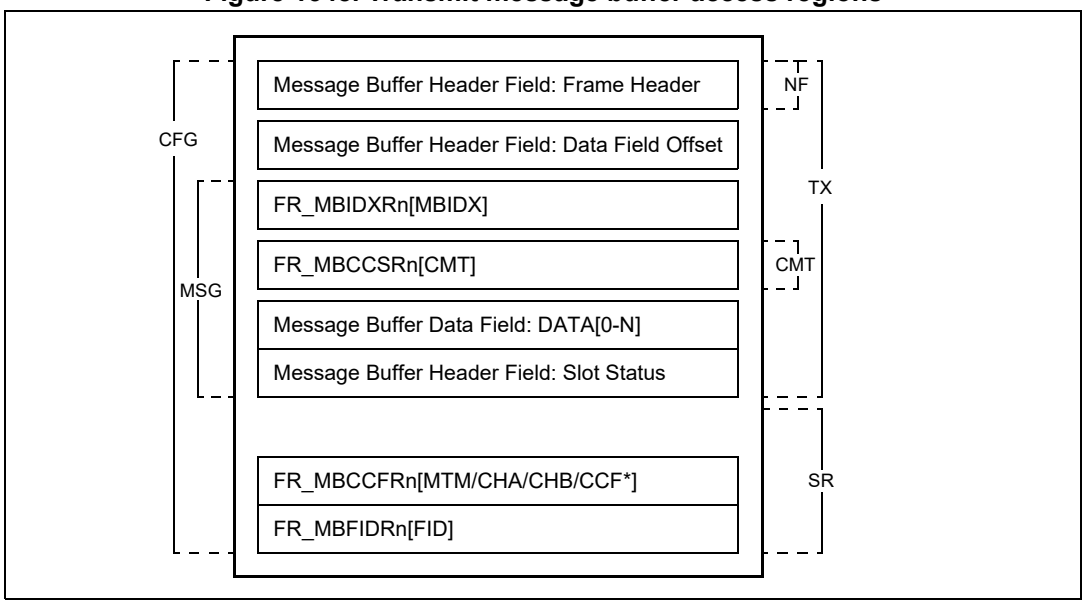

Table 1400. Transmit message buffer access regions description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration
MSG	Read/write	—	Message data and slot status access
NF	—	Read-only	Message header access for null frame transmission
TX	—	Read/write	Message transmission and slot status update
CMT	—	Read-only	Message buffer validation
SR	—	Read-only	Message buffer search

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT], and the interrupt enable bit FR_MBCCSR*n*[MBIE], are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in *Figure 1349*. A description of the states is given in *Table 1401*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

53.6.6.2.2 Message buffer states

This section describes the transmit message buffer states and provides a state diagram.

Figure 1349. Transmit message buffer states

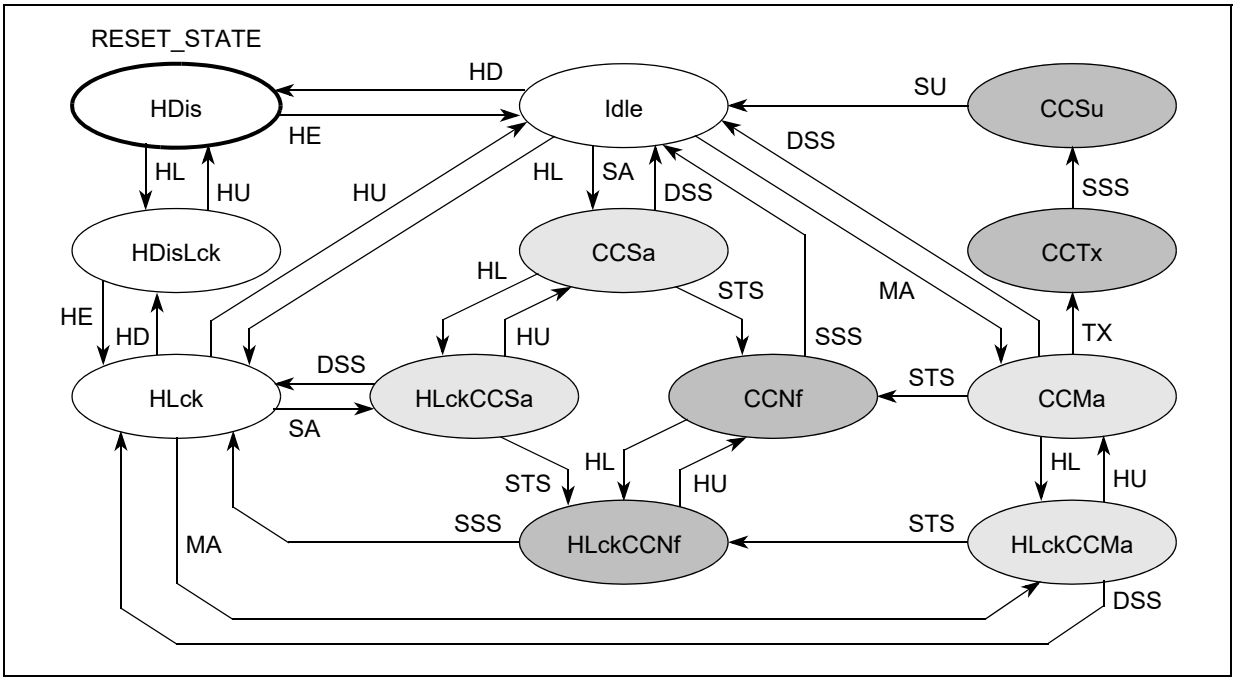

Table 1401. Transmit message buffer state description

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	CMT, SR	Idle – Message Buffer is idle. Included in message buffer search
HDis	0	0	CFG	—	Disabled – Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message Buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	SR	Locked – Application access to data, control, and status. Included in message buffer search.
CCSa	1	0	—	—	Slot Assigned – Message buffer assigned to next static slot. Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	—	Locked and Slot Assigned – Application access to data, control, and status.Message buffer assigned to next static slot.
CCNf	1	0	—	NF	Null Frame Transmission – Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	Locked and Null Frame Transmission – Application access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	—	CMT	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.

Table 1401. Transmit message buffer state description (continued)

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
HLckCCMa	1	1	MSG	—	Locked and Message Available – Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	—	TX	Message Transmission – Message buffer data transmit. Payload data from buffer transmitted.
CCSu	1	0	—	TX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

53.6.6.2.3 Message buffer transitions

53.6.6.2.3.1 Application transitions

The application transitions can be triggered by the application using the commands described in *Table 1407*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

- Message Buffer Enable and Disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

- Message Buffer Lock and Unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 1402. Transmit message buffer application transitions

Transition	Command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable.

Table 1402. Transmit message buffer application transitions (continued)

Transition	Command	Condition	Description
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock.

53.6.6.2.3.2 Module transitions

The module transitions that can be triggered by the CC are described in *Table 1403*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1403. Transmit message buffer module transitions

Transition	Condition	Description
SA	Slot match and static slot	Slot Assigned – Message buffer is assigned to next static slot.
MA	Slot match and CycleCounter match	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.
TX	Slot start and FR_MBCCSR*n*[CMT] = 1	Transmission Slot Start – Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	Status updated	Status Updated – Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	Static slot start	Static Slot Start – Start of static slot.
DSS	Dynamic slot start or symbol window start or NIT start	Dynamic Slot or Segment Start – Start of dynamic slot or symbol window or NIT.
SSS	Slot start or symbol window start or NIT start	Slot or Segment Start – Start of static slot or dynamic slot or symbol window or NIT.

53.6.6.2.3.3 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of *Table 1404*, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and, subsequently, the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions are given in the second part of *Table 1404*.

Table 1404. Transmit message buffer transition priorities

State	Priorities	Description
Module vs. application		
Idle, HLck	SA > HD MA > HD	Slot Assigned > Message Buffer Disable Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
Module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS TX > DSS	Transmission Slot Start > Static Slot Start Transmission Slot Start > Dynamic Slot Start

53.6.6.2.4 Transmit message setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit, CMT, in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). The physical access to the message buffer data field is described in *Section 53.6.3.1: Individual message buffers*.

As indicated by *Table 1395*, the application will write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the following states: HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in *Table 1395*. The state change is indicated through the FR_MBCCSR*n*[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters the HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa state, the FR_MBCCSR*n*[DVAL] flag is negated.

53.6.6.2.5 Message transmission

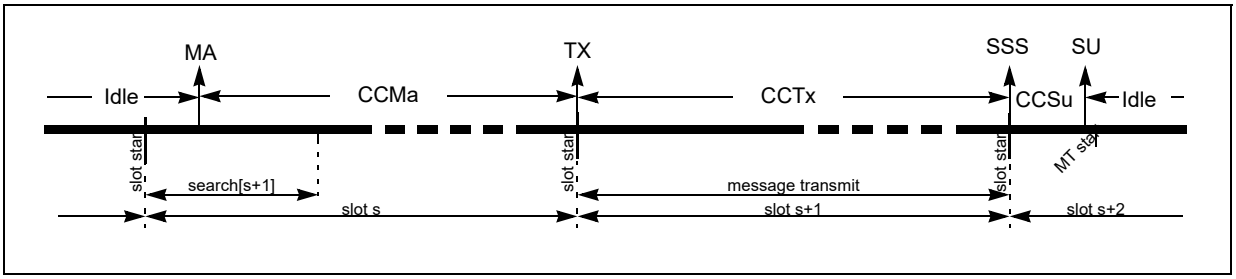
As a result of the message buffer search described in *Section 53.6.7: Individual message buffer search*, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. The message buffer is in the message available state CCMa
2. The message data is still valid (that is, FR_MBCCSR*n*[CMT] = 1)

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in *Figure 1350*. In this example, the message buffer with message buffer number *n* is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid (that is, FR_MBCCSR*n*[CMT] = 1).

Figure 1350. Message transmission timing



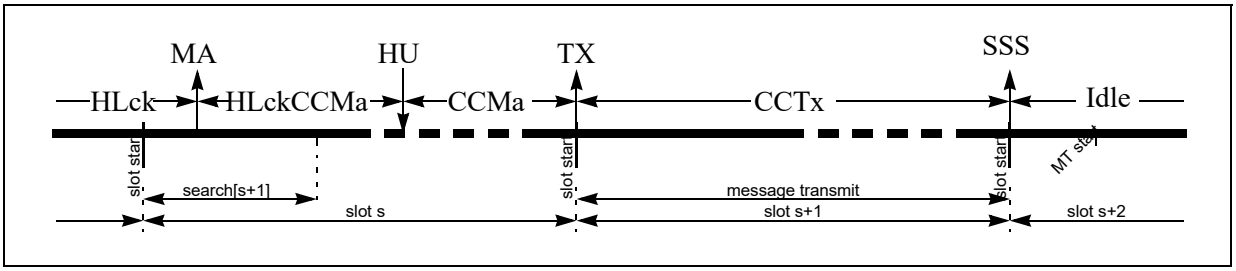


Figure 1351. Message transmission from HLck state with unlock

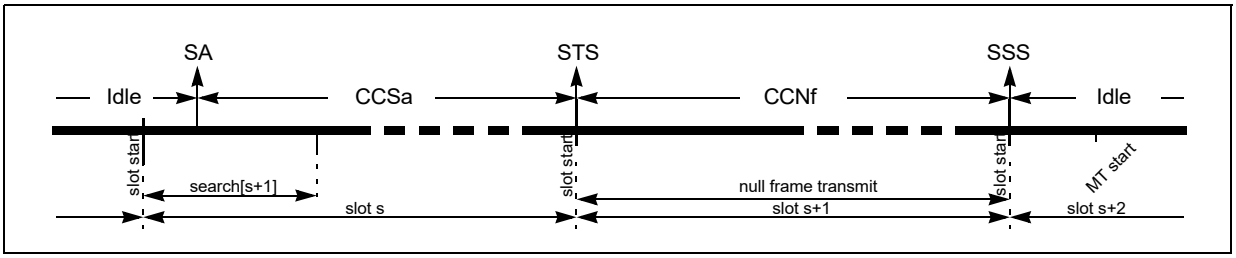
The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items:

1. The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. The value of the PLDLEN field in the message buffer header field, as described in *Section 53.6.5.2.1: Frame header description*

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN ≤ MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

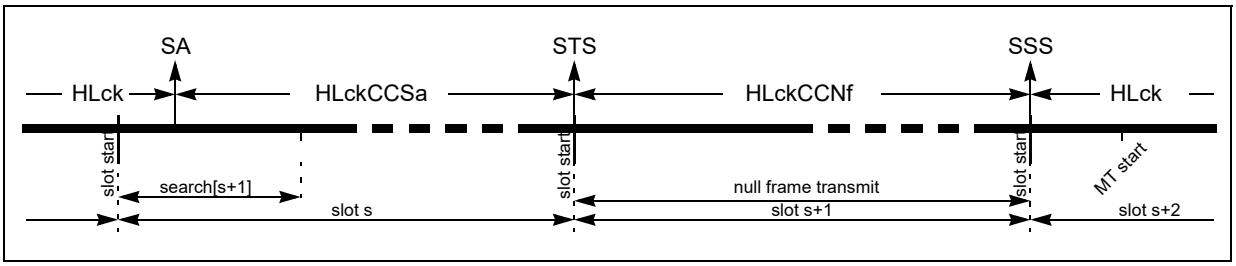
53.6.6.2.6 Null frame transmission



A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDR*n*[FID] set to S and FR_MBCCFR*n*[CHA] set to 1. A null frame is transmitted in the static slot *s* on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDR*n*[FID] = S and FR_MBCCFR*n*[CHA] = 1 are either not committed (that is FR_MBCCSR*n*[CMT] = 0), or are locked by the application (that is, FR_MBCCSR*n*[LCKS] = 1), or the cycle counter filter is enabled and does not match.

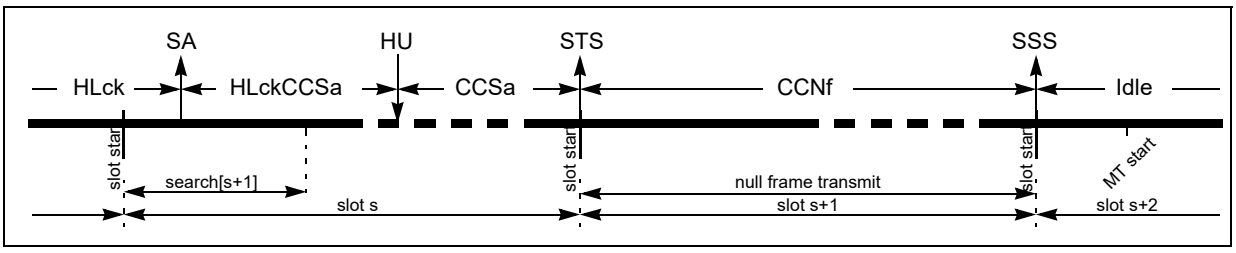
Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in *Section 53.6.7: Individual message buffer search*, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or



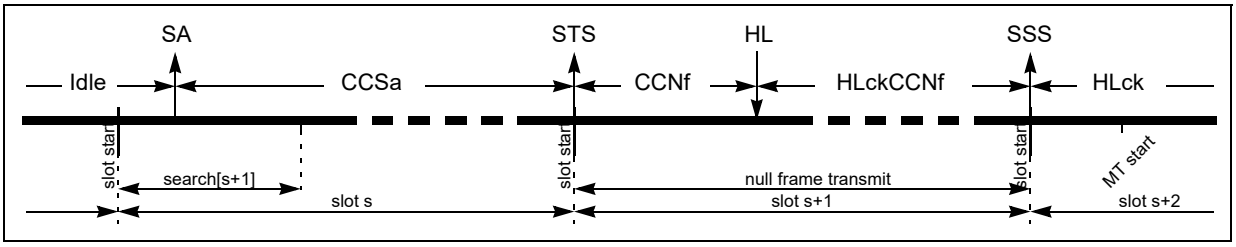
from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in *Figure 1352*.

Figure 1352. Null frame transmission from Idle state



A message buffer timing and state change diagram for null frame transmission from HLck state is given in *Figure 1353*.

Figure 1353. Null frame transmission from HLck state



If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 1354*.

Figure 1354. Null frame transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 1355*.

Figure 1355. Null frame transmission from Idle state with locking

53.6.6.2.7 Message buffer status update

After the end of each slot, the PE generates the slot status vector. Depending on the status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

53.6.6.2.7.1 Message buffer status update after complete message transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer was sent to the FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSR*n*[MBIF] to indicate the successful message transmission.

Depending on the Transmission Mode flag FR_MBCCFR*n*[MTM], the CC changes the commit flag FR_MBCCSR*n*[CMT] and the valid flag FR_MBCCSR*n*[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in *Event Transmission mode.* In this case, each committed message is transmitted only once. The commit flag FR_MBCCSR*n*[CMT] is cleared with the SU transition. If the FR_MBCCFR*n*[MTM] flag is asserted, the message buffer is in the *State Transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSR*n*[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSR*n*[DVAL] to indicate that the message will be transmitted again.

53.6.6.2.7.2 Message buffer status update after incomplete message transmission

The term *incomplete message transmission* refers to the fact that not all payload data that should be transmitted was sent to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

In either of these two cases, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

53.6.6.2.7.3 Message buffer status update after null frame transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

53.6.6.3 Receive message buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used, the related receive shadow buffer must be configured as described in *Section 53.6.3.2: Receive shadow buffers*.

A receive message buffer is used to receive a message from the FlexRay bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application:

- Message data received
- Information about the reception process
- Status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration setting:

- FR_MBCCSR*n*[MTD] = 0 (receive message buffer)

Both the application and the CC have access to certain message buffers. To ensure data consistency, a message buffer locking scheme controls the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in *Figure 1356*. A description of the regions is given in *Table 1405*. If a region is active as indicated in *Table 1406*, the access scheme given for that region applies to the message buffer.

Figure 1356. Receive message buffer access regions

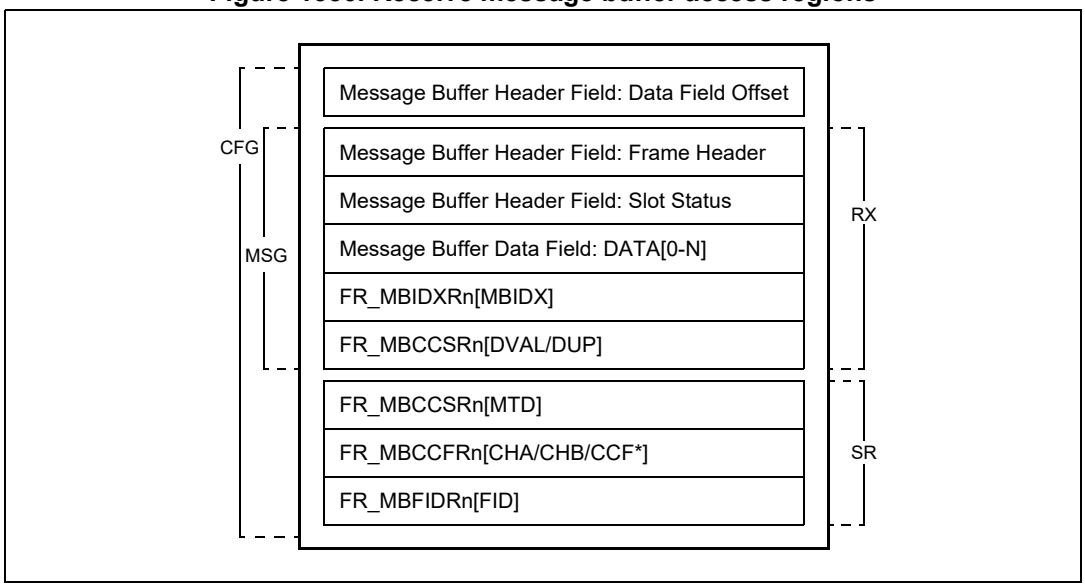


Table 1405. Receive message buffer access region description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration, message data, and status access
MSG	Read/write	—	Message data, header, and status access
RX	—	Write-only	Message reception and status update
SR	—	Read-only	Message buffer search data

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT] and the interrupt enable bit FR_MBCCSR*n*[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in *Figure 1357*. A description of the message buffer states is given in *Table 1401*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

Figure 1357. Receive message buffer states

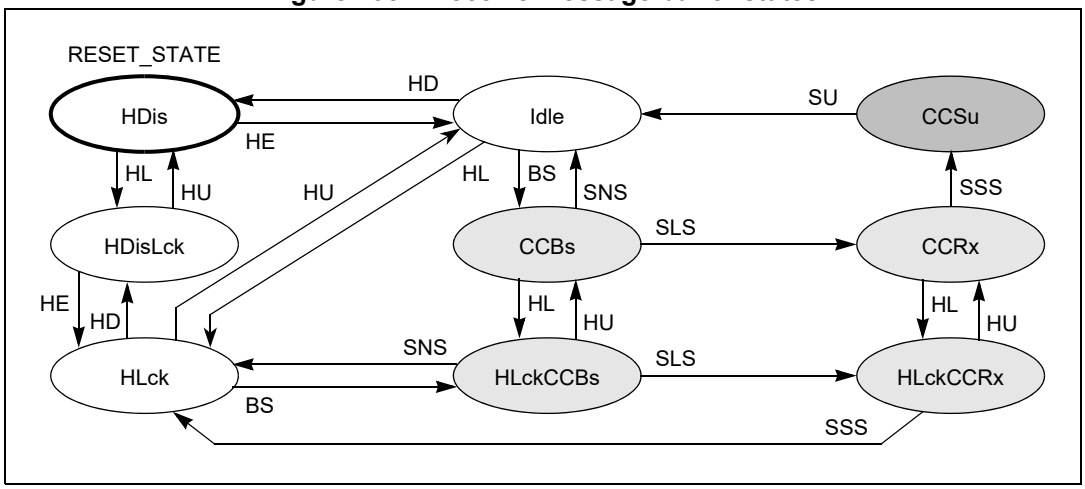

Table 1406. Receive message buffer states and access

State	FR_MBCCSR*n*		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	SR	Idle – Message buffer is idle. Included in message buffer search.
HDis	0	0	CFG	—	Disabled – Message buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	—	Locked – Application access to data, control, and status. Included in message buffer search.
CCBs	1	0	—	—	Buffer Subscribed – Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	—	Locked and Buffer Subscribed – Application access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	—	—	Message Receive – Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	—	Locked and Message Receive – Application access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	—	RX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

53.6.6.3.1 Message buffer transitions

53.6.6.3.1.1 Application transitions

The application transitions that can be triggered by the application using the commands are described in *Table 1402*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

Message buffer enable and disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCBs, HLckCCBs, or CCRx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

Message buffer lock and unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSR*n*[LCKS]. If the command triggers the lock transition HL while the message buffer is in the CCRx state, the lock transition has no effect (command is ignored) and the message buffer state is not changed.

In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 1407. Receive message buffer application transitions

Transition	Host command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS = 0	Application triggers message buffer lock
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock

Module Transitions

The module transitions that can be triggered by the CC are described in *Table 1408*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1408. Receive message buffer module transitions

Transition	Condition	Description
BS	Slot match and cycle counter match	Buffer Subscribed – The message buffer filter matches next slot and cycle.
SLS	Slot start	Slot Start – Start of either Static Slot or Dynamic Slot.
SNS	Symbol window start or NIT start	Symbol Window or NIT Start – Start of either Symbol Window or NIT.
SSS	Slot start, symbol window start, or NIT start	Slot or Segment Start – Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	Status updated	Status Updated – Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

53.6.6.3.1.2 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in *Table 1409*, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the CCBs buffer subscribed state and the module triggers the SLS slot start transition at the same time that the application locks the message buffer through the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state, HLckCCRx.

Table 1409. Receive message buffer transition priorities

State	Priorities	Description
Module vs. Application		
Idle	BS > HD	Buffer subscribed > Message buffer disable

Table 1409. Receive message buffer transition priorities (continued)

State	Priorities	Description
HLck	BS > HD	Buffer subscribed > Message buffer disable
CCRx	SSS > HL	Slot or segment start > Message buffer lock

53.6.6.3.2 Message reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffer is assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot, the module triggers the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data is written into the shadow buffers. For details on receive shadow buffers, refer to *Section 53.6.6.3.5: Receive shadow buffer concept*. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

53.6.6.3.3 Message buffer update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer is in the locked state HLckCCRx, no update will be performed. The received data is lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state, it is now in the CCSu state. After the evaluation of the slot status provided by the PE, the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to, as described in *Table 1410*.

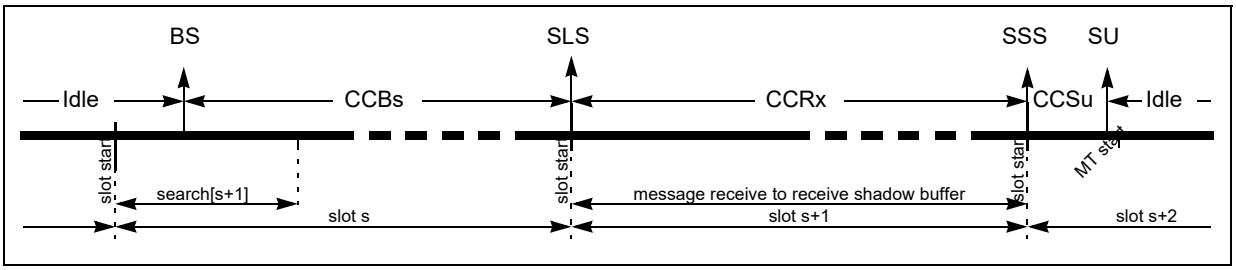

Table 1410. Receive message buffer update

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
1	1	Valid non-null frame received. – Message Buffer Data field updated. – Frame Header field updated. – Slot Status field updated. – DUP = 1 – DVAL = 1 – MBIF = 1
1	0	Valid null frame received. – Message Buffer Data field *not* updated. – Frame Header field *not* updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed – MBIF = 1
0	x	No valid frame received. – Message Buffer Data field not updated. – Frame Header field not updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed. – MBIF = 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: vSS!ValidFrame = 0 and vSS!SyntaxError = 0 and vSS!ContentError = 0 and vSS!BViolation = 0.

Note: If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > n will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in *Figure 1358*.

Figure 1358. Message reception timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following items:

- The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
- The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR).
- The number of bytes received over the FlexRay bus.

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

53.6.6.3.4 Received message access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in *Section 53.6.3.1: Individual message buffers*.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

53.6.6.3.5 Receive shadow buffer concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in *Section 53.6.3.2: Receive shadow buffers*.

The receive shadow buffers temporarily store the received frame header and message data. The slot status information is generated after the slot boundary. If the slot status information indicates the reception of the valid non-null frame (refer to *Table 1410*), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXRn) with the content of the corresponding internal shadow buffer index register. In all cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXRn).

53.6.7 Individual message buffer search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel whether a slot *s* in a communication cycle *c* is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm invoked at the following protocol-related events:

- NIT start
- Slot start in the static segment
- Minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *s* searches for message buffers assigned or subscribed to slot *s* + *1*.

In general, the message buffer search for the next slot *s* considers only message buffers that

1. Are enabled (that is, FR_MBCCSR*n*[EDS] = 1), and
2. Match the next slot *s*, (that is, FR_MBFIDR*n*[FID] = *s*)

On top of that, for the static segment, only those message buffers are considered that match the condition of at least one row of *Table 1411*. For the dynamic segment, only those message buffers are considered that match the condition of at least one row of *Table 1412*. These message buffers are called *matching* message buffers.

For each enabled channel, the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers, the message buffers with highest priority according to *Table 1411* for the static segment and according to *Table 1412* for the dynamic segment are selected.

Table 1411. Message buffer search priority (static segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(Highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	1	—	0	1	Transmit buffer, matches cycle count, not committed	SA
	1	1	—	1	Transmit buffer, matches cycle count, locked	SA
2	1	—	—	—	Transmit buffer	SA
3	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(Lowest) 4	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, refer to *Section 53.6.7.1: Message buffer cycle counter filtering*.

Table 1412. Message buffer search priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(Highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(Lowest) 2	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, refer to *Section 53.6.7.1: Message buffer cycle counter filtering*

If there are multiple message buffers with highest priority, the message buffer with the lowest message buffer number is selected. All message buffers that have the highest priority must have a consistent channel assignment as specified in *Section 53.6.7.2: Message buffer channel assignment consistency*.

Depending on the message buffer channel assignment, the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in *Section 53.6.3.1: Individual message buffers*.

53.6.7.1 Message buffer cycle counter filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled (CCFE = 0), this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

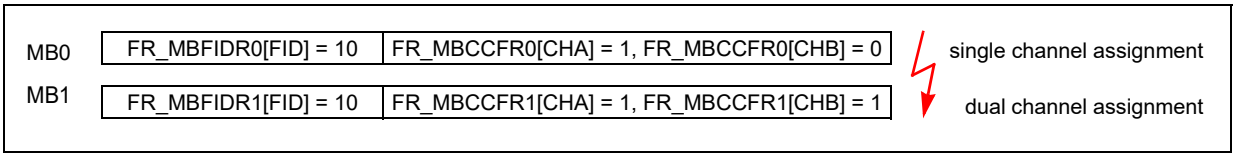
The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following condition is true.

Equation 47

$$MBCCFRn[CCFE] = 0$$

Equation 48

$$CYCCNT \& MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \& MBCCFRn[CCFMSK]$$



53.6.7.2 Message buffer channel assignment consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFR*n*[CHA] = 1 and transmits or receives on channel B if FR_MBCCFR*n*[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The

behavior of the message buffer search is not defined if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in *Figure 1359*.

Figure 1359. Inconsistent channel assignment

53.6.7.3 Node-related slot multiplexing

The term *node-related slot multiplexing* applies to the dynamic segment only and refers to the functionality if transmit as well as receive message buffers are configured for the same slot.

According to *Table 1412* the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

53.6.7.4 Message buffer search error

There are two kinds of error that may occur during message buffer search[(r)].

53.6.7.4.1 Message buffer search start while running

If the message buffer search is running in slot *s – 1* and the next message buffer search start event appears due to the start of slot *s*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *s*. Additionally, the search engine will not be started in slot *s*, and consequently no individual message buffer is identified for transmission or reception in slot *s + 1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency, refer to *Section 53.7.5: Number of usable message buffers*.

53.6.7.4.2 Illegal message buffer index found

If the message buffer search has finished the message buffer search in slot *s – 1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) and no individual message buffer is identified for transmission or reception in slot *s*. The legal message buffer index values for the individual and receive shadow

r. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to a search error, the received frame is considered for FIFO reception.

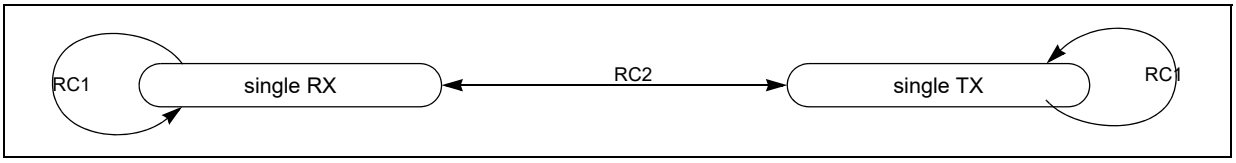
buffers are specified in *Section 53.5.2.53: Receive Shadow Buffer Index Register (FR_RSBIR)* and *Section 53.5.2.85: Message Buffer Index Registers (FR_MBIDXRn)*.

53.6.8 Individual message buffer reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data cannot be reconfigured when the protocol is out of the *POC:config* state.

53.6.8.1 Reconfiguration schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.



53.6.8.1.1 Basic type not changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSR*n*[MTD] is not changed. This type of reconfiguration is denoted by RC1 in *Figure 1360*. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

53.6.8.1.2 Buffer type not changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in *Figure 1360*. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

Figure 1360. Message buffer reconfiguration scheme

53.6.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

53.6.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.* One FIFO is assigned to channel A, and the other FIFO is assigned to channel B. Both FIFOs work independently from each other.

The message buffer structure of each FIFO is described in *Section 53.6.3.3: Receive FIFO*. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- The FIFO system memory base address.
- The index of the first FIFO entry given by the Receive FIFO Start Index Register (FR_RFSIR).
- The data field offset of the data field belonging to the first FIFO entry given by the Receive FIFO Start Data Offset Register (FR_RFSDOR).
- The number of FIFO entries and the length of each FIFO entry as given by the Receive FIFO Depth and Size Register (FR_RFDSR).

53.6.9.2 FIFO configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO Address Mode bit FAM in the Module Configuration Register (FR_MCR).

53.6.9.2.1 Single System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is the System Memory Base Address Register (FR_SYMBADR).

53.6.9.2.2 Dual System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is the Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data is given in *Section 53.6.3.7: Receive FIFO control and configuration data*. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details, refer to *Section 53.6.4: FlexRay memory area layout*.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

1. Configure the FIFO update and address modes in Module Configuration Register (FR_MCR).
2. Configure the FIFO system memory base address.
3. Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO.
4. Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO.
5. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size.
6. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth.
7. Configure the FIFO filters.

53.6.9.3 FIFO periodic timer

The FIFO periodic timer is used to generate a FIFO almost-full interrupt at a certain point in time, if the almost-full watermark is not reached but the FIFO is not empty. This can be used to prevent frames from getting stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd,* greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

53.6.9.4 FIFO reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case, the FIFO filter path shown in *Figure 1361* is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented.If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

53.6.9.5 FIFO almost-full interrupt generation

If the FIFO fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM (that is, FLA > WM_A (FLB > WM_B)), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.If the periodic timer expires, and FIFOA (FIFOB) is not empty (that is, FLA > 0 (FLB > 0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

53.6.9.6 FIFO overflow error generation

If the FIFOA (FIFOB) is full (that is, FLA = $FIFO_DEPTH_A$ (FLB=$FIFO_DEPTH_B$)) and the conditions for a FIFO reception as described in *Section 53.6.9.4: FIFO reception* are fulfilled, then the FIFO overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

53.6.9.7 FIFO message access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the (Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to *Equation 42*.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, then the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case, the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to *Equation 42*. The application can access the message data as described in *Section 53.6.3.3: Receive FIFO*. When the application has read the message buffer data and status information, it can update the FIFO as described in *Section 53.6.9.8: FIFO update*.

53.6.9.8 FIFO update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

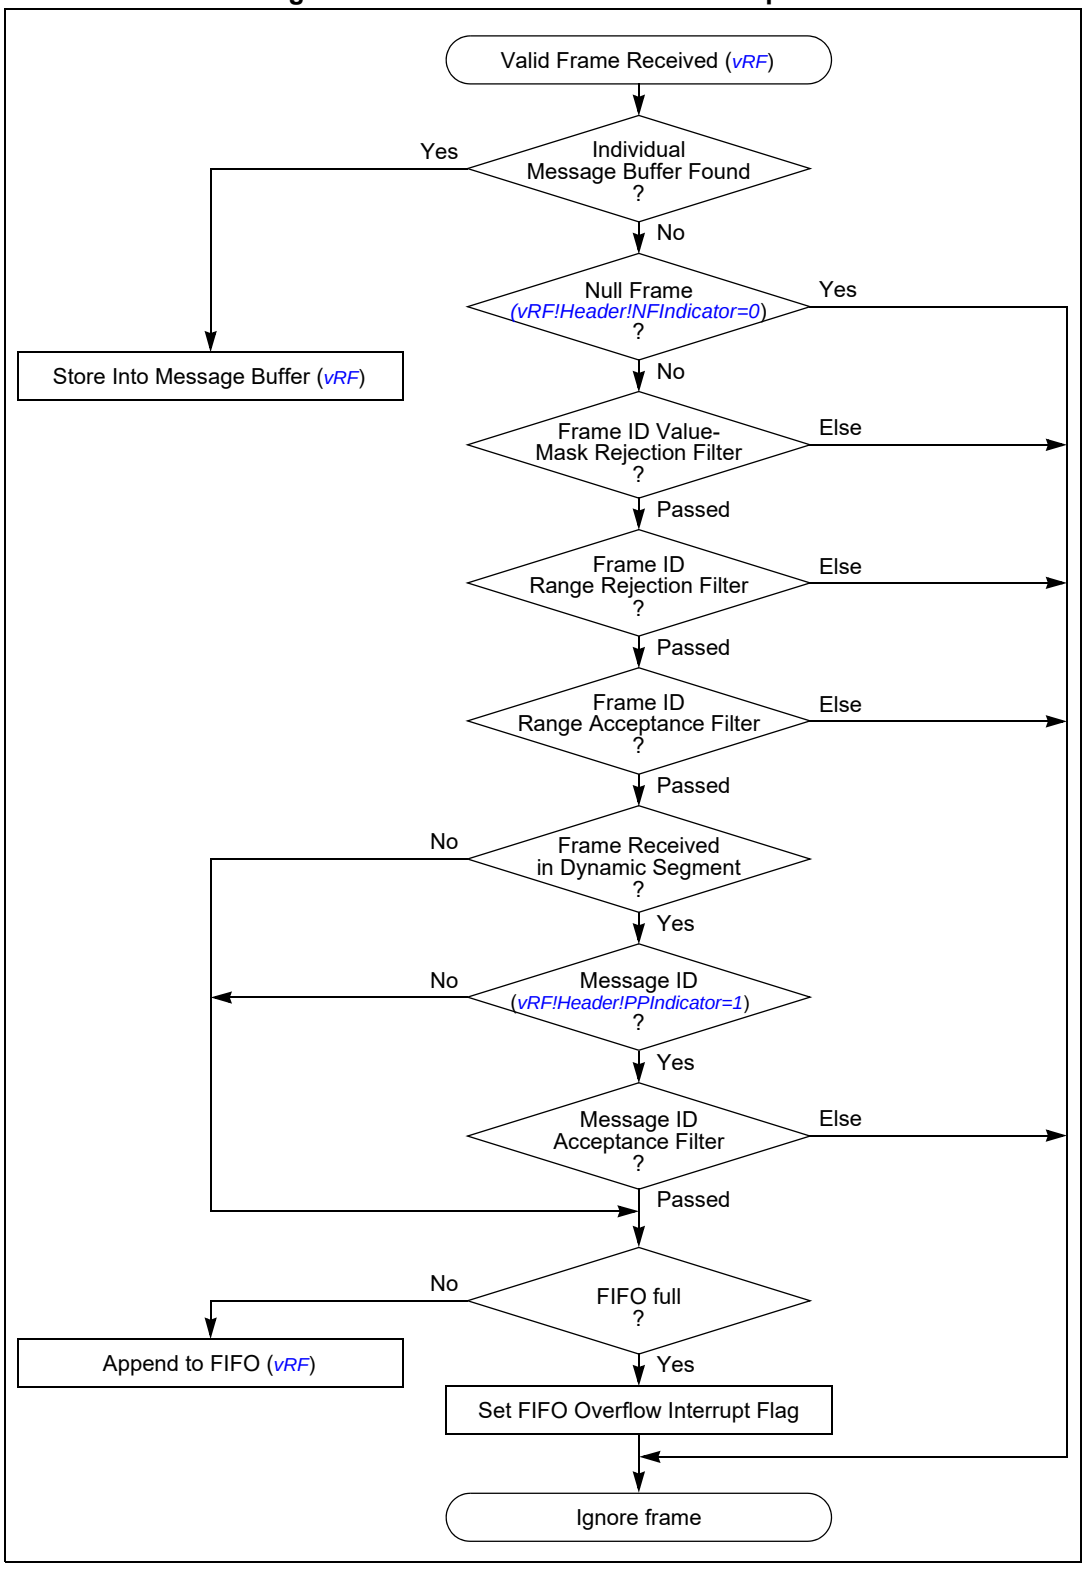
If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

53.6.9.8.1 FIFO interrupt flag update

The FIFO Interrupt Flag Update mode is configured when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode, FIFOA (FIFOB) will be updated by one entry when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.



The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1 if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

53.6.9.9 FIFO filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides four sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in *Figure 1361*.

Figure 1361. Received frame FIFO filter path

A received frame passes the FIFO filtering if it has passed all four types of filter.

53.6.9.9.1 RX FIFO Frame ID Value-mask Rejection filter

The Frame ID Value-mask Rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter (that is, it is not rejected).

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-mask Rejection filter if *Equation 49* is fulfilled.

Equation 49

$$FID \,\&\, FR_RFFIDRFMR[FIDRFMSK] \neq FR_RFFIDRFVR[FIDRFVAL] \,\&\, FR_RFFIDRFMR[FIDRFMSK]$$

The RX FIFO Frame ID Value-mask Rejection filter can be configured to pass all frames by using the following setting:

FR_RFFIDRFVR[FIDRFVAL] = 0x000 and FR_RFFIDRFMR[FIDRFMSK] = 0x7FF

Using the setting above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-mask Rejection filter can be configured to reject all frames by using the following setting:

FR_RFFIDRFMR[FIDRFMSK] = 0x000

Using the setting above, *Equation 49* can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

53.6.9.9.2 RX FIFO Frame ID Range Rejection filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range Rejection filters if either no rejection filter is enabled, or, if for all of the enabled RX FIFO Frame ID Range Rejection filters (that is, FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1), *Equation 50* is fulfilled.

Equation 50

$$(FID < FR_RFRFCFR_{SEL}[SID_{IBD=0}]) \text{ or } (FR_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Consequently, all frames with a frame ID that fulfills *Equation 51* for at least one of the enabled rejection filters will be rejected and thus not pass.

Equation 51

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

53.6.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, if for at least one of the enabled RX FIFO Frame ID Range acceptance filters (that is, FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1), *Equation 52* is fulfilled.

Equation 52

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

53.6.9.9.4 RX FIFO Message ID Acceptance filter

The RX FIFO Message ID Acceptance filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance filter if *Equation 53* is fulfilled.

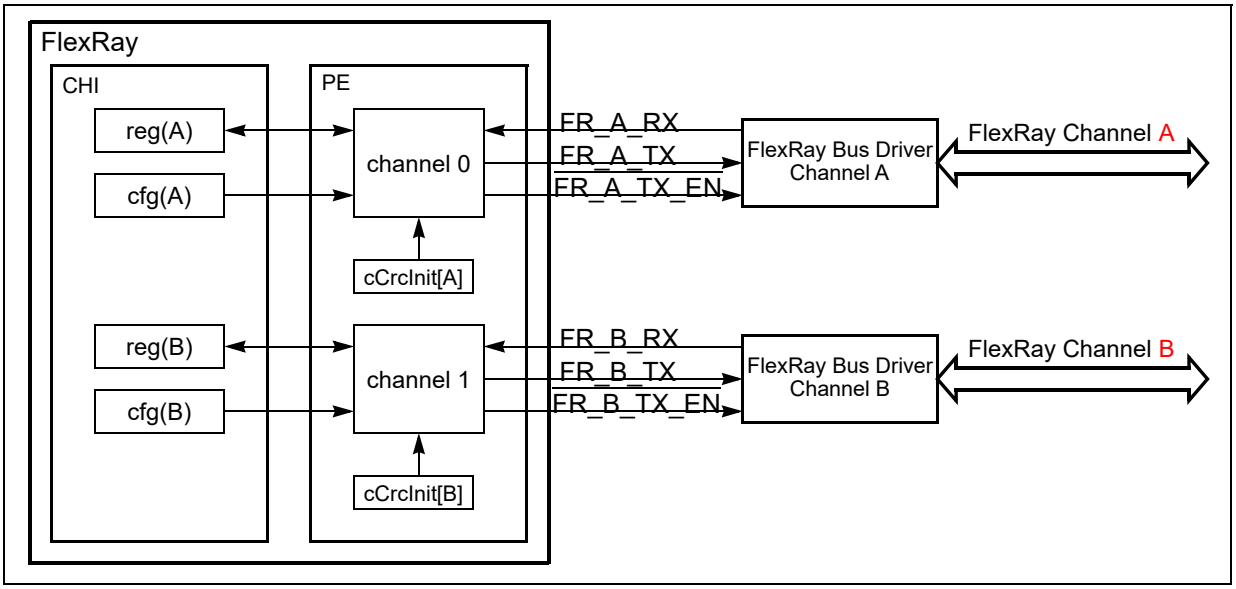
Equation 53

$$MID \,\&\, FR_RFMIDAFMR[MIDAFMSK] = FR_RFMIDAFMR[MIDAFVAL] \,\&\, FR_RFMIDAFMR[MIDAFMSK]$$

The RX FIFO Message ID Acceptance filter can be configured to accept all frames by setting

- FR_RFMIDAFMR[MIDAFMSK]:= 0x000

Using the setting above, *Equation 53* is always fulfilled and all frames will pass.



53.6.10 Channel device modes

This section describes the two FlexRay channel device modes that are supported by the CC.

53.6.10.1 Dual-Channel Device mode

In Dual-Channel Device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and FR_A_TX_EN is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and FR_B_TX_EN is connected to the physical bus channel B. The dual-channel system is shown in *Figure 1362*.

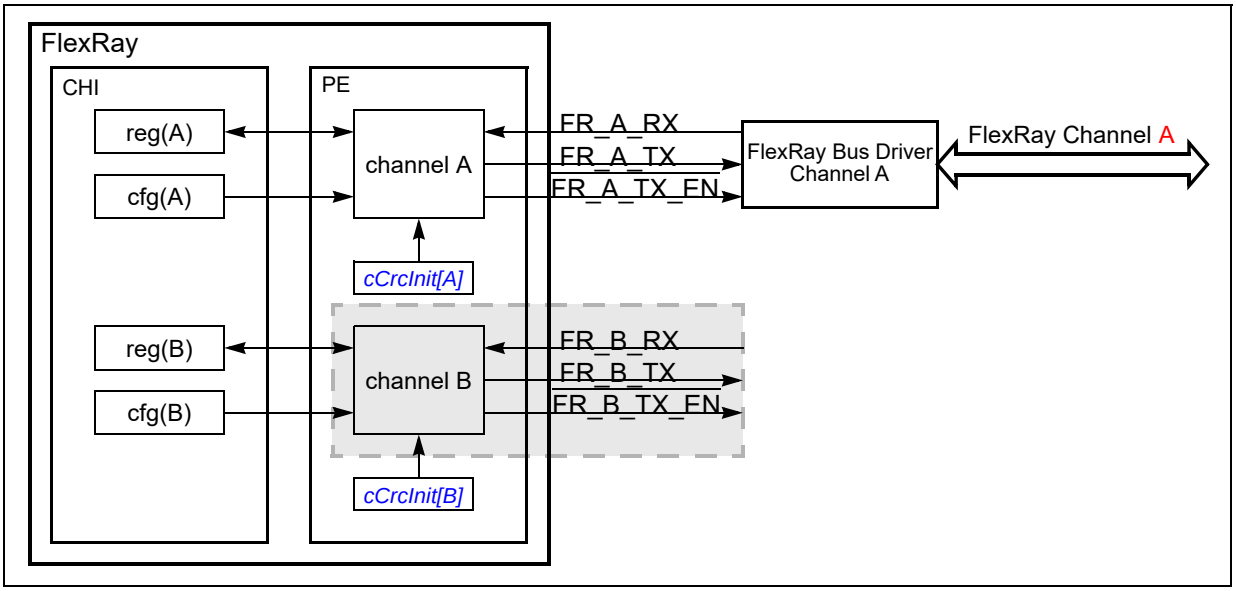
Figure 1362. Dual-Channel Device mode

53.6.10.2 Single-channel device mode

Single-Channel Device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and FR_A_TX_EN and can be connected to either the physical bus channel A (shown in *Figure 1363*) or the physical bus channel B (shown in *Figure 1364*).

If the device is configured as a single-channel device by setting FR_MCR[SCM] to 1, only the internal channel A and FlexRay port A are used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay channel A or FlexRay channel B. The bit FR_MCR[CHA] must be set, if FlexRay port A is connected to FlexRay channel A. The bit FR_MCR[CHB] must be set if FlexRay port B is connected to FlexRay channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single-channel device, the application can access and configure only the registers related to internal channel A.

Figure 1363. Single-channel device mode (channel A)



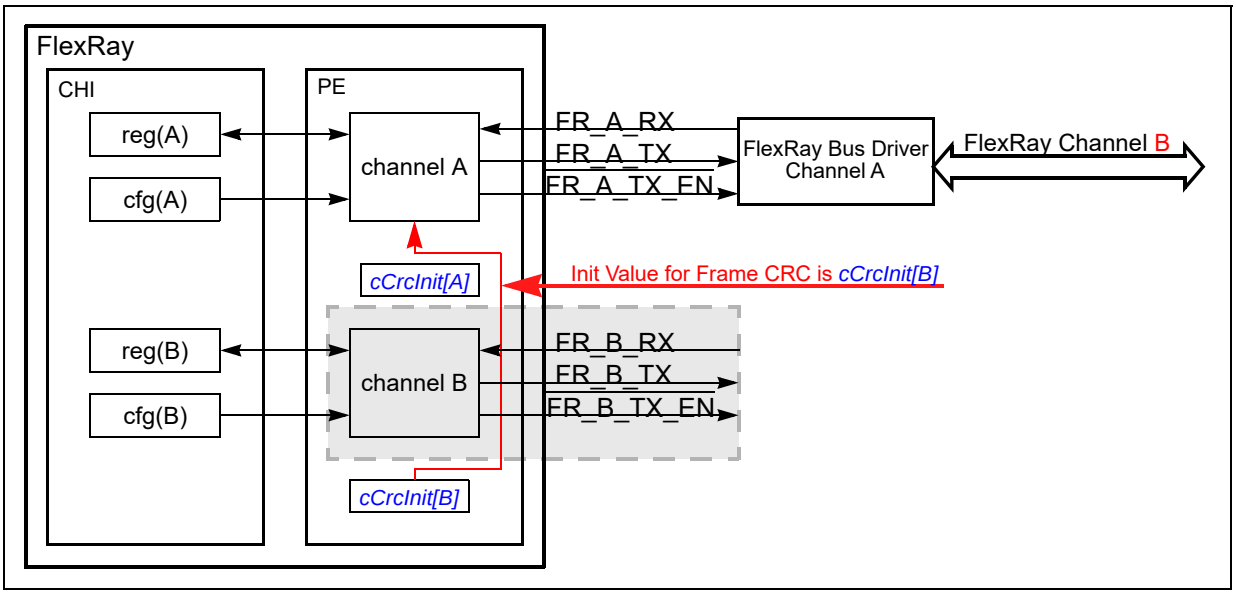


Figure 1364. Single-channel device mode (channel B)

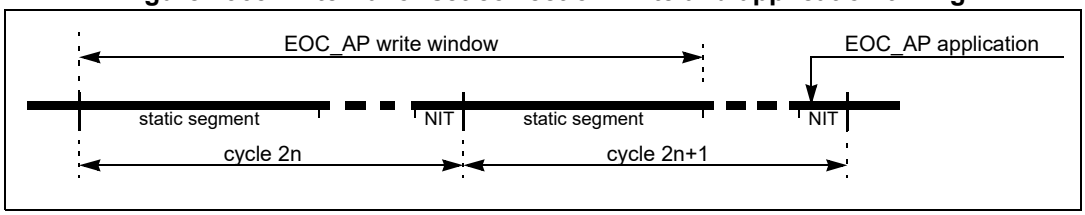
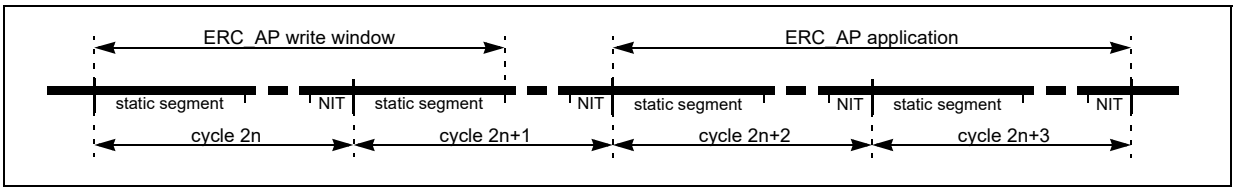
53.6.11 External clock synchronization



The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in *Figure 1365* and *Figure 1366*.

Note: The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these values were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n + 1 will be affected by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end



of the static segment of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle 2n + 1. If the value is not applied in cycle 2n + 1, then the value will be applied in the cycle 2n+3. Refer to *Figure 1365* for timing details.

Figure 1365. External offset correction write and application timing

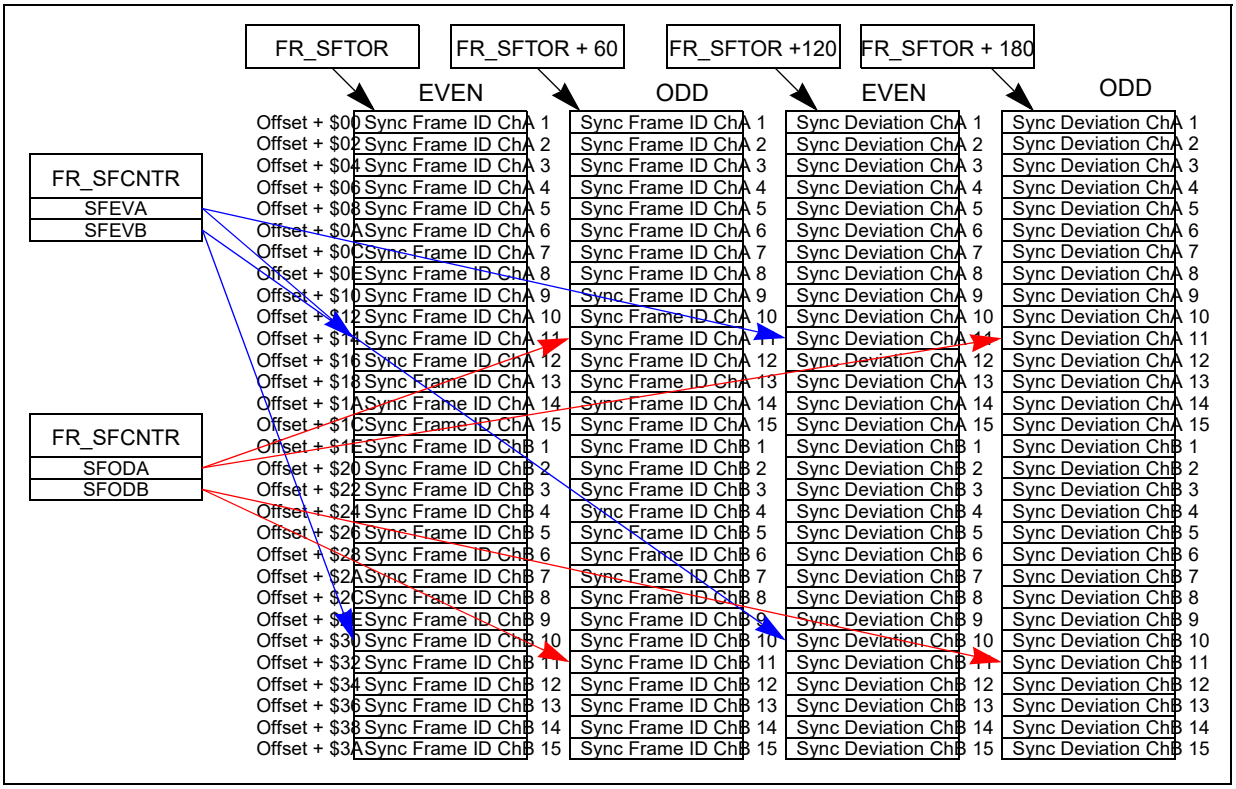
If the rate correction for the cycle pair [2n + 2, 2n + 3] will be affected by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle pair [2n + 2, 2n + 3]. If the value is not applied for cycle pair [2n + 2, 2n + 3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to *Figure 1366* for details.

Figure 1366. External rate correction write and application timing

53.6.12 Sync frame ID and sync frame deviation tables

The FlexRay protocol requires the provision of a snapshot of the synchronization frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note: Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.



53.6.12.1 Sync frame ID table content

The sync frame ID table is a snapshot of the protocol-related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

53.6.12.2 Sync frame deviation table content

The sync frame deviation table is a snapshot of the protocol-related variable zsDev(id)(oe)(ch)!Value. Each sync frame deviation table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the sync frame ID table.

Figure 1367. Sync table memory layout

53.6.12.3 Sync frame ID and sync frame deviation table setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in *Figure 1367*. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

53.6.12.4 Sync frame ID and sync frame deviation table generation

The application controls the generation process of the sync frame ID and sync frame deviation tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in *Table 1413*.

Table 1413. Sync frame table generation modes

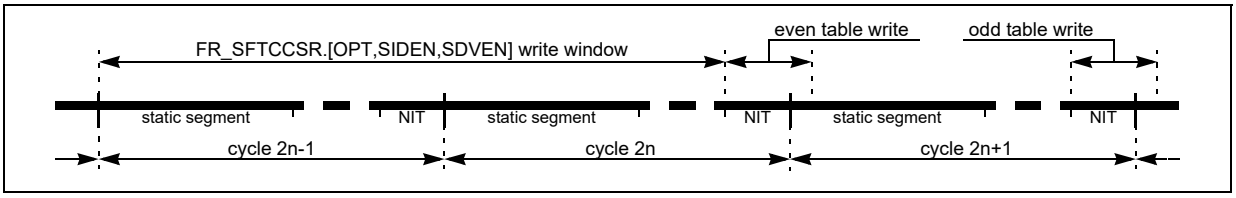
FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No sync frame table copy
0	0	1	Sync frame ID tables will be copied continuously
0	1	0	Reserved

Table 1413. Sync frame table generation modes (continued)

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	1	1	Sync frame ID tables and sync frame deviation tables will be copied continuously
1	0	0	No sync frame table copy
1	0	1	Sync frame ID tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync frame ID tables and sync frame deviation tables for next even-odd-cycle pair will be copied

The sync frame table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even-cycle-related tables after the start of the NIT of the next even cycle. The CC checks whether the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. When all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.



To read the generated tables, the application must lock the tables to prevent the CC from updating them. The locking is initiated by writing a 1 to the Even Table Lock trigger, FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding status information fields, SFRA and SFRB, in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in *Figure 1367*.

After reading all the data from the locked tables, the application must unlock the table by writing to the Even Table Lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

Figure 1368. Sync frame table trigger and generation timing

53.6.12.5 Sync frame table access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in *Figure 1367*. During the table write, the application cannot lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

53.6.12.5.1 Sync frame table locking and unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

53.6.13 MTS generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol (MTS) in the symbol window on channel A or channel B.

The application can configure the set of communication cycles that transmit the MTS over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT if *Equation 54*, *Equation 55*, and *Equation 56* are fulfilled.

Equation 54

FR_PSR0[PROTSTATE] = *POC:normal active*

Equation 55

FR_MTSACRF[MTE] = 1

Equation 56

CYCCNT & FR_MTSACFR[CYCCNTMSK] = FR_MTSACFR[CYCCNTVAL] & FR_MTSACFR[CYCCNTMSK]

The MTS is transmitted over channel B in the communication cycle with number CYCCNT if *Equation 54*, *Equation 57* and *Equation 58* are fulfilled.

Equation 57

$$FR_MTSBCRF[MTE] = 1$$

Equation 58

$$CYCCNT \& FR_MTSBCFR[CYCCNTMSK] = FR_MTSBCFR[CYCCNTVAL] \& FR_MTSBCFR[CYCCNTMSK]$$

53.6.14 Key slot transmission

53.6.14.1 Key slot assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less than or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2); otherwise no key slot is assigned.

53.6.14.2 Key slot transmission in *POC:startup*

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

53.6.14.3 Key slot transmission in *POC:normal active*

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in *Table 1414* is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (refer to *Section 53.6.6.2.5*). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (refer to *Section 53.6.6.2.6*).

Table 1414. Key slot frame type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	Normal frame
0	1	Normal frame(1)
1	0	Sync frame
1	1	Startup frame

1. The frame transmitted has a semantically incorrect header and will be detected as an invalid frame at the receiver.

53.6.15 Sync frame filtering

Each received synchronization frame must pass the Sync Frame Acceptance filter and the Sync Frame Rejection filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled (that is, the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared), all received synchronization frames are considered for clock synchronization. If a received synchronization frame did not pass at

least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

53.6.15.1 Sync frame acceptance filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if *Equation 59* or *Equation 60* evaluates to true.

Equation 59

$$FR_MCR[SFFE] = 0$$

Equation 60

$$FID \,\&\, FR_SFIDAFMR[FMSK] = FR_SFIDAFVR[FVAL] \,\&\, FR_SFIDAFMR[FMSK]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

53.6.15.2 Sync frame rejection filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if *Equation 61* or *Equation 62* evaluates to true.

Equation 61

$$FR_MCR[SFFE] = 0$$

Equation 62

$$FID \neq FR_SFIDRFR[SYNFRID]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

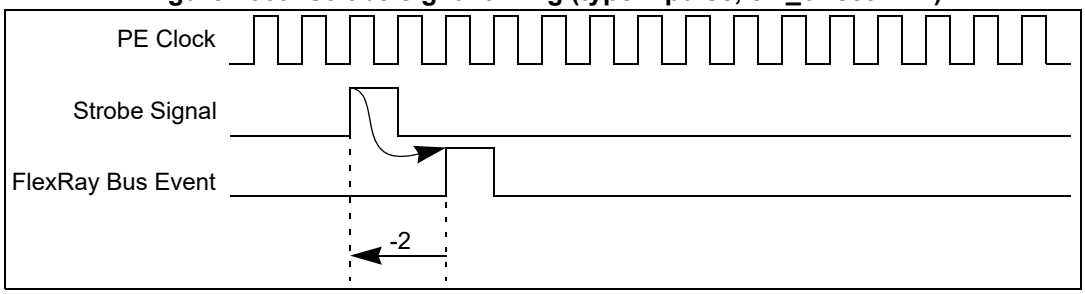
53.6.16 Strobe signal support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in *Table 1299*.

53.6.16.1 Strobe signal assignment

Each of the strobe signals listed in *Table 1299* can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

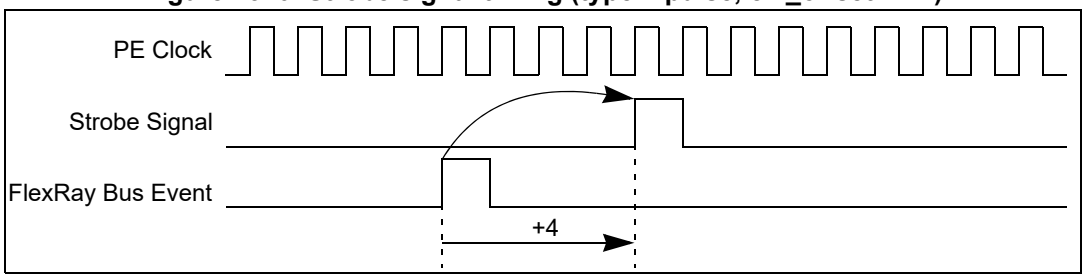
To read out the current settings for a strobe signal with number *n*, the application must execute the following sequence.



1. Write to FR_STBSCR with WMD = 1 and SEL = *n*. (Updates the SEL field only.)
2. Read STBCSR.
   The SEL field provides *n* and the ENB and STBPSEL fields provides the settings for signal *n*.

53.6.16.2 Strobe signal timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.



The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay bus. These signals are listed in *Table 1299* with a negative clock offset. An example waveform is given in *Figure 1369*.

Figure 1369. Strobe signal timing (type = pulse, clk_offset = –2)

Other signals refer to events that occurred on the FlexRay bus some cycles before the strobe signal is changed. These signals are listed in *Table 1299* with a positive clock offset. An example waveform is given in *Figure 1370*.

Figure 1370. Strobe signal timing (type = pulse, clk_offset = +4)

53.6.17 Timer support

The CC provides two timers that run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In Non-repetitive mode, the timer stops if it expires. In Repetitive mode, the timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

53.6.17.1 Absolute timer T1

Absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if *Equation 63* and *Equation 64* are fulfilled.

Equation 63

$$CYCTR[CTCCNT] \& FR_TI1CYSR[T1_CYC_MSK] = FR_TI1CYSR[T1_CYC_VAL] \& FR_TI1CYSR[T1_CYC_MSK]$$

Equation 64

$$FR_MTCTR[MTCT] = FR_TI1MTOR[T1_MTOFFSET]$$

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding interrupt condition (that is, when *Equation 63* and *Equation 64* are fulfilled) also leads to an event-out indication on an output port (fr_evt_tim1) based on the FR_PEOER[TIM1_EE].

53.6.17.2 Absolute/relative timer T2

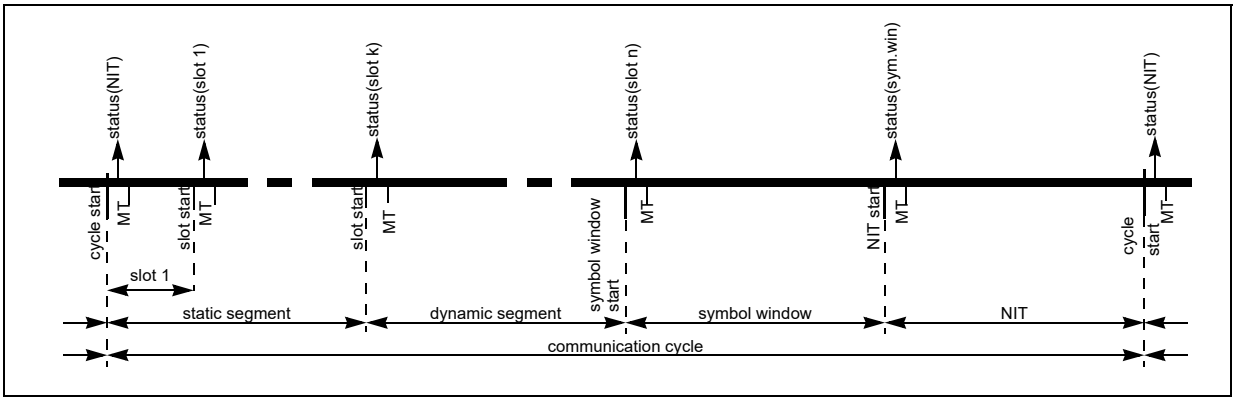
Timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

53.6.17.2.1 Absolute timer T2

If timer T2 is configured as an absolute timer, it has the same functionality as timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. When timer T2 expires, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

53.6.17.2.2 Relative Timer T2



If timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set when the programmed amount of macroticks MT[31:0] – defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) – has elapsed since the trigger or restart of timer T2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

53.6.18 Slot status monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per-channel base. The content of the slot status vector is described in *Table 1415*. The PE provides the

slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in *Figure 1371*.

Figure 1371. Slot status vector update

Note: The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 1415. Slot status content

Slot	Status content

Static/dynamic slot	Slot-related status
	vSS!ValidFrame: valid frame received
	vSS!SyntaxError: syntax error occurred while receiving
	vSS!ContentError: content error occurred while receiving
	vSS!BViolation: boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict: reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict: reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	Received-frame-related status
	extracted from
	a) header of valid frame, if vSS!ValidFrame = 1
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator: null frame indicator (0 for null frame)
	vRF!Header!SuFIndicator: startup frame indicator
	vRF!Header!SyFIndicator: sync frame indicator

Symbol window	Window-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: reception ongoing while transmission starts Received-symbol-related status *vSS!ValidMTS*: valid Media Test Access Symbol received Received-frame-related status see static/dynamic slot

Table 1415. Slot status content (continued)

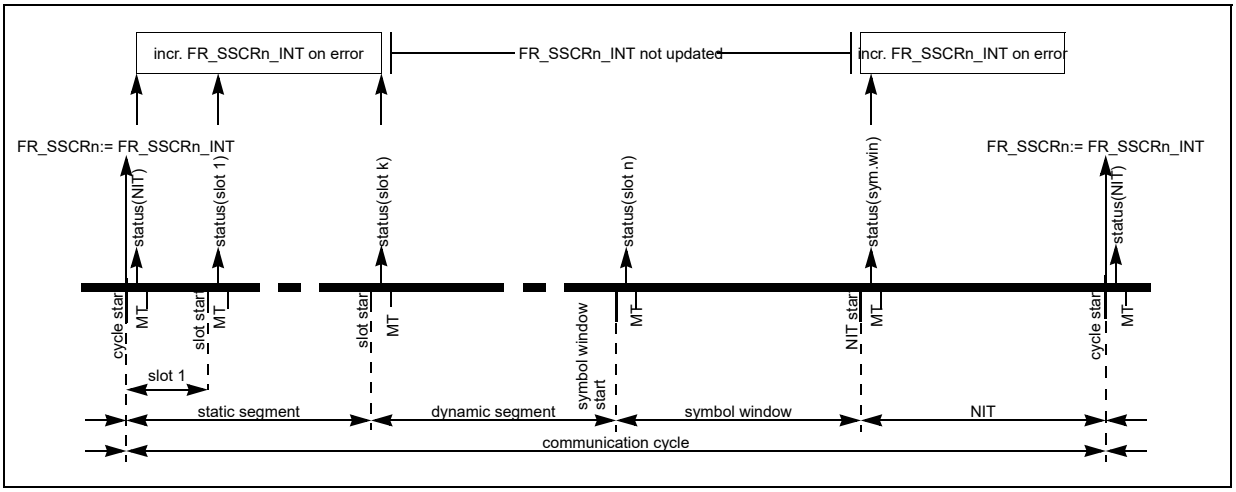
Slot	Status content
NIT	NIT-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: always 0 Received-frame-related status see static/dynamic slot

53.6.18.1 Channel status error counter registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR) are incremented by one if at least one of four slot status error bits, *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap around after they have reached the maximum value.

53.6.18.2 Protocol status registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the NIT and the symbol window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.



53.6.18.3 Slot status registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status-related and received frame/symbol-related status information, as given in *Table 1415*, except for the *first valid* indicator for non-transmission slots.

53.6.18.4 Slot status counter registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in *Figure 1372*.

Figure 1372. Slot status counting and FR_SSCR*n* update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCR*n* register reflects, in cycle n, the status of the NIT of cycle n – 2, and the status of all static slots and the symbol window of cycle n – 1.

The increment condition for each slot status counter consists of two parts: the frame-related condition part and the slot-related condition part. The internal slot status counter FR_SSCR*n*_INT is incremented if at least one of the following conditions is fulfilled:

1. Frame-related condition:

- (FR_SSCCR*n*[VFR] | FR_SSCCR*n*[SYF] | FR_SSCCR*n*[NUF] | FR_SSCCR*n*[SUF]) // count on frame condition
  = 1;

and

- ((~FR_SSCCR*n*[VFR] | vSS!ValidFrame) & // valid frame restriction
  (~FR_SSCCR*n*[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction
  (~FR_SSCCR*n*[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction
  (~FR_SSCCR*n*[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction
  = 1;

Note: The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus, the VFR must always be set whenever the count-on-frame condition is used.

2. Slot-related condition:

- ((FR_SSCCR*n*[STATUSMASK[3]] & vSS!ContentError) | // increment on content error
  (FR_SSCCR*n*[STATUSMASK[2]] & vSS!SyntaxError) | // increment on syntax error
  (FR_SSCCR*n*[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation
  (FR_SSCCR*n*[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict
  = 1;

If the slot status counter is in Single-cycle mode (that is, FR_SSCCR*n*[MCY] = 0), the internal slot status counter FR_SSCR*n*_INT is reset at each cycle start. If the slot status counter is in Multicycle mode (that is, FR_SSCCR*n*[MCY] = 1), the counter is not reset and incremented until the maximum value is reached.

53.6.18.5 Message buffer slot status field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in *Table 1415* for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update sections in *Section 53.6.3.4.1*.

53.6.19 System bus access

This section provides a description of the system bus access failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in *Section 53.6.19.1*.

The behavior of the CC after the occurrence of a system bus access failure is described in *Section 53.6.19.2*.

53.6.19.1 System bus access failure types

This section describes the two types of system bus access failures.

53.6.19.1.1 System bus illegal address access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions that are treated as a system bus illegal address access:

- The system bus subsystem detects a CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (refer to *Section 53.6.24.3.1*).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

53.6.19.1.2 System bus access timeout

A system bus access timeout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (refer to *Section 53.7.1.1*).

If a system bus access timeout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

53.6.19.2 System bus access failure response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

53.6.19.2.1 Continue after system bus access failure

If FR_MCR[SBFF] is 0, the CC will continue its operation after the occurrence of the system bus access failure, but it will not generate any system bus accesses until the start of the next communication cycle. Since no data is read from or written to the FlexRay memory

area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated in which the remaining header and frame data are replaced by all zeros. Depending on the point in time, this can affect the PPI bit, the header CRC, the payload length in the case of a dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted or received, except for the key slot; a sync or startup null-frame is transmitted if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

53.6.19.2.2 Freeze after system bus access failure

If FR_MCR[SBFF] is set to 1, the CC will go into Freeze mode immediately after the occurrence of one of the system bus access failures.

53.6.20 Interrupt support

The CC provides 172 individual interrupt sources and five combined interrupt sources.

53.6.20.1 Individual interrupt sources

53.6.20.1.1 Message buffer interrupts

The CC provides 128 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSR*n*[MBIF] and an interrupt enable bit FR_MBCCSR*n*[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

53.6.20.1.2 FIFO interrupts

The CC provides two FIFO interrupt sources.

Each of the two FIFOs provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding receive FIFO fill level exceeds the defined watermark.

53.6.20.1.2.1 Wakeup interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

53.6.20.1.2.2 Protocol interrupts

The CC provides 25 interrupt sources for protocol-related events. For details, refer to the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

53.6.20.1.2.3 CHI interrupts

The CC provides 16 interrupt sources for CHI-related error events. For details, refer to the CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

53.6.20.2 Combined interrupt sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

53.6.20.2.1 Receive message buffer interrupt

The receive message buffer interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

53.6.20.2.2 Transmit message buffer interrupt

The transmit message buffer interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

53.6.20.2.3 Protocol interrupt

The protocol interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set.

53.6.20.2.4 CHI interrupt

The CHI interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

53.6.20.2.5 Module interrupt

The module interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

Figure 1373. Scheme of FR_GIFER interrupt signal generation

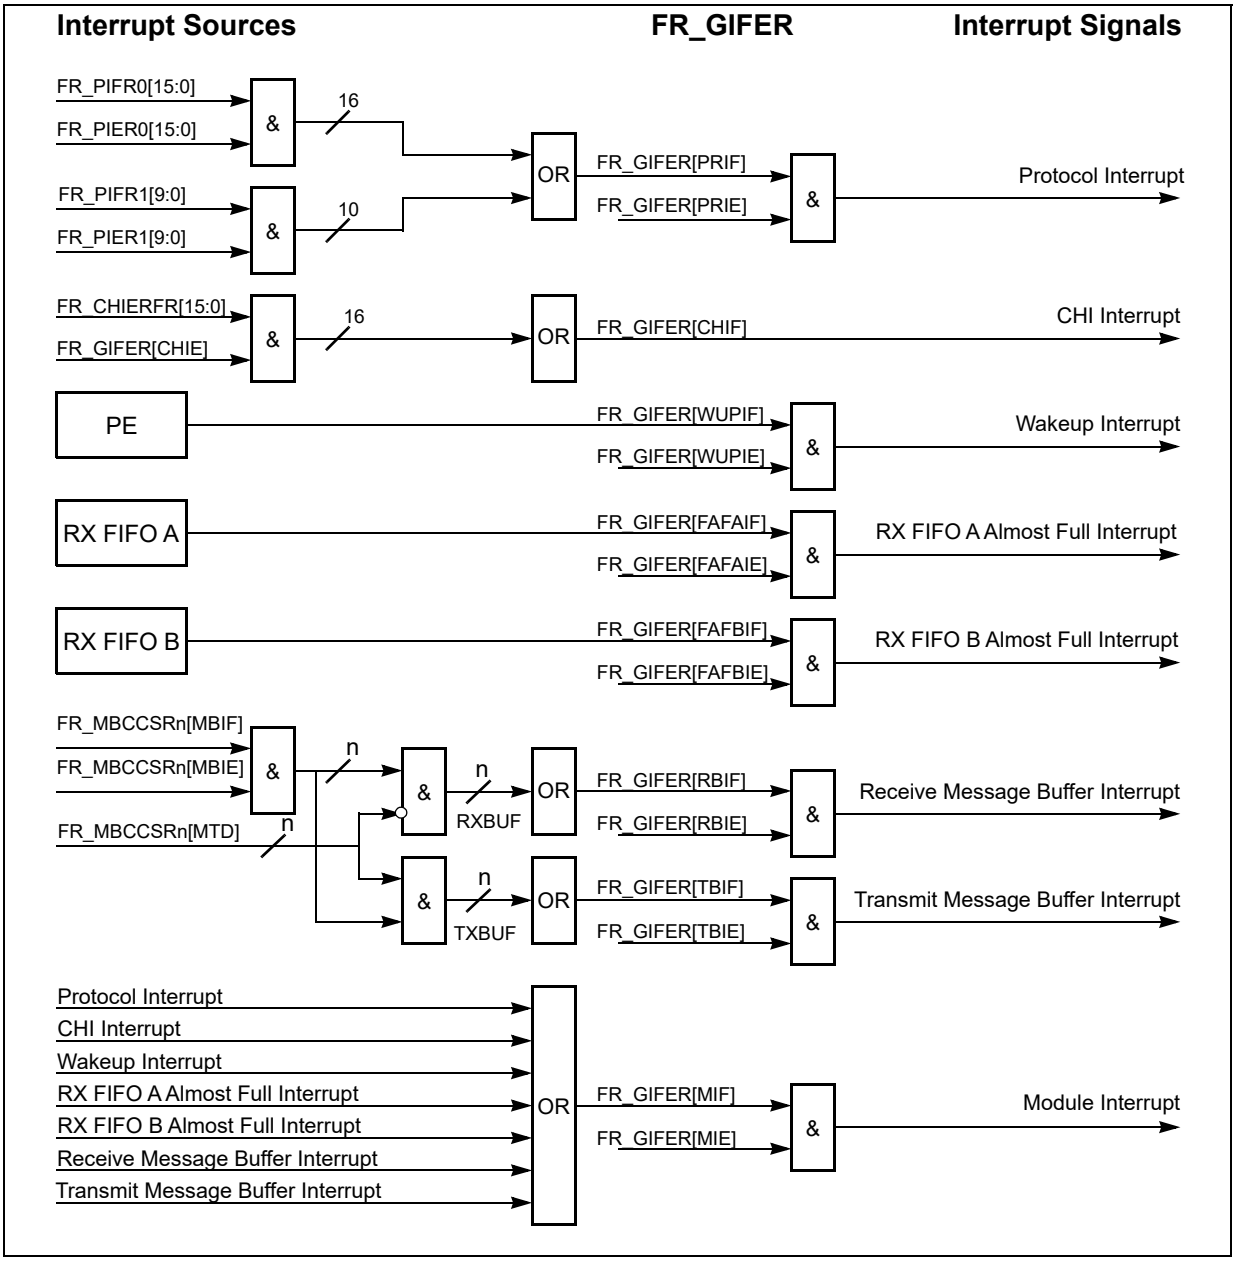


Figure 1374. FR_EEIFER interrupt signal generation scheme

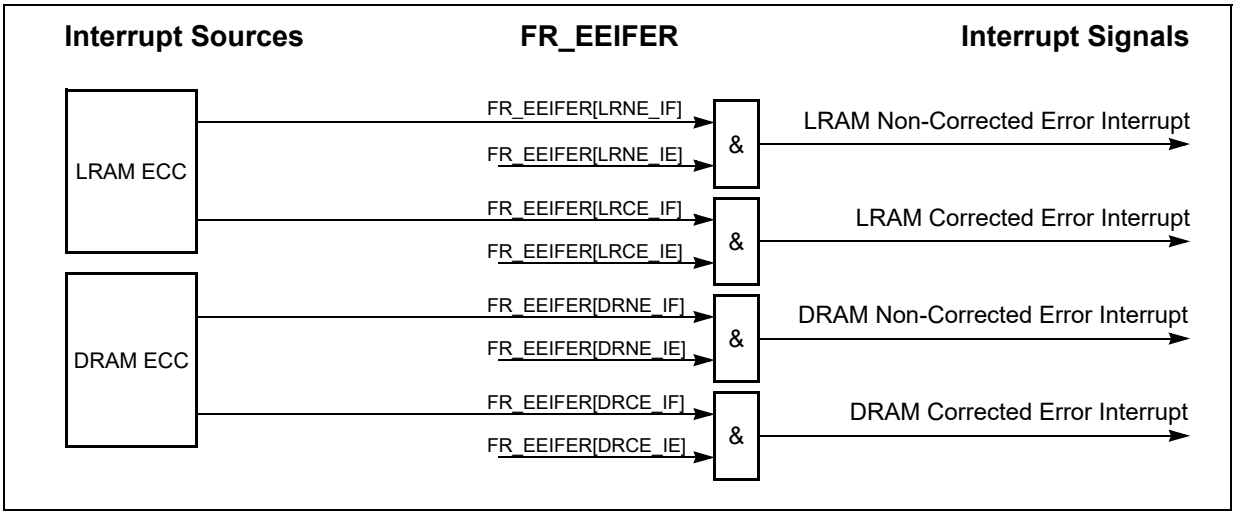

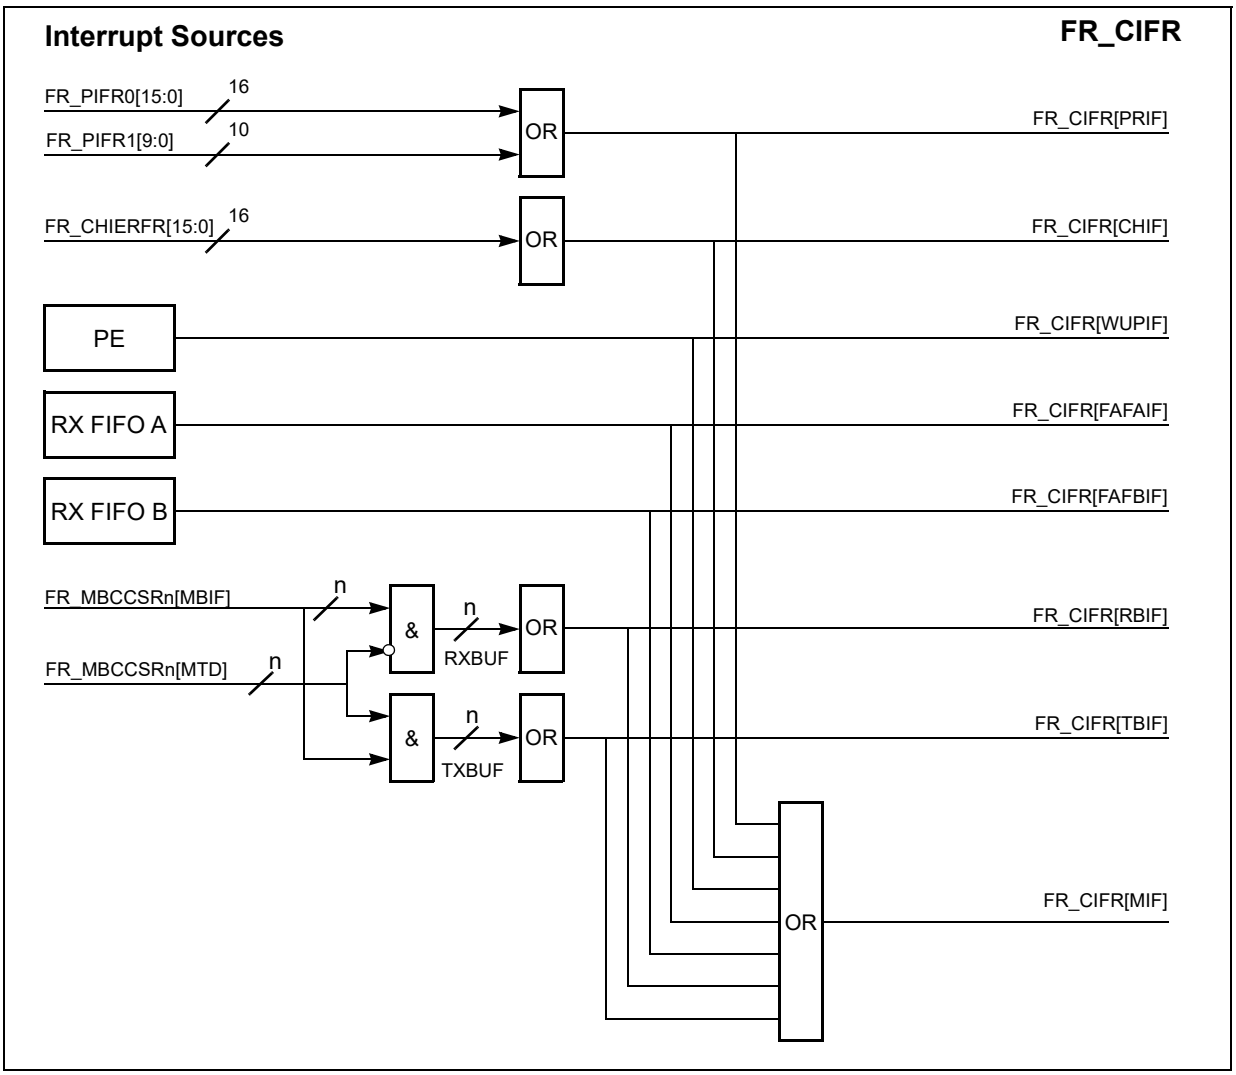

Figure 1375. FR_CIFR flag generation scheme

53.6.21 Lower bit rate support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset.* The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings, and the related protocol parameter values are shown in *Table 1416*.

Table 1416. FlexRay channel bit rate control

FlexRay channel bit rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick* [ns]	*gdSampleClockPeriod* [ns]	pSamplesPerMicrotick	cSamplesPerBit	cStrobeOffset
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note: The bit rate of 8 Mbit/s is not defined by the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

53.6.22 PE data memory (PE DRAM)

The PE data memory (PE DRAM) is 128 word, 16-bit wide memory with byte access that contains the program data of the PE internal CPU. The PE DRAM is divided into two banks of 8 bits each. The memory data [7:0] is assigned to BANK0 and the memory data [15:8] is assigned to BANK1.

Table 1417. PE DRAM layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via *Section 53.5.2.10: PE DRAM Access Register (FR_PEDRAR)*. This functionality is used to check the memory error detection.

53.6.22.1 PE DRAM read access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;
   // INST=0x5; ADDR=070
2. Wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA];
   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

53.6.22.2 PE DRAM write access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;
   // write value to be written into data register
2. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
3. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
4. val = FR_PEDRDR[DATA];
   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

If the conditions given in *Section 53.6.22.3: PE DRAM write access limitations* are fulfilled, the data provided in PE DRAM Access Register (FR_PEDRAR) is written into the PE DRAM, read back in the next clock cycle, and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data is not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

53.6.22.3 PE DRAM write access limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not in *POC:default config* state, only PE DRAM address 0x70 is writable.

53.6.23 CHI lookup-table memory (CHI LRAM)

The CHI lookup-table memory (CHI LRAM) is a CHI-internal memory that contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or six data field offsets are contained in one memory row. The CHI LRAM is divided into six memory banks.

Table 1418. CHI LRAM layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x3F	FR_MBIDXR127	FR_MBFIDR127	FR_MBCCFR127	FR_MBIDXR126	FR_MBFIDR126	FR_MBCCFR126
0x40	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0x55	FR_MBDOR131	FR_MBDOR130	FR_MBDOR129	FR_MBDOR128	FR_MBDOR127	FR_MBDOR126
0x56	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

53.6.23.1 CHI LRAM read and write access

The CHI LRAM is accessed by the application via regular register read and write accesses.

53.6.24 Memory content error detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses a standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED). The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

53.6.24.1 Memory error types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as a special case. The FlexRay module detects and indicates the memory errors as shown in *Table 1419*. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error-free bank has been read.

Table 1419. Detected memory error types

Memory	Priority	Memory data	Indication
CHI LRAM	0 (highest)	All zeros	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM		All ones	Non-corrected error
PE DRAM			
CHI LRAM	1 (lowest)	One bit flipped	Non-corrected error
PE DRAM			Corrected error
CHI LRAM		Two bits flipped	Non-corrected error
PE DRAM			
CHI LRAM		Three or more bits flipped	One out of {no error, non-corrected error}, defined by coding given in *Section 53.6.24.2.3* and *Section 53.6.24.2.4*
PE DRAM			One out of {no error, corrected error, non-corrected error}, defined by coding given in *Section 53.6.24.2.1* and *Section Note:*

53.6.24.2 Memory error reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories, there are two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.
- If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to the above, the error indications (corrected/non-corrected) along with the failing address are sent out from the module for external error logging and corrective actions by the software.

53.6.24.2.1 PE DRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 1419*. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1420. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4(1)	X	X	X	X	X	X	X	X	X	X	X	X
3(2)	—	—	—	—	X	X	X	X	—	—	—	—
2	—	—	—	—	X	—	—	—	X	X	X	—
1	—	—	—	—	—	X	X	—	X	X	—	X
0	—	—	—	—	—	X	—	X	X	—	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is an even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is an odd number of 1's in all columns with X.

Note: This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words written into the memory.

53.6.24.2.2 PE DRAM syndrome

The coding of the syndrome reported in the ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 1421*.

Table 1421. FR_EERCR[CODE] PE DRAM syndrome coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected error (parity bit 0)
0x0	0x2	Corrected error (parity bit 1)
0x0	0x3	Corrected error (data bit 0)
0x0	0x4	Corrected error (parity bit 2)
0x0	0x5	Corrected error (data bit 1)
0x0	0x6	Corrected error (data bit 2)
0x0	0x7	Corrected error (data bit 3)
0x0	0x8	Corrected error (parity bit 3)
0x0	0x9	Corrected error (data bit 4)
0x0	0xA	Corrected error (data bit 5)
0x0	0xB	Corrected error (data bit 6)
0x0	0xC	Corrected error (data bit 7)
0x0	0xD–0xF	Non-corrected error
0x1	0x1–0xF	Non-corrected error

53.6.24.2.3 CHI LRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 1422*. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1422. CHI LRAM checkbits coding

CODE(1)	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	—	—	—	—	—	—	—	—	—	—	—
3	—	—	—	—	—	X	X	X	X	X	X	X	—	—	—	—
2	X	X	—	—	—	X	X	X	X	—	—	—	X	X	X	—
1	—	—	X	X	—	X	X	—	—	X	X	—	X	X	—	X
0	X	—	X	—	X	X	—	X	—	X	—	X	X	—	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is an odd number of 1's in all columns with X.

53.6.24.2.4 CHI LRAM syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 1423*.

Table 1423. FR_EERCR[CODE] CHI LRAM syndrome coding

FR_EERCR[CODE]	Description
0x00	No Error (never appears in error report registers)
0x01–0x1F	Non-corrected error

53.6.24.3 Memory error response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case a *corrected* memory error is detected, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

53.6.24.3.1 CHI LRAM error response after CC read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access, the error response of the module depends on LRAM location where the error occurred.

- If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current

search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.

  – If the affected message buffer is a Tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is an Rx message buffer, no frame will be received to this message buffer in the next slot.

- If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx, the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs with respect to payload access for the complete frame.

53.6.24.3.2 CHI LRAM error response after application read

The application can read the content of the CHI LRAM by reading the FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBIDXR*n*, FR_MBDOR*n* and FR_LEETR*n* registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read, and continues its normal operation.

53.6.24.3.3 PE DRAM error response after CC read

If the CC detects a non-corrected memory error during an internal read of program data contained in PE DRAM, this is considered a fatal protocol error and the module enters the protocol freeze state immediately.

53.6.24.3.4 PE DRAM error response after application read in *POC:default config* state

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered a fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

53.6.24.3.5 PE DRAM error response after application read out of *POC:default config*

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is not in the *POC:default config* state, this error is not considered a fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

53.6.25 Memory error injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

Error Injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).When error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

53.6.25.1 CHI LRAM error injection

The following sequence describes a memory error injection sequence for the CHI LRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke a distortion of the memory content. The content of the CHI LRAM is described in *Table 1418*.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config,* refer to *Section 53.7.3*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 1;
   // select CHI LRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // select address for error injection; I_ADDR ≤ 0x56
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application write access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;
If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;
If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;
If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;
If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;
If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;
// write DATA to the defined injection bank and injection address (refer to *Table 1418*).

53.6.25.2 PE DRAM error injection

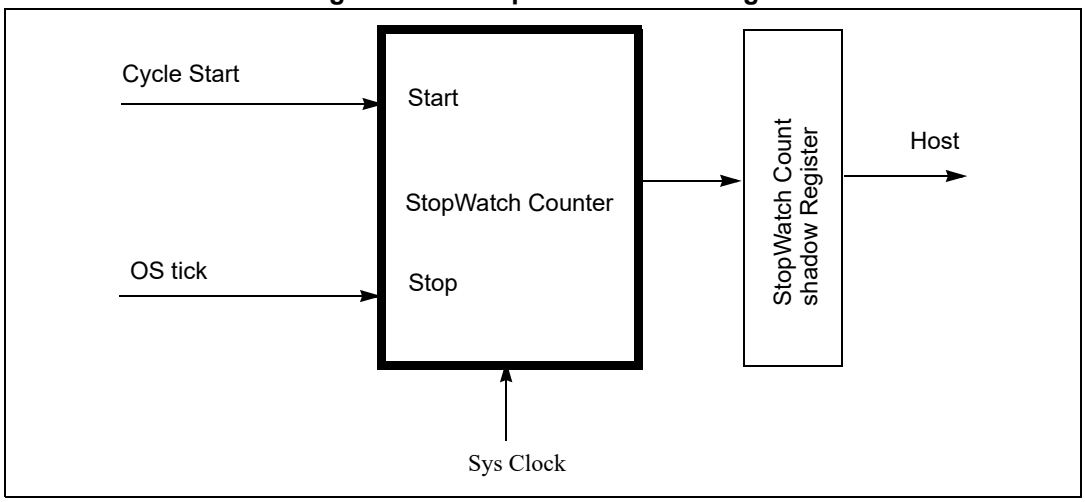
The following sequence describes a memory error injection sequence for the PE DRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke a distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config,* refer to *Section 53.7.3.2*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 0;
   // select PE DRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // define bank for error injection; I_BANK = {0,1}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // define address for error injection; I_ADDR ≤ 0x7F
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application write access (for example, I_ADDR=0x70):



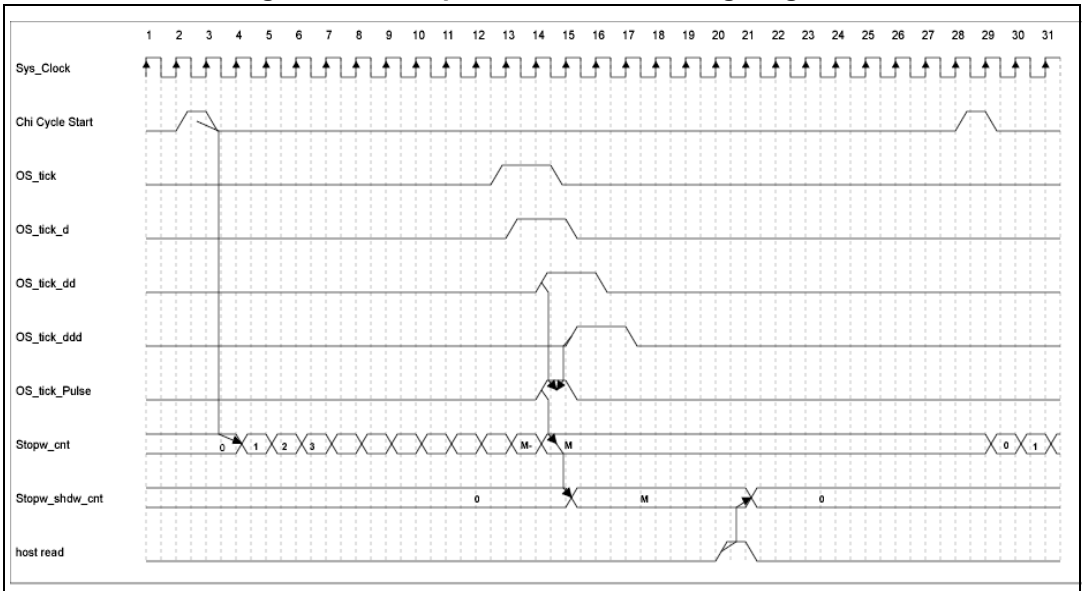
1. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
2. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA]; |
   // get read back PE DRAM data

Note: The write access to the PE DRAM triggers a subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

53.6.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick.

Figure 1376. StopWatch counter logic



As shown here, there is a 32-bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (*Section 53.5.2.68: Stop Watch Count Register (FR_STPWR)*) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared.

The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (*Section 53.5.2.69: Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)*. The counter runs only when this bit is set.

Figure 1377 shows the actual timing of the stopwatch counter logic operation.

Figure 1377. StopWatch function timing diagram

Note: 'Host read' implies that all 32 bits have been read out completely. Any partial read (that is for 8/16 bits access) will not clear the StopWatch count register.

If cycle start and OS tick occur simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and Cycle_start has a single stage synchronizer into Chi clock domain. So simultaneously here means OS_tick_Pulse and Chi_Cycle_Start occurring at the same cycle.

53.7 Application information

53.7.1 Module configuration

This section describes the essential parts of the module configuration.

53.7.1.1 Configure System Memory Access Timeout Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in the System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill *Equation 65*[(s)].

Equation 65

$$0 \leq \text{SYMATOR[TIMEOUT]} \leq \lfloor 0.45 \cdot f_{CHI} - 8 \rfloor$$

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in *Table 1424*.

s. Refer to *Section 53.3: Controller host interface clocking* for all constraints of minimum CHI clock frequency.

Table 1424. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
≥ 18 MHz	0	≥ 100 MHz	≤ 37
≥ 23 MHz	≤ 2	≥ 120 MHz	≤ 46
≥ 27 MHz	≤ 4	≥ 140 MHz	≤ 55
≥ 32 MHz	≤ 6	≥ 160 MHz	≤ 64
≥ 60 MHz	≤ 19	≥ 180 MHz	≤ 73
≥ 80 MHz	≤ 28	≥ 200 MHz	≤ 82

53.7.1.1.1 System bus wait state constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single-channel configurations and situations in which the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0), no timeout will be detected if fewer than 2 × SYMATOR[TIMEOUT] + 1 wait states will be seen on the system bus for each system bus access.

For dual-channel configurations, or situations in which the sync frame table generation functionality is used, no timeout will be detected if fewer than SYMATOR[TIMEOUT] – 1 wait states will be seen on the system bus for each system bus access.

53.7.1.2 Configure data field offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDORn) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers that are used.

When the module is enabled, the initialization value of the FR_MBDOR*n*[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (refer to *Section 53.6.19.1.1*).

53.7.2 Initialization sequence

This section describes the steps required to initialize the CC. The first subsection describes the steps required after a system reset; the second section describes the steps required after preceding shutdown of the CC.

53.7.2.1 Module initialization

This section describes the module-related initialization steps after a system reset.

1. Configure the CC.
   a) Configure the control bits in the Module Configuration Register (FR_MCR).
   b) Configure the system memory base address in the System Memory Base Address Register (FR_SYMBADR).
2. Enable the CC.
   a) Write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR).

The CC now enters Normal mode. The application can commence with the protocol initialization described in *Section 53.7.2.2*.

53.7.2.2 Protocol initialization

This section describes the protocol-related initialization steps.

1. Configure the Protocol Engine.
   a) Issue CONFIG command via the Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:config* in the Protocol Status Register 0 (FR_PSR0).
   c) Configure the FR_PCR0,..., FR_PCR30 registers to set all protocol parameters.
2. Configure the message buffers and FIFOs.
   a) Set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
   b) Define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR).
   c) Configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), and Message Buffer Index Registers (FR_MBIDXRn).
   d) Configure the FIFOs.
   e) Issue CONFIG_COMPLETE command via the Protocol Operation Control Register (FR_POCR).
   f) Wait for *POC:ready* in the Protocol Status Register 0 (FR_PSR0).

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

53.7.2.3 CHI LRAM initialization

The CHI LRAM initialization is performed by the CC when it leaves Disabled mode. The initialization runs for 87 CHI clock cycles. All fields in the FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBDOR*n* and LEETR*n* registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

53.7.2.4 PE DRAM initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs and will delay the state transition from *POC:default config* into *POC:config*.

53.7.3 Memory error injection out of *POC:default config*

This section provides information for application-driven memory error injection out if *POC:default config.* The CC provides the means to inject memory errors from the application without any impacts to the internal protocol operation of the CC.

53.7.3.1 CHI LRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independently from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in *Section 53.6.25.1*.

53.7.3.2 PE DRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM locations to inject memory errors into the PE DRAM. The injection sequence is described in *Section 53.6.25.2*.

53.7.4 Shutdown sequence

This section describes a secure shutdown sequence to stop the CC gracefully. The main targets of this sequence are:

- Finish all ongoing reception and transmission
- Do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication

For a graceful shutdown, the application should perform the following tasks:

1. Disable all enabled message buffers.
   a) Repeatedly write 1 to FR_MBCCSR*n*[EDT] until FR_MBCCSR*n*[EDS] == 0.
2. Stop the Protocol Engine.
   a) Issue HALT command via Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0).

53.7.5 Number of usable message buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[t].

Additional constraints for the minimum CHI clock frequency are given in *Section 53.3*.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of the slot and must be finished before the start of the next slot.

t. Refer to *Section 53.3: Controller host interface clocking* for all constraints of minimum CHI clock frequency.

The shortest FlexRay slot is a corrected empty dynamic slot. A corrected empty dynamic slot is a mini-slot and consists of *gdMinislot* corrected macroticks with a duration of *gdMacrotick*. The minimum duration of a corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of a correct slot.

Equation 66

$$\Delta_{slotmin} = 39 \cdot pdMicrotick \cdot gdMinislot$$

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

Equation 67

$$\Delta_{search} = \frac{1}{f_{chi}} \cdot (FR_MBSSUTR[LAST_MB_UTIL]+27)$$

The message buffer search must be finished within one slot which requires that *Equation 68* must be fulfilled:

Equation 68

$$\Delta_{search} \leq \Delta_{slotmin}$$

This results in the formula given in *Equation 69* which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

Equation 69

$$f_{chi} \geq \frac{(FR_MBSSUTR[LAST_MB_UTIL]+27)}{39 \cdot pdMicrotick \cdot gdMinislot}$$

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 127 is given in *Table 1425*.

Table 1425. Minimum CHI clock frequency [MHz] examples (128 message buffers used)

pdMicrotick [ns]	gdMinislot					
	2	3	4	5	6	7
25.0	79.5	53	39.8	31.8	26.5	22.8
50.0	39.8	26.5	19.9	15.9	13.3	11.4

Note: If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to Section 53.5.2.18: CHI Error Flag Register (FR_CHIERFR) for details.

53.7.6 Protocol control command execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of *Table 1305* by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in *Table 1426*. If the current protocol state does not allow the execution of this protocol command (refer to POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by *Table 1426*. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 1426. Protocol control command priorities

Protocol command	Priority	Interrupted by	Cleared and terminated by

53.7.7 Message buffer search on simple message buffer configuration

This section describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

53.7.7.1 Simple message buffer configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *s*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has the following configuration.

Table 1427. Transmit buffer configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	Transmit buffer
FR_MBCCFR*t*	MTM	0	Event Transition mode
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000011	Cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	S	Assigned to slot s

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number *r* and has the following configuration.

Table 1428. Receive buffer configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	Receive buffer
FR_MBCCFR*r*	MTM	—	N/A
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000001	Cycle set = {2n} = {0,2,4,6,…}
	CCFVAL	000000	
FR_MBFIDR*r*	FID	S	Subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSR*t*[EDS] = 1 and FR_MBCCSR*r*[EDS] = 1).

Note: The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

53.7.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *s* in the *static* segment.

The configuration of a transmit buffer for a static slot *s* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *s.* In any case, the result of the message buffer search will be the transmit message buffer *t.* The receive message buffer *r* will not be found, no reception is possible.

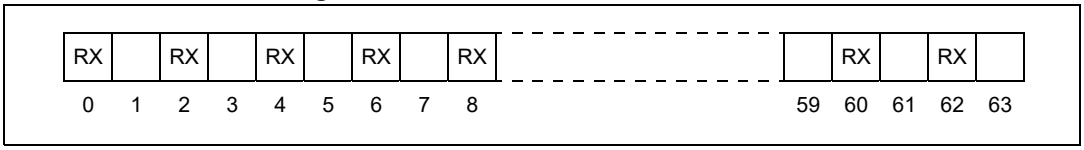
53.7.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *s* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

53.7.7.3.1 Transmit Data Not Available



If transmit data are not available, that is the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 or locked FR_MBCCSR*t*[LCKS]=1, or both.

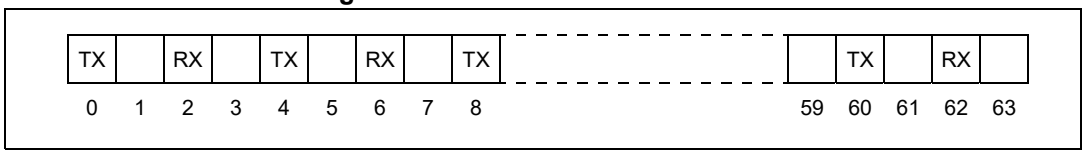
a) For the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and,

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in *Figure 1378*.

Figure 1378. Transmit data not available

53.7.7.3.2 Transmit data available



If transmit data are *available,* that is, the transmit buffer is committed FR_MBCCSR*t*[CMT] = 1 and not locked FR_MBCCSR*t*[LCKS] = 0,

a) For the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in *Figure 1379*.

Figure 1379. Transmit data available

54 Inter-Integrated Circuit (I2C)

54.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- *Section 54.2: Introduction to I2C*
- *Section 54.3: External signal descriptions*
- *Section 54.4: Memory map and register definition*
- *Section 54.5: Functional description*
- *Section 54.6: Initialization and application information*

54.2 Introduction to I2C

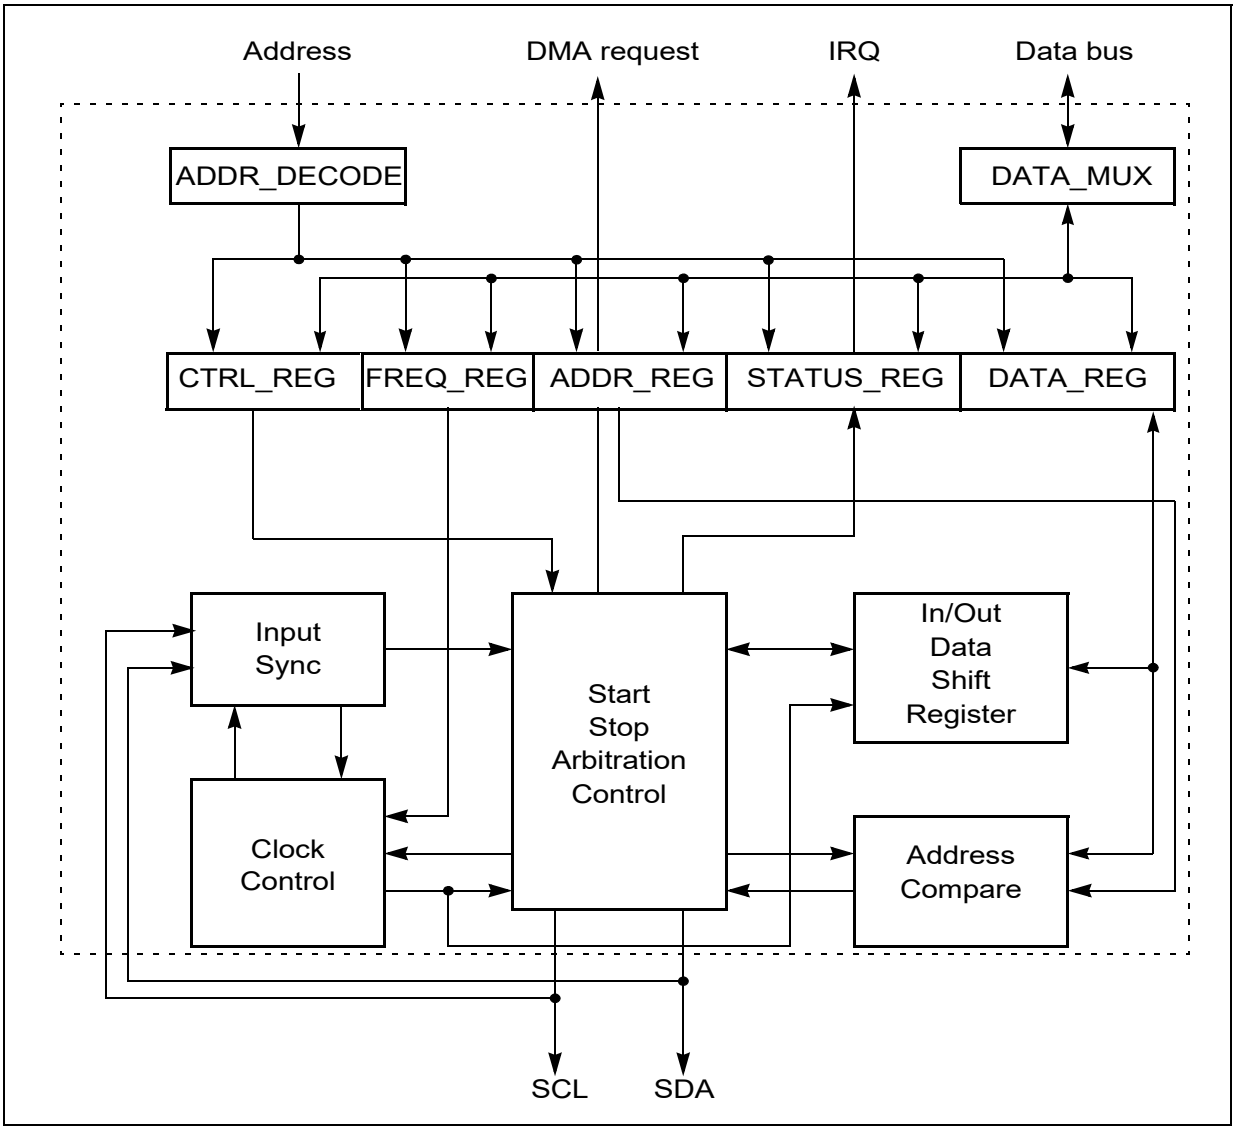
This section presents the following topics:

- *Section 54.2.1: Definition: I2C module*
- *Section 54.2.2: Advantages of the I2C bus*
- *Section 54.2.3: Module block diagram*
- *Section 54.2.4: Features*
- *Section 54.2.5: Modes of operation*
- *Section 54.2.6: Definition: I2C conditions*

54.2.1 Definition: I2C module

The I^2C module is a functional unit that provides a two-wire – serial data (SDA) and serial clock (SCL) – bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

54.2.2 Advantages of the I2C bus



The synchronous, multiple-master two-wire I^2C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

54.2.3 Module block diagram

Figure 1380 shows a block diagram of the I^2C module.

Figure 1380. I²C block diagram

54.2.4 Features

The I^{2}C module has the following key features:

- Compatible with I^{2}C bus standard[u]
- Operating speeds
  - Up to 100 kbps in Standard Mode
  - Up to 400 kbps in Fast Mode
  - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

54.2.5 Modes of operation

The I^{2}C module supports the chip modes described in *Table 1429*.

Table 1429. Chip modes supported by the I^{2}C module

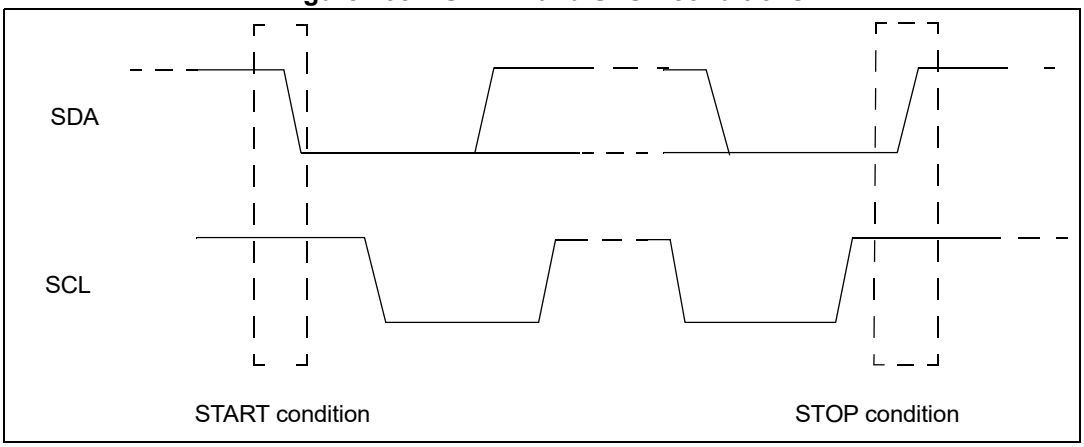
Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^{2}C module	The I^{2}C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. Refer to *Section 54.5.6: IPG STOP mode*.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging.	Refer to *Section 54.5.7: IPG DEBUG mode*.

In addition to chip modes, the I^{2}C module has several module-specific modes. These are described in *Table 1430*.

u. Compliant with I^{2}C 2.0 standard with the exception that HS (high speed) mode is not supported

Table 1430. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I²C module is the driver of the SDA line.	– Do not use the I²C module's slave address as a calling address. – The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	– Enable the I²C module before a START condition from a non-I²C master is detected. – By default the I²C module performs as a slave receiver.



54.2.6 Definition: I²C conditions

Table 1431 shows the I²C-specific conditions defined for the I²C module.

Table 1431. I²C conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in *Figure 1381*.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in *Figure 1381*.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

Figure 1381. START and STOP conditions

54.3 External signal descriptions

This section presents the following topics:

- *Section 54.3.1: Signal overview*
- *Section 54.3.2: Detailed external signal descriptions*

54.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, refer to the data sheet for this chip.

54.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in *Table 1432*.

Table 1432. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

54.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- *Section 54.4.1: I2C memory map*
- *Section 54.4.2.1: Register accessibility*
- *Section 54.4.2.2: I2C Bus Address register (IBAD)*
- *Section 54.4.2.3: I2C Bus Frequency Divider register (IBFD)*
- *Section 54.4.2.4: I2C Bus Control Register (IBCR)*
- *Section 54.4.2.5: I2C Bus Status Register (IBSR)*
- *Section 54.4.2.6: I2C Bus Data I/O Register (IBDR)*
- *Section 54.4.2.7: I2C Bus Interrupt Config register (IBIC)*
- *Section 54.4.2.8: I2C Bus Debug register (IBDBG)*

54.4.1 I^2C memory map

The memory map for the I^2C module is given below in *Table 1433*. The total address for each register is the sum of the base address for the I^2C module and the address offset for each register.

Table 1433. I²C memory map

Address offset	Register	Section
0x0000	I²C Bus Address Register (IBAD)	*Section 54.4.2.2*
0x0001	I²C Bus Frequency Divider Register (IBFD)	*Section 54.4.2.3*
0x0002	I²C Bus Control Register (IBCR)	*Section 54.4.2.4*
0x0003	I²C Bus Status Register (IBSR)	*Section 54.4.2.5*
0x0004	I²C Bus Data I/O Register (IBDR)	*Section 54.4.2.6*
0x0005	I²C Bus Interrupt Config Register (IBIC)	*Section 54.4.2.7*
0x0006	I²C Bus Debug Register (IBDBG)	*Section 54.4.2.8*
0x0007–0x3FFF	Reserved(1)	

1. If enabled at the SoC level, reads or writes to these registers will cause bus aborts. Refer to the System Services Module documentation for more details.

54.4.2 Registers definition

54.4.2.1 Register accessibility

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

54.4.2.2 I²C Bus Address register (IBAD)

This register contains the address the I²C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0000

	0	1	2	3	4	5	6	7
R	ADR							0
W								
Reset	0	0	0	0	0	0	0	0

Figure 1382. I²C Bus Address register (IBAD)

Table 1434. IBAD field descriptions

Field	Description
0:6 ADR	Slave Address Specific slave address to be used by the I^2C Bus module. **Note:** The default mode of I^2C Bus is slave mode for an address match on the bus.

54.4.2.3 I^2C Bus Frequency Divider register (IBFD)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0001

	0	1	2	3	4	5	6	7
R W	IBC							
Reset	0	0	0	0	0	0	0	0

Figure 1383. I^2C Bus Frequency Divider register (IBFD)

Table 1435. IBFD field descriptions

Field	Description
0:7 IBC	I-Bus Clock Rate This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 0:1 Selects the prescaled shift register (refer to *Table 1444*) 2:4 Selects the prescaler divider (refer to *Table 1445*) 5:7 Selects the shift register tap point (refer to *Table 1446*)

54.4.2.4 I^2C Bus Control Register (IBCR)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0002

	0	1	2	3	4	5	6	7

W						RSTA		
Reset	1	0	0	0	0	0	0	0

Figure 1384. I^2C Bus Control Register (IBCR)

Table 1436. IBCR field descriptions

Field	Description
0 MDIS	Module disable This bit controls the software reset of the entire I^2C Bus module. 0 The I^2C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect. 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled. **Note:** If the I^2C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I^2C Bus module losing arbitration, after which, bus operation would return to normal.
1 IBIE	I-Bus Interrupt Enable 0 Interrupts from the I^2C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I^2C Bus module are enabled. An I^2C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave mode. 1 Master mode.
3 TXRX	Transmit/Receive mode select This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive. 1 Transmit.
4 NOACK	Data Acknowledge disable This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I^2C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **Note:** Values written to this bit are only used when the I^2C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, acknowledge bit = 1).

Table 1436. IBCR field descriptions (continued)

Field	Description
5 RSTA	Repeat Start Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect. 1 Generate repeat start cycle.
6 DMAEN	DMA Enable When this bit is set, the DMA Tx and Rx lines will be asserted when the I^2C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I^2C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. Refer to the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals. 1 Enable the DMA TX/RX request signals.

54.4.2.5 I^2C Bus Status Register (IBSR)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0003

	0	1	2	3	4	5	6	7
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

Figure 1385. I^2C Bus Status Register (IBSR)

Table 1437. IBSR field descriptions

Field	Description
0 TCF	Transfer complete While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **Note:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
3 IBAL	Arbitration Lost The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: – SDA is sampled low when the master drives a high during an address or data transmit cycle. – SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. – A start cycle is attempted when the bus is busy. – A repeated start cycle is requested in slave mode. – A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
5 SRW	Slave Read/Write When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave

Table 1437. IBSR field descriptions (continued)

Field	Description
6 IBIF	I-Bus Interrupt Flag The IBIF bit is set when one of the following conditions occurs: – Arbitration lost (IBAL bit set) – Byte transfer complete (TCF bit set and DMAEN bit not set) – Addressed as slave (IAAS bit set) – NoAck from Slave (MS and Tx bits set) – I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

54.4.2.6 I^2C Bus Data I/O Register (IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

Note: The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/$\overline{W}$ bit (in position D0).

Note: When the I^2C is configured in master mode and receiving data from a slave that is transmitting data bytes on an irregular basis, the master cannot know whether the data received in the IBDR is the old latched data or the new data received from the slave. To avoid this, 2 consecutive intermittent data bytes from slave should be different.

Table 1440. IBDBG field descriptions

Field	Description
6 IPG_DEBUG_HALTED	Debug Halted Bit This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
7 IPG_DEBUG_EN	Debug enable bit This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode **Note:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited.

54.5 Functional description

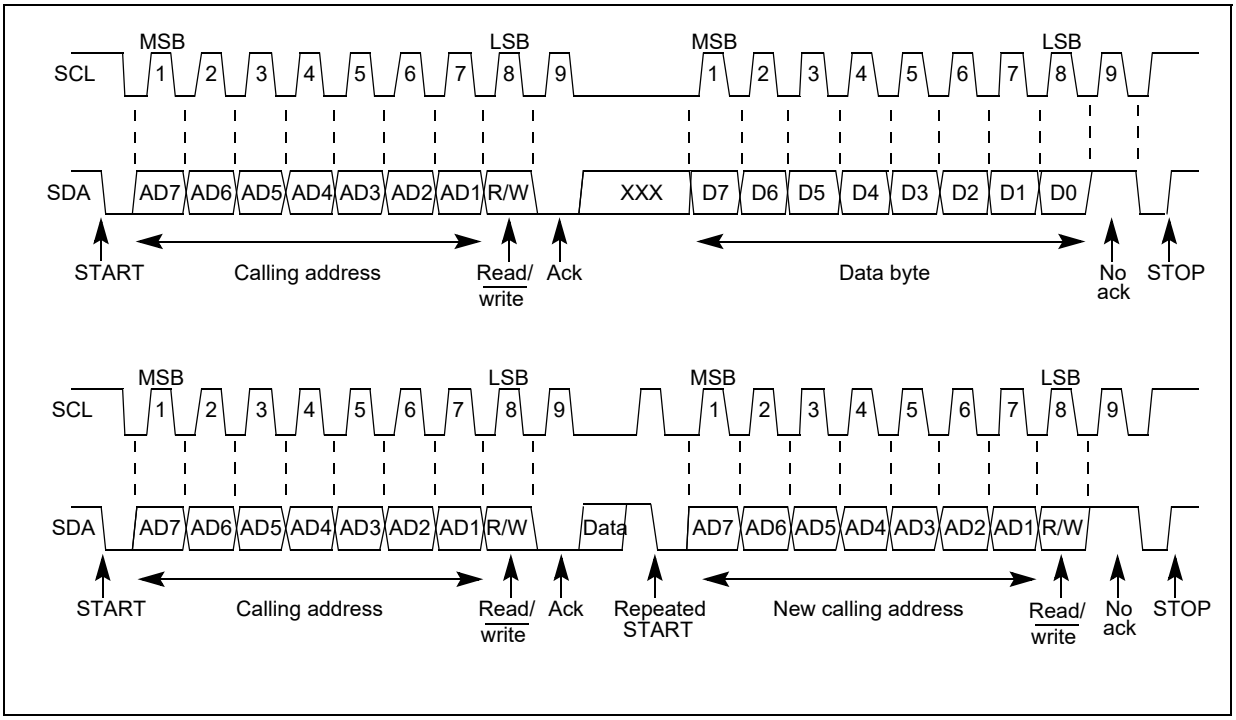
This section presents the following topics:

- *Section 54.5.1: Notes about module operation*
- *Section 54.5.2: Transactions*
- *Section 54.5.3: Arbitration procedure*
- *Section 54.5.4: Clock behavior*
- *Section 54.5.5: Interrupts*
- *Section 54.5.7: IPG DEBUG mode*
- *Section 54.5.8: DMA interface*

54.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

54.5.2 Transactions



This section presents the following topics:

- *Section 54.5.2.1: Protocol overview*
- *Section 54.5.2.2: Transaction protocol definitions*
- *Section 54.5.2.4: High-level protocol steps*
- *Section 54.5.2.5: START condition*
- *Section 54.5.2.6: Slave address transmission*
- *Section 54.5.2.7: Data transmission*
- *Section 54.5.2.8: STOP condition*
- *Section 54.5.2.9: Repeated START condition*

54.5.2.1 Protocol overview

Figure 1389 shows the behavior of SCL and SDA during a typical I^2C transaction.

Figure 1389. I²C transaction protocol

54.5.2.2 Transaction protocol definitions

This section defines several important terms presented in *Figure 1389*.

Table 1441. I²C definitions

Term	Definition
START	A START condition, as defined in *Section 54.2.6: Definition: I2C conditions*"
STOP	A STOP condition, as defined in *Section 54.2.6: Definition: I2C conditions*"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in *Section 54.5.2.3: I2C calling address requirements*."
Read/write (R/$\overline{W}$)	A bit that specifies the direction of the data transfer to the slave as follows: 0 The data is being transferred from the master to the slave ("write"). 1 The data is being transferred from the slave to the master ("read").
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

54.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

54.5.2.4 High-level protocol steps

The I^{2}C protocol conceptually supports two types of transfers, which are illustrated in *Figure 1389*. The significant steps in these transfers are presented in *Table 1442*. Details of each of these steps are presented in subsequent sections.

Table 1442. I^{2}C high-level protocol steps

Standard transfer	Repeated START transfer
1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. STOP condition 6. (repeat Steps 1–4)	1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. Repeated START condition 6. (repeat Steps 2–4 as needed) 7. STOP condition 8. (repeat Steps 1–7)

54.5.2.5 START condition

When the bus is free, that is no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (refer to *Section 54.2.6*). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

54.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (refer to *Section 54.5.2.5*). The process of slave address transmission is presented in *Table 1443*.

Table 1443. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/$\overline{W}$ bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: – The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. – The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

54.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/$\overline{W}$ bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

54.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (refer to *Section 54.2.6*). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, refer to *Section 54.5.2.9*.

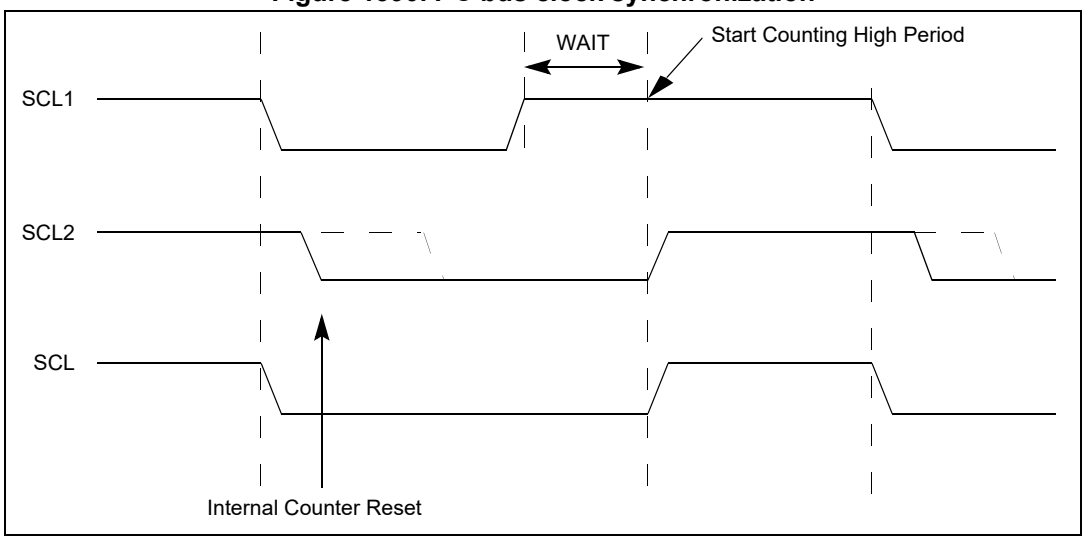
54.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of *Figure 1389*.

54.5.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic “1” while another master transmits logic “0”. The losing masters immediately switch over to slave receive mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

54.5.4 Clock behavior



This section presents the following topics:

- *Section 54.5.4.1: Clock synchronization*
- *Section 54.5.4.2: Clock stretching*
- *Section 54.5.4.3: Handshaking*
- *Section 54.5.4.4: Clock rate and IBFD settings*

54.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (refer to *Figure 1390*). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

Figure 1390. I²C bus clock synchronization

54.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

54.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

54.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (refer to *Section 54.4.2.3: I2C Bus Frequency Divider register (IBFD)*).

Table 1444. I-Bus multiplier factor

IBC[0:1]	MUL
00	01
01	02
10	04
11	Reserved

Table 1445. I-Bus prescaler divider values

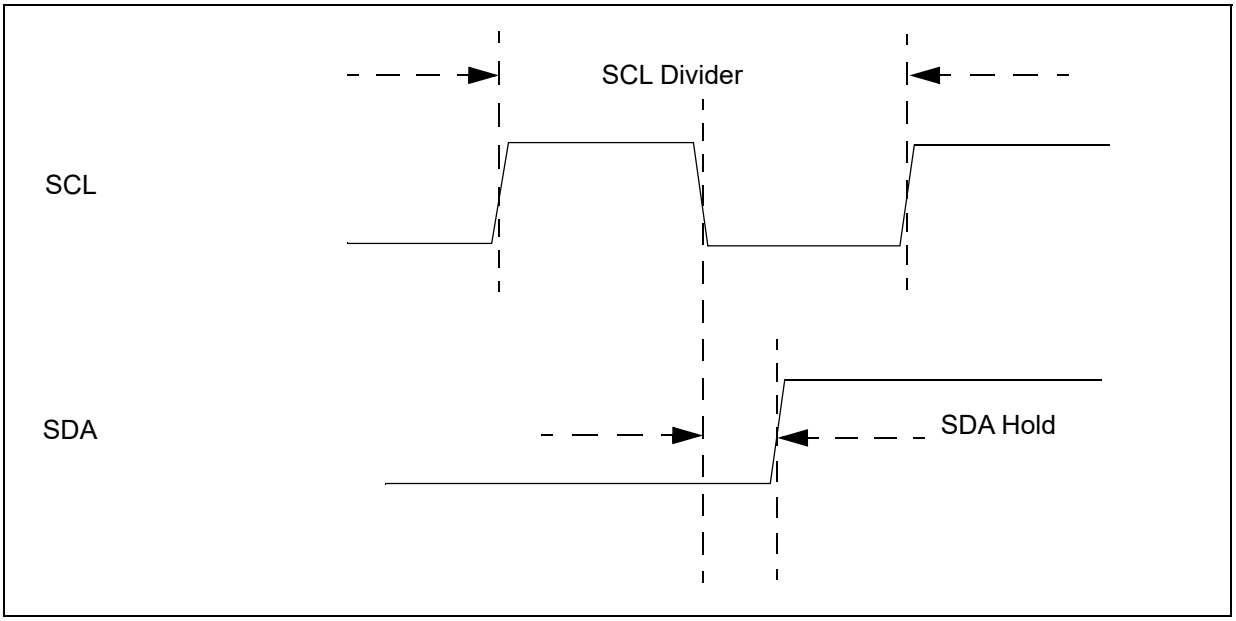
IBC[2:4]	scl2start (clocks)	scl2stop (clocks)	scl2tap (clocks)	tap2tap (clocks)
000	2	7	4	1
001	2	7	4	2
010	2	9	6	4
011	6	9	6	8
100	14	17	14	16
101	30	33	30	32
110	62	65	62	64
111	126	129	126	128

Table 1446. I-Bus tap and prescale values

IBC[5:7]	SCL tap (clocks)	SDA tap (clocks)
000	5	1
001	6	1
010	7	2
011	8	2
100	9	3
101	10	3
110	12	4
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of *Table 1445*. All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in *Table 1445*. The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

Figure 1391. SDA Hold time



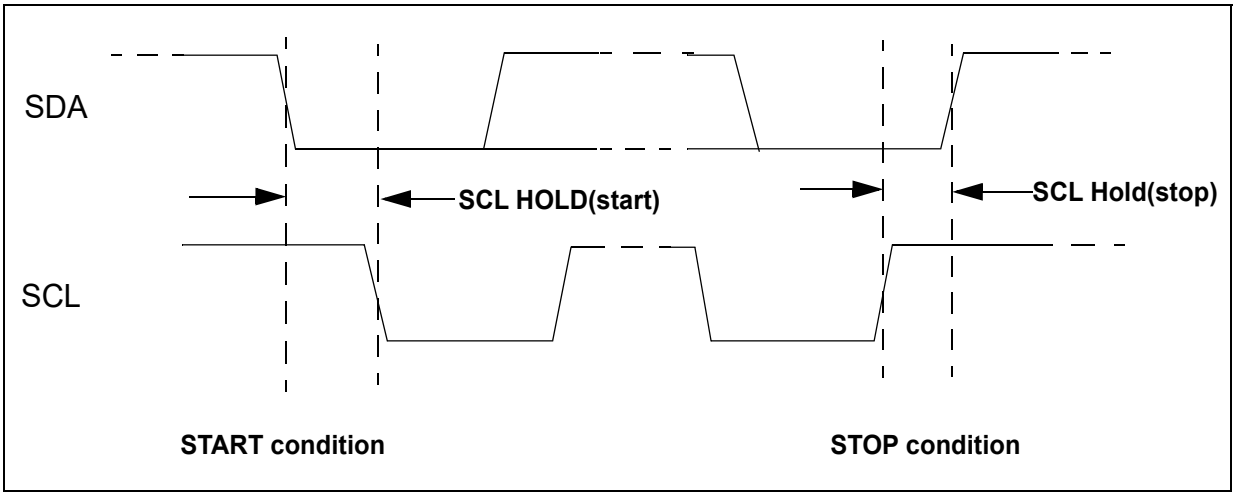


Figure 1392. SCL divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

Equation 70 SCL Divider = MUL x {2 x (scl2tap + [(SCL_Tap -1) x tap2tap] + 2)}

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in *Table 1447*. The equation used to generate the SDA Hold value from the IBFD bits is:

Equation 71 SDA Hold = MUL x {scl2tap + [(SDA_Tap - 1) x tap2tap] + 3}

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

Equation 72 SCL Hold(start) = MUL x [scl2start + (SCL_Tap - 1) x tap2tap]

Equation 73 SCL Hold(stop) = MUL x [scl2stop + (SCL_Tap - 1) x tap2tap]

Table 1447. I²C divider and hold values

54.5.5 Interrupts

This section presents the following topics:

- *Section 54.5.5.1: Interrupt vector*
- *Section 54.5.5.2: Interrupt description*

54.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 1448. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I^2C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

54.5.5.2 Interrupt description

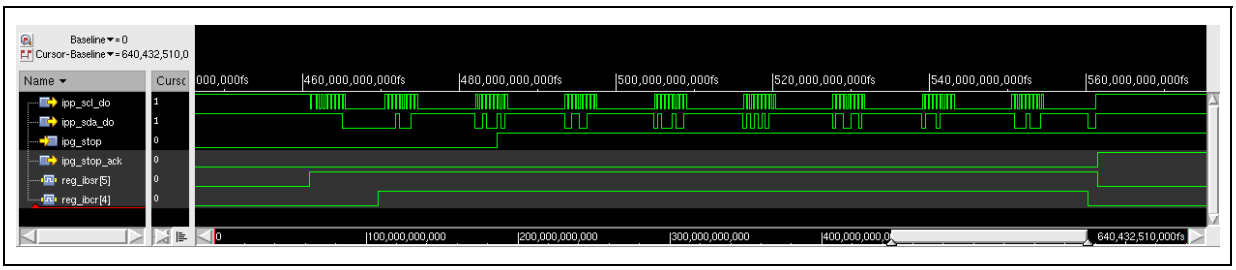
There are five types of internal interrupts in the I^2C. The interrupt service routine can determine the interrupt type by reading the Status register.

I^2C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I^2C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

54.5.6 IPG STOP mode



This mode allows the software to put the I^2C module in power-down state. Once the STOP request is asserted, the I^2C module comes to a graceful halt after completing all the ongoing transactions.

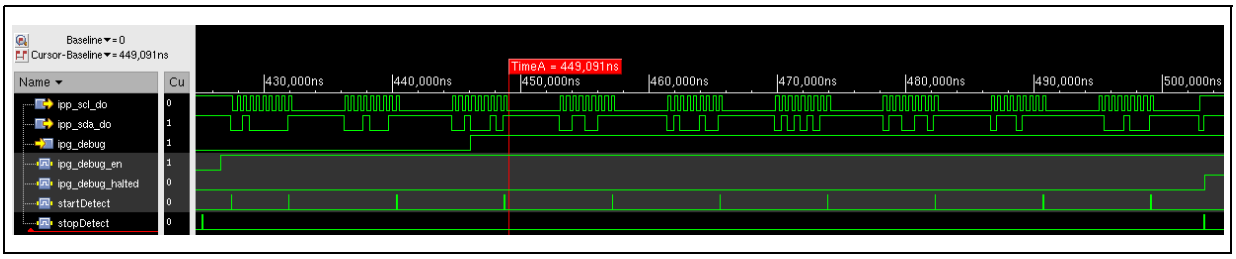
As soon as the I^2C module enters IPG STOP mode:

- The I^2C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I^2C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. Refer to *Figure 1393* for more details.

Figure 1393. I^2C stop mode behavior when master is in Rx and slave is in Tx

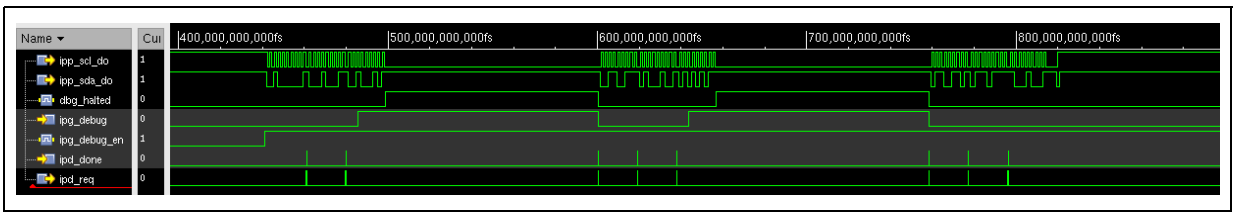
54.5.7 IPG DEBUG mode



This mode allows CPU to debug the I^{2}C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I^{2}C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^{2}C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.



The I^{2}C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. Refer to the simulation result in *Figure 1394* for more details.

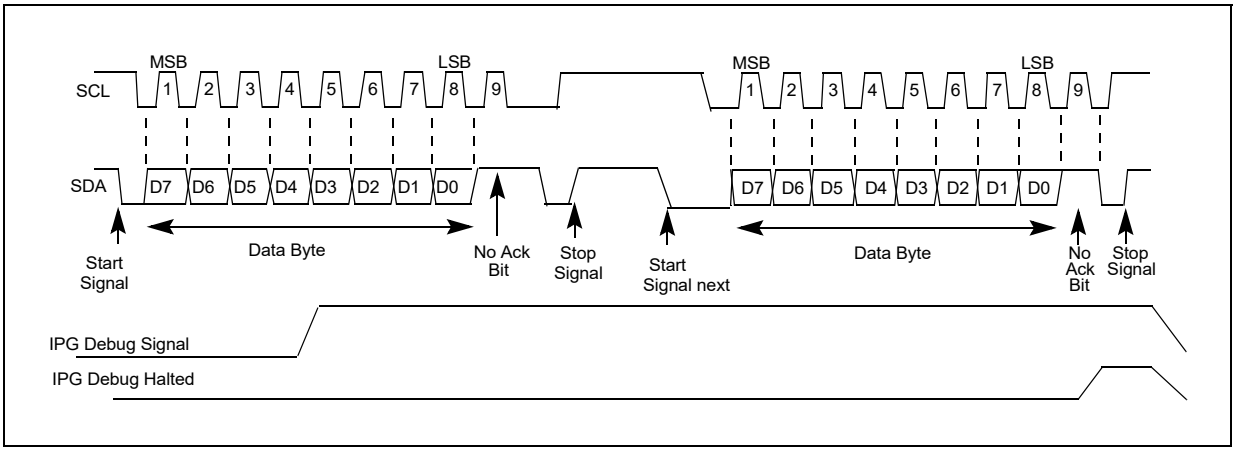
Figure 1394. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I^{2}C module enters IPG DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits IPG DEBUG mode, transmission or reception of the remaining bytes resumes. Refer to the simulation snapshot shown in *Figure 1395* for details where the I^{2}C is transmitting 8 bytes using DMA and IPG DEBUG mode is requested while a second byte is being transmitted. IPG DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits IPG DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

Figure 1395. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I^{2}C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I^{2}C module has entered the IPG DEBUG mode. Refer to *Figure 1396* for more details.

Figure 1396. PG DEBUG mode



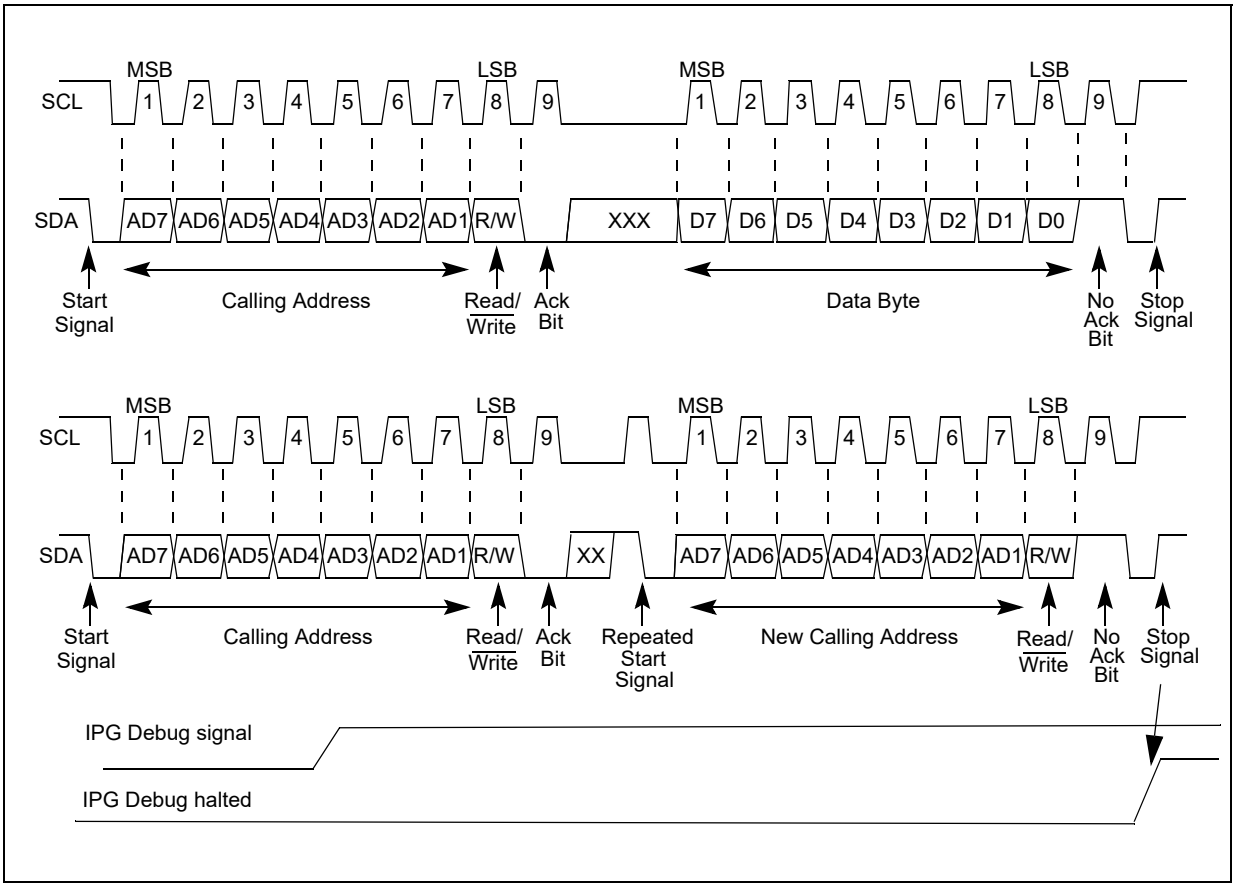


Figure 1397 shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters IPG DEBUG mode.

Figure 1397. IPG debug mode with repeated start

54.5.8 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (refer to *Section 54.6.5*). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

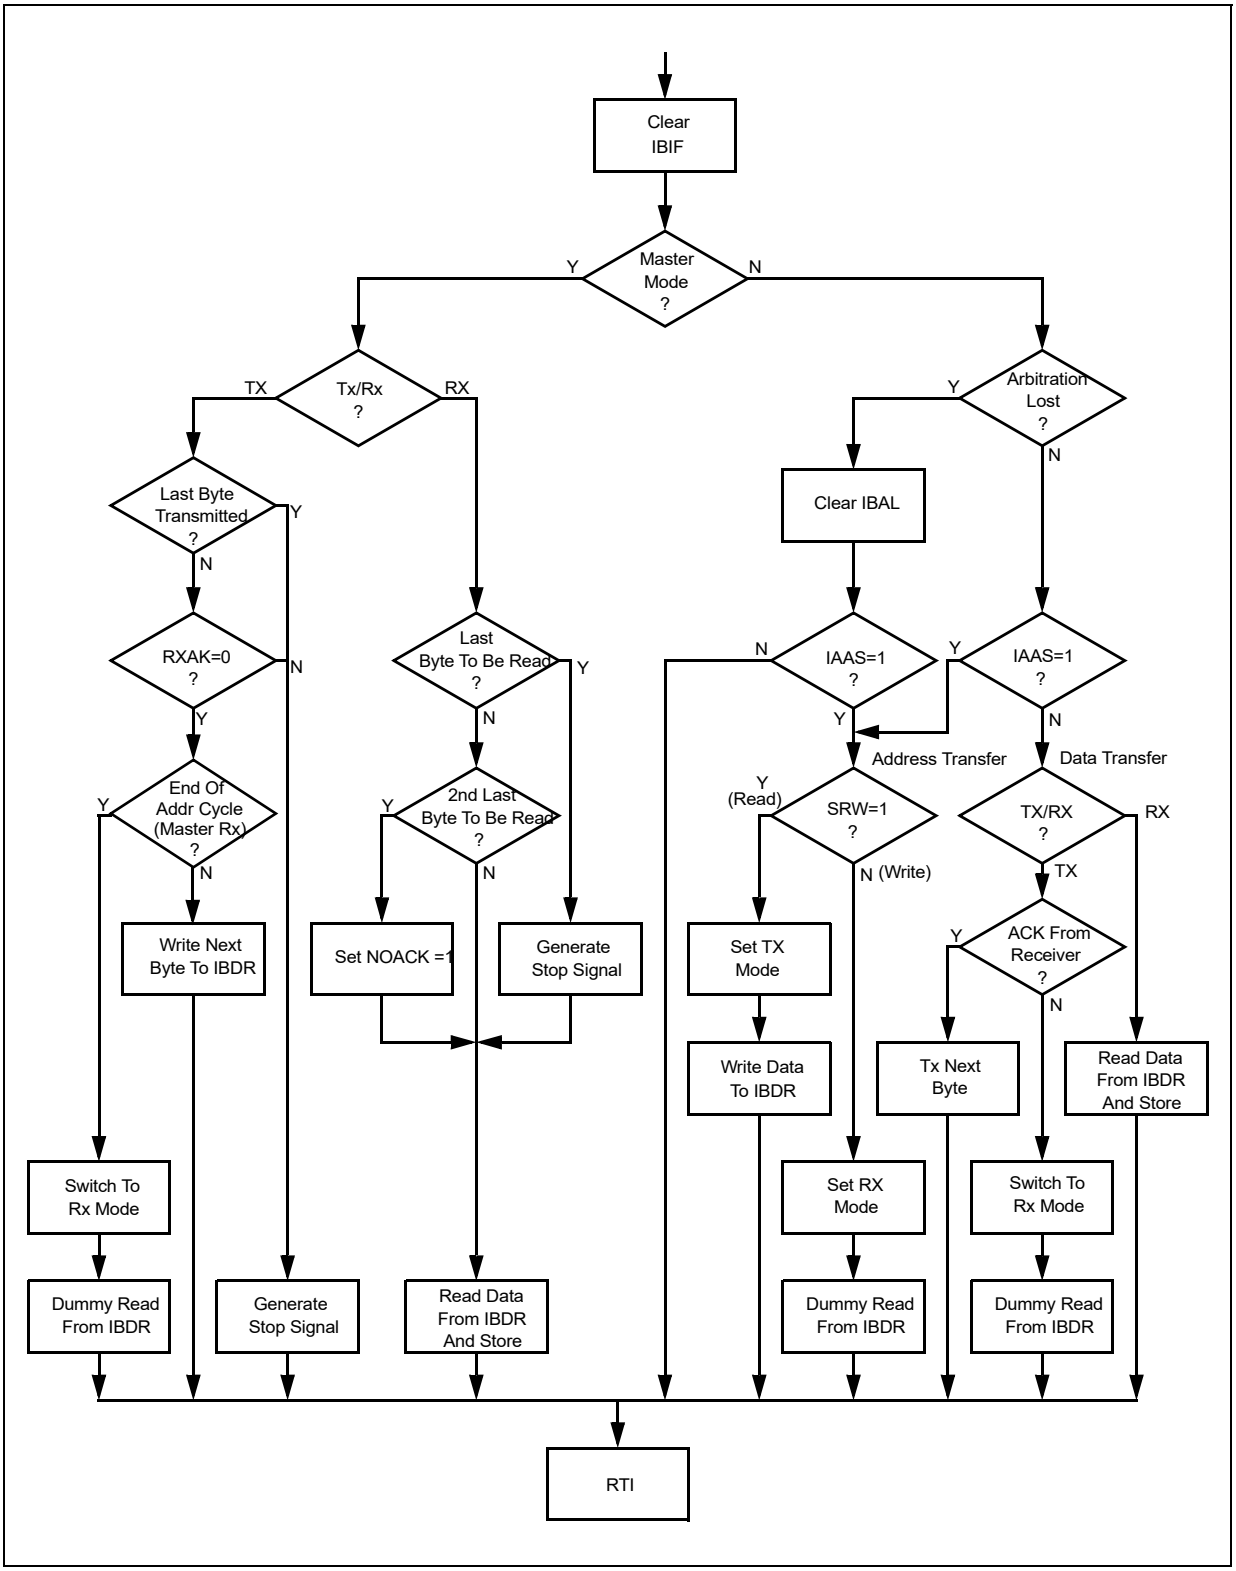
The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the *Section 54.6*.

54.6 Initialization and application information



This section presents the following topics:

- *Section 54.6.1: Recommended interrupt service flow*
- *Section 54.6.2: General programming guidelines (for both master and slave mode)*
- *Section 54.6.3: Programming guidelines specific to master mode*
- *Section 54.6.4: Programming guidelines specific to slave mode*
- *Section 54.6.5: DMA application information*

54.6.1 Recommended interrupt service flow

Figure 1398 shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

Figure 1398. Recommended I²C interrupt service routine flowchart

54.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^{2}C module in both master and slave mode. It presents the following topics:

- *Section 54.6.2.1: Initializing the I2C module*
- *Section 54.6.2.2: Software response after a transfer*

54.6.2.1 Initializing the I^{2}C module

The following sequence initializes the I^{2}C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[IBDIS] bit to enable the I^{2}C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

54.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^{2}C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^{2}C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^{2}C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a “Transfer Complete” interrupt occurs at the end of the address cycle, the master will always be in transmit mode, that is the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

54.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- *Section 54.6.3.1: Generating START*
- *Section 54.6.3.2: Transmit/receive sequence*
- *Section 54.6.3.3: Generating STOP*
- *Section 54.6.3.4: Generating repeated START*
- *Section 54.6.3.5: Loss of arbitration*

54.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB = 0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (that is the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                    // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1        // master and transmit mode, that is,
                                        // generate start condition
IBDR = calling_address                  // send the calling address to the data
register
while (bit 5, IBSR ==0)                 // wait in loop for IBB flag to be set
```

54.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 1449. Master transmit sequence

Step	Action
a	Use the IBFD register to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Use the IBCR to select Master mode, Transmit mode and interrupt enable.
d	Write 0 to IBSR[IBIF].

Table 1449. Master transmit sequence (continued)

Step	Action
e	Write data to IBDR.
f	Observe changes in IBSR[TCF]: – When IBSR[TCF] becomes 0, the transfer is in progress. – When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until IBSR[IBIF] = 1.
h	Read the fields in the IBSR to determine what happened: – If TCF = 1, the transfer completed. – If RXAK = 1, a No Acknowledge condition occurred. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** Address Detect (IAAS = 1) can be ignored for master mode (it is valid only for slave mode).
i	Examine IBSR[RXAK] for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 1450. Master receive sequence

Step	Action
a	Follow steps a through i in *Table 1449* for address dispatch.
b	Write 0 to IBSR[IBIF].
c	Write 0 to IBCR[TXRX] to select Receive mode.
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** The No Acknowledge condition (RXAK = 1) can be ignored in receive mode.
h	Read the IBDR to determine the data received from the slave.

Table 1451. Slave transmit sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
c	Write data to IBDR.
d	Wait until IBSR[IBIF] = 1.

Table 1451. Slave transmit sequence (continued)

Step	Action
e	Wait until IBSR[RXAK] = 0.
f	Write 0 to IBSR[IBIF].
g	Repeat steps c through for the next consecutive data transfers.

Table 1452. Slave receive sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
c	Write 0 to IBSR[IBIF].
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read the IBDR to determine the data received from the master.

54.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the “master” device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or          // check to see if all data bytes have been
transmitted
    (bit 0, IBSR == 1) {       // or if no ACK generated
         clear bit 5, IBCR     // generate stop condition
        }
else {
IBDR = data_to_transmit        // write byte of data to DATA register
         tx_count --           // decrement counter
      }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --                  // decrease the rx counter
if (rx_count ==1)            // 2nd last byte to be read ?
   bit 3, IBCR = 1           // disable ACK
if (rx_count == 0)           // last byte to be read ?
  bit 5, IBCR = 0            // generate stop signal
else
data_received = IBDR         // read RX data and store
```

54.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown below.

```
bit 2, IBCR = 1              // generate another start (restart)
IBDR == calling_address      // transmit the calling address
```

54.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL = 1 and MS/SL = 0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

54.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an “end of data” signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

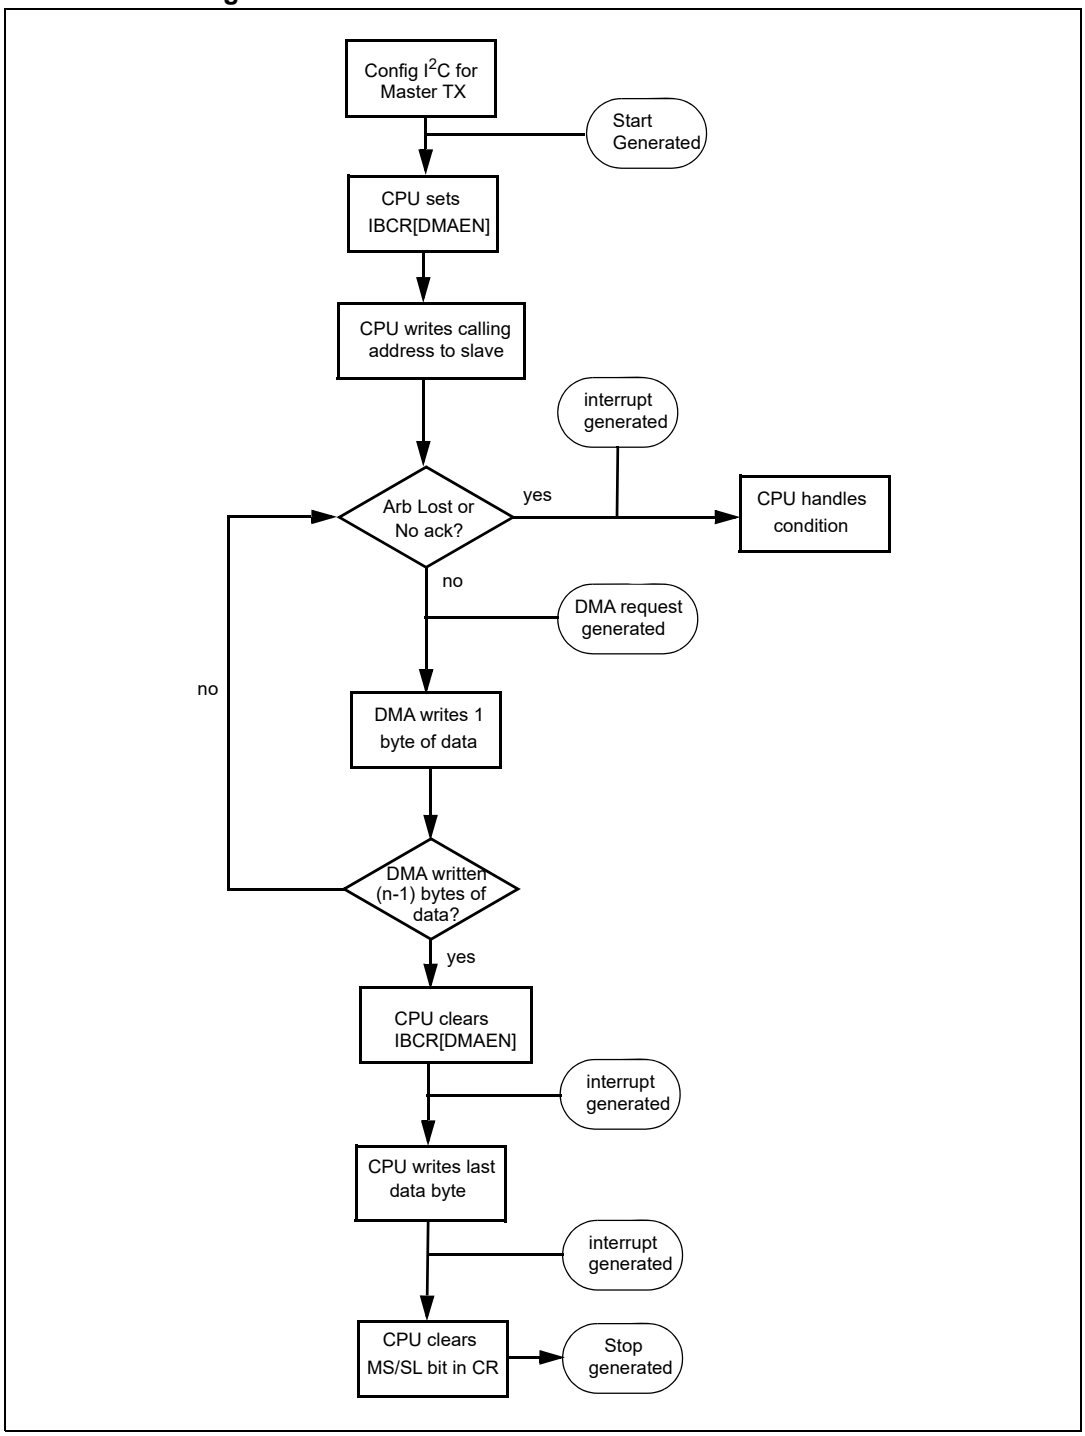
54.6.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master

transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.



The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- *Section 54.6.5.1: DMA mode, master transmit*
- *Section 54.6.5.2: DMA mode, master reception*
- *Section 54.6.5.3: Exiting DMA mode, system requirement considerations*

54.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit ‘n’ data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

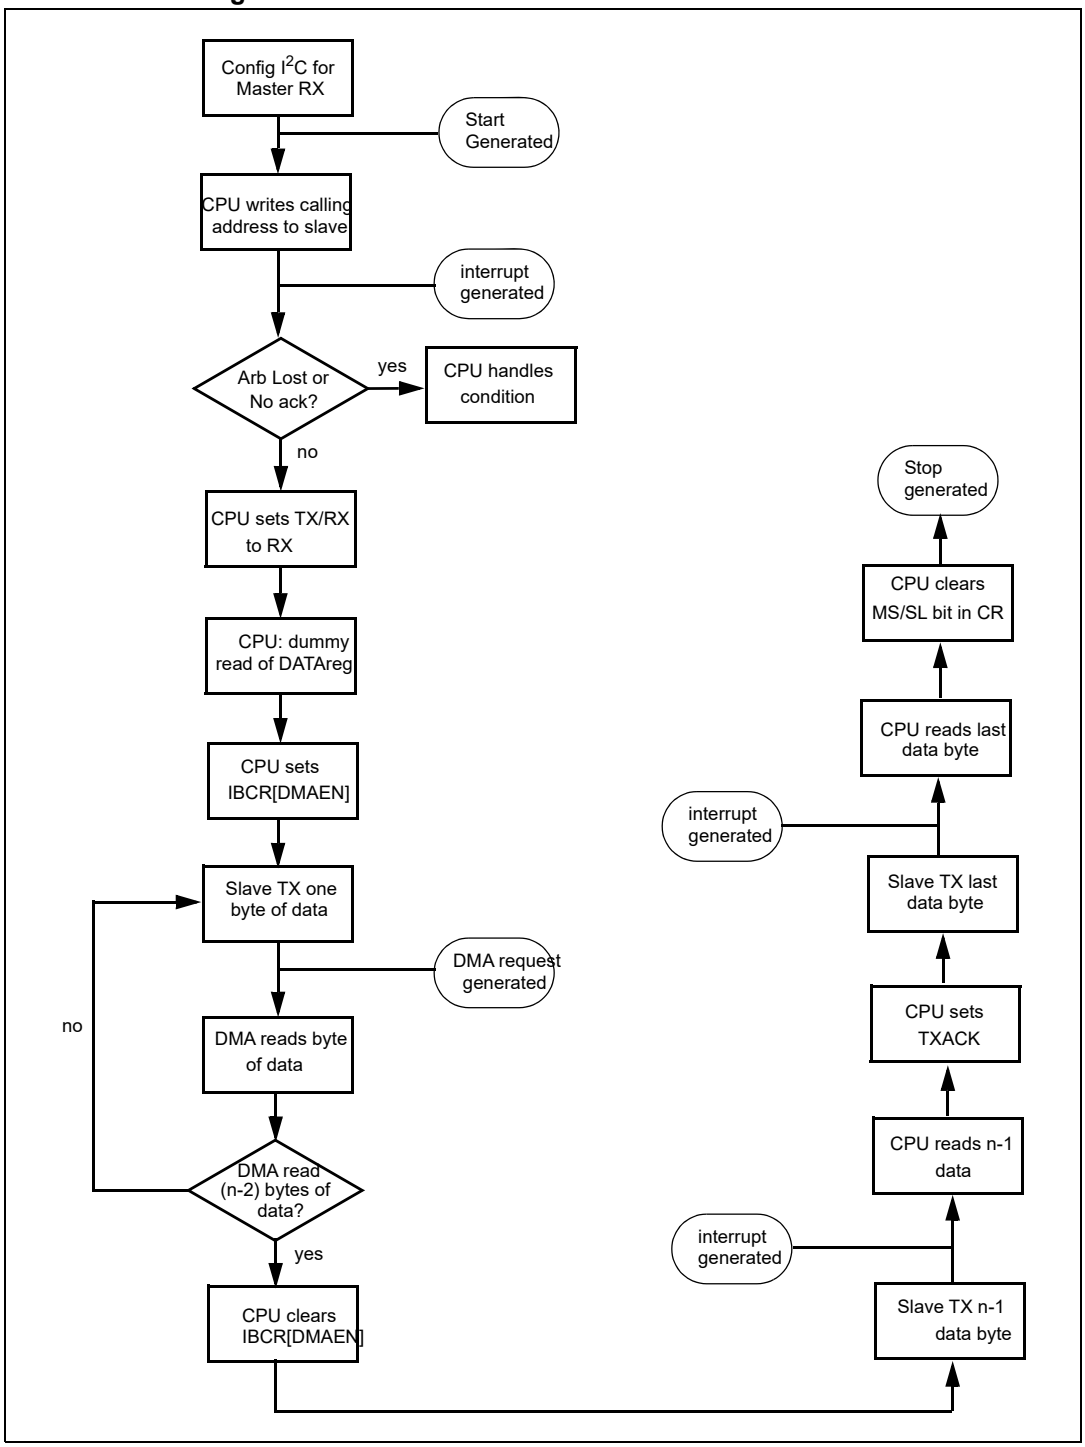


Figure 1399. Flow-Chart of DMA mode master transmit

54.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive ‘n’ data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

Figure 1400. Flow-Chart of DMA mode master receive

54.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^{2}C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is

that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For “fast reaction” the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

Equation 74 $T_R = 8 \times T_{SCL}$

In fast mode, with 400 kbit/s, T_{SCL} is 2.5 µs, so T_R is 20 µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note: The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

Note: Make sure, at system level, that no higher priority DMA requests occur between the two linked TCDs as they could create a slow reaction scenario again.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload

the initial TCD upon completion, bringing the system back into a “ready-for-I^2C-transfer” state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note: Make sure, at system level, that no higher priority DMA requests occur during the scatter/gather process, as they could create a slow reaction scenario again.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

Equation 75 $4 \times T_{IPI} = 4 / 16 \text{ MHz} = 250 \text{ ns}$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

Equation 76 $8 \times T_{AHB} = 8 / 32 \text{ MHz} = 250 \text{ ns}$

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I2C could be faster):

Equation 77 $4 \times T_{IPI} = 4/150 \text{ MHz} = 26.6 \text{ ns}$

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

Equation 78 $4 \times T_{AHD} = 4/150 \text{ MHz} = 26.6 \text{ ns}$

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

55 SENT Receiver (SRX)

55.1 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver to receive serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled “SENT - Single Edge Nibble Transmission for Automotive Applications” and released on January 27, 2010 (SAE web site), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

55.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. Refer to the Device Configuration chapter for details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA.
  - Programmable option per channel to support reading of messages via DMA or Interrupt.
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process.
  - A FIFO for storing the received Fast messages from all channels that are to be read out via DMA. FIFO depth is device-specific. Refer to the Device Configuration chapter for details.
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow serial messages).
  - Separate buffers for storing Fast and Slow serial messages.
  - Separate DMA and Interrupts generated for Fast and Slow serial messages.
- Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel.
  - Calibration pulse correction factor per channel is available for use by software.
- Implements for each channel all receiver diagnostics as specified by the SAE specifications.
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT specification) for both Fast and Short serial message per channel.
- Internal 6-bit CRC calculator for Enhanced serial messages per channel.
- Supports all bit rates by having per channel configurable Rx clock periods from 1.27 µs to 90 µs.
- Support for configurable number of data nibbles per channel.
- Option to disable individual channel via programmable control bit.
- Time stamping on start of each valid message (such as, without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings.
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel.
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages.
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See *Section 55.5: Clocks and resets* for more details on the clocks.

55.1.2 Modes of operation

55.1.2.1 Debug mode

In debug mode, message reception will be halted and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

55.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

Modes where both system bus clock and protocol clock are gated:

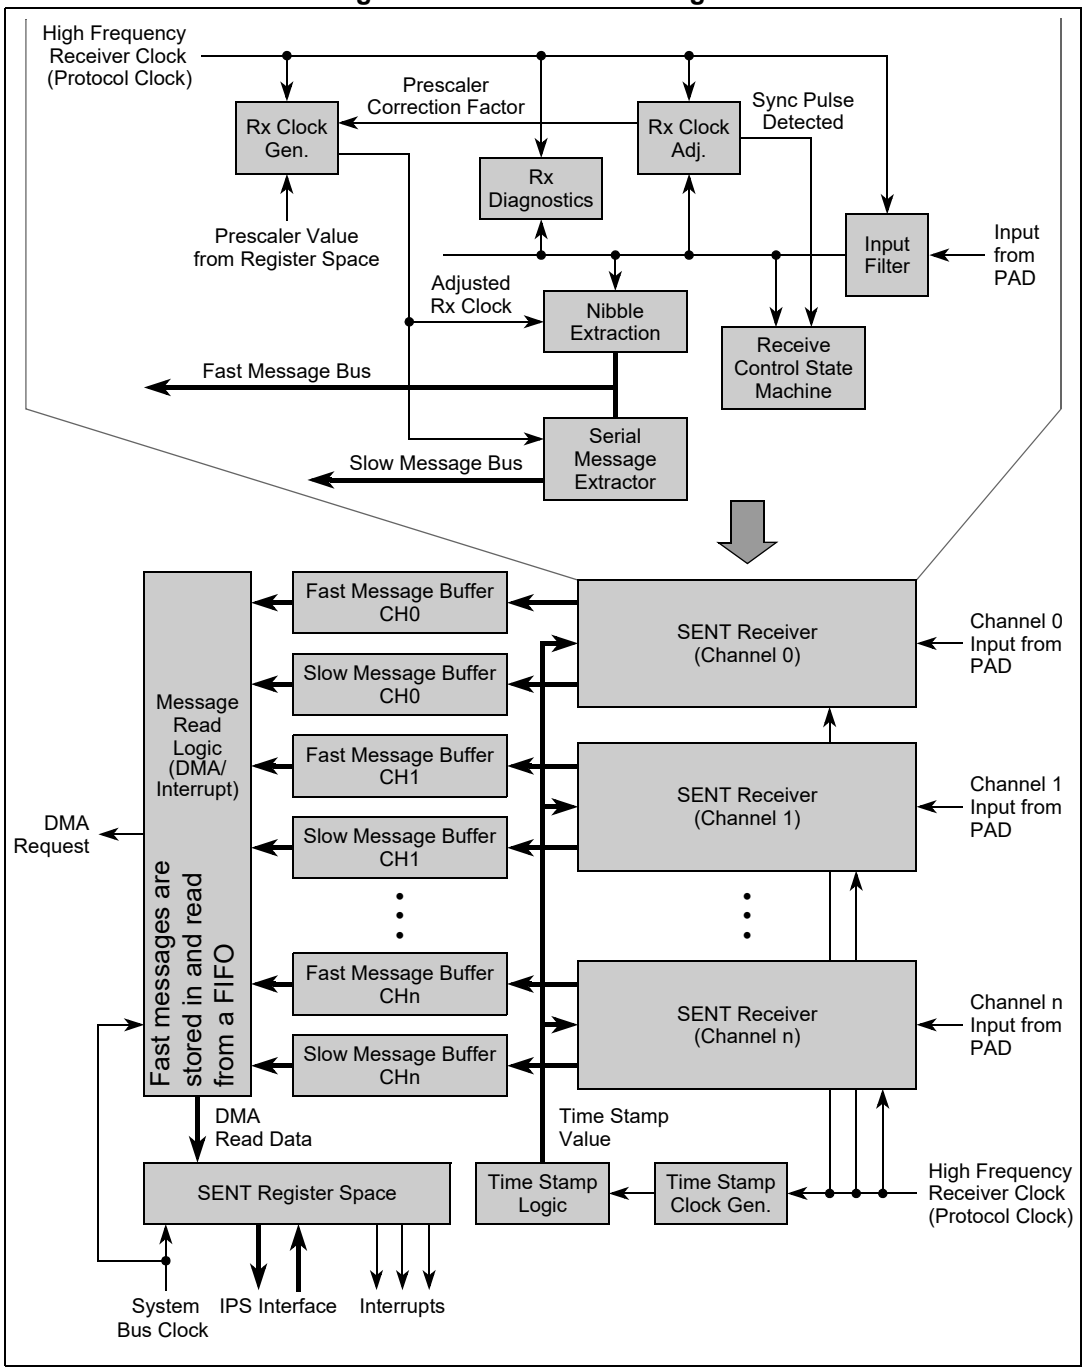
In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed:

For reduced power consumption the system bus clock can be reduced but not below a minimum value (See *Section 55.5.2: System bus clock requirements*) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See *Section 55.5.3: High frequency receiver clock (protocol clock) requirements*) for accurate receive operations.

Note: Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.



The message read registers [Channel ‘n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA), Channel ‘n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC), Channel ‘n’ Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS), Channel ‘n' Fast Message Data 2 Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA2), Channel ‘n’ Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3), Channel ‘n’ Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2), Channel ‘n’ Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS), DMA Fast Message Data Read Register (DMA_FMSG_DATA), DMA Fast Message CRC Read Register (DMA_FMSG_CRC), DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS), Channel ‘n' Fast Message Data 2 Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA2), DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)] will appear to lose their contents in the following conditions:

- *The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros.*
- *Auto clear functionality is enabled (GBL_CTRL[FAST_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.*

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable “Auto Clear” (GBL_CTRL[FAST_CLR] = 0), to allow messages to be read in debug or stop mode.

55.1.3 Block diagram

Figure 1401. SENT block diagram

55.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. *Figure 1401* shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages. A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the DMA FIFOs (for channels which are selected to be connected to the DMA) or in corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the FIFOs or buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

55.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message FIFOs or buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the DMA FIFO or message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the FIFOs or buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops

out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see *Section 55.4: Functional description*.

55.2 External signal description

This section lists all inputs to the SENT block.

55.2.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note: The value of the CH is device-specific. Refer to the Device Configuration chapter for details.

55.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT block.

55.3.1 Memory map

Table 1453 gives an overview on all SENT registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module are in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

Note: Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. Refer to the Device Configuration chapter for details.

The value of the CH is device-specific. Refer to the Device Configuration chapter for details.

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Global Control register (GBL_CTRL)*

55.3.2 Register descriptions

This section describes in address order all the SENT registers and their individual bits.

55.3.2.1 Global Control register (GBL_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT_EN bit must be programmed after all other modules settings and control bits have been written to.

Offset: 0x0000 Access: Read/Write

Figure 1402. Global Control register (GBL_CTRL)

Table 1454. GBL_CTRL field descriptions

Field	Description
0:7 TSPRSC	Time Stamp Prescaler Value Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. (0 to 255) Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 µs. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1µs clock. **Note:** Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
11:15 FIFOWM	DMA Read FIFO Water Mark Level Indicates the number of Fast messages to be stored in FIFO before a DMA request is asserted. Default = 1 message. 0x00: Invalid Value. Should not be used. 0x01: Valid water mark levels. Value fixed by user software. ... 0x1F: Valid water mark levels. Value fixed by user software. The number of bytes to be transferred set in the DMA controller's TCD must be set equal to the number of bytes corresponding to the set water mark value.
16 NIB_LEN_VAR _LIMIT	Decides the allowable jitter/clock drift limit for nibble length measurement. 0 Allows a jitter/clock drift of approx up to 12.5% of transmitter clock tick period. This actual allowed jitter/drift value is dependent on the transmitter clock tick period and HF receiver clock period. 1 Allows a jitter/clock drift as per SAE spec (50%). This bit should be set to 1 for proper functioning of SRX.
18 SENT_8NIB_EN	Decides maximum number of data nibbles that can be supported by a SENT channel in case of Fast message reception. Default value is 0. 0 Maximum 6 data nibbles supported per channel. 1Maximum 8 data nibbles supported per channel.
21 FMFOIE	Fast Message FIFO Overflow Interrupt Enable Enables interrupt assertion when Fast Message is received on a channel which has DMA enabled after FIFO is full. Default value is 0. 0 Interrupt is disabled. 1Interrupt is enabled.
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 Interrupt is disabled. 1Interrupt is enabled.

Table 1454. GBL_CTRL field descriptions (continued)

Field	Description
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable Enables interrupt assertion when there is an underflow condition on Slow message DMA registers. Default value is 0. 0 Interrupt is disabled. 1Interrupt is enabled.
25 FIFO_EN	FIFO enable bit Enables FIFO when DMA is enabled. When this bit is low, data is read from module as explained in *DMA request for Fast message reading when FIFO is disabled* and when the bit is high, data is read from module as explained in *DMA request for Fast message reading via FIFO*. Default value is 0. 0 FIFO is disabled. 1 FIFO is enabled.
27 FAST_CLR	Fast Clearing Enable bit Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See *Fast Message Ready status register (FMSG_RDY)* and *Slow Serial Message Ready status register (SMSG_RDY)* for details on the ready status bits. 0 Fast Clearing is disabled. Bits will be cleared by writing 1. 1 Fast Clearing is enabled.
29 DBG_FRZ	Debug Freeze This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 No effect in debug mode. 1 Freeze in debug mode.
31 SENT_EN	SENT Receiver Global Enable This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 Entire module is disabled. 1 Module is enabled.

55.3.2.2 Channel Enable register (CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

Note: The following register, figure and table show the maximum possible configuration but the exact number of valid register bits depends on supported SENT channels on the device. Refer to the Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and these bits must be written to 0.

Figure 1404. Global Status register (GBL_STATUS)

Table 1456. GBL_STATUS field descriptions

Field	Description
21 FMFO	Fast Message FIFO Overflow Interrupt status bit which indicates that Fast Message is received on any channel which has DMA enabled after FIFO is full. Default value is 0. This bit is valid only when FIFO is enabled. 0 No Overflow 1 Overflow occurred
22 FMDU	Fast Message DMA Underflow Interrupt Status bit that indicates when there is an underflow in Fast Message buffers or FIFO in any channel which has DMA enabled. If FIFO is enabled, it is set when FIFO is empty and software still reads Fast Message DMA registers. And if FIFO is not enabled, it is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 No underflow 1 Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow Interrupt status bit that indicates when there is an Underflow in Slow serial message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow serial message registers. Default value is 0. 0 No underflow 1 Underflow occurred

55.3.2.4 Fast Message Ready status register (FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via *Fast Message DMA Control register (FDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Fast Message Ready Interrupt Control register (FRDY_IE)*) and the channel is enabled, the message ready status bit in this register will get asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Global Control register (GBL_CTRL)*.

Note: Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits are un-advisable and may cause unexpected behavior.

Note: Under certain conditions, the Single Edge Nibble Transmission (SENT) Receiver (SRX) stalls and the Fast Message Data Ready bit for the SENT channel (FMSG_RDY[F_RDYn]) will no longer get set to indicate that a fast message is available. Reads of any of the fast message registers by the MCU core will stall and not complete. The registers affected are: DMA_FMSG_DATA (Direct Memory Access (DMA) Fast Message Data Read Register), DMA_FMSG_DATA2 (Direct Memory Access (DMA) Fast Message Data 2 Read Register), DMA_FMSG_CRC (DMA Fast Message Cyclic Redundancy Check Register), DMA_FMSG_TS (DMA Fast Message Time-stamp Register), CHn_FMSG_DATA (Channel Fast Message Data Read Register), DMA_FMSG_DATA2 (Direct Memory Access (DMA)

Fast Message Data 2 Read Register), CHn_FMSG_CRC (Channel Cyclic Redundancy Check Register), CHn_FMSG_TS (Channel Fast Message Time-stamp Register).

This condition occurs when the SENT Receiver is configured as follows:

- *SENT high frequency clock is set higher than the Peripheral Bridge clock.*
- *Polling of ready status bit (FMSG_RDY[F_RDYn]) is used to detect a new message reception instead of interrupt or DMA request.*
- *The fast clear mechanism is used (GBL_CTRL[FAST_CLR] = 1) or the Software Clear (GBL_CTRL[FAST_CLR] = 0) is used for clearing the ready status bits (FMSG_RDY[F_RDYn]).*
- *An overflow status condition is detected in the SENT Receiver Channel Status register (CHn_STATUS[FMSG_OFLW] = 1).*

The overflow occurs when two messages are allowed to queue in the internal buffers of the SENT Receiver.

Program the clock dividers in MCU for peripheral bridge clock and SENT clock such that SENT clock is always less than or equal to the peripheral bridge clock. In this case, the stall does not occur and MCU transactions to SENT registers will complete.

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Global Control register (GBL_CTRL)*.

Figure 1405. Fast Message Ready status register (FMSG_RDY)

Table 1457. FMSG_RDY field descriptions

Field	Description
(32-CH):31 F_RDY[(CH-1):0]	Fast Message Data Ready Status Bit Indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast message read registers would automatically clear this bit (Fast Clearing Mechanism). **Note:** These bits are either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL). 0 No Fast Message is available to be read out via Interrupt. 1 Fast Message is available to be read out via Interrupt. The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Global Control register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

55.3.2.5 Slow Serial Message Ready status register (SMSG_RDY)

The bits of this register are asserted when a Slow serial message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via *Fast Message DMA Control register (FDMA_CTRL)* and *Slow Serial Message DMA Control register (SDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Fast Message Ready Interrupt Control register (FRDY_IE)* and *Slow Serial Message Ready Interrupt Enable register (SRDY_IE)*) and the channel is enabled, the message ready status bit in this register will get asserted on Slow message reception. The software must ensure that if a channel is enabled either the DMA or the interrupt must be enabled for that channel. Erroneous flow can happen if neither of them is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Global Status register (GBL_STATUS)*.

Note: Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits are un-advisable and may cause unexpected behavior.

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Global Control register (GBL_CTRL)*.

Figure 1406. Slow Serial Message Ready status register (SMSG_RDY)

Table 1458. SMSG_RDY field descriptions

Field	Description
(32-CH):31 S_RDY[(CH-1):0]	Slow Serial Message Data Ready Status Bit Indicates that a Slow serial message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped serial message Read Registers would automatically clear this bit (Fast Clearing Mechanism). 0 No Slow serial message is available to be read out via Interrupt 1 Slow serial message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Global Control register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 Fast Message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

55.3.2.6 Data Control register 1 (DATA_CTRL1)

The Data Control Register 1 (DATA_CTRL1) is described below.

Note: Reset value changes depending on the number of channels that are enabled on the device.

This register should be programmed after SENT_8NIB_EN bit is programmed in GBL_CTRL register and before enabling the SENT_EN bit.

(32-CH):31 SRDY_IE[(CH-1):0]	Enable for Slow Serial Message Ready Interrupt on Channels 0 to (CH-1) These bits are writable when corresponding DMA enable bits are set to 0 in the Slow Serial DMA Control Register. The availability of message is indicated via assertion of corresponding bit in Slow Serial Message Ready Status Register irrespective of the value set in corresponding interrupt enable bit and DMA is not enabled. When a bit in this register is asserted, an interrupt for corresponding channel is generated. 0 Interrupt on reception of Slow serial messages is disabled. 1 Interrupt on reception of Slow serial messages is enabled.

55.3.2.12 DMA Fast Message Data read register (DMA_FMSG_DATA)

DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_DATA) via DMA. When FIFO is enabled, the DMA must read the complete message using this register only.
Four read accesses (Three accesses if SENT_8NIB_EN bit is 0 in GBL_CTRL register) must be made to read complete message.

55.3.2.16 DMA Slow Serial Message Bit3 read register (DMA_SMSG_BIT3)

The DMA_SMSG_BIT3 is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced serial messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE specification as shown in *Figure 1434*, *Figure 1435* and *Figure 1436*. *Figure 1434* and *Figure 1435* show the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 1436* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Offset: 0x0050 Access: User read-only

Figure 1417. DMA Slow Serial Message Bit3 read register (DMA_SMSG_BIT3)

Table 1469. DMA_SMSG_BIT3 Field Descriptions

Field	Description
0:3 CHNUM	Channel Number Indicates the channel number of the received message being read by DMA. Valid values are 0 to ‘15’.
4 TYPE	Serial Message Type Indicates the type of serial message received. 0 Short serial message 1 Enhanced serial message
20	Placed as 0 by specification.
21 CFG	Configuration bit ‘C’ Indicates the type of Enhanced Serial message. 0 Enhanced serial message with 8-bit ID field 1 Enhanced serial message with 4-bit ID field
22:23 ID7_6/ID3_2	ID Field Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[7:6] and if the ‘C’ bit is 1, this field is ID[3:2].
24:25 ID5_4/ID1_0	ID Field Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[5:4] and if the ‘C’ bit is 1, this field is ID[1:0].
26	0 as per SAE specification
27:30 ID3_0/DATA15_12	ID or Data Field Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[3:0] and if the ‘C’ bit is 1, this field is Data[15:12].
31	0 As per SAE specification.

Note: If the TYPE bit in the register reads ‘0’, then remaining bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is ‘1’, then the message in register is Enhanced serial message and using CFG bit, software can decode the ID and DATA fields.

55.3.2.17 DMA Slow Serial Message Bit2 read register (DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE specification as shown in *Figure 1434*, *Figure 1435* and *Figure 1436*. *Figure 1434* and *Figure 1435* show the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 1436* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Figure 1419. DMA Slow Serial Message Time Stamp read register (DMA_SMSG_TS)

Table 1471. DMA_SMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for the received message Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the serial message. Time Stamp for Slow serial messages is not latched when the Slow serial message starts but when the Slow serial message is completely received.

55.3.2.19 Channel n Clock Control register (CHn_CLK_CTRL)

Note: The value of the CH is device-specific. Refer to the Device Configuration chapter for details.

The SENT module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock. See *Section 55.4.5: Adjustment for variation in sensor (Tx) clock* for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (CHNL_EN).

Offset: 0x0060 + n*0x10 (n = 0 to (CH-1)) Access: Read/Write

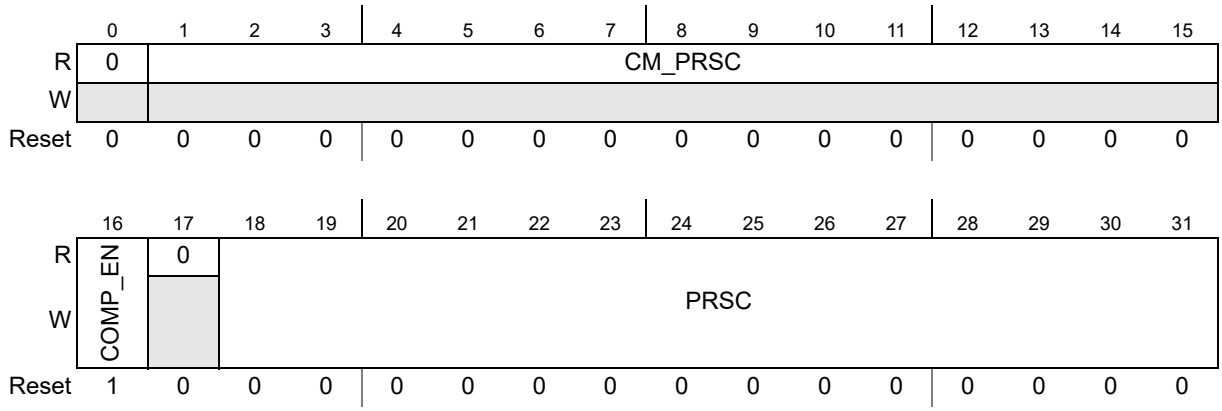

Figure 1420. Channel n Clock Control register (CHn_CLK_CTRL))

Table 1472. CH*n*_CLK_CTRL field descriptions

Field	Description
1:15 CM_PRSC	Compensated Prescaler Value This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' – No variation, hence no compensation or Compensation is disabled. '< Rx Prescaler Value' – Tx Clock is SLOWER than the programmed receive clock. '> Rx Prescaler Value' – Tx Clock is FASTER than the programmed receive clock. Thus, the new Receiver Clock Tick Period can be computed by software as Compensated Prescaler Value × High Frequency Receiver Clock Period **Note:** The value provided in this field is ceiling value of actual tick period as measured by the Receiver.

Table 1472. CH*n*_CLK_CTRL field descriptions (continued)

Field	Description
16 COMP_EN	Compensation Enable To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 Compensation is disabled. 1 Compensation is enabled.
18:31 PRSC	Rx Prescaler Value This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (T_{rx_clk}) is not divisible by the high frequency receiver clock (protocol clock) period (T_{hf_clk}), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 Prescaler is bypassed. Should not be used. Non-Zero Value Enables Prescaler. The required value is computed by software as follows: **Equation 79 Prescaler_value = floor (Trx_clk / Thf_clk)** (Both clock periods taken in µs). See *Section 55.5.3: High frequency receiver clock (protocol clock) requirements* before setting this value. For example, if the required receiver clock tick period is 43 µs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 µs) then: Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

55.3.2.20 Channel *n* Status register (CH*n*_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the bit for the corresponding channel.

Note: The value of the CH is device-specific. Refer to the Device Configuration chapter for details.

Figure 1421. Channel n Status register (CHn_STATUS)

Table 1473. CHn_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value (in *Channel n Configuration register (CHn_CONFIG)*). CPU should write 1 to this clear this bit once it is read. 0 Bus is not idle. 1 Channel has been idle for more than the allowed value.
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 No interrupt. 1 Interrupt Status condition has occurred.
5 CAL_20_25	Calibration Variation 20–25% Interrupt Status This bit indicates that the calibration pulse received on this channel has variation in between ±20% to ±25% from 56 ticks. 0 No Interrupt. 1 Interrupt Status condition has occurred.
6 SMSG_OFLW	Slow Serial Message Overflow Status This bit indicates overflow occurred on this channel. Overflow will cause the older messages (which are not read out) to be overwritten with newly received messages. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt. 1 Interrupt Status condition has occurred.

Table 1473. CHn_STATUS field descriptions (continued)

Field	Description
7 FMSG_OFLW	Fast Message Overflow Status This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt. 1 Interrupt Status condition has occurred.
9 PP_DIAG_ERR	This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than ±1.5625% between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
10 CAL_LEN_ERR	This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks ±25%. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
11 CAL_DIAG_ERR	Successive Calibration pulses differ by ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (see *Section 55.5.3: High frequency receiver clock (protocol clock) requirements*). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
12 NIB_VAL_ERR	Any nibble data value <0 or >15. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
13 SMSG_CRC_ERR	Checksum error in Slow Serial Message This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.

Table 1473. CHn_STATUS field descriptions (continued)

Field	Description
14 FMSG_CRC_ERR	Checksum error in Fast Message This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.
15 NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of “Option 2” for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it. 0 Error Check has passed. 1 Error Check has failed.

55.3.2.21 Channel n Configuration register (CHn_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in *Channel n Status register (CHn_STATUS)* and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (CHNL_EN).

Note: The value of the CH is device-specific. Refer to the Device Configuration chapter for details.

Table 1474. CHn_CONFIG field descriptions

Field	Description
0:3 BUS_IDLE_CNT	Bus Idle Count This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000 Disabled 0001 127*2 Receiver Clock Tick Counts 0010 127*4 Receiver Clock Tick Counts 0100 127*8 Receiver Clock Tick Counts 1000 127*16 Receiver Clock Tick Counts
4 IE_CAL_RESYNC	Successive Calibration Check Resynchronized Interrupt Enable This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of “Option 2” being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled. 1 Interrupt is enabled.
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable This bit enables interrupt assertion when overflow occurs on reception of Slow serial messages in corresponding channel 0 Interrupt is disabled. 1 Interrupt is enabled.
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable This bit enables interrupt assertion when overflow occurs on reception of Fast messages in corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 FCRC_CHK_OFF	Fast Message CRC Check Off This bit can be used to switch off CRC check in Fast Message 0 Check is enabled. 1 Check is disabled/off.
9 IE_PP_DIAG_ERR	Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_CAL_LEN_ERR	Calibration pulse is wider than 56 ticks ±25%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 1474. CHn_CONFIG field descriptions (continued)

Field	Description
11 IE_CAL_DIAG_ERR	Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_NIB_VAL_ERR	Any nibble data value <0 or >15 This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_SMSG_CRC_ERR	Checksum error in Slow Serial Message This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_FMSG_CRC_ERR	Checksum error in Fast Message This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer or FIFO, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast messages will be received even if data nibbles are same. 1 Only Fast messages with differing values of data nibbles will be received.
17 CAL_RNG	Valid Calibration Pulse Range Selection This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable. 1 25% variation is acceptable.

Table 1474. CHn_CONFIG field descriptions (continued)

Field	Description
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run. 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 XOR based implementation (Recommended by SAE specification). 1 Legacy LUT based implementation.
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast messages. 0 Status and Communication Nibble not included in CRC calculation. 1 Status and Communication Nibble is included in CRC calculation.
21 SCRC_TYPE	Slow Serial Message CRC Type This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 XOR based implementation (Recommended by SAE specification). 1 Legacy LUT based implementation.
22 PAUSE_EN	Pause Pulse Enable Enables the channel receiver to detect a pause pulse. 0 Detection of Pause Pulse is disabled. 1 Detection of Pause Pulse enabled.
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 such as Low Latency Option as per SAE specification. 1 Option 1 such as Preferred but High Latency Option as per SAE specification.
24:31 FIL_CNT	Input Filter Sample Count This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0x00: No filtering. Input from device's pad is only synchronized. Non-Zero: Filtering is enabled.

55.3.2.22 Channel n Fast Message Data read register (CHn_FMSG_DATA)

55.4 Functional description

55.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the Channel Enable Register (CHNL_EN). There are some registers which must be configured and some others which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in *Global Control register (GBL_CTRL)* to generate the time stamping clock.
- Rx Prescaler Value in *Channel n Clock Control register (CHn_CLK_CTRL)* to generate the channel's receiver clock.
- Compensation enable in *Channel n Clock Control register (CHn_CLK_CTRL)*.
- Channel Configuration settings in the *Channel n Configuration register (CHn_CONFIG)*.
- Maximum number of data nibbles supported per channel in *Global Control register (GBL_CTRL)*.
- Number of Data Nibbles in Channel in the *Data Control register 1 (DATA_CTRL1)* and *Data Control register 2 (DATA_CTRL2)*.
- Control bits that control whether messages received in channel are to read by interrupt or DMA in *Fast Message DMA Control register (FDMA_CTRL)*, *Slow Serial Message DMA Control register (SDMA_CTRL)*, *Fast Message Ready Interrupt Control register (FRDY_IE)* and *Slow Serial Message DMA Control register (SDMA_CTRL)*.

Note: When configuring the Single Edge Nibble Transmission (SENT) Receiver (SRX) to receive message with the Option 1 of the successive calibration pulse check method (CHn_CONFIG[SUCC_CAL_CHK] = 1), the number of expected edges error (CHn_STATUS[NUM[EDGES_ERR]) gets randomly asserted. Option 2 is not affected as the number of expected edges are not checked in this mode.

The error occurs randomly when the channel input (on the MCU pin) goes from idle to toggling of the calibration pulse.

Note: The Successive Calibration Pulse Check Method Option 1 and Option 2 are defined as follows:

- *Option 1: Preferred but High Latency Option per SAE specification.*

- *Option 2: Low Latency Option per SAE specification.*

To avoid getting the error, the sensor should be enabled first (by the MCU software) and when it starts sending messages, the SENT module should be enabled in the SENT Global Control register (by making GBL_CTRL[SENT_EN] = 1). The delay in start of the two can be controlled by counting a fixed delay in software between enabling the sensor and enabling the SENT module. The first message will not be received but subsequent messages will get received and there will be no false assertions of the number of expected edges error status bit (CHn_STATUS[NUM[EDGES_ERR]).

Alternatively, software can count the period from SENT enable (GBL_CTRL[SENT_EN] = 1) to the first expected calibration pulse. If the number of expected edges error status bit (CHn_STATUS[NUM[EDGES_ERR]) is asserted, software can simply clear it as there have no messages which have been completely received.

Alternatively, the software can clear this bit at the start and move ahead. When pause pulse is enabled, then NUM_EDGES will not assert spuriously for subsequent messages which do not have errors in them or cause overflows.

55.4.2 DMA read logic

The SENT module generates separate DMA requests for all Fast messages and Slow serial messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in *Section 55.4.8: Time stamp logic*.

55.4.2.1 DMA request for Fast message reading via FIFO

A single DMA request is generated for all Fast messages received on any channel. There is a DMA read FIFO to store the incoming messages from all the channels and allow them to be read via DMA.

The DMA operation will happen as follows:

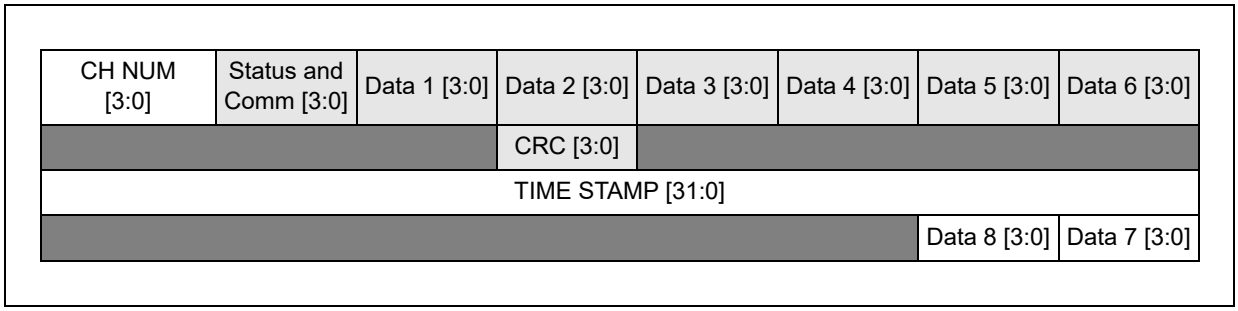
- DMA request will be asserted when number of messages stored in FIFO crosses the configured watermark level (in *Global Control register (GBL_CTRL)*).
- DMA request will be de-asserted when number of messages stored goes below watermark level. It is assumed that DMA controller's TCD would be set to transfer bytes equal to the messages indicated by watermark level so as to empty the FIFO.
- It is assumed that when responding to a DMA request, the DMA controller will read at a rate faster than the rate at which messages are getting received and stored in FIFO. This will cause DMA request to de-assert in the next clock after a message is read out.
- The complete received message can be read by four consecutive read accesses to DMA Fast Message Data Read Register. The message will be read out in following sequence:
  - Fast Message data nibbles 1 to 6 as described by *DMA Fast Message Data read register (DMA_FMSG_DATA)*
  - CRC for the Fast Message as described by *DMA Fast Message CRC read register (DMA_FMSG_CRC)*
  - Time stamp value for the Fast Message as described by *DMA Fast Message Time Stamp read register (DMA_FMSG_TS)*
  - Fast Message data nibbles 7 and 8 as described by *DMA Fast Message Data 2 read register (DMA_FMSG_DATA2)*(1)

1. The DMA_FMSG_DATA2 register will be read only if SENT_8NIB_EN is set in GBL_CTRL register. If this bit is 0 then only 3 accesses will read complete message.

- The channel number is prefixed in each valid message (no error) to allow software to identify messages pertaining to a channel.
- The store signal from the synchronization logic will push the message into the DMA FIFO.
- *Figure 1430* shows the format in which the messages will be stored in any memory-mapped message buffer and when being read out from FIFO.
- Since multiple messages can be received (channels asserts the ready signal together) at the same time, there is a *Fixed round robin sequencing logic*, which will scan all active channels configured for DMA and store their message into the FIFO one by one. Channel configured for DMA but do not have ready messages will be automatically skipped till their turn comes again in the round robin sequence.
- Messages received can be stored in a different order to which they are actually received. The time stamp will indicate the order of reception of messages in a particular channel. However, the time stamp cannot be used to determine the order across channels.

This figure below shows the data for the four 32-bit accesses to be made by DMA to get one complete message with time stamp.

Figure 1430. Format of storing of Fast messages in FIFO



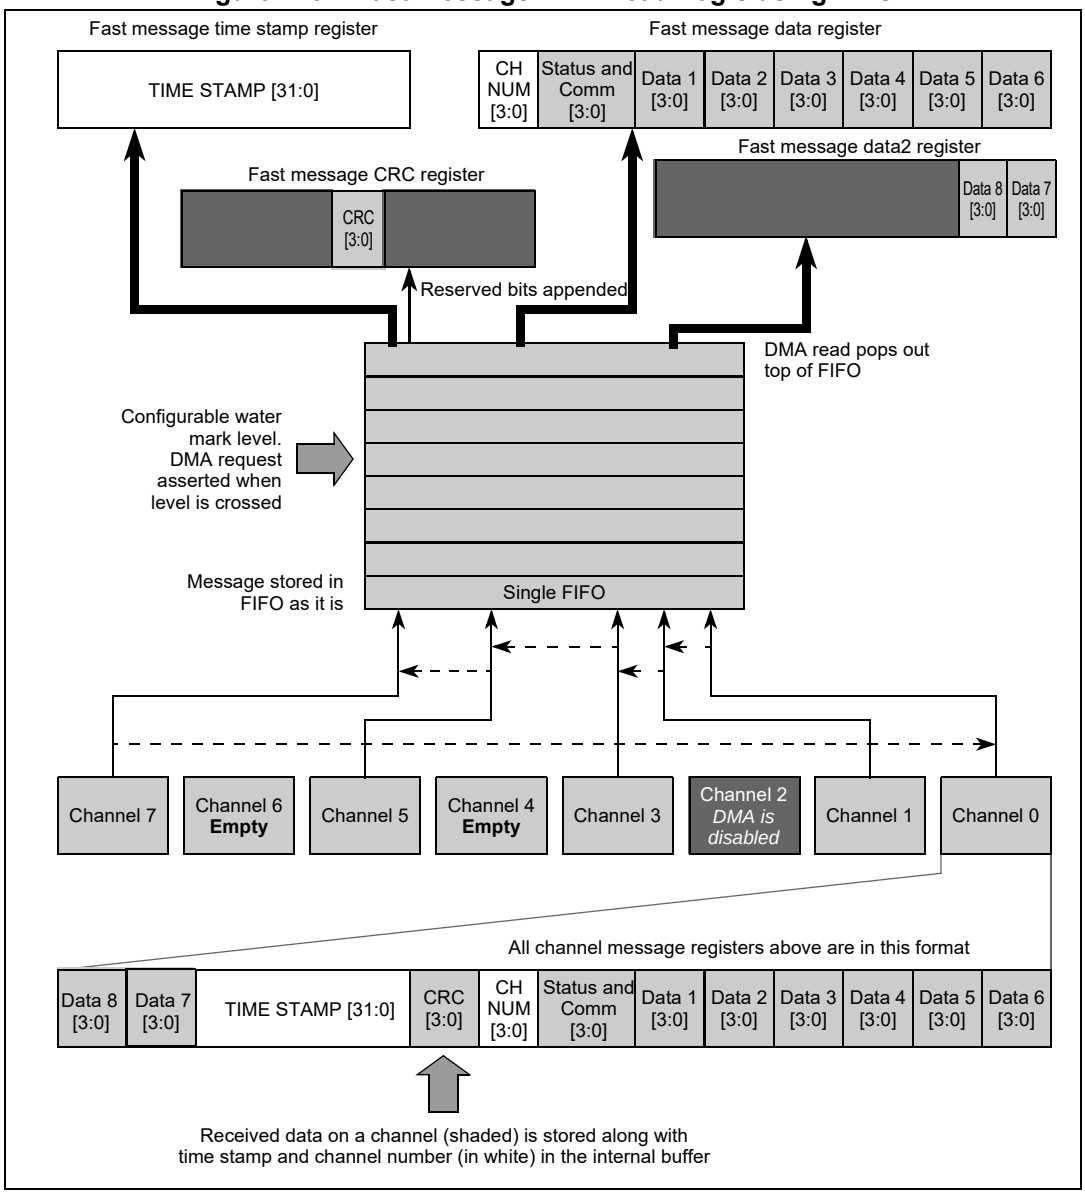


Figure 1431. Fast message DMA Read Logic using FIFO

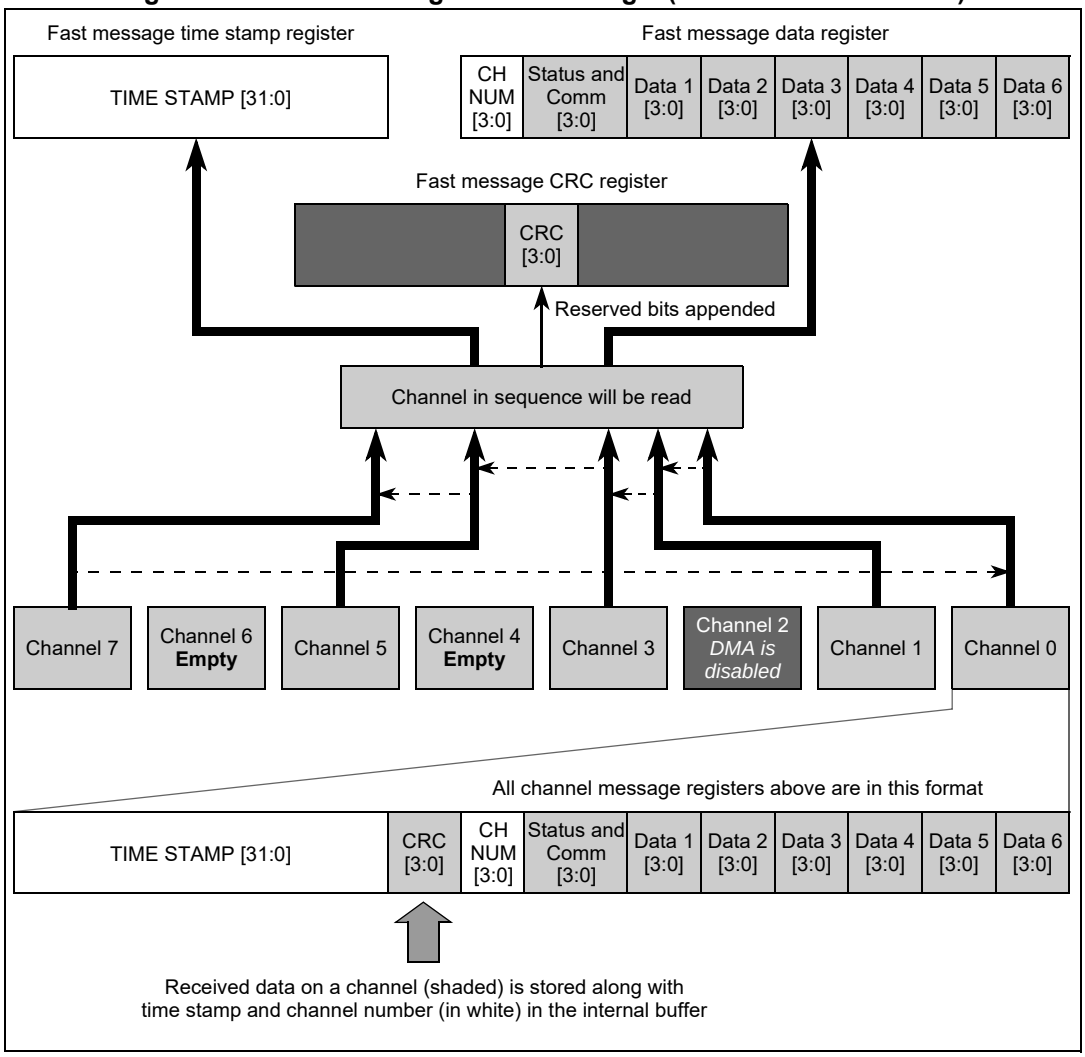
55.4.2.1.1 Fixed round robin sequencing logic

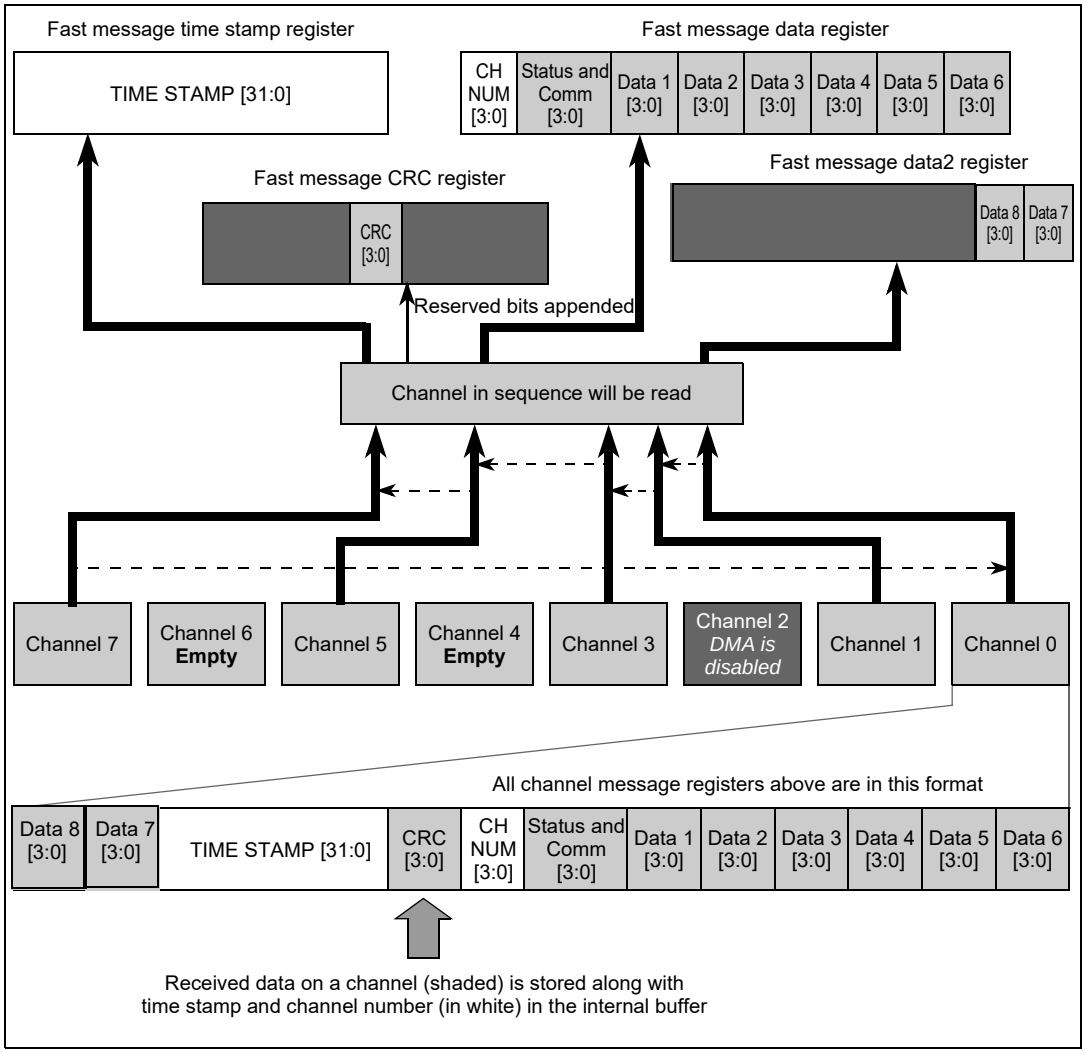
Figure 1431 shows a scenario where 8 channels (0-7) with all channels are enabled for DMA reading except channel 2. DMA request will be asserted when FIFO has received packets more than watermark level set. Figure shows channels 6 and 4 have not received the complete message. The following points describe the complete round robin sequencing scheme.

- The round robin sequencing logic which stores the messages in the FIFO by looping through each channels' Fast Message register and checking for the availability of the message.
- As shown in *Figure 1431*, the arbitration logic will check for messages in sequence 0 -> 1 -> 3 -> 5 -> 7 and back to channel 0 and keep looping. Channel 2 is skipped as it is not enabled to be read via DMA) and channel 4 and 6 are skipped as message is not received completely at the instance the sequencing logic checked their buffers. This sequence continues in this fashion.
- The sequence in which messages are stored in FIFO is not deterministic and depends on the sequence they are detected after the noise filtering by the input filter of the channel.
- The DMA controller responds to the DMA request by reading from the DMA Fast message read register. When a DMA read happens, a message is read from the FIFO and split into four 32-bit values and provided to DMA in the order as described in previous section. The four 32-bit values together form one complete Fast message.
- Once all four 32-bit access are completed, the next data from the FIFO is popped. If the SENT_8NIB_EN bit is 0 in GBL_CTRL register then only three accesses will read complete message.

Figure 1431 also shows how the received data (light gray colored boxes) from a channel is stored in FIFO along with the time stamp and channel number appended (both white colored).



55.4.2.2 DMA request for Fast message reading when FIFO is disabled



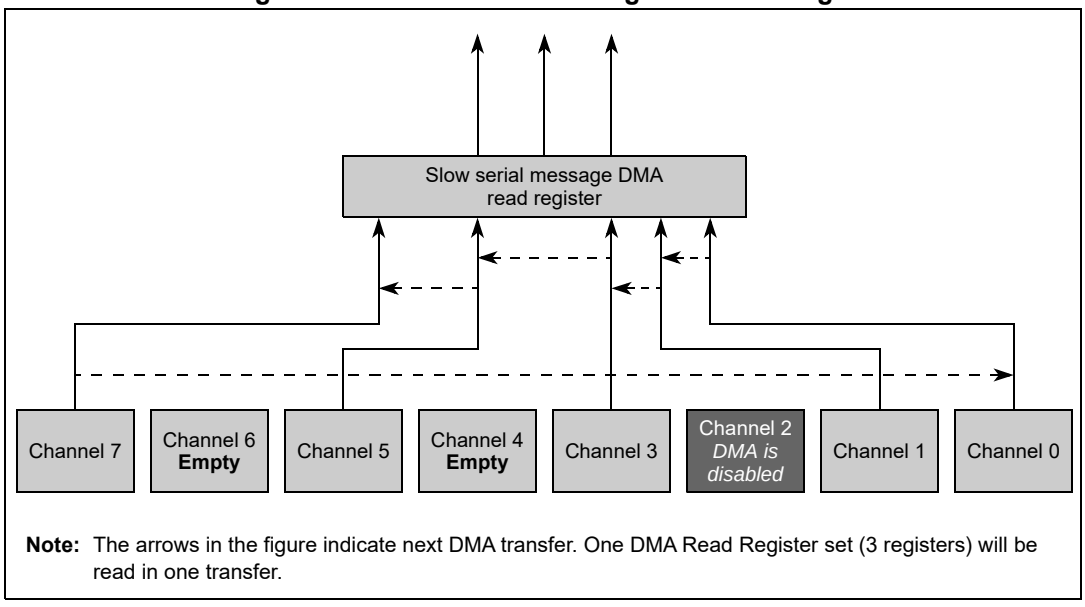
In this mode no FIFO will be used as it is disabled via the FIFO Enable bit in the *Global Control register (GBL_CTRL)*. Fast messages received are stored in a single system bus clock domain buffer to be read out by the DMA controller via the DMA Fast message read register set. Note that the DMA controller must read all 4 DMA read registers to obtain the complete message.
This is unlike the case when FIFO is enabled and message is read out from the DMA Fast Message Data Read register only.

The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA controller should read the complete message by accessing each register of the DMA Fast message read register set, the registers being:
  - *DMA Fast Message Data read register (DMA_FMSG_DATA)*
  - *DMA Fast Message CRC read register (DMA_FMSG_CRC)*
  - *DMA Fast Message Time Stamp read register (DMA_FMSG_TS)*
  - *DMA Fast Message Data 2 read register (DMA_FMSG_DATA2)* (read only if SENT_8NIB_EN is set in GBL_CTRL register)
- A fixed round robin sequencing runs, as shown in *Figure 1432*, and this logic checks for messages in sequence 0→1→3 →5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast message read register set for DMA read and move to the next channel when this message is read out completely (such as, 4 read accesses to the above mentioned registers).
- The DMA controller should be programmed to read only one message in one DMA transfer (such as,16 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur.
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA controller.

Figure 1432. Fast message DMA read logic (when FIFO is disabled)

Note: The data buffer related to the SENT data transferred by the DMA in the system memory is in the following order DMA_FMSG_TS, then DMA_FMSG_CRC, DMA_FMSG_DATA and then DMA_FMSG_DATA2.



55.4.2.3 DMA request for Slow serial message reading

A separate DMA request (different from DMA request for Fast message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers.
- Similar to DMA read for Fast messages, data for slow serial messages will be read from DMA Slow serial message status register set in memory map, the register set comprising of:
  - *DMA Slow Serial Message Bit3 read register (DMA_SMSG_BIT3)*
  - *DMA Slow Serial Message Bit2 read register (DMA_SMSG_BIT2)*
  - *DMA Slow Serial Message Time Stamp read register (DMA_SMSG_TS)*
- A fixed round robin sequencing logic will be running and it will update the DMA Slow serial message status register set for DMA read and move to the next channel when this message is read out completely (such as, 3 DMA read accesses to the above mentioned registers).
- The channel number and time stamp will also be appended for every message.
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages.
- The DMA controller should be programmed to read only one message in one DMA transfer (such as, 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur.
- Since serial messages receive rate is very slow, user software should ensure there is no overflow.
- The fixed round robin sequence logic for DMA read is the same as that used for Fast messages (see *DMA request for Fast message reading when FIFO is disabled*).

Figure 1433 shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow serial message status register set.

Figure 1433. Slow serial message DMA read logic

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in one transfer.

The formats in which the 3 types of serial messages will be stored in the buffers are shown in the figures below.

Figure 1434. Enhanced serial message with 8-bit ID field

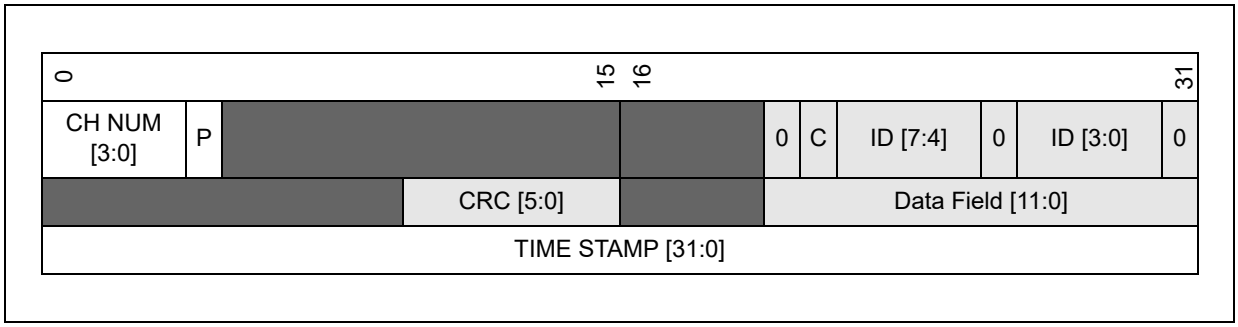


Figure 1435. Enhanced serial message with 4-bit ID field

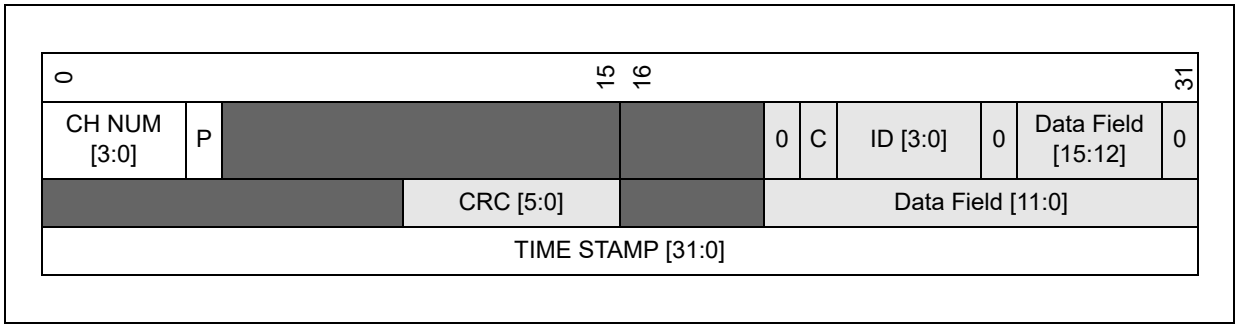

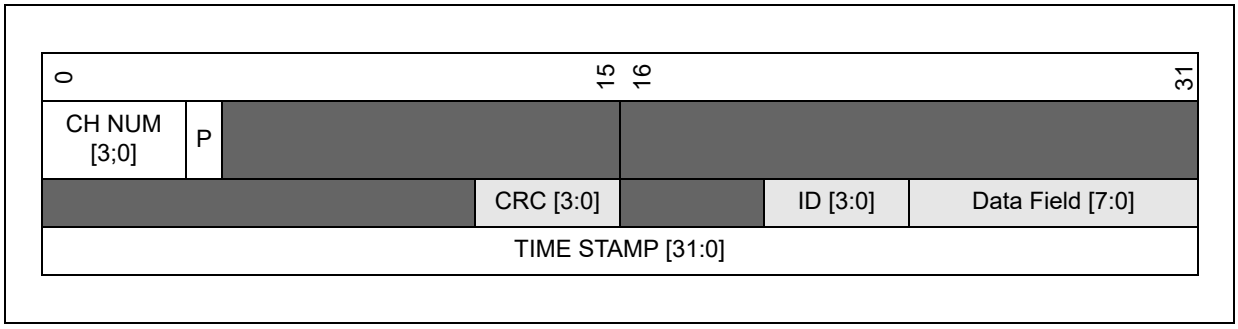

Figure 1434 and *Figure 1435* show the enhanced serial messages. Bit C (shown in figure) or bit CFG (as shown in *DMA Slow Serial Message Bit3 read register (DMA_SMSG_BIT3)* description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in *DMA Slow Serial Message Bit3 read register (DMA_SMSG_BIT3)* description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Figure 1436 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE specification.

Figure 1436. Short serial message

Three 32-bit accesses to be made by DMA to get one complete message with time stamp.

55.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast message, an interrupt will be asserted when any of the channels has received a complete Fast message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the register interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or slow messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast message read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

55.4.3.1 Suggested software interrupt service routine steps

These are the suggested steps to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast message and Slow serial message interrupts are used:

The Fast message Interrupt should have higher priority than Slow serial message interrupt. The suggested ISR steps for a Fast message interrupts can be:

- Read the Fast message ready register and store it in a variable.
- Shift out bits starting from MSB from this variable.
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast message read register set (4/3 registers).
- If SENT_8NIB_EN bit is set in GBL_CTRL register then four read accesses else only three read accesses will fetch the complete message. Shift out new bit. Repeat step.
- Else if bit is 0, shift out new bit.
- When all bits are shifted out, read the Fast message status registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow serial message interrupt can be the same as for Fast message ISR. Only three read accesses will fetch complete message in case of slow serial message.

When common Fast message and Slow serial message interrupts are used:

The suggested ISR steps can be:

- Read the Fast message status register and store it in a variable.
- Shift out bits starting from MSB from this variable.
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast message read register. **Three or four** read accesses will fetch complete message depending on SENT_8NIB_EN bit. Shift out new bit. Repeat step.
- Else if bit is 0, shift out new bit.
- When all bits are shifted out, read the Slow serial message status register into a new variable.
- Shift out bits starting from MSB from this new variable.
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow serial message status register. Three read accesses will fetch complete message. Shift out new bit. Repeat step.
- Else if bit is 0, shift out new bit.
- When all bits are shifted out, software can again check both Fast and Slow serial message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

55.4.4 Overflow behavior

This section describes the overflow behavior.

55.4.4.1 Fast messages buffers/FIFO

Overflow in Fast message buffers or FIFO can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full. When FIFO is used, overflow is indicated when the FIFO gets full and another fast message is to be stored.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (such as, all 4 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

55.4.4.2 Slow message buffers

Overflow in Slow message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

55.4.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register (*Channel n Clock Control register (CHn_CLK_CTRL)*). Software can use this value to determine the variation in Tx Clock.

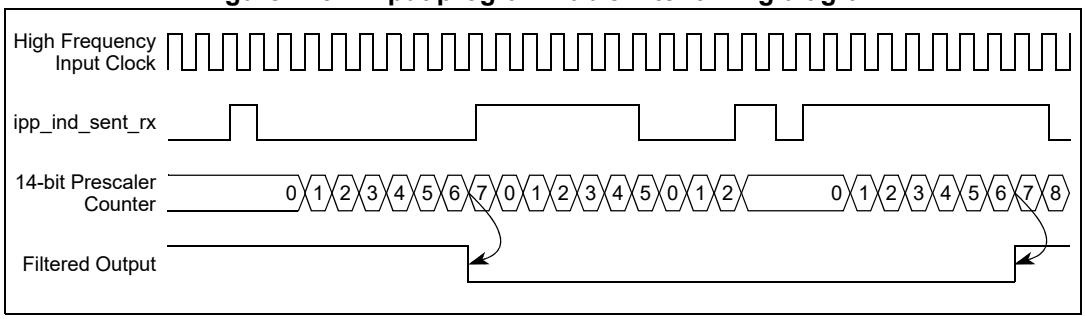
Note: A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

Note: At ambient temperatures above 114 degree C, Single Edge Nibble Transmission (SENT) Receiver (SRX) generates CAL_LEN_ERR and NUM_EDGES error when calibration pulse length from sensor is 25% higher than normal length. As temperature is increased, the frequency of occurrence of these errors also increases.

By configuring the SENT high frequency clock in the SRX module to run at a slower frequency (40 MHz) will help to reduce the occurrence of these errors.

55.4.5.1 Adjustment for nibble length variation



Section 6.2 of SAE specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

55.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (such as, sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver

clock). If the opposite edge appears on the sensor input before validation (such as, overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register (*Channel n Configuration register (CHn_CONFIG)*). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (*Channel n Configuration register (CHn_CONFIG)*). A timing diagram of the input filter when FIL_CNT is 4, is shown in *Figure 1437*.

Figure 1437. Input programmable filter timing diagram

55.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel.

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%.
- Not the expected number of falling edges between calibration pulses (Message length is pre-defined by each sensor device and programmed by user for each channel).
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use such as, Legacy or XOR-based.
- Any nibble data values measured as < 0 or > 15.
- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (*Channel n Status register (CHn_STATUS)*). If an error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to the CPU in case the channel becomes unstable and sends wrong data continuously.

55.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

55.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%.

So if protocol clock is T_{HF_CLK} and channel tick period is T_{TX_CLK} then the check will be of 1.5625% ± $\{100 \times (4 \times T_{HF_CLK}) / (42 \times T_{TX_CLK})\}$.

So it will not allow variance in clock of a channel by 1.5625% - $\{100 \times (4 \times T_{HF_CLK}) / (42 \times T_{TX_CLK})\}$.

This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

55.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check (“Not the expected number of edges check”) will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

55.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

55.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow serial message (4-bit CRC) and Enhanced serial message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new XOR-based CRC implementation via a control bit in the channel's corresponding control register. Refer to SAE SENT specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast serial messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast message or Slow message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

Note: The Single Edge Nibble Transmitter (SENT) Receiver does not properly round off incoming data to nearest nibble. For example, if the data nibble input to the SENT receiver is 3.5 to 3.87, it is rounded off to 3 instead of 4 as the jitter tolerance is 12.5% instead of 50%. As a result, the Channel n Fast Message Data Read Register (CHn_FMSG_DATA), Channel n Fast Message Data 2 Read Register (CHn_FMSG_DATA2) or Channel n Fast Message Cyclic Redundancy Check (CRC) register (CHn_FMSG_CRC) register values may not match the expected values or the Message is not received at all because of the CRC mismatch.

Disable the CRC check by setting (to 0b1) the Fast Message CRC Check Off bit in the Channel Configuration register (CHn_CONFIG) and perform the CRC check of messages in software.

55.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per specification). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel 'n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and

the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel ‘n' Status Register - CHn_STATUS(NUM_EDGES_ERR] = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. *Table 1482* contains information due to erratum behavior and *Table 1483* below contains clarification of normal NUM_EDGES_ERR behavior.

Table 1482. Behavior of NUM_EDGES_ERR

First error detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error
FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR errors
CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error
FMSG_OFLW	NUM_EDGES_ERR asserted once (random occurrence)	A message buffer overflow may lead the state machine to enter a state where it waits for a calibration pulse (behavior also seen in ERR007404). When in this state, the state machine can detect both a Pause pulse and a Calibration pulse as back to back calibration pulses and no edges in between. Then, the NUM_EDGES_ERR can get asserted. Since entry into this state is random, the error can be seen occasionally.	Ignore NUM_EDGES_ERR error

Table 1483. Expected behavior, clarification of NUM_EDGES_ERR cases

First error detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.	Ignore the NIB_VAL_ERR
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

55.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.*Global Control register (GBL_CTRL)*

The clock for the counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value in *Global Control register (GBL_CTRL)* in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 µs. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value to generate a time stamp clock of 1 µs resolution is 59.

Note: The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

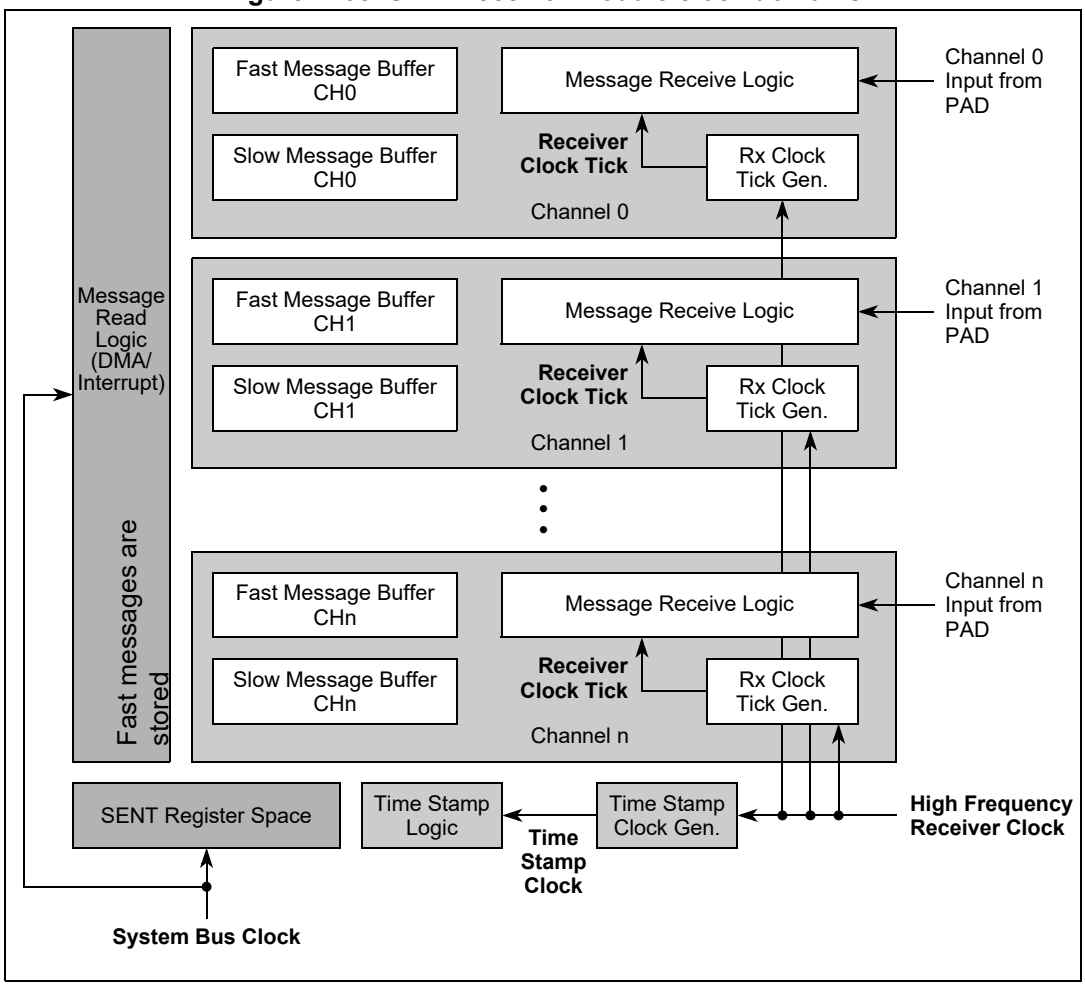
The time stamp for a serial message is sampled at the end of the message such as when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

55.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

55.4.9 Bus-idle diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in *Channel n Configuration register (CHn_CONFIG)*). Status bit (bus_idle in *Channel n Status register (CHn_STATUS)*) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.



55.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's register interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

55.5.1 Clocking strategy

Figure 1438 shows the clock domain in which each module is functioning.

Figure 1438. SENT receiver module clock domains

55.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast message size with valid checksum as per SAE specifications is 154 ticks. At 3 µs receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 µs (after compensation). This gives us the time in which the minimum size Fast message is received in any channel as 154 $\times$ 2.4 = 369.6 µs. Now since messages are arriving in parallel, 369.6 µs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that 'N_{CHNL}' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be 369.6/N_{CHNL} µs or ~370/N_{CHNL} µs. Since the CPU or the DMA needs to make four 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as 'T_{RD}' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

Equation 80 $$4 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370/N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode.

For DMA,

Equation 81 $$4 \times T_{RD} + T_{WAKUP} < 370/N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get:

For CPU,

Equation 82 $$(4 \times N_{RD} + N_{ISR}) \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is µs).

For DMA,

Equation 83 $$4 \times N_{RD} \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is µs).

Note: The above calculation is given assuming SENT_8NIB_EN bit is set and each channel can have up to 8 data nibbles. In this case four read accesses are required to read the complete message.

55.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per the formula below.

Equation 84 $$F_{HF_CLK} > 332 / (3 \times T_{Tx_CLK})$$

where F_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in MHz and T_{Tx_CLK} is the Transmitter or Sensor Clock Frequency in µs.

Note: T_{TX_CLK} in the above equation should be chosen based on the fastest sensor clock among all channels in the device.

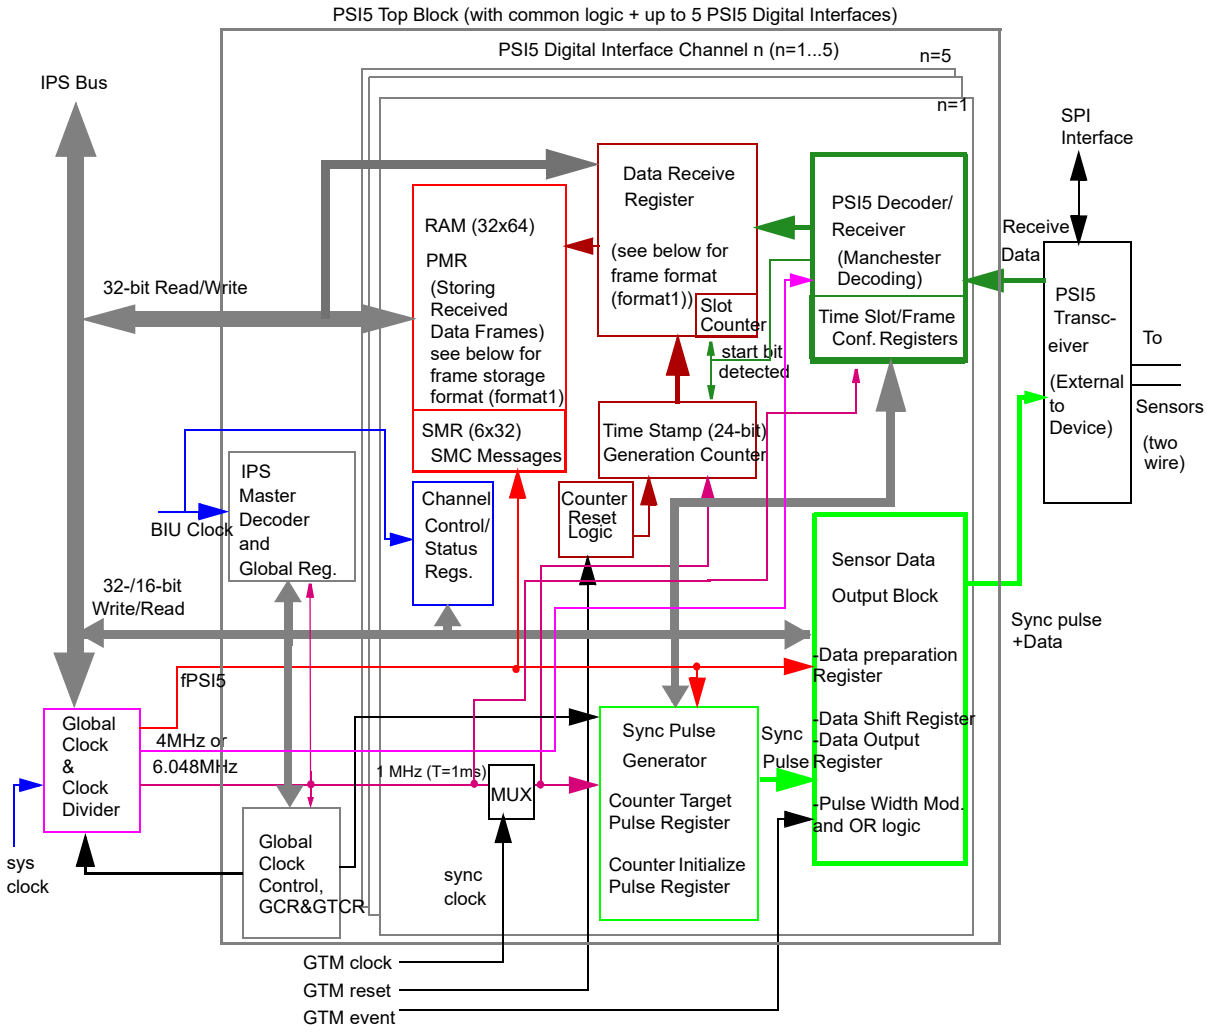
56 Peripheral Sensor Interface (PSI5)

56.1 Introduction

The PSI5 interface offers power supply and data transfer between the application and multiple sensors over a two-wire interface. Data transmission from the application to the sensor or sensors is achieved through modulation of the power supply voltage (sync pulse). Data reception from the sensor or sensors to the application is achieved through modulation of the current drawn by a sensor using Manchester encoding.

At the system level, the PSI5 interface consists of mechanisms integrated on the microcontroller and an external physical layer that provides the high-voltage supply and converts the current drawn by the sensor into a digital Manchester-encoded data stream.

56.1.1 Overview



The PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make the PSI5 also suitable for many other automotive sensor applications. The development goal of the PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented free of charge.

The main features of the PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s or optional 189 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

In short, PSI5 standardizes the low-level communication between peripheral sensors and electronic control units. Note that the physical layer for the IP (transceiver) is to be implemented separately outside the IP.

Figure 1439. PSI5 digital interface block diagram

Format1: Stored in RAM Registers

O	F	EM	E	T	Slot Counter	Time Stamp	Header+ Sensor Data(i)	CRC or Parity bits	C

1. **"C"** is set to 1 when CRC or Parity check identifies Error.
2. **"T"** is set to 1 at timing errors of the incoming frame.
3. **"E&EM"** is set to 1 at electric errors at any bit PSI5/SMC
4. **"F"** is set to 1 if no frame received in the slot.
5. **"O"** is set to 1 if any new frame overwrites previous Unread.Fr.
6. **"Slot Counter"** Gives the slot number in which the start bits of the frame were detected.
7. **"Sensor Data"** are stored in RAM automatically after all data bits are received in data receive register.
8. **"Time Stamp"** is appended to received frame in once start bits are received or rise edge of sync pulse.

56.1.2 Features

- IPS interface for register read/write (big endian)
- Supports bidirectional full duplex operations, but with differing baud rate—low, ECU-to-sensor, fast sensor to ECU
- Manchester decoder operating at both 125 Kbit/s and 189 Kbit/s bit rates with ×32 sample clock rate
- One 64-bit sensor data receive register to which the decoded received sensor data—including header, data, timestamp, frame counter, status bits (E, EM, T, C, F) and CRC, but not including start bits—are written
- A 24-bit time stamp register with a 1 µs (or the GTM clock) resolution. When first rising edge of start bits (S0) of a message or the rising edge of the SYNC pulse is recognized, the value in the time stamp register will be written to the data receive register
- Provision of resetting the Time Stamp Counter through the reset from the GTM module
- Single 32 × 64-bit RAM buffer for storing (moving) content of the data receive register once end of message is recognized
  - Related to each RAM buffer are two diagnostic registers, N and EI. Register N is used to identify the occurrence of new messages in the corresponding RAM buffer, while register EI identifies the error status of these messages. The errors that can set the EI register bits are the F (no frame), E (electrical error), EM (electrical error for SMC bits embedded in PSI5 messages), T (Timing bit error) and C (CRC error). Which of these errors actually set the EI register bits is configurable.
- DMA support for transferring RAM data (including diagnostic data) to system memory
- DMA transfer through IPS bus
- Support for optional serial messaging channel (SMC) and additional logic to extract SMC frames from PSI5 frames
- Operating modes supported:
  - Asynchronous mode (sensor periodically sends data, no sync pulse, one sensor per interface)
  - Synchronous mode (sync pulse generated, multiple sensor per interface)
- Sync pulse generation for synchronous modes:
  - The start of each time slot (1 to 6) (see *Figure 1486*) on the bus (after the end of the sync pulse) can be defined with a 1 µs resolution
  - The end of the last time slot on the bus can be defined with a 1 µs resolution, up to a maximum sync period time of 16 ms
  - Trigger logic to generate sync pulses
    - 16-bit Channel Trigger Counter (CTC) used to generate the sync pulses by comparing the values with CIPR and CTPR
    - Counter Initialize Pulse Register (CIPR) to allow configuration of initialization (offset) period
    - Channel Trigger Period (CTP) register to allow configuration of sync period. Value in CTP is the value to which the CTC is updated after each sync pulse generation

  - Possibility to have a common 1 MHz clock source
- An upstream register bit chain consisting of Preparation Register, Buffer Register, Shift register (output data) and pulse width modulation logic, is implemented. Using this, it is possible to send a data word to the sensors through use of data sync pulses: logic 1 with programmable data sync pulse width W1, logic 0 with programmable data sync pulse width W0. The data sync pulse timing can be configured to be dependent on the periodic or event driven timing SYNC pulse. Further, there is no difference between timing sync pulse and data sync pulse during transmission (ECU-to-sensor communication).

56.1.3 Modes of operation

56.1.3.1 Disable mode

Disable mode in the PSI5 reduces power consumption. This mode is entered by setting GCR[GLOBAL_DISABLE_REQ]. All the channels enter Disable mode at once when this bit is set, irrespective of the setting of PCCR[PSI5_CH_EN] and PCCR[PSI5_CH_CONFIG]. In this mode the RX, TX and common time base counters are disabled for any operation. This is the default state after module reset is released. PSI5 can exit Disable mode by clearing the GLOBAL_DISABLE_REQ bit and enabling individual PSI5 channels (setting PCCR[PSI5_CH_EN]). Note that when entering Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter AND the internal sync pulse generator are, however, reset when entering Disable mode.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of PCCR[PSI5_CH_CONFIG].

56.1.3.2 Initialization/Configuration mode

This is the configuration phase, in which all PSI5 global, channel specific configuration/control registers can be written. The receiver and transmitter sub-blocks are disabled in this mode. The message receive registers/buffers can be accessed in this mode. This mode can be entered by clearing GCR[GLOBAL_DISABLE_REQ] and setting PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN]. All the channel specific control registers can be programmed only in the CONFIG mode. This prevents the software from accidentally causing a change in any critical register.

56.1.3.3 Normal mode (NORMAL mode)

In Normal mode, the receiver and the transmitter blocks become active, error handling is enabled and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. Data Preparation Register, Shift Register and data output registers are writable in this mode. Apart from them, there are some register bits that can be written in this mode also. Refer to the detailed register description. This mode can be entered clearing GCR[GLOBAL_DISABLE_REQ], clearing PCCR[PSI5_CH_CONFIG], and setting PCCR[PSI5_CH_EN].

56.1.3.3.1 PSI5 topology

The different PSI5 user operation modes define topology and parameters of the communication between ECU and sensors such as communication mode, number of data bits, error detection, cycle time, number of time slots per cycle, and bit rate.

These modes as generally denoted as

PSI5-(A / P / U / D)-dd-(P / CRC)-tttt / n(L / H)

Table 1484 provides a key for these notations.

Table 1484. Normal operating states

Communication modes		Description
A	Asynchronous mode	PSI5-A describes a point-to-point connection for unidirectional, asynchronous data transmission. Each sensor is connected to the ECU by two wires. After switching on the power supply, the sensor starts transmitting data to the ECU periodically. Timing and repetition rate of the data transmission are controlled by the sensor. No Sync pulse is send from ECU side.
P	Synchronous Parallel Bus mode	The synchronous operation modes work according to the TDMA method (Time Division Multiple Access). Each sensor is connected to the ECU by two wires. The sensor data transmission is synchronized by the ECU using voltage modulation. Synchronization (sync pulses) can be optionally used for point-to-point configurations; it is mandatory for bus modes. The sensors can be arranged as parallel bus, universal bus and daisy chain topology based on sensor addressing and interchangeability of sensors.
U	Synchronous Universal Bus mode	
D	Synchronous Daisy Chain Bus mode	
Data bits		
dd	No. of data bits	—
Error detection		
P	1 parity bit	—
CRC	3-bit Cyclic Redundancy Check (CRC)	—
Cycle time		
tttt	Cycle Time in µs	—
n	Number of time slots per cycle	—
Bit rate		
L	125 Kbit/s	—
H	189 Kbit/s	—

56.1.3.4 Stop mode

When the Stop mode request is asserted, and if there is no active PSI5 transaction ongoing, then the acknowledgment to stop the clocks is given immediately.If start bits of any PSI5 packet have been detected (successful detection of both S0 and S1) then the

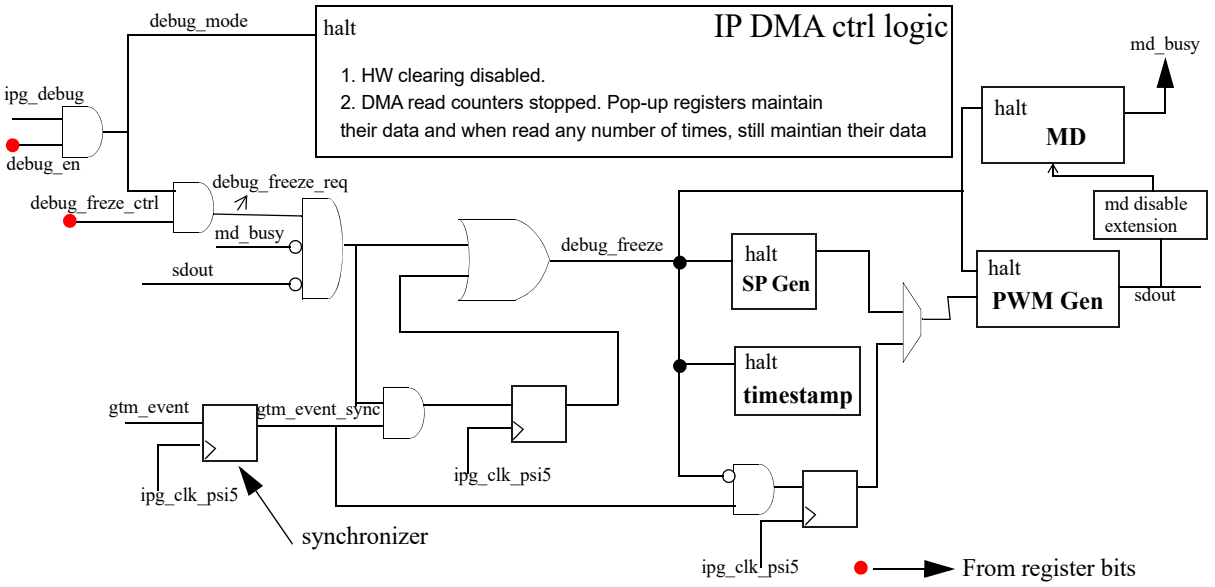
concerned PSI5 packet is successfully stored and then the Stop mode acknowledgment is generated by the IP. Note that for generating the acknowledgment, the IP does not wait for the complete reception of any ongoing SMC message, but only waits for the complete reception of any ongoing PSI5 packet transaction.

If the PSI5 transceiver is asynchronous to the PSI5 IP receiver then loss of data can result when the STOP mode is deasserted. Hence the following guidelines should be followed :

- If the IP is in synchronous mode of operation, then the IP gets resynchronized on the next available sync pulse which occurs after STOP mode deassertion. Hence the PSI5 packets occurring between the STOP mode deassertion event and the subsequent synch pulse would not be reliable and should be ignored by the application.
- If the IP is configured in asynchronous mode, then it should be ensured that the idle time gap between PSI5 packets is greater than or equal to the length of one PSI5 message. In this case only one PSI5 message will get corrupted, but the IP will sample the subsequent PSI5 messages correctly.

56.1.3.5 Debug mode

In order to enter this mode the debugger has to be connected and it has to encounter a breakpoint. In addition, the DEBUG_EN bit has to be written to 1. The DEBUG_EN bit can be written by either the CPU or by the debugger but only in Configuration mode. Once the above conditions are satisfied the IP enters the Debug Mode. There are two debugging modes available. For simplicity these are being referred to as the “Freeze” and “Open” modes. The IP enters one of the above debugging modes, based on the configuration of a register bit DEBUG_FREEZE _CTRL mentioned in the *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*.



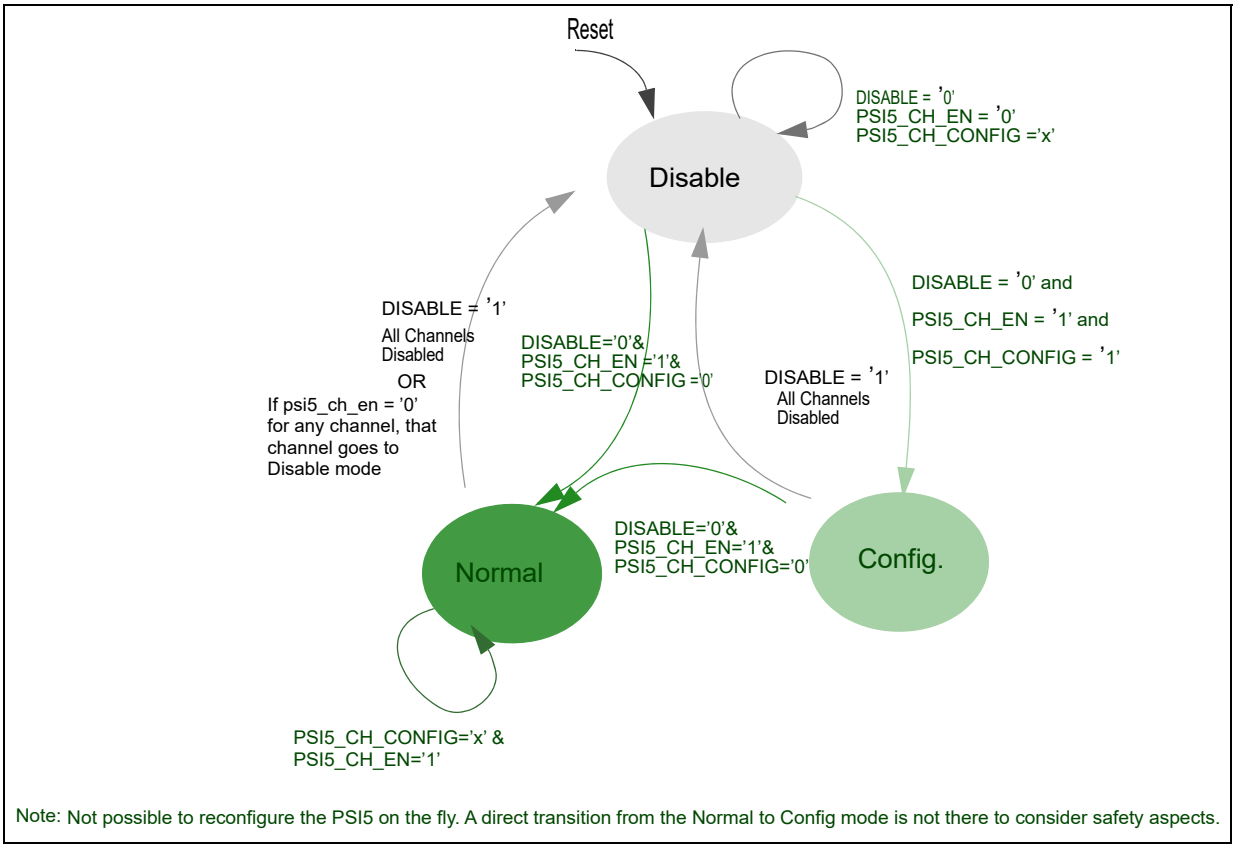
In “Open” mode, the core of the IP keeps on working normally and all the registers are updated from the hardware; just like they were being done in the functional mode (when the IP was out of the debug mode). Thus, even a long term entry to the Debug Mode, wont affect the normal operation of the various registers that are to be updated by the hardware. Down side is that the IP can keep on changing the internal status bits and the registers as the time progresses.

In “Freeze” mode, the core of the IP, the output and the input paths are all stopped coherently. Once the input and the output paths are stopped coherently, then all the internal status bits and registers maintain their status and value irrespective of the time progression. Coherent halting of the input path would mean that there is no active reception ongoing in the Manchester decoder. Thus, if the Manchester decoder has already detected valid start bits(S0 and S1) and then there is a request to enter the “Freeze” mode, then the current reception is completed before the IP enters the Freeze mode. Coherent halting of the output path would mean that the “sdout” output pin of the IP should be at a logic 0. Once the above conditions are satisfied, only then can the IP enter the “Freeze” mode. Once the IP enters the Freeze mode, the time stamp counter is also halted.

In both the above modes, the various interface registers would be completely visible to the debugger, but debugger action would have no impact on the various status bits and counters that normally get affected by a CPU/DMA read. In this mode, the read pointers of the FIFO do not get incremented, when being read through the Pop-up registers. Thus in Debug mode, reading the DMA PSI5 Message Register (PSI5_CH0_DPMR),DMA SMC Frame Register (PSI5_CH0_DSFR) or the DMA Diagnostic Status Register (PSI5_CH0_DDSR) would keep on returning the same data. Hence the interrupts related to DMA completion operation would not get generated. Further the hardware clearing related

to FAST_CLR_SMC and FAST_CLR_PSI5 bits would not have any effect and the hardware clearing would remain disabled. This is also highlighted in *Figure 1440*.

Figure 1440. Block Diagram of Debug Mode



1. “halt” in the above block means, that when “1”, then the specified block will stall its operation.
2. When “debug_mode” == 1, then the IP enters debug mode.
3. When “md_busy” is “1”, it means that MD is busy in reception of some data.
4. “ipg_debug” when “1” is an indication from the Debugger Logic that a breakpoint has been encountered and IP has to stop its operation.
5. Once the “debug_freeze_req” is asserted, then the “debug_freeze” is asserted ONLY when no pending reception is there in the MD and the “sdout” has a low level. Once the “debug_freeze” == 1, then the blocks are halted as shown above.
6. During deassertion of the “debug_freeze_req”, if the “gtm_event_sync” is already high, then the “debug_freeze” is not de-asserted until the “gtm_event” goes low. This is to prevent an “untimed” sync pulse from going to the output path.
7. “debug_en” bit allows selective disabling of the debug mode of the IP.

The debugger can write to all the registers just like the CPU can. However, no special privilege is given to the debugger as compared to the CPU. The read/write behavior of the debugger for various registers in Normal/Configuration mode is identical to the behavior of the CPU. Note that the various status bit and counter protections become active ONLY in Debug mode.

56.1.3.6 Operating modes

Figure 1441 shows the operating modes and *Table 1485* shows the state transition.

Figure 1441. Operating modes

Note: Not possible to reconfigure the PSI5 on the fly. A direct transition from the Normal to Config mode is not there to consider safety aspects.

Table 1485. State transition table

GCR [GLOBAL_DISABLE_REQ]	PCCR		State	
	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
1	x	x	x	All channel Disable
0	x	0	x	Specific channel Disable
0	1	1	Disable	Config
0	0	1	Config	Normal
0	x	1	Normal	Normal
0	0	1	Disable	Normal

56.2 External signal description

Table 1486. PSI5 port list

Name	Function	I/O
Signals to/from pads		
SDINn_PSI5_m(1)	Digital sensor data input pin of PSI5 module	I
SDOUTn_PSI5_m (1)	Digital sensor data output pin of PSI5 module (sync pulse + data)	O

1. “n” is the Channel Number and “m” is the Module Instance Number.

56.3 Memory map and register description

56.3.1 Memory map

Table 1487 shows the memory map.

Refer to the Device Configuration Chapter for instance specific PSI5 channels.

1. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot, always read as 0,” D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable. All 16-bit registers are half word/byte addressable for write. Read is always word addressable. Trying to access any register space of PSI5, other than those mentioned in the memory map, results in the generation of transfer error. Note that the generation of transfer error is confined to this scenario only.
2. In this column, the format of the reset value indicates the register width. Thus, reset values of the formats 0xHH, 0xHHHH, and 0xHHHH_HHHH, where “H” is a hexadecimal digit, indicate 8-bit, 16-bit, and 32-bit registers, respectively.
3. This register is not present if the specific instance is configured as a slave . Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave then its operating mode and staggering can only be controlled by another master instance. Refer to the Device Configuration Chapter for instance specific details.

4. The reset value is dependent on the parameter PSI5_PDIS_RST:
When PSI5_PDIS_RST = 0 then the reset value is “0x0000”(PSI5 module is enabled after reset).
When PSI5_PDIS_RST = 1 then the reset value is “0x0001” (PSI5 module is disabled after reset).
For the value of parameter PSI5_PDIS_RST refer to the Device Configuration File.
5. Not all the register bits are writable in this mode. Refer to the Register Description section for details.
6. The bits can be cleared by hardware or by software using w1c. This is controlled by the “fast_clr_xxx” bit in the PSI5_PCCR. However not all bits of this register have this behavior. Refer to the Register Description section for details.
7. Writable ONLY in Config mode for test purposes. Otherwise updated by hardware.
8. The bits are set by hardware. Alternatively the software can also set these bits by writing to the corresponding SET registers. This provision should be used only for test purpose. Clearing of these bits is either by w1c or by hardware depending on the setting of the “fast_clr_xxx” bit in the PSI5_PCCR.
9. Few bits are writable to One Shot. Refer to the Register Description section for details.
10. The bits of this register are writable ONLY when the corresponding DxR_RDY bit in the PSI5_GISR is equal to 1.
11. Refer to the Device Configuration Chapter for instance specific PSI5 reserved locations.

56.3.2 Register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

Note that, an access (read/write) to any register in the unimplemented register space will result in the generation of transfer error. All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to do a word operation on 16-bit registers will NOT result in the generation of any transfer error. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error. Trying to write to any register outside its intended mode of write (Normal/config) will be ignored without the generation of any transfer error.

For a summary of the register bit accesses in various device modes, refer to *Section 56.3.2.42: Device modes and Register bit accesses*

56.3.2.1 Global Control Register (PSI5_GCR)

The Global Control Register (PSI5_GCR) provides control functions for all the PSI5 channels simultaneously.

Address: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CTC_GED	GLOBAL_DISABLE_REQ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—(1)

Figure 1442. Global Control Register (PSI5_GCR)

1. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is “0” (PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1 then the reset value is “1” (PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST refer to the Device Configuration Chapter.

Table 1488. PSI5_GCR(1) field descriptions

Field	Description
14 CTC_GED	Channel Target Counter (CTC) Global Enable/Disable. 0 All the CTC counters having PCCR[CTC_GED_SEL] = 1 are reset. 1 Simultaneously starts the CTC of all the channels that have PCCR[CTC_GED_SEL] = 1. **Note:** This bit is writable in all modes.
15 GLOBAL_ DISABLE_REQ	PSI5 Receive Global disable request. When set, all PSI5 channels enter Disable mode (from individual Normal or Config modes) regardless of the settings of the PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN] bits. When cleared, each PSI5 channel enters Config mode or Normal mode based on the setting of the PCCR[PSI5_CH_CONFIG] bit if PCCR[PSI5_CH_CONFIG] is set for that channel; otherwise, that particular channel continues to stay in Disable mode. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is "0"(PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1then the reset value is "1"(PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST refer to the Device Configuration Chapter. This bit is writable in all the modes. 0 PSI5 channel(s) enters Normal or Config mode, depending on the value of the PCCR[PSI5_CH_CONFIG] bit. 1 All PSI5 Channels are in Disable mode. **Note:** When GLOBAL_DISABLE_REQ == 1 then all the clock enables (shown in *Figure 1507*) from the IP go to a 0 (inactive) state.

1. This register is not present if the specific instance is configured as a slave. Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave then its operating mode and staggering can only be controlled by another master instance. Refer to the Device Configuration Chapter for instance specific details.

56.3.2.2 PSI5 Channel Control Register (PSI5_CH0_PCCR)

Figure 1443 shows the PSI5 Channel Control Register.

Address: 0x0008 + *i**0x1C0 (*i*=0) Access: User read/write

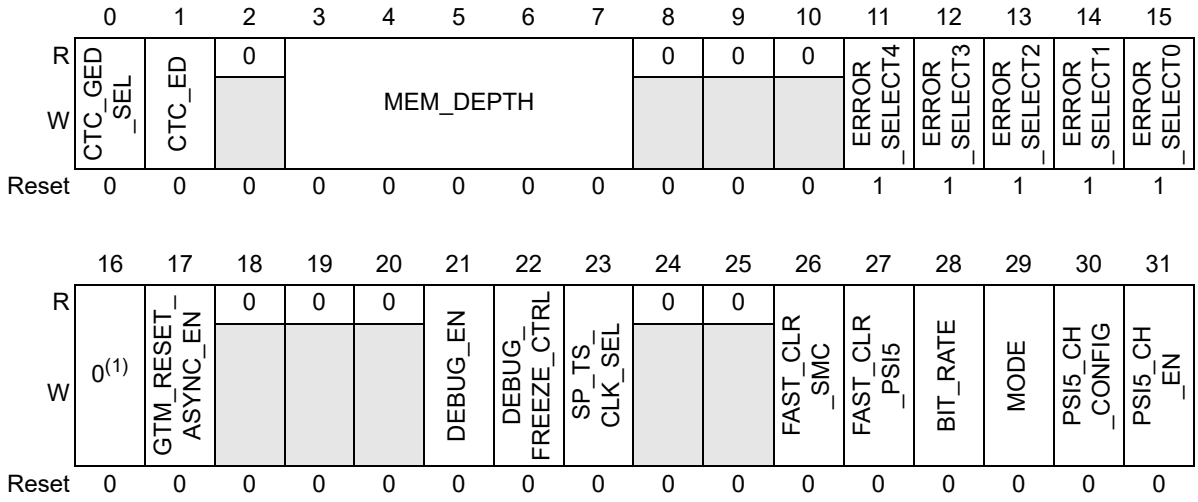

Figure 1443. PSI5 Channel Control Register (PSI5_CH0_PCCR)

1. This is a redundant bit and RW will not have any effect.

Table 1489. PSI5_CH0_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting. **Note:** This bit is writable in Normal mode and the Config mode.

Table 1489. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
3:7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access. Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0x00 Indicates that only 1 location of the memory is available for storage. 0x1F (31) Indicates that all the 32 locations of the memory are available for storage. **Note:** Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. For more details refer to description of DMA_PM_DS_CONFIG in the DCRs. The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the Manchester decoder. The memory area above the configured MEM_DEPTH size will always be read as 0. Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
11 ERROR_SELECT4	The ERROR_SELECT bitfield indicates which of the C, E, EM, T or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_SELECT2	Error_Select[2] or EM_INT_SEL 0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_SELECT1	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.

Table 1489. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
15 ERROR_SELECT0	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
17 GTM_RESET _ASYNC_EN	GTM_RESET_ASYNC_EN 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the GTM reset is synchronized on the "ipg_clk_psi5". This can delay the impact of the GTM reset by 1 to 2 system clock(ipg_clk_psi5). Refer to *Figure 1507* for the definition of "ipg_clk_psi5". 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the ipg_clk_psi5.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_FREEZE _CTRL	0 When the IP enters the Debug mode then it goes into the "Open" mode, that is, the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. **Note:** In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 When the IP enters the "Debug mode" then it goes into the "Freeze Mode". Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the "freeze mode", if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the "sdout" line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit. 0 The 1 MHz clock generated from the CGM goes for clocking the Time Stamp Unit and sync pulse generator. 1 The clock generated from the GTM goes for clocking the Time Stamp Unit and Sync Pulse Generator. **Note:** The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the CGM. The clock selected using this bit is called SP_TS_CLK.

Table 1489. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled. **Note:** This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c.

Table 1489. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
27 FAST_CLR_PSI5	This bit controls the clearing mechanism of bits in NDSR (in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR (in conf2 and conf3 modes). 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1) **Note:** This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: – In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. – In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. – In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresponding to a specific location are always cleared simultaneously. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. – In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/PMRL register. Hence the OWSR has to be cleared only by w1c. – In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. – Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c.

Table 1489. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
28 BIT_RATE	This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects one of the two driven clocks (4 MHz or 6.048 MHz) in CGM. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 189 Kbit/s bit rate selected (6.048 MHz clock).
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_CONFIG	PSI5 Channel Config mode request If this bit is set (and PCCR[PSI5_CH_EN] = ’1’) this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set cannot be changed until this bit is set again after entering the Disable mode 1 (If PCCR[PSI5_CH_EN] = ’1’ and GCR[GLOBAL_DISABLE_REQ] = ’0’) - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = ’1’ and GCR[GLOBAL_DISABLE_REQ] = ’0’) PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a “0” in the Normal mode will not change the operation mode of the device. **Note:** This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details refer to *Figure 1441* and to *Table 1485*. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. 0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode. **Note:** When PSI5_CH_EN == 0 then the clock enable for that particular channel that goes from the IP, goes to “0” (inactive state). “”The enable for the GTM Clock is not controlled by the IP and should be controlled externally. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.

56.3.2.3 DMA Control Register (PSI5_CH0_DCR)

Figure 1444 shows the DMA Control Register.

Address: 0x000C + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1444. DMA Control Register (PSI5_CH0_DCR)

Table 1490. PSI5_CH0_DCR field descriptions

Field	Description
3:7 DMA_PM _DS_WM	0–31 Valid Water Mark levels Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words is present. The default and minimum value of dma_pm_ds_wm is '0', that is, 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, that is, the actual watermark = 32 RAM locations. **Note:** These bits are ineffective if DMA_PM_DS_CONFIG = conf1. These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO, before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
13 IE_DMA_TF_SF	Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
14 IE_DMA_TF _PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
20 IE_DMA_PM_DS_ FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases that generate these FIFO FULL conditions, refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. **Note:** This bit is writable in Config and Normal modes.

Table 1490. PSI5_CH0_DCR field descriptions (continued)

Field	Description
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, that is, it is empty. Default value is 0. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
23 IE_DMA_PM _DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.

Table 1490. PSI5_CH0_DCR field descriptions (continued)

Field	Description
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30:31 DMA_PM_DS _CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. 00 **c**onf1 The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 conf2 After transferring the “dma_pm_ds_wm” number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 conf3 “dma_pm_ds_wm” number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 conf4 Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. **Note:** For more details refer to the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message that was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA.

56.3.2.4 DMA Status Register (PSI5_CH0_DSR)

Figure 1445 shows the DMA Status Register.

Address: 0x0010 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1445. DMA Status Register (PSI5_CH0_DSR)

Table 1491. PSI5_CH0_DSR field descriptions

Field	Description
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes. For the various configurations of this request refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.

Table 1491. PSI5_CH0_DSR field descriptions (continued)

Field	Description
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to the DMA request ipd_psi5_dma_req_pm_ds. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. conf1: FIFO FULL disabled conf2 and conf3: FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. conf4: FIFO FULL occurs when there is a “REGISTER FULL” in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. conf1: underflow disabled conf2 and conf3: Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). conf4: Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. 0 No underflow has occurred. 1 Underflow has occurred. The bits are cleared by a w1c.

56.3.2.5 General Interrupt Control Register (PSI5_CH0_GICR)

The General Interrupt Control Register (PSI5_GICR) contains the bits for controlling the SMC message related interrupts, interrupts related to ECU-to-sensor communication, and interrupts to the Time Stamp.

Address: 0x0014 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1446. General Interrupt Control Register (PSI5_CH0_GICR)

Table 1492. PSI5_CH0_GICR field descriptions

Field	Description
2:7 IE_CESM[6:1]	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.

Table 1492. PSI5_CH0_GICR field descriptions (continued)

Field	Description
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
18:23 IE_OWSM[6:1]	Interrupt request enable for the SMC message Overwrite bits. The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. **Note:** These bits are writable in Config and Normal modes.
26:31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5}, that is, during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

56.3.2.6 New Data Interrupt Control Register (PSI5_CH0_NDICR)

The New Data Interrupt Control Register (PSI5_NDICR) contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

Address: 0x0018 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1447. New Data Interrupt Control Register (PSI5_CH0_NDICR)

Table 1493. PSI5_CH0_NDICR field descriptions

Field	Description
0:31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

56.3.2.7 Overwrite Interrupt Control Register (PSI5_CH0_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

Address: 0x001C + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1449. Error Interrupt Control Register (PSI5_CH0_EICR)

Table 1495. PSI5_CH0_EICR field descriptions

Field	Description
0:31 IE_ERROR	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31]. This interrupt is generated only when the corresponding RAM buffer is Ready with new data. Which error condition (any of C, E, EM, T, or F) generates the interrupt is selectable by the PCCR[ERROR_SELECT] field. If all are selected, then which of C,E,EM,T or F is set can be isolated by reading the corresponding received message. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

56.3.2.9 General Interrupt Status Register (PSI5_CH0_GISR)

The General Interrupt Status Register (PSI5_GISR) contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Address: 0x0024 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1450. General Interrupt Status Register (PSI5_CH0_GISR)

Table 1496. PSI5_CH0_GISR field descriptions

Field	Description
0 IS_DEBUG_FREEZE	This flag is set to “1” when the IP enters the debug freeze mode. Refer to *Section 56.1.3.5: Debug mode* for details about the debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode 1 IP in debug freeze mode
2:7 IS_CESM[6:1]	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1 or by w1c.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.

Table 1496. PSI5_CH0_GISR field descriptions (continued)

Field	Description
13 DSR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When “0” it indicates that there is a ongoing command transmission of the data in DSR, or the CPU has done a “w1c” to this bit leading to the new command transmission. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, and PSI5_DOBCR[SW_READY] == 1, then it indicates to the IP that the data in DSR is valid and is to be used for command shifting. This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit refer to *Section 56.4.3.4: Data transmission*.
14 DBR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When “0” it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR. This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit refer to *Section 56.4.3.4: Data transmission*.
15 DPR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Preparation register is ready to receive new data from the system bus side. When “0” it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == “7” then this bit remains at value “0”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR. For detailed action of this bit refer to *Section 56.4.3.4: Data transmission*.
18:23 IS_OWSM[6:1]	Status for the SMC message overwrites bits. Each of the 6 locations corresponds to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are cleared automatically upon message read when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1 or by w1c.
26:31 IS_NVSM[6:1]	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are cleared automatically upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1 or by w1c.

1. For these register bits individual “bit setting” commands should not be used. Rather, the normal register read/write commands should be used.

56.3.2.10 DMA PSI5 Message Register (PSI5_CH0_DPMR)

Figure 1451 shows the DMA PSI5 Message Register.

Address: 0x0028 + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1451. DMA PSI5 Message Register (PSI5_CH0_DPMR)

Table 1497. PSI5_CH0_DPMR field descriptions

Field	Description
0:31 PSI5_RXDATA	PSI5_RXDATA[31:0] This popup register contains the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations, the DATA is pushed sequentially until all the data corresponding to the programmed watermark is complete, after which the DMA request is deasserted. The depth of the FIFO is 32 × 64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG = conf2 then it pops the PSI5 message, followed by NDSR, followed by EISR. When DMA_PM_DS_CONFIG = conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG = conf4, it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details refer to the *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 56.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, and *Section 56.3.2.4: DMA Status Register (PSI5_CH0_DSR)*.

56.3.2.11 DMA SMC Frame Register (PSI5_CH0_DSFR)

Figure 1452 shows the DMA SMC Frame Register.

Figure 1452. DMA SMC Frame Register (PSI5_CH0_DSFR)

Table 1498. PSI5_CH0_DSFR field descriptions

Field	Description
0:31 SMC_RXDATA	When the DMA_EN_SF = 1, then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted until all the registers that have pending data, have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location pointed to by the DMA read pointer.

56.3.2.12 DMA Diagnostic Status Register (PSI5_CH0_DDSR)

Figure 1453 shows the DMA Diagnostic Status Register.

Address: 0x0030 + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1453. DMA Diagnostic Status Register (PSI5_CH0_DDSR)

Table 1499. PSI5_CH0_DDSR field descriptions

Field	Description
0:31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details refer to the *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*,*Section 56.3.2.3: DMA Control Register (PSI5_CH0_DCR)* and *Section 56.3.2.4: DMA Status Register (PSI5_CH0_DSR)*.

Note: No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR or EISR directly) or the DMA (reading the DDSR successively).

56.3.2.13 PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

Figure 1454 shows the PSI5 Message Receive Register Low.

Address: 0x0034 + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1454. PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

Table 1500. PSI5_CH0_PMRRL field description

Field	Description
0:27 DATA_REGION	These are application-specific optional bits + data payload of received message. See *Section 56.4.2.1: Reception of data frames* for more details. The data is left-aligned, that is, Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 <= n <= 28). If n < 28 remaining bit positions are filled with '0's, that is, between last received bit and CRC field.
28:30 CRCP	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

56.3.2.14 PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

Figure 1455 shows the PSI5 Message Receive Register High.

Figure 1455. PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

Table 1501. PSI5_CH0_PMRRH field descriptions

Field	Description
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, that is, at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error, that is, frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5:7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. For asynchronous modes the slot counter has a fixed value of “1”. The six slots are numbered as Slot1, Slot2,....Slot6.
8:31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the *Section 56.3.2.27: Slot n Frame Configuration Register (PSI5_CH0_SnFCR)*. In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependent on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”. It is possible to reset the time stamp counter by asserting to “1” the “gtm_reset” signal from the GTM.

Note: Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occurred.

56.3.2.15 PSI5 Message Register Low *n* (PSI5_CH0_PMRL*n*)

Figure 1456 shows the PSI5 Message Register Low *n*.

Address: 0x003C + *i**0x1C0 (*i*=0) + *n**0x8 (*n*=0 to 31) Access: User read/write

Table 1502. PSI5_CH0_PMRL*n* field descriptions

Field	Description
0:27 DATA_REGION	These are application-specific optional bits + data payload of received message. See *Section 56.4.2.1: Reception of data frames*for more details. The data is left-aligned, that is, Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 <= n <= 28). If n < 28 remaining bit positions are filled with '0's, that is, between last received bit and CRC field. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
28:30 CRCP	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRCP[2] bits denotes the parity. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
31 C	This bit will be set if CRC/Parity recalculation return an Error.

56.3.2.16 PSI5 Message Register High *n* (PSI5_CH0_PMRH*n*)

Figure 1457 shows the PSI5 Message Register High *n*.

Address: 0x0040 + *i**0x1C0 (*i*=0) + *n**0x8 (*n*=0 to 31) Access: User read/write

Figure 1457. PSI5 Message Register High *n* (PSI5_CH0_PMRH*n*)

Table 1503. PSI5_CH0_PMRH*n* field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error). In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0, M1), that is, at least one bit is absent during the Tbit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
3 E	This Bit Indicates Electrical Error, that is, at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
4 T	This bit indicates timing error, that is, frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

Table 1503. PSI5_CH0_PMRH*n* field descriptions (continued)

Field	Description
5:7 Slot_Counter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of “1”. **Note:** The six slots are numbered as Slot1, Slot2,...., Slot6.In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
8:31 Time_Stamp _Value	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the *Section 56.3.2.27: Slot n Frame Configuration Register (PSI5_CH0_SnFCR)*. In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependent on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”. It is possible to reset the time stamp counter by asserting to “1” the “gtm_reset” signal from the GTM.In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

56.3.2.17 SMC Frame Register *n* (PSI5_CH0_SFR*n*)

Figure 1458 shows the SMC Frame Register *n*.

Address: 0x013C + *i**0x1C0 (*i*=0) + (*n*-1)*0x4 (*n*=1 to 6) Access: User read/write

Figure 1458. SMC Frame Register *n* (PSI5_CH0_SFR*n*)

Table 1504. PSI5_CH0_SFR*n* field descriptions

Field	Description
0:2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
3 CER	CRC Error 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message. **Note:** If the corresponding SOWSM bits in the SSESR have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set.
5:10 CRC	6-bit CRC for slow serial message **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
11 C	Configuration bit 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
12:15 ID	Message ID: If C = ’0’ indicates ID[7:4], if C = ’1’ indicates ID[3:0]. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
16:19 IDDATA	Message ID/DATA: If C = ’0’ indicates ID[3:0], if C = ’1’ indicates DATA[15:12]. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
20:31 DATA[11:0]	DATA payload **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

Note: Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

56.3.2.18 New Data Status Register (PSI5_CH0_NDSR)

Figure 1459 shows the New Data Status Register.

Figure 1465. Set SMC Error Status Register (PSI5_CH0_SSESR)

Table 1511. PSI5_CH0_SSESR field descriptions

Field	Description
2:7 SCESM[6:1]	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** These bits are writable in Config and Normal modes.
18:23 SOWSM[6:1]	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** These bits are writable in Config and Normal modes.
26:31 SNVSM[6:1]	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** This bit is writable in Config and Normal modes.

56.3.2.25 Sync Time Stamp Read Register (PSI5_CH0_STSRR)

Figure 1467. Data Time Stamp Read Register (PSI5_CH0_DTSRR)

Table 1513. PSI5_CH0_DTSRR field descriptions

Field	Description
5:7 SLOT_COUNTER	3-bit Slot Counter, which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode, the slot counter has a fixed value of “1”.
8:31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected, the value of the Time Stamp counter captured at the rising edge of the S0 is stored in this register at the rising edge of S1.

Note: If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter, both will correspond to the first slot (S0)

56.3.2.27 Slot *n* Frame Configuration Register (PSI5_CH0_S*n*FCR)

Figure 1469. Slot *n* Start Boundary Register (PSI5_CH0_S*n*SBR)

Table 1515. PSI5_CH0_S*n*SBR field descriptions

Field	Description
1:15 S*n*SBT	Slot *n* Start Boundary Time This field specifies the time in intervals of 1 µs, occurring after the *rising edge* of the timing sync pulse, at which the slot *n* should start. n = 1 to 6 dedicated for each of the six slots.

56.3.2.29 Slot *n* End Boundary Register (PSI5_CH0_SNEBR)

Figure 1469 shows the Slot *n* Start Boundary Register (PSI5_S*n*SBR).

Slot n End Boundary register is a single register, which can be programmed to define the “end” of the nth slot. The n can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR+, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SNEBR (Slot n End Boundary register) defines the end of the nth slot. The n is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SNEBR. The SNEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the S*n*FCR. When the start slot boundaries are properly defined in the SnSBR (Slot *n* Start Boundary Register) register but the slot_en bit = 0 in the corresponding S*n*FCR (Slot *n* Frame Configuration register) register, then the corresponding slot is treated as “available” but “unconfigured.” For such a slot the data/diagnostic bits all remain 0*. The “T” bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots.* Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if “S0” and “S1” are detected in different slots then a T-bit error is set.

Figure 1470. Slot *n* End Boundary Register (PSI5_CH0_SNEBR)

Table 1516. PSI5_CH0_SNEBR field descriptions

Field	Description
13:15 SLOT_NO	The field indicates the Slot number{1–6} for which Slot End Boundary Time is defined. Any value other than 1–6 is defaulted to 0. A value 0 here would mean that the Manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
17:31 SNEBT	Slot *n* End Boundary Time This field specifies the time in intervals of 1 µs, occurring after the rising edge of timing sync pulse, at which the slot *n* should end.

Note: The start slot boundaries in the SnSBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SNEBR are treated as being unavailable (that is, the data in all the slots occurring after the SNEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the SNEBR and define the end boundary of the third slot in SNEBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the SNEBR by putting slot_no = 6 and define the end boundary of the sixth slot in SNEBR.

56.3.2.30 Data Output Block Configuration Register (PSI5_CH0_DOBCR)

Figure 1471 shows the Data Output Block Configuration Register.

Address: 0x01A0 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W							DBR_RST	DSR_RST								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1471. Data Output Block Configuration Register (PSI5_CH0_DOBCR)

Table 1517. PSI5_CH0_DOBCR field descriptions

Field	Description
0-5 DATA_LENGTH	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard), then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0 then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH=1 then the length of the command that can be written to DSR and the DBR is 2 and so on until a maximum of 64-bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits, that shift out of DSR register once the DSR_RDY goes low. After these many shifts have happened, then the value corresponding to “DEFAULT_SYNC” starts getting shifted out and DSR_RDY goes as “1”.
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as “1” then the contents of the DBR are reset to all “0s” (if DEFAULT_SYNC= = 0) or all “1s” (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a “0” (w1s). Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register.When this bit is written as “1” then the contents of the DSR are reset to all “0s” (if DEFAULT_SYNC= = 0) or all “1s” (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data.Reading this bit would always return a “0” (w1s). Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
8-10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. *Table 1518* is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to “0” then the default value of DSR and DBR registers are all “0s”; when this bit is set to 1 then the default value of DBR and DSR registers are all “1s”. This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 1 GTM event shift triggered 0 Internal sync pulse generator shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 1 SP module directly gets input from the GTM_event/internal sync pulse generator 0 SP module gets the data from the DSR

Table 1517. PSI5_CH0_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects the driving source of the "ipp_do_psi5_sdout" port. 0 The sync pulse generator select as per the PSI5_DOBCR[GTM_TRIG_SEL] 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending. Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1, will the transfer happen. This bit can be written in CONFIG and the Normal modes.

Table 1518. CMD_TYPE details

CMD_TYPE	PSI5 Frame	Effect on registers	Writable Register lengths
"000" - 0	Short Frame with 31 "1s" as the start condition(1)	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15 bits(2) in DBR/DSR.
"001" - 1	Short Frame with 5 "0s" as the start condition(1)	-do-	-do-
"010" - 2	Long Frame with 31 "1s" as the start condition(1)	-do-	16 bits in DPR. 29 bits(2) in DBR/DSR.
"011" - 3	Long Frame with 5 "0s" as the start condition(1)	-do-	-do-
"100" - 4	X-Long Frame with 31 "1s" as the start condition(1)	-do-	22 bits in DPR. 37 bits(2) in DBR/DSR
"101" - 5	X-Long Frame with 5 "0s" as the start condition(1).	-do-	-do-
"110" - 6	XX-Long	-do-	24 bits in DPR. 43 bits(2) in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCR[DATA_LENGTH] field.

1. The start condition (31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command; neither is this visible in any register.
2. This is also the length of the command, that will be shifted out during the ECU to Sensor communication, irrespective of how many "actual" number of bits are written to DBR/DSR.

Table 1519. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1(1)	0	1	1
State2(1)	0	0	1
State3(1)	1	1	1
State4(1)	1	0	1
State5(1)	1	x	0

1. These states are shown in *Section 56.8.2: Valid states for integrated sync pulse generator*. In State5 the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

Note: Refer to Figure 1505 for the details about the above bits.

56.3.2.31 Manchester Decoder Disable Offset Register (PSI5_CH0_MDDIS_OFF)

The Manchester decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 µs, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 µs to 128 µs. This works on the 1 µs clock from the CGM.

Address: 0x01A2 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	MDDIS_OFF						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1472. Manchester Decoder Disable Offset Register (PSI5_CH0_MDDIS_OFF)

Table 1520. PSI5_CH0_MDDIS_OFF field descriptions

Field	Description
9:15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the Manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse. Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester decoder BEYOND the Sync Pulse High Time as well. *Figure 1510* shows the "MDDIS_OFF" definition.

56.3.2.32 Pulse Width for Data Bit 0 Register (PSI5_CH0_PW0D)

Figure 1473 shows the Pulse Width for Data Bit 0 Register.

Address: 0x01A4 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1473. PSI5_Pulse Width for Data Bit 0 Register (PSI5_CH0_PW0D)

Table 1521. PSI5_CH0_PW0D field descriptions

Field	Description
9:15 Pulse_Width0	This defines the width (in µs) of data value ’0’ to be sent from Data Output Register. It is the number of clock cycles (1µs clock) counted up to width “Pulse_Width0”; starting as soon as trigger appears from the ISPG (Internal Sync Pulse Generator) or the GTM. Can take max value of 127. When, intending to use the” tooth gap method” of PSI5 command transmission, the Pulse_Width0 should be configured to 0. *Figure 1510* shows the definition of “Pulse_Width0”.

56.3.2.33 Pulse Width for Data Bit 1 Register (PSI5_CH0_PW1D)

Figure 1474 shows the Pulse Width for Data Bit 1 Register.

Address: 0x01A6 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	Pulse_Width1						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1474. PSI5_Pulse Width for Data Bit 1 Register (PSI5_CH0_PW1D)

Table 1522. PSI5_CH0_PW1D field descriptions

Field	Description
9:15 Pulse_Width1	This defines the width (in µs) of data value ’1’ to be sent from Data Output Register. It is the number of clock cycles (1µs clock) counted up to width “Pulse_Width1”; starting as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM. Can take max value of 127. *Figure 1510* shows the definition of “Pulse_Width1”.

Note: When using the “tooth gap method” of PSI5 command transmission, the pulse width is NOT disabled. In this case, PSI5_PW0D has to be programmed as 0. PSI5_PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

56.3.2.34 Counter Target Pulse Register (PSI5_CH0_CTPR)

Figure 1475 shows the Counter Target Pulse Register.

Address: 0x01A8 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1475. Counter Target Pulse Register (PSI5_CH0_CTPR)

Table 1523. PSI5_CH0_CH0_CTPR field descriptions

Field	Description
0:15 CTPR	Counter Target Pulse Register This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16-bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the time period of the internally generated sync pulses. The un-modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles, that is, the duty cycle of the un-modulated internally generated sync pulses is (4/|CTPR| *100). The 4 sp_ts_clk cycles is just the nascent value of the pulse that, actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in *Section 56.8.2: Valid states for integrated sync pulse generator*. This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length, which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

Note: Refer to Section 56.8.1 for details about the Sync Pulse generation and coordination.

56.3.2.35 Counter Initialize Pulse Register (PSI5_CH0_CIPR)

Figure 1476 shows the Counter Initialize Pulse Register.

Address: 0x01AA + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	CIPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1476. Counter Initialize Pulse Register (PSI5_CH0_CIPR)

Table 1524. PSI5_CH0_CIPR field descriptions

Field	Description
0:15 CIPR	Counter initialization pulse register This is the value at which the CTC gets reset the first time, after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be |CIPR_channel1 - CIPR_channel2| sp_ts_clk cycles. Thus if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

Note: The CIPR resolution is in terms of the time period of the "sp_ts_clk" ($T_{sp_ts_clk}$). Therefore the total "CIPR" time is "CIPR$T_{sp_ts_clk}$", beginning from when the CIPR counters are enabled using the sync pulse trigger bits(PSI5_PCCR[CTC_ED] or PSI5_GCR[CTC_GED]). Due to internal Flop synchronization, this time would not exactly be CIPR*$T_{sp_ts_clk}$ but would have an inaccuracy of $1T_{sp_ts_clk}$. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy.*
The CTPR resolution is also in terms of the "sp_ts_clk". Therefore the total "CTPR" time is "CTPR$T_{sp_ts_clk}$". However when measured on the "sdout" pin of the IP this time would not exactly be "CTPR*$T_{sp_ts_clk}$". Due to internal Flop synchronization on the 1Mhz clock, an in accuracy of "1µs" would be added. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy. Hence the "CTPR" period measured on the "sdout" pin, can range from (CTPR*$T_{sp_ts_clk}$) -1µs -$T_{ipg_clk_psi5}$ to (CTPR*$T_{sp_ts_clk}$) +1µs + $T_{ipg_clk_psi5}$. Refer to Figure 1510 for more details about this inaccuracy.*

Refer to Section 56.8.1 for details about the Sync Pulse generation and coordination.

56.3.2.36 Data Preparation Register Low (PSI5_CH0_DPRL)

Figure 1477 shows the Data Preparation Register Low.

Address: 0x01AC + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1477. Data Preparation Register Low (PSI5_CH0_DPRL)

Table 1525. PSI5_CH0_DPRL field descriptions

Field	Description
8:31 DPR	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length, standard ECU-to-Sensor commands, comprising of the address, data and other fields. Note that the IP is transparent to the arrangement of the address, data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writable only when using the standard length PSI5 frames. For details about CRC calculation refer to *Section 56.4.3.4: Data transmission*. The writable bits in this register are governed by the PSI5_DOBCR[CMD_TYPE] bit fields as per *Table 1526*. Note that the unwritable bits in this register field are always read as “0s”. This register has to be written by the CPU.These bits can be written only in the Normal mode.

Table 1526. DPR details

PSI5_DOBCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writable bits in PSI5_DPRL
“0” or “1”	Short Frame	6(DPR[5:0])
“2” or “3”	Long Frame	16(DPR[15:0])
“4” or “5”	X-Long Frame	22(DPR[21:0])
“6”	XX-Long Frame	24(DPR[23:0])
“7”	Not Available for write	Not Available for write

Note: This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when PSI5_GISR[DPR_RDY] == 1. Whenever PSI5_GISR[DPR_RDY] == 1, then each bit of this register defaults to 0. Writing to this register when PSI5_GISR[DPR_RDY] == 0 will cause the PSI5_GISR[IS_PROW] status bit to be set and the generation of an error interrupt, if it is enabled. Further, trying to write to this register when PSI5_DOBCR[CMD_TYPE] = “7” results in the setting of the PSI5_GISR[IS_PROW] bit and the resulting write is rejected.

56.3.2.37 Data Preparation Register High (PSI5_CH0_DPRH)

Address: 0x01B0 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1479. Data Buffer Register Low (PSI5_CH0_DBRL)

Table 1528. PSI5_CH0_DBRL field descriptions

Field	Description
0:31 DBR	This register contains the Lower 32 bits(DBR[31:0]) of the max-64 bit length command (DBR[63:0]). The higher bits, DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU (when PSI5_GISR[DBR_RDY] == 1 in the Normal mode). Hardware update occurs when PSI5_GISR[DPR_RDY]== 0 and PSI5_GISR[DBR_RDY] == 1. It cannot be written in Config mode. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in *Table 1529*. The tables (except when PSI5_DOBCR[CMD_TYPE] = “7”) show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == “7”), then only the CPU can write to these registers.

Table 1529. DBRL[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
“7” (Non Standard Length)	DBR[31:0]]	Variable length of writable bits, as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]
“6”(XX Long)	DBR[31:30]	DPR[19:18]

	DBR[7]	1'b1(stuff)
	DBR[6:4]	DPR[2:0]
	DBR[3]	1'b1(stuff)
	DBR[2:0]	"010"(start seq)

This register is CPU writable only in Normal mode.

Note: When DEFAULT_SYNC == 0 then default value of this register is 00000000. When DEFAULT_SYNC== 1 then the default value of this register is FFFFFFFF.Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

56.3.2.39 Data Buffer Register High (PSI5_CH0_DBRH)

Figure 1480 shows the Data Buffer Register High.

Address: 0x01B8 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1480. Data Buffer Register High (PSI5_CH0_DBRH)

Table 1530. PSI5_CH0_DBRH field descriptions

Field	Description
0:31 DBR	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU (when PSI5_GISR[DBR_RDY] == 1 in the Normal mode). Hardware update occurs when PSI5_GISR[DPR_RDY]== 0 and PSI5_GISR[DBR_RDY] == 1. It cannot be written in Config mode. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as described in the below tables. Note that when PSI5_DOBCR[CMD_TYPE] == “7”), then only the CPU can write to these registers.

Table 1531. DBRH[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
“7” - Non Standard Frame lengths	DBR[63:32]]	Variable length of writable bits, as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]
“6” - XX Long	DBR[63:43]	All 0s
	DBR[42:37]	{CRC[5],CRC[4],CRC[3],CRC[2],CRC[1],CRC[0]}
	DBR[36]	1’b0(stuff)
	DBR[32:35]	DPR[23:20]

Table 1531. DBRH[DBR] details (continued)

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
"4" or "5" -X Long	DBR[63:37]	All 0s
	DBR[36]	CRC[0]
	DBR[35]	1'b1((stuff)
	DBR[34:32]	{CRC[1],CRC[2],DPR[21]}
"3" or "2"(Long) OR "1" or "0" (Short)	DBR[63:32]	All 0s

This register is CPU writable only in Normal mode.

Note: When DEFAULT_SYNC == 0 then the default value of this register is 00000000. When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY]== 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

56.3.2.40 Data Shift Register Low (PSI5_CH0_DSRL)

Figure 1481 shows the Data Shift Register Low. This register is CPU writable only in Normal mode.

Address: 0x01BC + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DSR

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1481. Data Shift Register Low (PSI5_CH0_DSRL)

Table 1532. PSI5_CH0_DSRL field descriptions

Field	Description
0:31 DSR	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[*CMD_TYPE*] register bits.When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRL. Thus when updated by the hardware, then DSR[31:0] = DBR[31:0]. Hardware update occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the update of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode, when PSI5_GISR[DSR_RDY] == 1'b1. It cannot be written in Config mode.

This register is CPU writable only in Normal mode.

Note: When DEFAULT_SYNC == 0 then default value of this register is 00000000. When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addition to PSI5_GISR[DSR_RDY] == 1.

56.3.2.41 Data Shift Register High (PSI5_CH0_DSRH)

Figure 1482 shows the Data Shift Register High.

Address: 0x01C0 + *i**0x1C0 (*i*=0) Access: User read/write

Field	Description
0:31 DSR	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[*CMD_TYPE*] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRH. Thus when updated by the hardware, then DSR[63:32]] = DBR[63:32]. Hardware update occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the update of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode, when PSI5_GISR[DSR_RDY] == 1'b1. It cannot be written in Config mode.

This register is writable only in Normal mode.

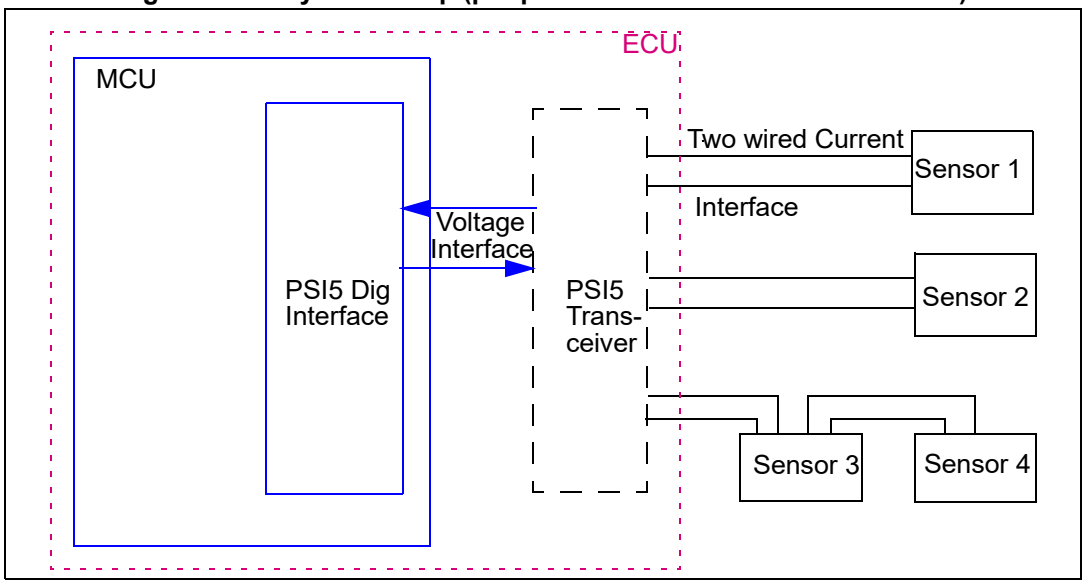
Note: When DEFAULT_SYNC == 0 then the default value of this register is 00000000. When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addition to PSI5_GISR[DSR_RDY] == 1.

56.3.2.42 Device modes and Register bit accesses

1. The following bits are writable in all modes (Normal, Config, and Disable).
   - GCR[GLOBAL_DISABLE_REQ]
   - PCCR[PSI5_CH_CONFIG]
   - PCCR[PSI5_CH_EN]
   - Global Counter Enable/Disable (GCR[CTC_GED]). This is to allow the Sync Pulse Generator to be enabled/disabled independently among those channels that are used for staggering, irrespective of the state of the channels NOT being used for staggering.
2. The following register is writable only in Normal mode and is initialized to all 0s.
   - DPRL
3. The following registers are writable ONLY in Normal mode. Initial is at ion in Config mode depends on the value of PSI5_DOBCR[DEFAULT_SYNC] bit.When PSI5_DOBCR[DEFAULT_SYNC] == 1 in Config mode, then the below registers are initialized to all 1s in Normal mode. When PSI5_DOBCR[DEFAULT_SYNC] = 0 in Config mode, then the below registers are initialized to all 0s in Normal mode. Once in

Normal mode, these registers can then be programmed for any command that needs to be sent.



- DBRH/DBRL
- DSRH/DSRL

4. The following registers are writable in Config and Normal modes only:
   - All interrupt control registers
   - All SET registers (the one shot registers that are used to set the error flags for software drivers)
   - Channel Enable/Disable (PCCR[CTC_ED]). Using this it is possible to allow the Sync Pulse Generator to be enabled/disabled in Normal mode. The counter is reset when CTC_ED == 0
   - All w1c bits
5. Apart from these, all other register bits can be written only in Config mode, including the Data registers (PMRH/PMRL/SFRn), that, in Normal mode, are updated by the hardware only.
6. Debug mode: If the device is in Normal mode and the debug mode is enabled, then ONLY the registers in *Section 1.*,*Section 2.*,*Section 3.*,*Section 4.* of *Section 56.3.2.42: Device modes and Register bit accesses*: can be written by the debugger. Register in *Section 5.* of *Section 56.3.2.42: Device modes and Register bit accesses* will not be available for write through the debugger. In case the debugger has to change any register, then the device has to be brought in the Disable → Config mode. The debugger can, however, read any register in any mode.

56.4 Functional description

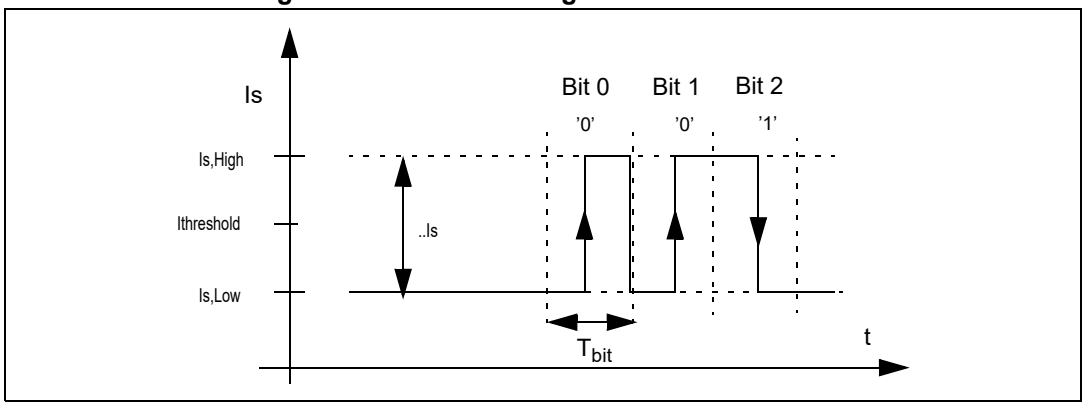
The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. *Figure 1483* shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1483. System setup (peripheral sensor connected to device)

ECU (Electronic Control Unit) is comprised of PSI5 digital interface and the PSI5 transceiver (present externally).

56.4.1 Sensor-to-ECU communication

56.4.1.1 Physical layer



The PSI5 uses two wires to provide both power supply and data transmission to the sensors. The ECU provides a pre-regulated voltage to the sensors. Data transmission from the sensor to the ECU is done by current modulation on the power supply lines. Current oscillations are damped by the ECU.

56.4.1.2 Bit encoding

A “low” level ($I_{S,Low}$) is represented by the Normal (quiescent) current consumption of the sensor(s). A “high” level ($I_{S,High}$) is generated by an increased current sink of the sensor ($I_{S,Low}$ + ...I_S). The current modulation is detected within the PSI5 transceiver.

Manchester coding is used for data transmission. A logic 0 is represented by a rising slope and a logic 1 by a falling slope of the current in the middle of T bit.

Figure 1484. Bit encoding of data from sensor

56.4.1.3 Synchronization

For synchronized operation and bus mode, a sync pulse is generated by the PSI5 receiver. The sync pulse is output from the integrated PSI5 receiver to an external PSI5 transceiver that processes these pulses to a pre-regulated voltage level on supply lines to sensors. The voltage change is detected within the sensors.

56.4.2 Data Link Layer

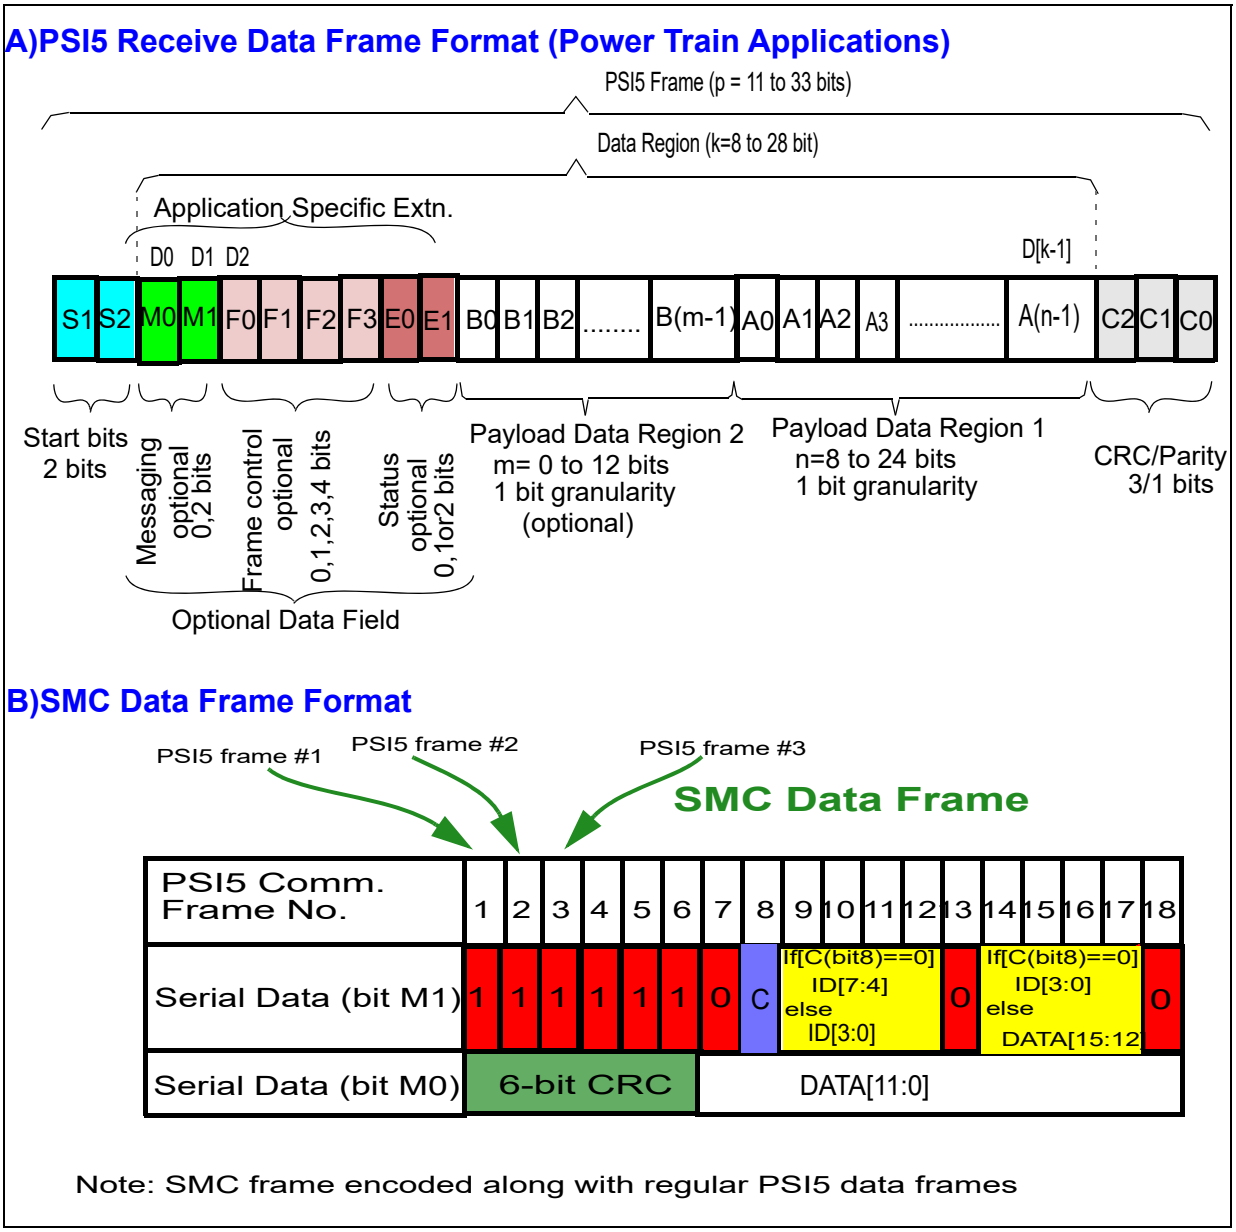
The PSI5 message is received as serial Manchester-coded bits. The bit stream is passed through a Manchester decoder stage that converts it to normal NRZ format bit by bit and stores it serially in the receive register (64 bits). This block clearly identifies start (00) and end of receive frame using preprogrammed frame configuration registers.

- The Manchester-coded bits can be received at the rate of 125 Kbit/s or 189 Kbit/s (selectable by programming frame configuration registers).
- The Manchester decoder is designed to consider data with duty cycle of 30–70%.
- The bit decoding is done using an oversampling and counting algorithm with majority voting and edge recognition. (125/189 kHz) × 32, that is, (4/6.048 MHz also referred as 32× clock) clocks are supplied from a common clock generator (to be implemented in CGM) module. This clock is used for oversampling of the receive bit and thereby decoding it as normal 1 or 0 (NRZ).
- The Manchester decoder is masked (switched off) for the duration when the sync pulse is transmitted. In addition to this, it can be configured to be off for an additional time, after the falling edge of the sync pulse. The duration of this time is configurable in the MDDIS_OFF register. It uses a 2oo3 voter to recognize the encoded half bits.
- There is a 3oo5 majority voting glitch filter at the data input of the Manchester decoder.

56.4.2.1 Reception of data frames

The extended PSI5 (Power Train Applications) receive data frame consists of *p* bits containing:

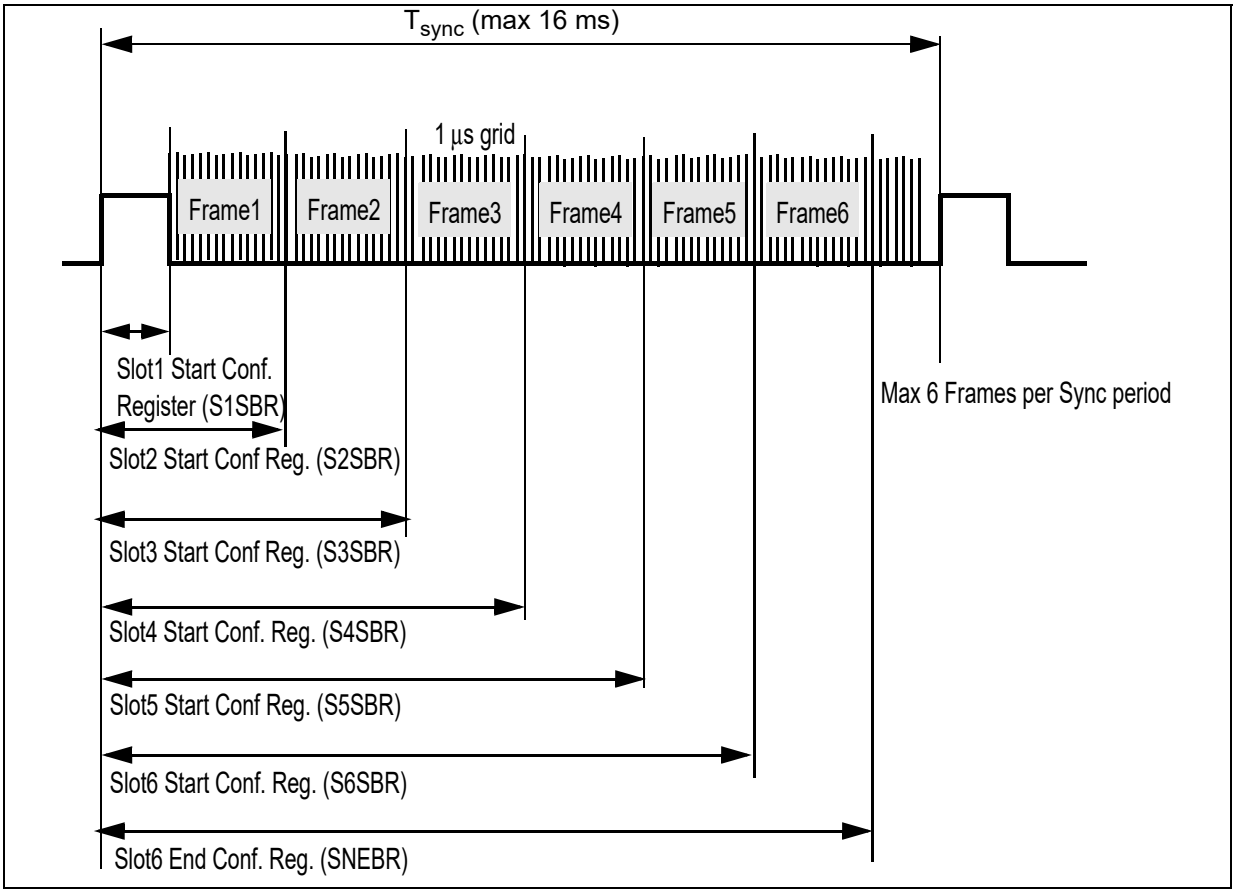
- Two start bits (S1 and S2) {S1=0, S2=0}.
- One parity bit (P) with even parity (or 3 CRC bits C0, C1, and C2).
- A data region (D0.....D[*k* – 1]) with *k* = 8 to 28 bits with 1-bit granularity.
- The total length of a PSI5 frame is p = *k* + 3 data bits (in case of frames with parity bit) or p = *k* + 5 data bits (in case of frames with CRC).
- Data bits are received LSB first. The parity or CRC check bits cover the bits of the entire data region.



The length of the data region can vary between *k* = 8 to 28 bits (with 1-bit granularity). The data region can be split into the following fields and regions:

- The bits D0 and D1 can optionally represent Serial Messaging Channel M0, M1.
  - This Serial Messaging Channel (SMC) is used to receive initialization data during fast startup phase or slow acknowledgment/response messages (to command transmitted from ECU requesting data or diagnostic information from the sensor).

Note that the maximum length of the entire data region is 28 bits. Thus the signal payload region and the optional data fields cannot concurrently be used at their maximum length in some cases.



As the PSI5 module is targeted for powertrain applications, the data frame format differs from standard PSI5 frames for safety applications specified in version 1.3 of the PSI5 specifications. More specifically for supporting the version 2.0 powertrain substandard. The Powertrain data frame format and optional Serial Messaging Channel (SMC) frame format are shown in *Figure 1485*.

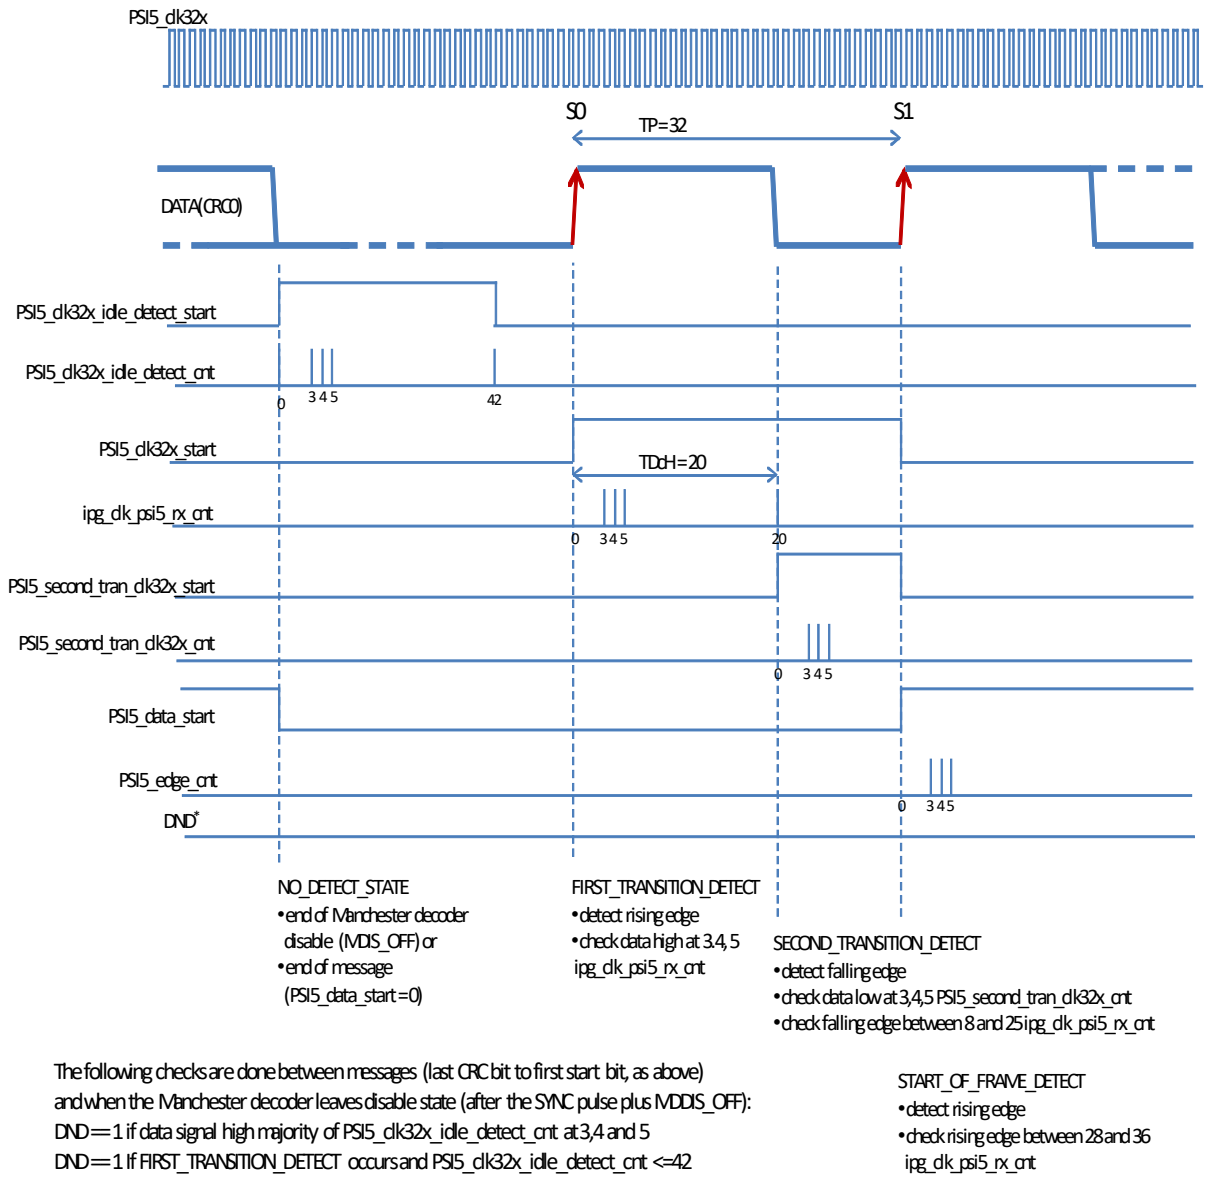
Figure 1485. Receive data frame format

56.4.2.2 Data Frame Configuration control

Figure 1486. Data frame configuration and sampling

At the receive path, as many as six frame slots (reception windows) can be programmed with a start time of consecutive slots (slot1 to slot6) and end time or last slot, which can be configured through the Slot *n* Start/End Configuration Registers (*Section 56.3.2.28: Slot n Start Boundary Register (PSI5_CH0_SnSBR)* and *Section 56.3.2.29: Slot n End Boundary Register (PSI5_CH0_SNEBR)*) there are seven registers for six slots. The slot time value is with respect to timing sync pulse.

The following range is always maintained for T_{sync} (during programming of the GCR and CTPR registers) when timing (sync) pulses are generated through the Sync Pulse Generator.



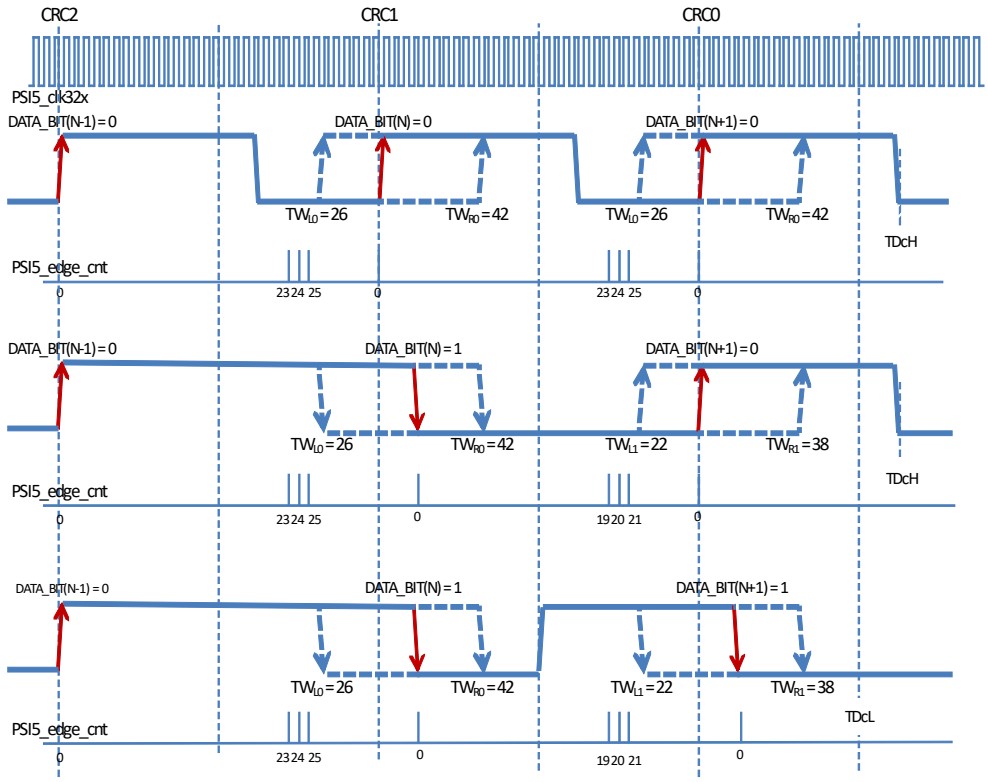
Equation 85 T_{sync} < 16 ms

For the maximum defined six frame slots, six frame configuration registers (S1FCR, S2FCR, S3FCR, S4FCR, S5FCR, and S6FCR) are also available. In these registers it is possible to configure the payload region of the expected frames, in addition to other channel-specific parameters.

56.4.2.3 Data frame handling

Figure 1487 shows the detection of the start bits and the various parameters for the same.

Figure 1487. Start bit detection



(*) If DND is set to ‘1’ because a message has overlapped with the Manchester decoder disable phase, then the Manchester decoder disable phase will be extended till the end of the first configured slot. DND will be cleared to ‘0’ at the end of this first slot and NO_DETECT_STATE will be entered immediately. No idle detection will be carried out (that is PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of slot2 will be captured.

If DND is set to ‘1’ because a first message (MSGn) has overlapped with a second message (MSGn+1), then MSGn+1 will be ignored, that is the Manchester decoder will be disabled until the end of the slot in which MSGn+1 was expected. This will be the case whether the first transition detection of MSGn+1 occurs in the expected slot of MSGn or MSGn+1. At the end of the slot in which MSGn+1 was expected, DND will be cleared to ‘0’ and NO_DETECT_STATE will be entered immediately. No idle detection will be carried out (that is PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of the slot in which the next message (MSGn+2) is expected will be captured.

Figure 1488 shows how the bits are differentiated into a “1” or a “0” based on the various margins and sample points.

Figure 1488. Bit extraction

Start Sequence Measured: Tp = 32 and TDcH = 20
Calculations:
TDcL = Tp – TDcH == 12; DeltaDC = TDcH – Tp/2 == 4; TMarginL = TDcL/2 == 6; TMarginH = TDcH/2 == 10
If DATA_BIT(N) = 0, TWI = TDcH + TMarginL == 26; signal sampled at TWI -3, -2 and -1
- if signal low, expect rising edge between TWL0 and TWR0 then DATA_BIT(N+1) == 0. TWL0 = TDcH+TMarginL, TWR0 = Tp + TMarginH.
- if signal high. expect falling edge between TWL0 and TWR0 then DATA_BIT(N+1) == 1. TWL0 = TDcH+TMarginL, TWR0 = Tp + DeltaDC + TMarginL.

If DATA_BIT(N) = 1, TWI = TDcL + TMarginH == 22; signal sampled at TWI -3, -2 and -1
- if signal low, expect rising edge between TWL1 and TWR1 then DATA_BIT(N+1) == 0. TWL1 = TDcL+TMarginH, TWR1 = Tp - DeltaDC + TMarginH.
- if signal high. expect falling edge between TWL1 and TWR1 then DATA_BIT(N+1) == 1. TWL1 = TDcL+TMarginH, TWR1 = Tp + TMarginL.

PSI5_edge_cnt will be stopped (PSI5_data_start low) at TDcH if CRC0 is logic 0 or TDcL if CRC0 is logic 1.

56.4.2.3.1 Start of frame recognition

The start of frame recognition is as follows:

- With the Manchester decoder in NO_DETECT state, the first rising edge of the incoming data signal is captured and assumed to be the midpoint transition of the first start bit S0.
- As soon as the first rising edge (S0) on the bus is recognized, the 24-bit time stamp value is captured internally. On the rising edge of the S1 this value is stored in the data

receive register and available for processing. If a valid S1 edge is NOT recognized then this time stamp value is discarded and not stored in any register.

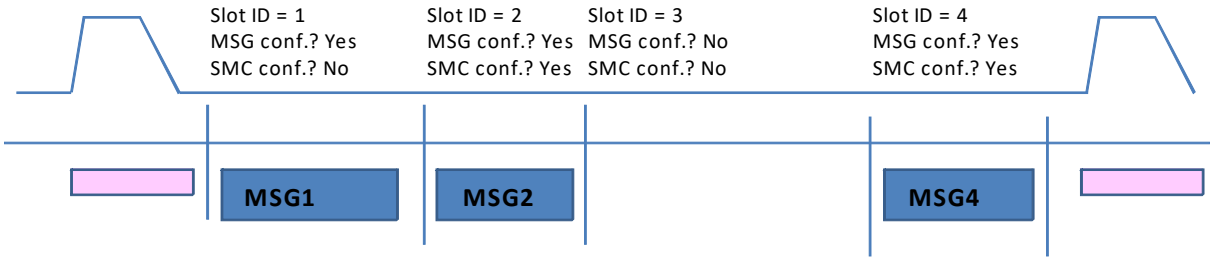
- The middle transition from the first start bit S0 to the second start bit S1 is assumed to be the bit duration for the rest of the bits.
- The time of the high period is measured using the 32x sample clock to enable analysis of the data signal duty cycle. The measured value is used in the data state to calculate the appropriate sample time of the first half-bit of the following data bits
- The second rising edge of the incoming data (S1) is captured and assumed to be the mid-point transition from the second start bit S1 if it appears in the allowed range of samples of the 32x sample clock.
- The time between the first and second rising edge is measured using the 32x sample clock to enable analysis of the sensor clock tolerance. The measured value is used together with the calculated duty cycle to set the window for capturing the mid-point bit transition the following data bits.
- *Figure 1487* and *Figure 1488* show the start bit and the data bit extraction mechanisms respectively, in the Manchester decoder.

56.4.2.3.2 Data state

In the data state, the Manchester decoder samples the number of data bits corresponding to the configured length of the data payload region and 3-bit CRC or 1-bit parity.

56.4.2.3.3 Message diagnostic checks

During the data state, electrical correctness of each bit in regard of Manchester encoding is checked. If an incorrect bit is detected, a 0 is written into the data payload region. Following completion of reception, correctness of the entire message is checked with the CRC and timing of the message reception.



- CRC is recalculated for the data and compared with received CRC bits. The CRC comparison result is stored as a status bit, denoted as the C field in the receive register and the RAM register. Irrespective of the value of the “C” bit the, the frame is always stored in the RAM register and is never discarded.
- If at least one bit is electrically faulty (apart from M0M1), then the bit field E is set to 1 and stored as status bit in the receive register and the RAM register.
- The EM bit is set to 1 if any of M0 or M1 bits are electrically faulty. Note that the E and the EM bits can be set only when a valid start sequence has been detected.
- Set status bit field T in the receive register to 1 if the frame received is in the wrong slot (boundary violations). This bit is NOT set for asynchronous modes.
- Set status bit F if no frame is received in defined frame slot. This bit is NOT set for asynchronous modes.
- The incoming frames after the sync pulse are to be numbered from 1 to 6 (max). This is done by a 3-bit slot counter, which is incremented automatically after the end of each slot irrespective of whether a valid message is received or not. This 3-bit value is stored in the receive register and the RAM registers as the “slot_counter” field.

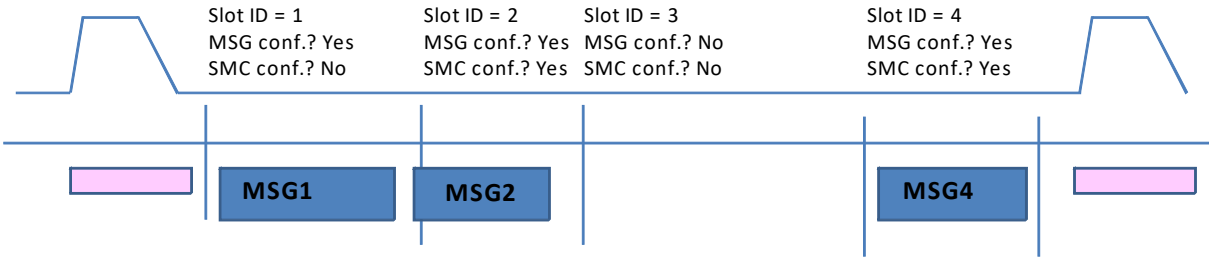
  T-bit Handling

The following paragraphs describe how the IP handles error cases that generate T bit errors. A number of examples are shown, including the error free case, which is used to explain the reception process.

56.4.2.3.3.1 Error free case

Figure 1489. Error free case

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1



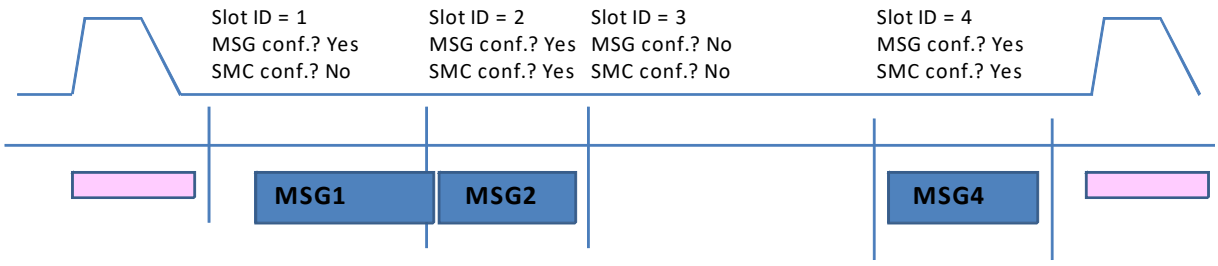
In this case, all messages are received in the correct slots.

- As soon as the Manchester decoder block is enabled (after the SYNC pulse has finished and any configured disable offset has expired, pink region) the IP checks for the first configured message and starts monitoring the output of the PSI5 transceiver.
- The IP identifies a correct start of message sequence (S0, S1)== '00', and captures the slot counter when the first rising edge of the start sequence is detected. This first rising edge detected is the mid-point transition of the Manchester encoded S0 bit of the message start sequence
- The expected number of bits configured in the message is received and decoded. Any error in the Manchester encoded bits of the message E bit is set - unless the error is in one of the first two bits and SMC message is configured, in which case the EM bit is set.
- After the final bit is received, a check is made that the message CRC or parity is correct. If the CRC or parity check is not correct, C bit is set for the message.
- Once the CRC checks have been made, the received message — along with the status bits, slot counter in which the start sequence was received, the timestamp of the message, the message data and CRC or parity is saved to the channel message FIFO.
- As soon as the received message has been stored, the idle state of the bus is verified and monitoring of the transceiver output restarts to check for the next configured message
- If the serial message channel (SMC) is configured, the first two data bits are extracted from a sequence of 7 PSI5 messages as long as no electrical error is detected in those bits (EM error). If the correct start sequence for the SMC message is detected on M1 (6 logical 1s and a logical 0) in those 7 messages, M0 and M1 from the following 11 messages are also extracted and saved in the SMC buffer allocated to the slot in which

the PSI5 message is received (in total, 18 PSI5 messages are needed to build one SMC message). When the SMC has been received, the CRC is checked and the status of the check is saved in the SMC buffer. If an EM error occurs after a start sequence has been detected and before the end of the message is reached, M0 and M1 are both saved as 0 and the rest of the message is received, at which point the CRC is checked as normal.

56.4.2.3.3.2 Message Too early

Figure 1490. Message Too early



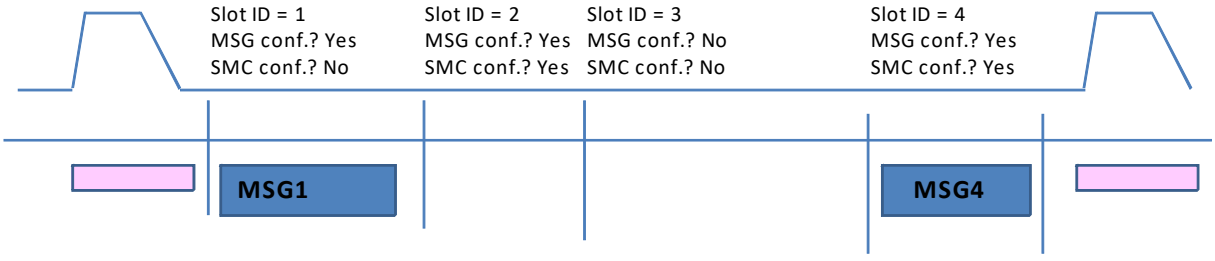
Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	1	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception starts early, before slot 2 boundary is crossed, and so the slot counter is captured as “1” and because the message starts in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG2 has been received but not entirely in its correct slot. The status of the message will include the T bit set and slot counter will be 1, so software can interpret that MSG2 was too early.

The SMC message is received correctly.

56.4.2.3.3.3 Message Too late

Figure 1491. Message Too late



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

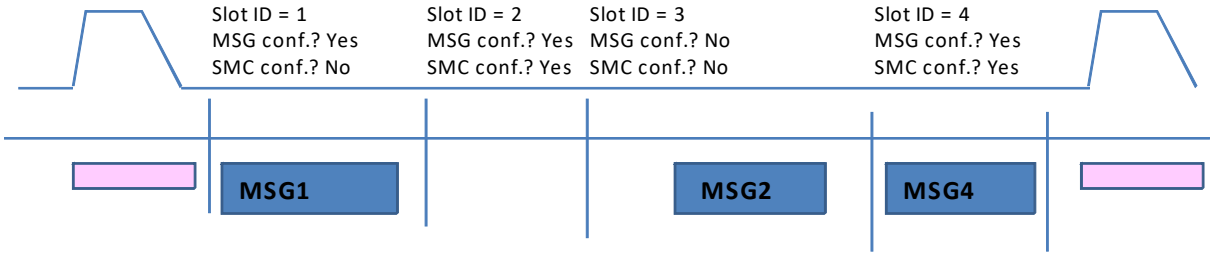
In this scenario, MSG1 reception starts later than expected and ends after slot 2 boundary is crossed. The slot counter is captured as “1” and because the message ends in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG1 has been received but not entirely in its correct slot. The status of the message will include the T bit set and slot counter will be “1”, so software can interpret that MSG1 was late.

The SMC message is received correctly.

56.4.2.3.3.4 Message missing

Figure 1492. Message missing

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	Yes	No	No	2	0/0
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, MSG2 is missing.

At the end of slot 2, the IP writes message buffer location 2 (MSG2 location) with slot counter 2 and the F bit set. The data and timestamp regions are filled with 0s.

The IP waits until the start of the next configured slot (slot 4) to update the SMC buffer 2 with “00”. If slot 4 was not configured, the SMC for the missing MSG2 would be updated at the end of the final slot.

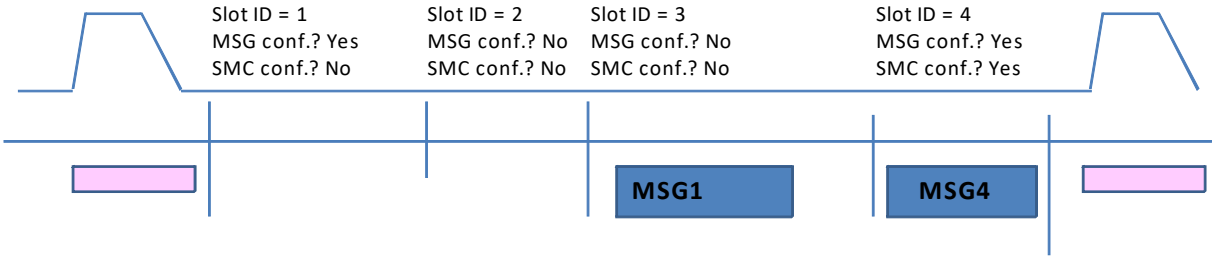
56.4.2.3.3.5 Message Much too late (in unconfigured slot)

Figure 1493. Message Much too late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2a	2	No	Yes	No	No	2	No update
MSG2b	3	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception does not start in its own slot, and the F bit is set for message buffer location 2 (MSG2a).

Because slot 3 is unconfigured, the IP continues to wait for MSG2 in slot 3 and does not update the SMC message buffer 2. The IP recognizes the MSG2 start condition in the normal way and updates PSI5 message buffer 3 (MSG2b), capturing slot 3 as the start slot counter and setting T bit, so that the software can recognize that MSG2 has come in slot 3.



When MSG2 has been received, SMC message buffer 2 is updated at the end of slot 3. MSG4 is received normally.

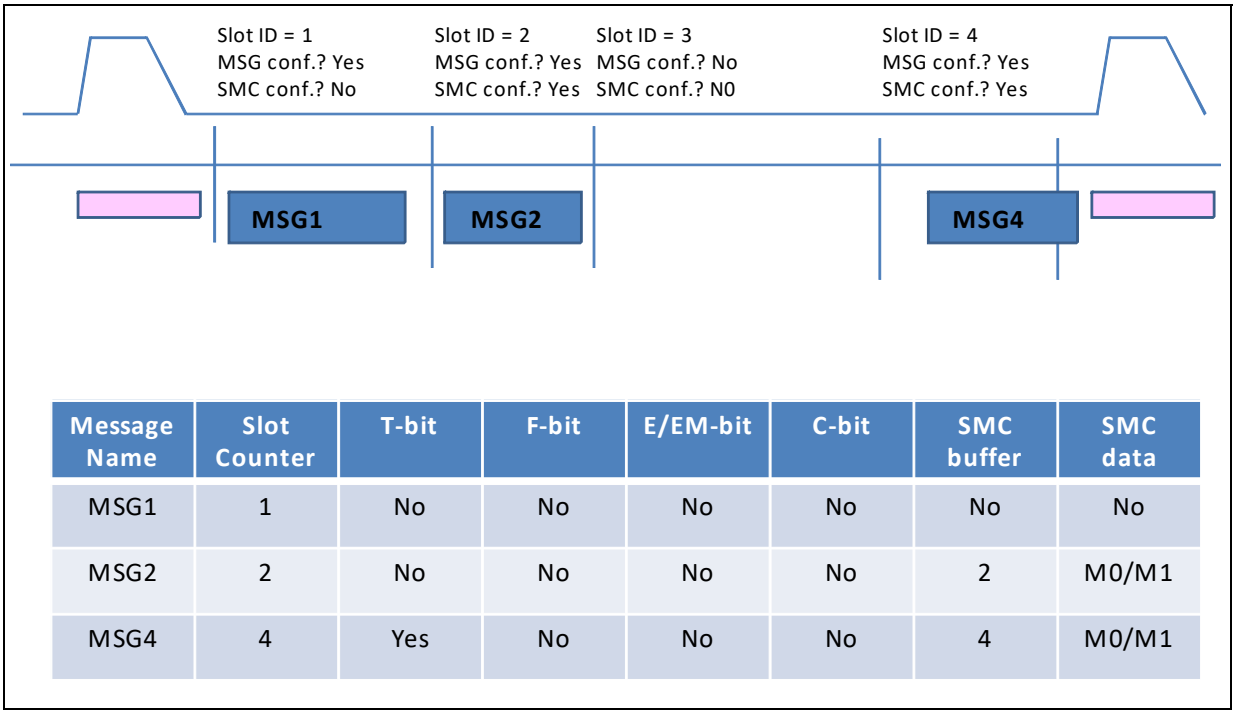
Note: Any scenario where an expected message arrives in an unconfigured slot, leads to an issue when DMA access is used to read the PSI5 message buffer. This is because instead of the expected three entries in the PSI5 message buffer, there will be four, and assuming the DMA watermark is set for the expected three messages, the DMA request will be activated before MSG4 has been received.

In order to overcome this, if DMA access is required, no slots can be left unconfigured and the DMA watermark must be set to the number of slots in the SYNC period. In that way, the DMA will always be synchronized, but depending on how the 'empty' slot is configured, when a message is too late as described here, the result can be that the late message and its associated SMC content is lost.

56.4.2.3.3.6 Message Much too late (in unconfigured slot)

Figure 1494. Message Much too late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1a	1	No	Yes	No	No	No	No
MSG1b	3	Yes	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, MSG1 is received much too late, in the second of two unconfigured slots.

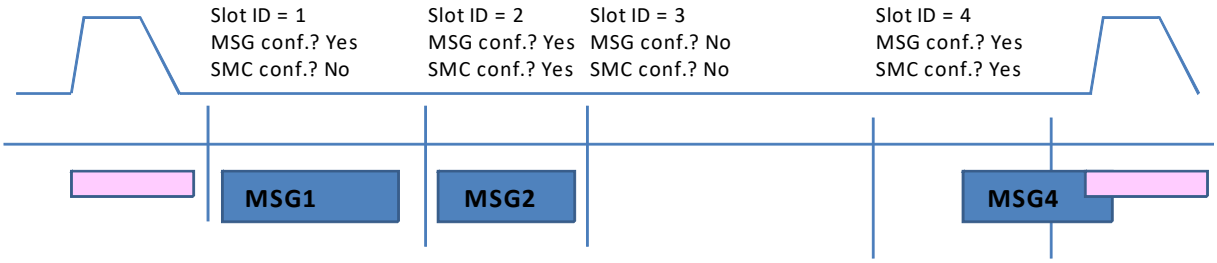
When MSG1 does not arrive in slot 1, MSG1a is saved in the message buffer with F bit set. The IP waits throughout the two unconfigured slots and is received in slot 3 with slot counter 3. Because MSG1b is received completely in slot 3 it is saved in the message buffer with T bit set.

MSG4 is received normally.

56.4.2.3.3.7 Message too late (in last slot)

Figure 1495. Message too late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	No	No	4	M0/M1



In this scenario, the last message is received late.

MSG1 and MSG2 are received error free.

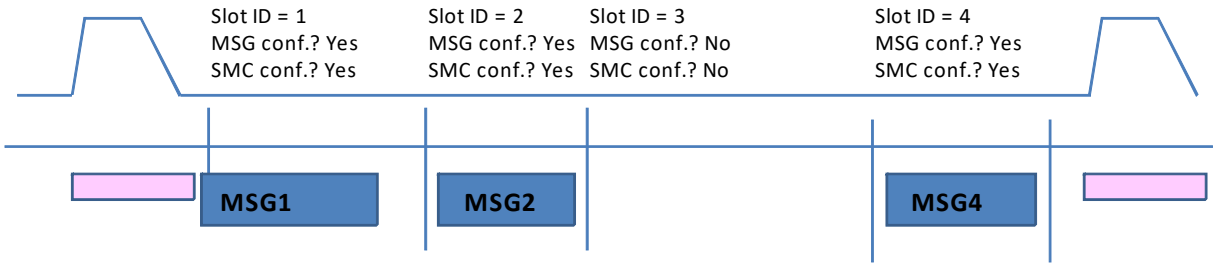
MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the end of the final slot, but before the Manchester decoder is disabled by the SYNC pulse on the bus. The message is received correctly with the T bit set.

56.4.2.3.3.8 Message Too late (in last slot)

Figure 1496. Message Too late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	Yes	Yes	4	M0/M1 or 0/0

In this scenario, the last message is received late in the last slot.



MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the Manchester decoder is disabled by the SYNC pulse on the bus, so the last part of the message cannot be received correctly. Nevertheless, the message reception is completed and the message is stored in the message buffer with the T bit set and 0 written in the buffer for all bits received while the Manchester decoder is disabled. This leads to E and C bit errors.

In an extreme case, it could also lead to EM bit errors, in which case the SMC buffer will also be written with (0,0) otherwise, the correct bits are written to the SMC buffer.

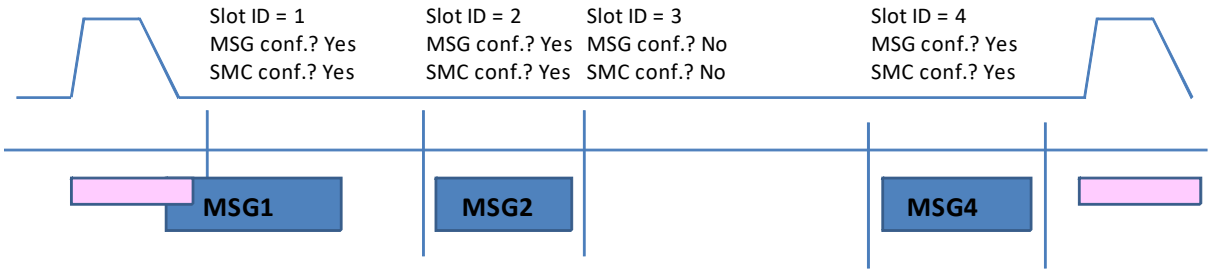
56.4.2.3.3.9 Message Too early (in first slot)

Figure 1497. Message Too early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	0	Yes	No	No	No	1	M0/M1
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, the first message is received early.

As soon as the Manchester decoder disable phase has ended, the IP verifies the idle condition on the signal line and then looks for the first message start sequence. MSG1 start sequence is received before the start of slot 1 with slot counter 0 captured. MSG1 is then received normally and saved with slot counter 0 and T bit set.



SMC bits M0/M1 are saved to SMC buffer 1.

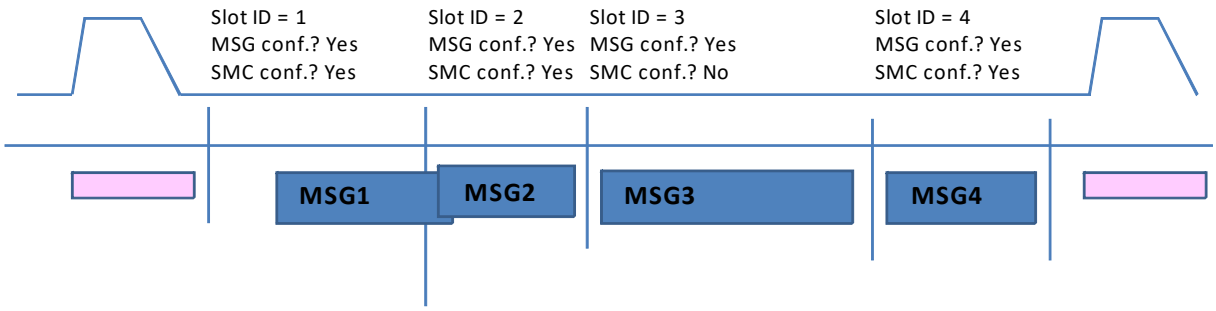
MSG2 and MSG4 are received normally.

Note: This scenario can be avoided if the start of slot 1 is configured to coincide with the end of the Manchester decoder disable phase.

56.4.2.3.3.10 Message Too early (in first slot and overlaps Manchester Decoder disable)

Figure 1498. Message Too early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	Yes	No	No	1	0/0
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, the first message is received early and overlaps with the Manchester decoder disable phase.

As soon as the Manchester decoder disable phase has ended, the IP starts looking for “idle condition” on the signal line by monitoring it for 42 counts of the sample clock. If the signal line is found to be initially high or if a valid transition occurs in the time frame of 42 samples of the sample clock, the Manchester decoder stops decoding until the end of slot 1. Decoding will restart at the beginning of slot 2.

MSG1 is assumed to be lost and the “F” bit is set for that message with the Slot Counter as “1”. If MSG1 SMC is configured then SMC is saved with “00” appended for the M0/M1 bits.

56.4.2.3.3.11 Message Too late (overlaps next message)

Figure 1499. Message Too late (overlaps next message)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	Yes	Yes	1	M0/M1
MSG2	2	No	Yes	No	No	2	0/0
MSG3	3	No	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG1 is received too late and overlaps with MSG2.

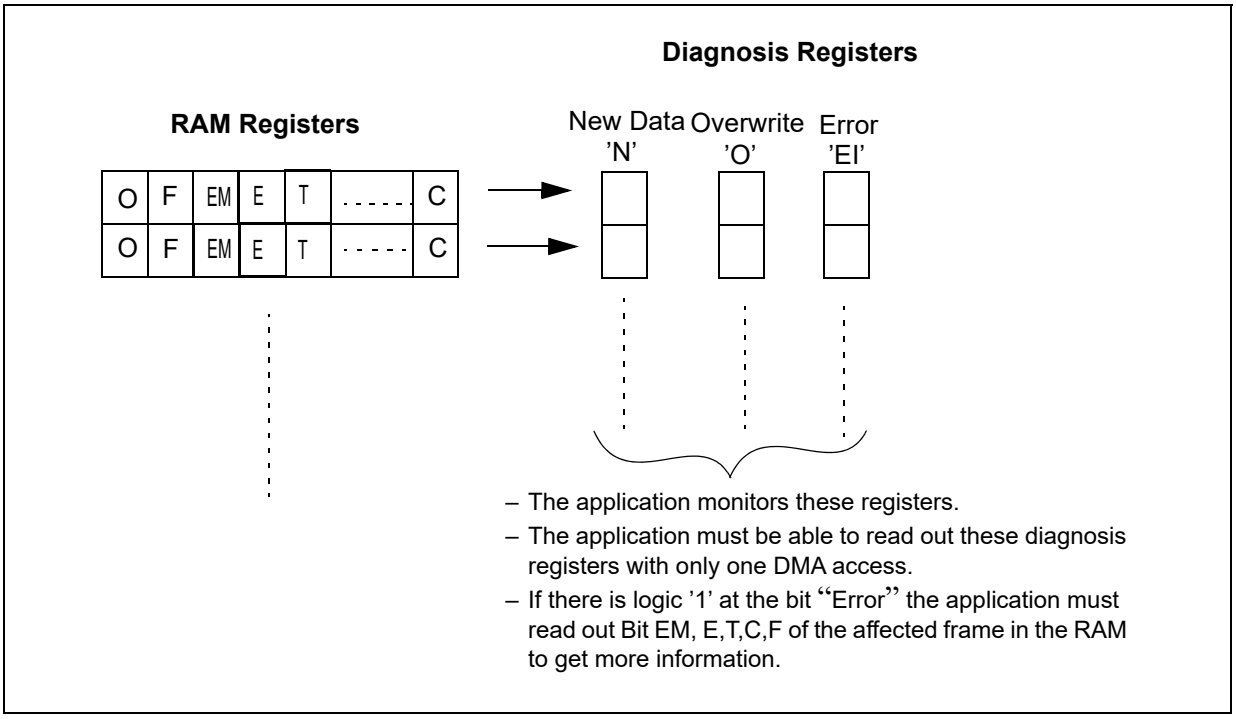
MSG1 start is recognized in slot 1. The last bits of MSG1 are disrupted by the start of MSG2 leading to likely E and C bit errors.

At the end of MSG1, idle time is found to be violated by either the signal line being high as soon as NO_DETECT_STATE is entered or FIRST_TRANSITION_DETECT occurs within 42 counts of the idle detect sample clock. The Manchester decoder stops decoding until the end of slot 2. Decoding is restarted at the start of slot3. MSG2 is not received and MSG2 location in the memory will be saved with the F-bit set. The SMC buffer 2 will be updated with 00.

MSG3 and MSG4 are received correctly in their own slots.

56.4.2.3.4 Data Frame storage

Once the data frame is received and all required status fields updated (for example, Time stamp, C, E, EM, T, F and Frame Counter), this 64-bit value in the data receive register is moved to the RAM Register (PMB).



- This RAM buffer is a 32 (depth) × 64 (frame size) register array with DMA transfer capability (both single or burst).
- Also, the individual RAM locations can be accessed directly by the microcontroller core any time.
- Care needs to be taken that receive data is assigned to the sensor and frame slot unambiguously.

56.4.2.3.5 Message diagnostics

Apart from the regular status bits (mentioned above), a few more diagnostic checks are done and stored as status bits along with each data frame location in RAM. These are:

- Diagnosis registers are associated with each sensor data RAM buffer to indicate:
  - RAM buffer has been filled with data.
  - RAM buffer has been overwritten before data previously stored was read.
  - Data written to buffer includes an error bit (E, EM, C, T, or F, configurable).
- The diagnosis registers are able to be read with a single DMA access.
- After successfully completing a read access, these registers are reset by hardware. This is done by mapping these diagnosis bits byte-wise so that one byte access clears a single bit without affecting other bits.

Figure 1500. Diagnosis Information attached to every frame

Note: See Section 56.8.3: Implementation of EI diagnostic register for more detail.

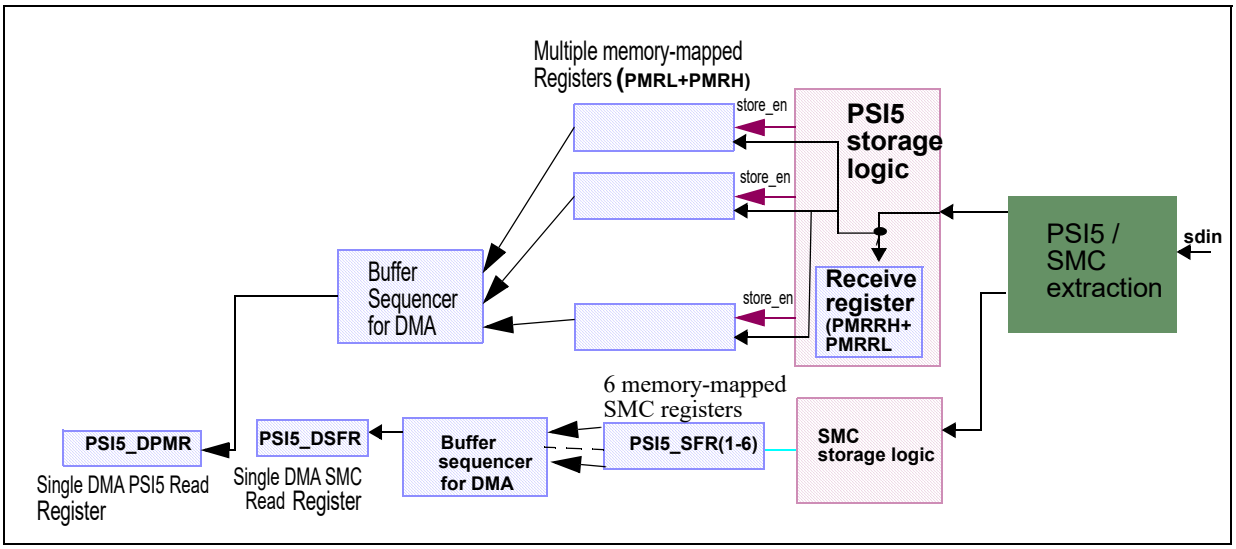
56.4.2.3.6 SMC message extraction

The optional messaging channel M0, M1 (shown in *Figure 1485*) is used by sensors to send an SMC frame along with the normal PSI5 frame. It takes 18 PSI5 frames to send one SMC frame.

The extraction of SMC bits is done for each slot separately and stored separately into the SMC frame receive buffers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame, as defined below).

The extraction logic works as follows:

- Search for SMC start sequence 111111 followed by 0 on M1 and keep storing last 6 bits {CRC} on M0.
- If the start sequence is detected it continues with further extraction and storage of M1 and M0.
  - Store the extracted frame on the corresponding slot buffer.
  - Move the SMC frame to corresponding SFR[i] register period. Once complete, the SMC frame is extracted and generates an interrupt, so that it can be read by the CPU.
  - If the start sequence is not detected, it continues with the search.



The SMC frame is extracted in hardware and stored separately as memory-mapped registers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame).

56.4.2.4 Message Read Logic

PSI5 supports two kinds of read access to received sensor data.

- Read access through memory-mapped RAM registers. These registers can be read by the CPU any time or, specifically, when the concerned interrupts are raised. Applicable for both the SMC and the PSI5 messages.
- Read access through DMA request. Here the DMA sequencer treats the memory-mapped registers as a block and reads them sequentially. Note that even if the DMA is used, the CPU can read the RAM registers any time by addressing them. This is applicable for both the SMC and the PSI5 messages. When reading the PSI5 messages, it is possible to read only the PSI5 messages or PSI5 + diagnostic registers.

Figure 1501. PSI5 and SMC Message Read Logic block

56.4.2.5 CRC recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1502. CRC calculation scheme

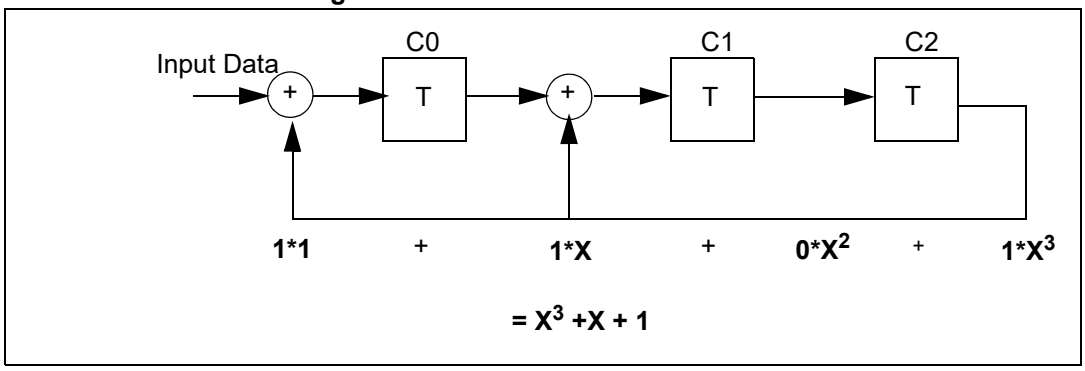


Table 1534. CRC calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1535. Transmitted and Received sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1536. CRC re-calculation (At Receiver side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

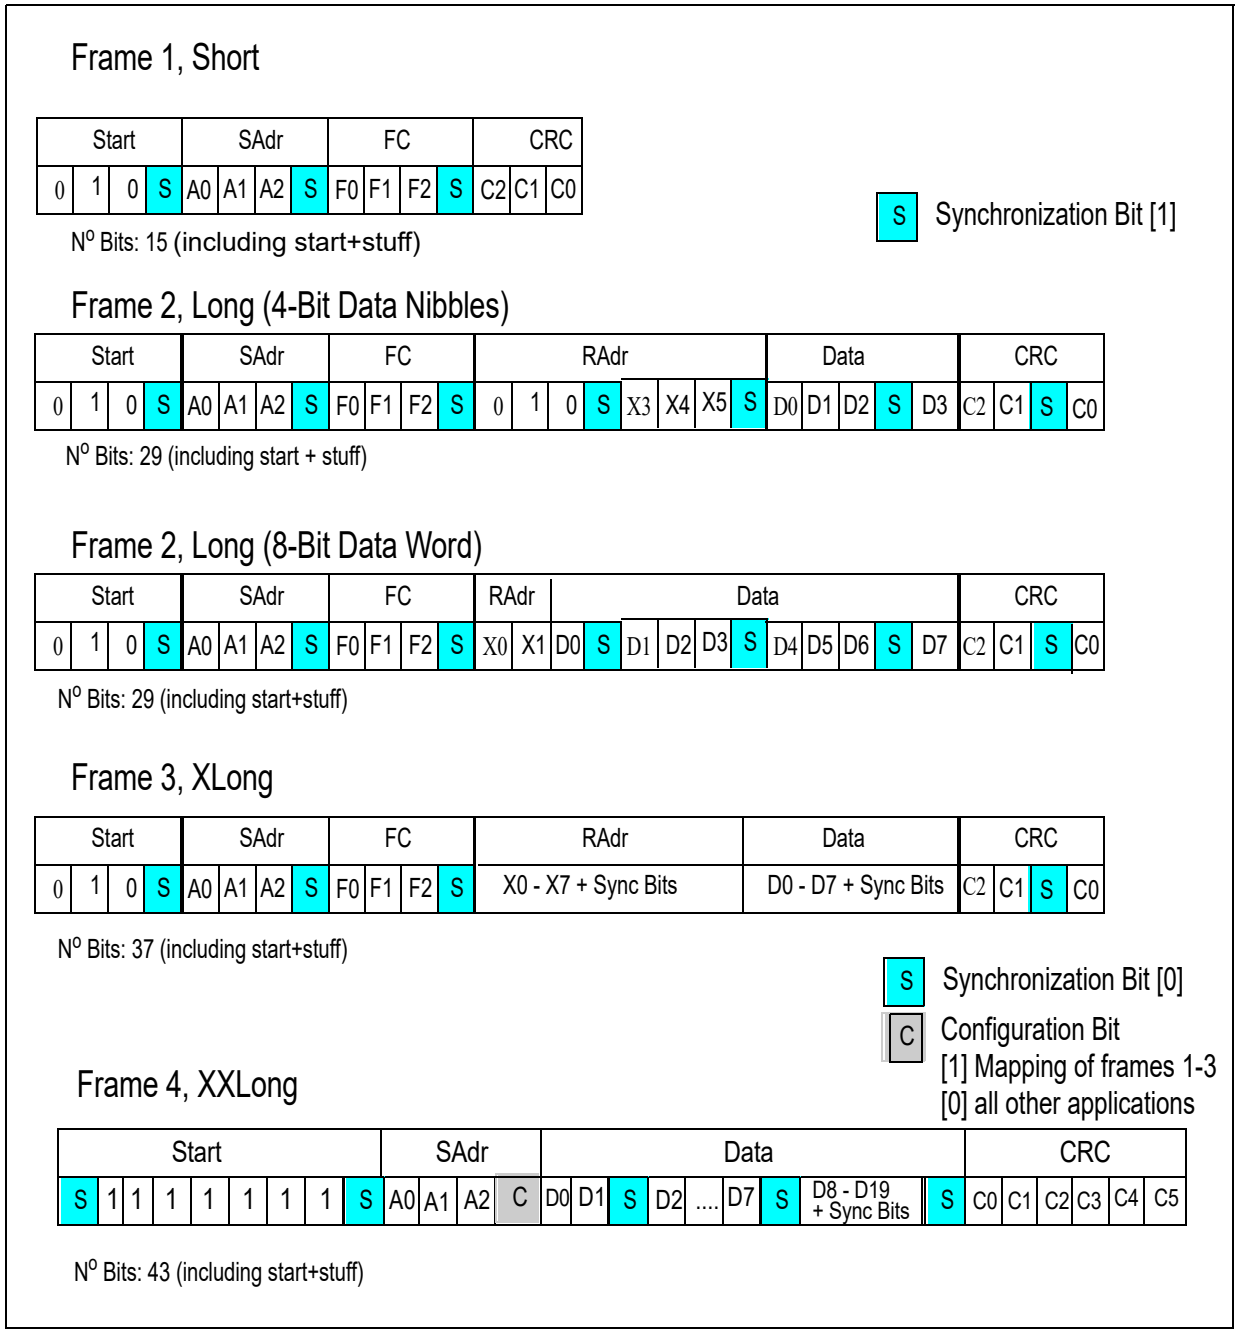
56.4.3 ECU-to-sensor communication

Whereas the sensor-to-ECU communication is realized by current modulation, voltage modulation on the supply lines is used to transmit commands to the sensors. A predefined start sequence allows the sensors to recognize that a command is being transmitted during all synchronous operation modes.

56.4.3.1 Physical layer

A logical 1/0 is represented by data sync pulse of variable length, a logical 1 by the sync pulse of width W1(programmable from 0 to 127 µs) and logical ’0’ by sync pulse with W0{programmable from 0 to 127 µs}.

56.4.3.2 Data Link Layer



56.4.3.3 Bit coding

The bit period is the cycle time as specified for the operation mode, for example, 500 µs in the PSI5-P10P-500/3L mode. (For details about this topology, refer to *Section 56.1.3.3.1: PSI5 topology*.) The lower limit depends on the filter characteristics of the hardware circuitry used for the sync signal detection (subsequent sync signals might vary the internal $V_{ss,\ base}$ reference).

56.4.3.4 Data transmission

The IP supports the standard and the Non-Standard ECU to Sensor communication Formats. In the Non-Standard mode of communication it can be used to send any frame size programmable from 1-64 bits. The IP supports the PSI5 ECU to Sensor Communication formats as briefed below in *Figure 1503* and the text that follows it.

Figure 1503. Standard Frame formats supported

- Short: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “C2, C1, C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor

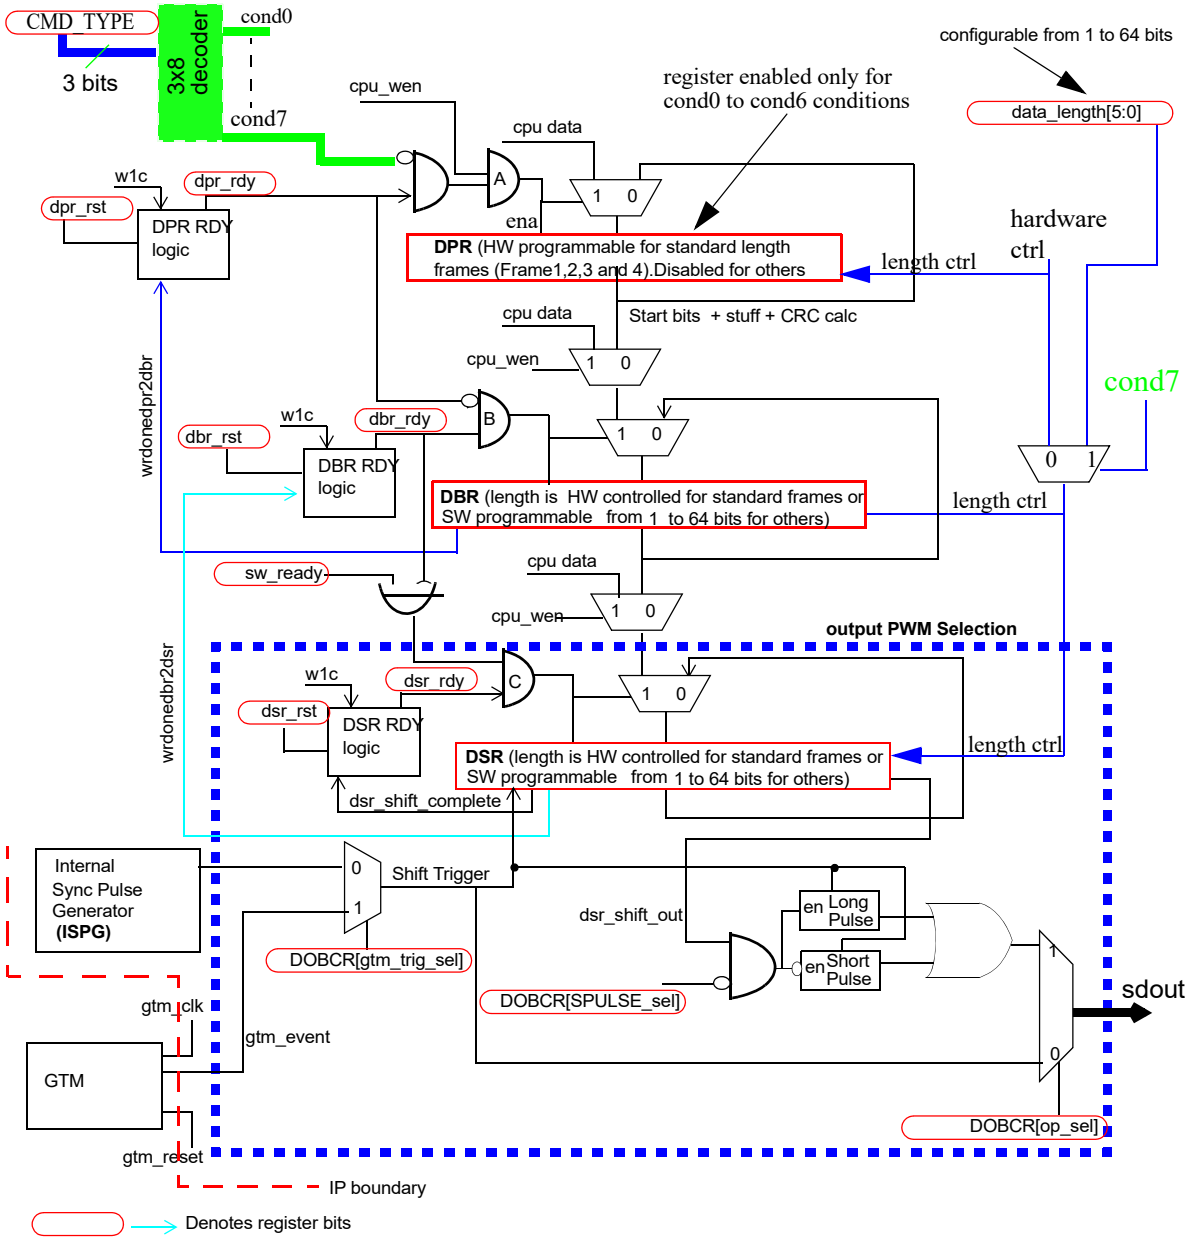
address, F0-F2 are the functional codes and “C2-C0” is the CRC. Refer *Figure 1503* for the frame structure.

  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[5],000) with DPR[0] being fed first in the CRC calculator.

- Long (4-bit Data Nibble): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, X2”, S, “X3, X4, X5, S, “D0, D1, D2”, S,“D3, C2, C1”,S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1503* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X5,D0...D3,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- Long (8-bit Data Word): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, D0”, S, “D1, D2, D3, S, “D4, D4, D6”, S,“D7, C2, C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,”X0-X1” is the Range Address, “D0-D7” is the data and “C2-C0” is the CRC. Refer *Figure 1503* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X1,D0...D7,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- X-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, X2”, S, “X3, X4, X5”, S, “X6, X7, D0”, S, “D1, D2, D3”, S, “D4, D5, D6”, S,“D7, C2, C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is

the sensor address, F0-F2 are the functional codes,"X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Refer to *Figure 1503* for the frame structure.

- The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X7,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[21],000) with DPR[0] being fed first in the CRC calculator.



- XX-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - "011111110", "A0, A1, A2", "C", "D0, D1", S, "D2, D3, D4" D5, D6, D7, S, "D8, D9, D10, D11, D12, D13", S,"D14, D15, D16, D17, D18, D19", S, "C0, C1, C2, C3, C4, C5" where "011111110" is the start sequence "S" is the stuff bit(0), A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Refer to *Figure 1503* for the frame structure.
  - The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0).
  - The transmitter extends the data bits by six zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,D0...D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[23],000000) with DPR[0] being fed first in the CRC calculator.

56.4.3.4.1 Transmission Data Framing

The output data transmission block is constructed of seven sub-blocks:

- Data preparation register
- Buffer register
- Data shift register
- Periodic Sync Pulse Trigger Generator
- "GTM driven" sync pulse trigger input (GTM external to PSI5)
- Pulse length modulation block
- OR gate

Figure 1504. Data transmission block

cond0 = Frame 1(short) - start condition: at least 31 "1s"
cond1 = Frame 1(short) - start condition: at least 5 "0s"
cond2 = Frame 2(long) - start condition: at least 31 "1s"
cond3 = Frame 2(long) - start condition: at least 5 "0s"
cond4 = Frame 3(x-long) - start condition: at least 31 "1s"
cond5 = Frame 3(x-long) - start condition: at least 5 "0s"
cond6 = Frame 4(xx-long)
cond7 = Non standard frames - programmable <data_length> 1 to 64 bits

When <sw_ready> == 0 the data from DBR to DSR is NOT transferred and remains pending even if DSR_RDY becomes 1. Only when <sw_ready> becomes 1, is the data from DBR to DSR transferred.

56.4.3.4.2 Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0)

Up to 24 bits of this register can be written by the CPU. These register bits contain the ECU to sensor command that needs to be transmitted after being appended with the CRC, start bits and stuff bits. The hardware automatically calculates the CRC, adds the start and the stuff bits, before transferring the command to DBR.

- When DPR_RDY == 1, the data to be transmitted to sensors is written to this register via system bus with order data bit to be transmitted first at LSB and furthest on MSB. This register can only be used for writing standard length data frames. Data to this register can be written only when PSI5_DOBCR[CMD_TYPE]!= 7. When PSI5_DOBCR[CMD_TYPE] == 7 then DPR_RDY remains at “0” and the commands cannot be written to this register. Bits writable in different settings of the PSI5_DOBCR[CMD_TYPE] can be seen in *Section 56.3.2.36: Data Preparation Register Low (PSI5_CH0_DPRL)*. Note that PSI5_DPRH is always = 0.
- Having written the data to the DPR, the DPR_RDY bit has be cleared with a w1c. This indicates to the internal logic that the data in the DPR is valid and is to be processed.
- If DPR_RDY = 0 and a new command is written to the DPR then the command is rejected and GISR[IS_PROW] is set.
- If the CRC or parity bit calculation is finished, then the data is shifted to the Buffer register with the start bits and the sync bits appended as well. This transfer is done to the Buffer register only if the Buffer register is ready for new data, which is indicated by GISR[DBR_RDY] == 1.
- As mentioned above, once this transfer is done, the DPR_RDY becomes 1 and a new command can be written to it.

56.4.3.4.3 Data Buffer Register (64-bit register)

- This register has two sub registers DBRH (higher register) and DBRL (lower register). Both of them are collectively referred to as DBR. DBR is of length 64 bits DBR[63:0]
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field refer bit description in *CMD_TYPE*
- When DPR_RDY == 0 and DBR_RDY goes to 1 then internal logic automatically transfers the data from the DPR (with CRC + stuff bits + sync bits) to the DBR. DBR_RDY goes low and DPR_RDY goes 1. In order to check the calculation of the DPR, register DBR can be read at this stage, that is, when DPR_RDY becomes “1”.
- If DBR_RDY == 1 AND DPR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping preparation register in case application includes the start and sync bits and calculates the CRC/Parity itself. If the CPU writes to the DBR when DBR_RDY == 1 but DPR_RDY == 0 and

PSI5_DOBCR[CMD_TYPE]!= 7, then the results can be unpredictable since the DPR has a pending data that needs to be transferred to DBR.

- If the CPU is writing to the DBR as mentioned above, then the DBR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DBR is valid and is to be used for the shift operation.
- If while DBR_RDY == 0, and a new command is directly written to the DBR then the command is rejected and GISR[IS_BROW] bit is set.
- If while DBR_RDY == 0 a new command HAS to be written in the DBR then DOBCR[DBR_RST] has to be written to 1. Writing a 1 to DBR_RST will reject the current command in the DBR and generate DBR_RDY = 1.
- If the Data Shift Register signals that it is ready for new data (PSI5_GISR[DSR_RDY] == 1), the data of the Buffer register is shifted into the data shift register provided PSI5_DOBCR[SW_READY] is 1.
- If PSI5_DOBCR[SW_READY] == 0 then the data from the DBR is NOT transferred to the DSR automatically even if the DSR_RDY goes as 1. In such a case the IP waits for the software to make the PSI5_DOBCR[SW_READY] bit as 1; only then does it transfer the contents to the DSR.

56.4.3.4.4 Data Shift Register (64-bit register)

- This register has two sub registers DSRH (higher register) and DSRL (lower register). Both of them are collectively referred to as DSR.DSR is of length 64 bits DSR[63:0]. This register has a 1-1 correspondence with the bits in the DBR register when this register is updated automatically by the hardware.
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field refer to bit description in *CMD_TYPE*.
- When DBR_RDY == 0 and DSR_RDY goes to 1 then internal logic automatically transfers the data from the DBR to the DSR provided PSI5_DOBCR[SW_READY] == 1'b1, else this transfer remains pending until PSI5_DOBCR[SW_READY] is '0'. Once the transfer is complete, DSR_RDY goes low and DBR_RDY goes 1. DSR contents that would finally get transferred, can be read at this stage, that is, when DBR_RDY becomes "1".
- Making PSI5_DOBCR[SW_READY] now as '0' will not interrupt the ongoing transfer in the DSR.
- If DPR_RDY == 1 AND DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY == 1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- When PSI5_DOBCR[CMD_TYPE] == 7 and If DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY ==

1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.

- If the CPU is writing to the DSR as mentioned above then the DSR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DSR is valid and is to be used for the shift operation.
- If while DSR_RDY == 0, and a new command is directly written to the DSR then the command is rejected and GISR[IS_DSROW] is set.
- If while DSR_RDY == 0 a new command HAS to be written in the DSR then DOBCR[DSR_RST] has to be written to 1. Writing a 1 to DSR_RST will reject the current command in the DSR and generate DSR_RDY = 1.
- This register is clocked by the ISPG pulses or the GTM pulses, as described in *Section 56.4.3.4.5: Sync Pulse Trigger Generation*.
- Once the shift operation is complete in the DSR then DSR_RDY becomes 1.

56.4.3.4.5 Sync Pulse Trigger Generation

The sync pulse trigger can be used to generate the timing pulses or the data pulses.

The sync pulse can be generated based on triggers from two different sources:

- ISPG (Internal Sync Pulse Generator): Composed of CTPR, CIPR and Channel Target Counter (per channel). The internal sync pulse generator is clocked by either the GTM clock (max frequency is 3.9Mhz) or the internal 1 MHz clock. The Channel Target Counter operates with a 1 µs resolution (when using the 1Mhz clock) or GTM clock resolution (when using the GTM clock). The ISPG is implemented to allow generation of internal periodic trigger. Refer to *Figure 1511* for the ISPG structure and *Figure 1509* for the CTPR and CIPR explanation. The ISPG uses the Channel Target Counters (CTCs) for generating the sync pulse. The CTCs can be triggered globally (simultaneous for all channels) or locally (individual to each channel). The CTC_GED bit in the Global Control Register (GCR) ensures that all the CTCs start/stop simultaneously. The individual target values when the trigger pulse is generated are set in the Counter Target Pulse Register (CTPR) and the Channel Initial Pulse Register (CIPR). These registers are present for each channel. When staggering the channels, the CTC_GED bit should be used for providing a simultaneous trigger to the staggered channels. It is also possible for a subset of channels to work on the above arrangement while the remaining channels independently generate trigger pulses for which start/stop is controlled locally to the channels.
  - For each channel, it is possible to configure the trigger period by software using sync pulse generator control/configuration register and setting compare values in Counter Target Pulse Register(s). The Counter Initial Pulse Register (CIPR) can be used to provide the initial offset between various channels.
  - It is possible to deactivate each channel separately for the purpose of sync pulse generation.
  - The periodic pulses can be used to synchronize sensor-to-ECU communication (synchronization timing pulses) [State 1 of *Section 56.8.2: Valid states for*

integrated sync pulse generator] or can be used as data pulse during ECU-to-sensor communication (through the DOBCR) [State 2 of *Section 56.8.2*].

– When programming the CTPR, the Tsync period should be programmed >= 6 SP_TS_CLK cycles (For details of SP_TS_CLK, refer to Bit 23 of *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*).

- GTM event controlled: Generation of sync trigger/pulse can be done based on events (for example, crank angle or software) through general timer module (GTM) output to the PSI5 interface.
  – Here the sync trigger pulses come from an external GTM module routed through a full XBAR, which is programmable at the system level.
  – The sync pulse programming (period, and so on) is done inside the GTM.
  – In *Figure 1504*, if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == 0 and DOBCR[OP_sel] == 1 then the GTM trigger is used for data pulse generation (data pulses for ECU-to-sensor communication). [State 4 of *Section 56.8.2*]
  – In *Figure 1504*, if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == 1 and DOBCR[OP_sel] == 1 the GTM trigger is used for timing pulse generation (synchronization pulse for sensor-to-ECU communication). [State 3 of *Section 56.8.2: Valid states for integrated sync pulse generator*]
  – In *Figure 1504*, if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == “x” and DOBCR[OP_sel] == 0 the GTM trigger is passed directly to data sync port without pulse length modulation. In this case, the sync pulse length is defined by the GTM pulse length. [State 5 of *Section 56.8.2*]
- Programming and control: For achieving the various states of ISPG control or the GTM control, the 3 equivalent bits (GTM_TRIG_SEL, SPULSE_SEL and OP_SEL) belonging to the DOBCR, can be programmed, as shown in *Figure 1504* and *Figure 1505*. The programming of various states mentioned above, with reference to the *Section 56.8.2: Valid states for integrated sync pulse generator* can be seen in *Table 1519* and also shown in *Figure 1513*. The sending of the ECU to sensor commands, can be controlled by PSI5_GISR[DPR_RDY,DBR_RDY,DSR_RDY] bits and the PSI5_DOBCR register bits.

56.4.3.4.5.1 Timing Pulses

Timing pulses can also be produced without pulse width modulation also. These timing pulses can be generated through two sources:

- Periodic sync pulse from ISPG. In this case the synchro pulse from the internal sync pulse generator can be made available without any modulation. Referring to *Figure 1505*, in synchronous mode, if DOBCR[GTM_TRIG_SEL] == 0 and DOBCR[OP_SEL] == 0 then the internal sync pulse generator output can be made available without any modulation. The high time of this pulse is fixed at 4 µs.
- Referring to *Figure 1505*, in synchronous mode, if DOBCR[GTM_TRIG_SEL] == 1 and DOBCR[OP_SEL] == 0, then the GTM trigger can be used for timing pulse generation without any Pulse Width Modulation.

56.4.3.4.5.2 Data pulse generation

Data pulses are produced by the Pulse Length Modulation Block based on triggers from one of the two selectable sources, the ISPG or the GTM, during ECU-to-sensor communication.

The two sync sources are selected by software programming of the Pulse Length Control/Configuration Register.

- A logical 1 in the Data Output Register LSB is coded as data sync pulse of width W1 {up to 127 µs}.
- A logical 0 in the Data Output Register LSB is coded as data sync pulse of width W0 {up to 127 µs}.
- The two widths are programmable in the Pulse Length Control/Configuration Register.
- The Data Shift Register is shifted right every time a bit is transmitted.

Figure 1504 shows the data transmission block.

Figure 1505. ECU-to-sensor communication registers

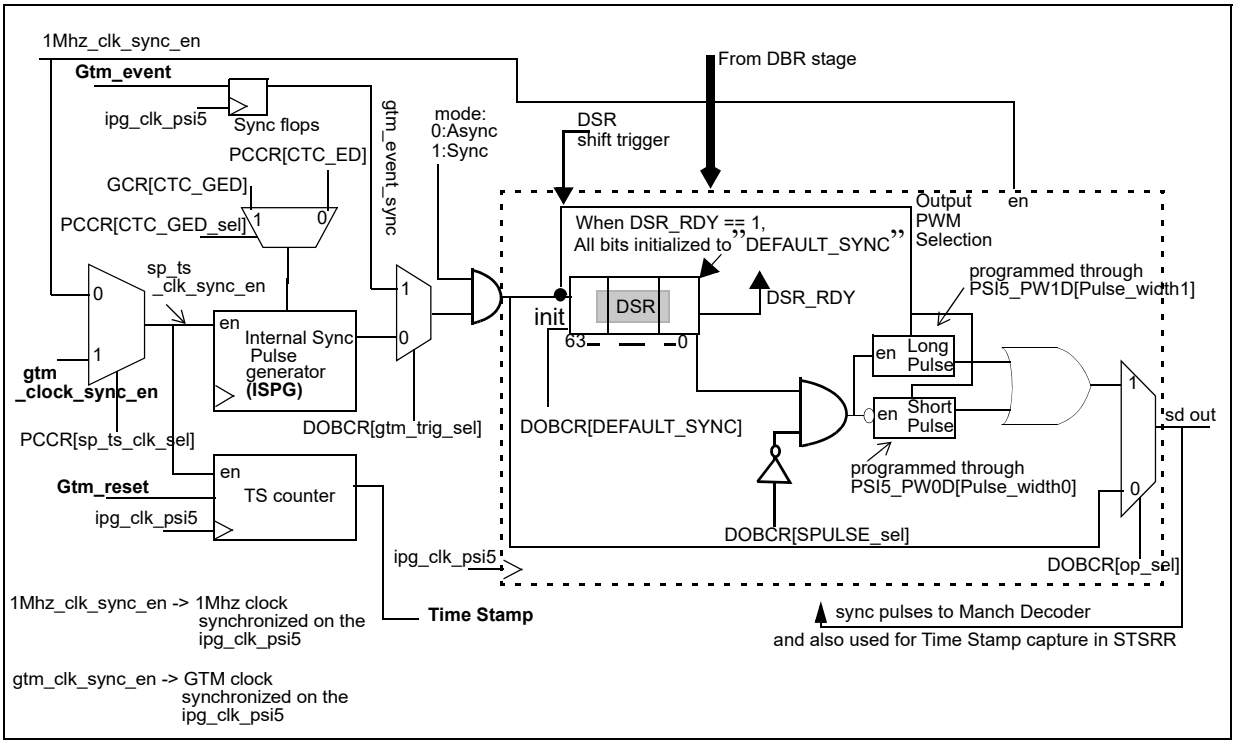


Figure 1505 details the implementation of *Figure 1504* and shows how the various bits mentioned in *Section 56.3.2.30: Data Output Block Configuration Register (PSI5_CH0_DOBCR)* control the behavior of the Output Command path. *Figure 1505* also shows the various clock sources to the Internal Sync Pulse Generator and the Time Stamp counter.

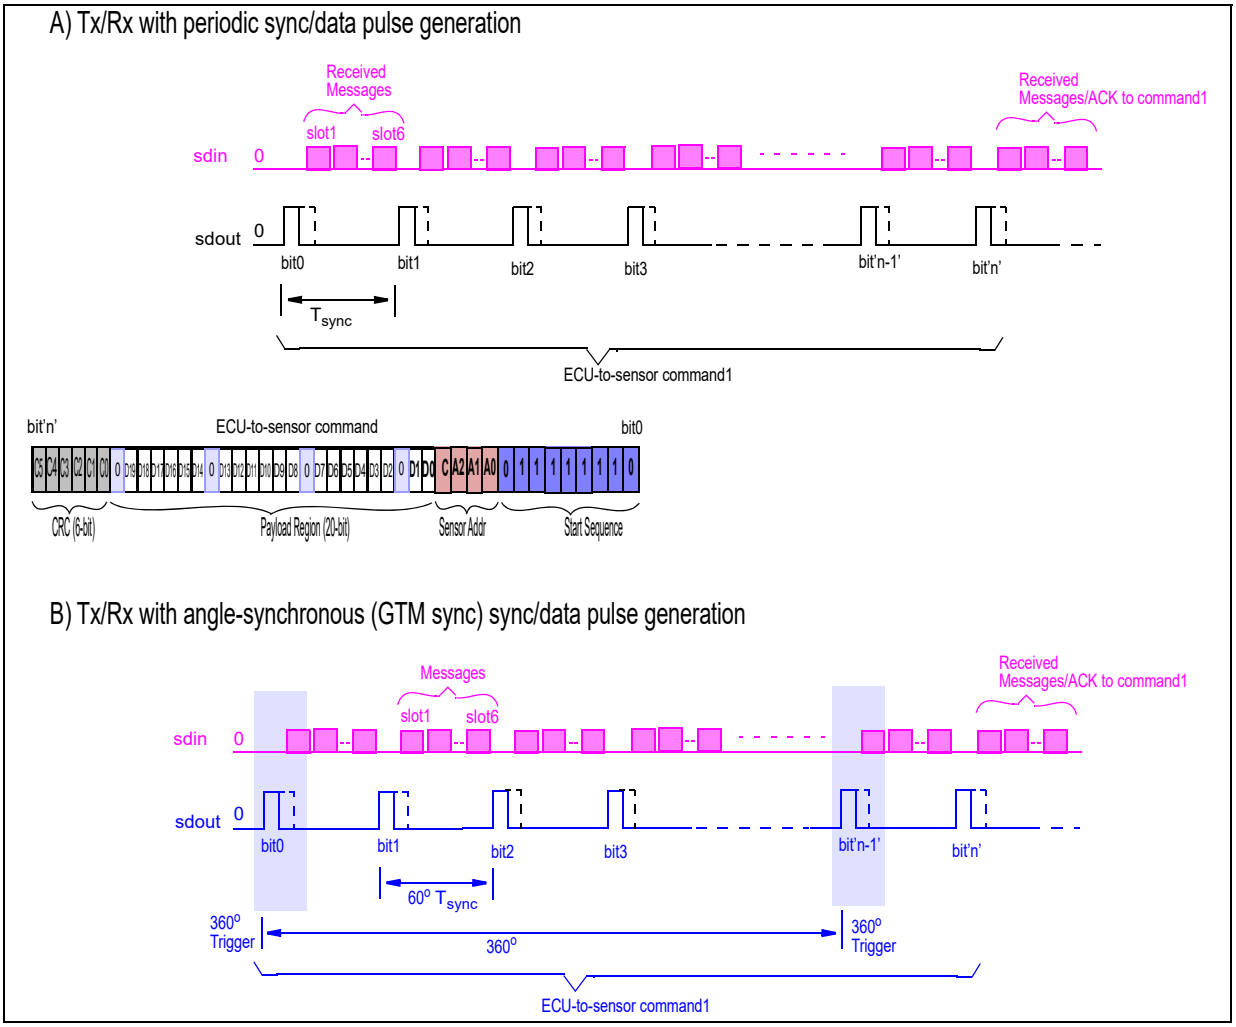
56.4.3.5 Response to ECU-to-sensor frames



The response to an ECU-to-sensor frame can be optionally transmitted in two ways:

- Out-of range values of data frame (as fast response coded as normal PSI5 payload region)
- Serial messaging channel (verification of the response frames must be handled by the software)

56.4.4 Tx/Rx scenario

The diagram below shows the communication scenario in synchronous modes. For asynchronous mode, sync pulses are not generated and sensor transmits data asynchronously.

Figure 1506. Synchronous mode communication scenarios

56.4.5 Interrupt handling

Configurable interrupts based on events (for example, reception of valid message), errors, DMA transfers, and so on are implemented. The following types of event can generate an interrupt:

- Reception of a new PSI5 message
- Reception of a new SMC message
- Unread SMC message overwritten in the SMC buffer area (PSI5_SFR)
- Unread PSI5 message overwritten in the PSI5 buffer area (PSI5_PMRH, PSI5_PMRL)
- Dedicated interrupts for selectable errors, mentioned below:
  - Bit C is set
  - Bit E or EM, or both, are set
  - Bit T is set
  - No PSI5 frame was received in a defined frame slot (Bit F is set)
- ECU-to-sensor communication-related interrupts
  - The application tries to load new data into the data preparation register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case).
  - The application loads new data into the data buffer register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case).
  - The application loads new data into the data shift register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case)
- DMA related interrupts (transfer finished/FIFO_FULL/underflow)
- Apart from this a single one sum interrupt OR-ing all the above events.

Various interrupt signals that represent the above events are:

- PSI5 new message arrival interrupt (Status flags in PSI5_NDSR)This is asserted when any of the programmed storage PSI5 locations (max 32) receive a new PSI5 message

(error/error free). This interrupt also indicates that the PSI5 receive register (PMRRL/PMRRH) has been updated with a new PSI5 message.

- SMC message, ECU-to-sensor communication, and Time Stamp related interrupts (All Status flags in PSI5_GISR): This is asserted during following events:
  - When a new SMC message is received in its corresponding slot OR
  - When there is a CRC error in any SMC message OR
  - When an unread message in some corresponding SMC location (in PSI5_SFR) gets overwritten by a new SMC message OR
  - When DPR is ready for receiving a new data OR
  - When DBR is ready for receiving a new data OR
  - When DSR is ready for receiving a new data OR
  - When there is an attempt to write to DPR while it is NOT ready OR
  - When there is an attempt to write to DBR while it is NOT ready OR
  - When there is an attempt to write to DSR while it is NOT ready OR
  - When data time stamp register is updated with new time stamp value OR
  - When the sync time stamp read register is updated with a new time stamp.
- PSI5 Message Overwrite Interrupt (Status Flags in PSI5_OWSR): This is asserted when any of the programmed storage locations in the memory (max 32) have an unread PSI5 message that is overwritten by a new upcoming PSI5 message. Corresponds to OWSR.
- PSI5 Error interrupt (Status Flags in PSI5_EISR): This is asserted when any of the programmed storage locations in the memory (max32) have an error in the PSI5 message. It is used only for PSI5 messages.
- DMA Interrupt (Status Flags in PSI5_DSR):
  - When the DMA transfer corresponding to conf2, conf3 or conf4 finishes OR
  - When the DMA transfer corresponding to SMC message gets over OR
  - When there is an FIFO_FULL/Underflow in the PSI5 RAM register area OR
  - When there is an underflow in the SMC message area.
- Global Interrupt: Single interrupt OR-ing all above interrupt events.

56.4.5.1 Error conditions

- C: CRC/parity error on received data, evaluated after recalculating CRC on received data and comparing with received CRC or recalculating parity on received data and comparing with received parity.
- E: Electrical error during any Tbit period (excluding Messaging field M0M1) during frame reception (not applicable during Idle state); that is, if at least one bit is absent during its Tbit period.
- EM: Electrical error on M0M1 field.
- T: Timing error during frame reception violates the slot boundary. Here, all the corner cases and conditions are taken care of (for example, the isolation of correct slot to correct message if the message is too early or too late with respect to its expected position, the crossing of the slot boundary when one frame overlaps the other, and so on).
- F: No frame received during a particular slot time in case of sync mode.

56.4.6 DMA support

- The PSI5 module generates separate DMA transfer requests for PSI5 message/diagnostic status and SMC messages.
- A single DMA request is used for PSI5 messages and diagnostic data. The request is triggered based on the selected DMA configuration (either PSI5 message or diagnostic data or both). After choosing the configuration, data is available on respective DMA pop-up registers.
- DMA requests for PSI5 messages and diagnostic registers are based on the watermark level of message buffers (to be treated as FIFO for the DMA). PSI5 message buffer FIFOs get data from the PSI5 receiver in the order they are received.
- DMA requests for SMC messages are based on successful storage of each SMC frame to the message buffers. The SMC message buffers get data from SMC extraction logic in fixed round-robin arbitration sequence.
- Refer to *Section 56.4.6.1: Single DMA request for PSI5/diagnostic message buffers* for PSI5 DMA handling and to *Section 56.4.6.2: Single DMA request for SMC received messages* for SMC DMA handling.

56.4.6.1 Single DMA request for PSI5/diagnostic message buffers

A common DMA request (per PSI5 block) is generated for PSI5 message/diagnostic buffers. The depth (up to 32 in present context) of the message buffer is programmable via the MEM_DEPTH filled in the PCCR. The width of each location of the PSI5 message buffer is 64 bits. When reading PSI5 message through the DMA, the 32-bit DPMR is sequenced with the data from the PSI5 message buffer. When reading the diagnostic registers through the DMA, the 32-bit DDSR is sequenced as NDSR followed by EISR. The DMA operation will happen as follows:

- Based on the DMA configuration chosen, one of the three DMA transfer sequence is initiated:
  - PSI5 buffer followed by diagnostic data sequenced to DPMR
  - PSI5 data sequenced to DPMR
  - Diagnostic buffer data sequenced to DDSR
- The DMA request is asserted when the number of messages stored in the buffer crosses the configured watermark number of messages.
- DMA request is deasserted once the “watermark” number of messages have been read.
- If the number of unread messages is still greater than the watermark programmed, then the DMA request is reasserted.
- The received message data is read from a common memory-mapped 32-bit DMA PSI5 message register (DPMR). Thus, a single PSI5 message (64 bits wide) will require two IPS read operations. The diagnostic data is read either through the DPMR or through the DDSR (single 32-bit register) by the DMA controller via the IPS interface.
- It is assumed that the DMA Controller’s Transfer Control Descriptor (TCD) would be set to transfer bytes equal to the messages indicated by watermark level, as described in *DMA_PM _DS_WM* in *Section 56.3.2.3: DMA Control Register (PSI5_CH0_DCR)*. It is assumed that when responding to a DMA request, the DMA controller will read faster

than the rate at which messages are received and stored in the buffer/FIFO, which will cause the DMA request to deassert.

- The next received message will be updated on the common memory map register once the previous message is read by the DMA (by the DMA sequencer).
- The store signal from the synchronization logic will push the message into the memory-mapped RAM registers and in parallel also into the PSI5 receive register. *Figure 1501* shows the format in which the messages will be stored in any message buffer (RAM registers) and finally when being read from DMA access register.
- For more details about DMA programming refer to *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 56.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, *Section 56.3.2.4: DMA Status Register (PSI5_CH0_DSR)*, *Section 56.3.2.10: DMA PSI5 Message Register (PSI5_CH0_DPMR)* and *Section 56.3.2.12: DMA Diagnostic Status Register (PSI5_CH0_DDSR)*.

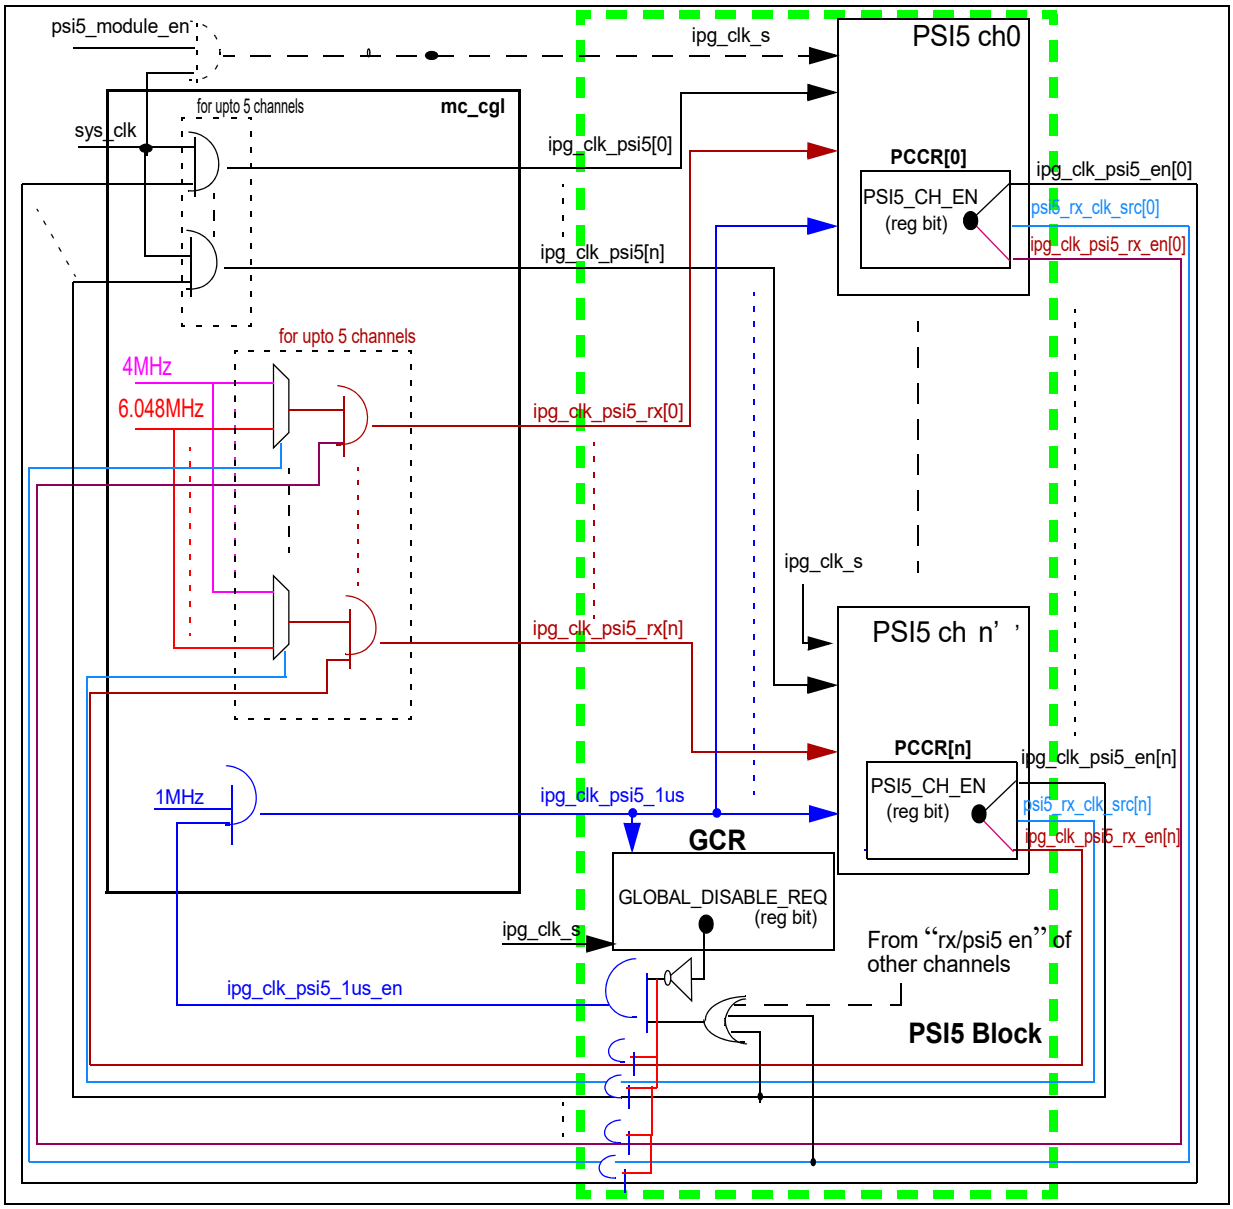
56.4.6.2 Single DMA request for SMC received messages

A separate DMA request (each channel) is generated for the SMC message buffer. Each SMC received message would be stored in the internal registers and read out by DMA controller via a common memory-mapped DMA SMC Frame Register (DSFR) (single 32-bit register for each message buffer). The data flow will happen as follows:

- A request is asserted when the system buffer successfully receives one complete SMC message, and remains asserted until all complete messages have been read. Data is read from the DMA PSI5 Message Register in the memory map.
- It is the job of an internal sequencing logic to provide the next complete received message. The internal sequencer works in a round-robin fashion checking for the slot-specific registers for each SMC message. Thus the sequence will be slot1— slot2—slot3—slot4—slot5—slot6—slot1 and so on. In whichever slot it encounters the first complete SMC message, the DMA request is asserted and the sequencer will wait for this data to be read before moving on to the next slot in its loop. If a particular slot message remains unread and a new SMC message for the same slot comes in, then the previous message would be overwritten and the OW bit would be set.
- The DMA controller should be programmed to read only one message in one DMA transfer. Otherwise, if it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur. User software should ensure there is no overflow.
- For more details about DMA programming refer to *Section 56.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 56.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, *Section 56.3.2.4: DMA Status Register (PSI5_CH0_DSR)* and to *Section 56.3.2.12: DMA Diagnostic Status Register (PSI5_CH0_DDSR)*.

56.4.7 Message read through interrupt generation

There is a separate interrupt request for received messages for each PSI5 channel. Each PSI5 channel can be configured individually to generate an interrupt on reception of messages. An interrupt is asserted when the corresponding PSI5 channel has received a complete message (PSI5 or SMC). Refer to *Section 56.4.5* for more details about interrupts. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing the corresponding PSI5 channel that is enabled to give out messages via interrupts through the IPS Interface. In response to these interrupts,



the CPU is expected to read interrupt status register for individual PSI5 Channel (depending on which interrupt was asserted) and store it in system memory.

56.5 Clock and reset

The proposed clock scheme of the PSI5 block is shown in *Figure 1507*. Global clock and clock divider are taken care of inside the CGM. Following is a brief description of these clocks with respect to the CGM:

- Global clock (refer to *Figure 1507*)
  - 1 Global clock generated from a single source but separately controllable for each PSI5 channel (“ipg_clk_psi5” for each channel that is generated from sys_clk).
  - It has a jitter of less than 5 ns at 1 MHz.
  - 1 global clock, which is enabled during any register read/write from IPS interface. (“ipg_clk_s”, which is common to all the PSI5 channels).
- Clock divider
  - Only one clock divider for all PSI5 interfaces (divider to generate 4 MHz/6.048 MHz from the system clock).
  - The clock divider generates all clocks that are needed for up to five interfaces.
  - The clock divider is configurable by software.
  - The output of the clock divider has a jitter of less than 5 ns at 1 MHz.
- Separate GTM clock (not shown in *Figure 1507*) for each channel, which is available from at the system level. For reliable operation, the GTM clock should be limited in frequency to up to 3.9 MHz.

Figure 1507. PSI5 clock scheme

Note: Refer to the Device Configuration chapter for value of PSI5_NUM_CH.

56.5.1 Latency and Jitter related requirements

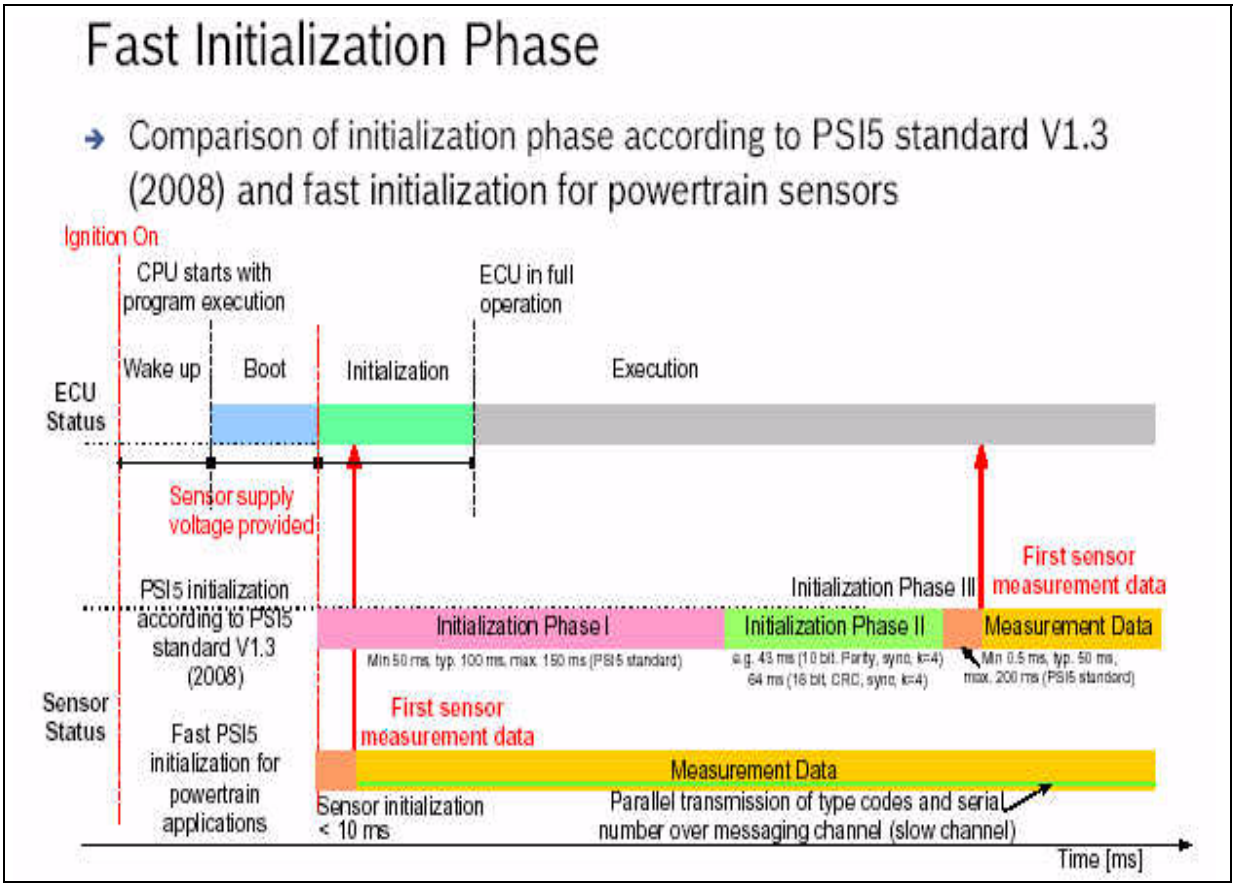
- Latency related
  - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): ≤ 3µs.
  - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: ≤ 2µs.
- Jitter related
  - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): <= $1T_{ipg_clk_psi5}$
  - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: <= 1 µs +$T_{ipg_clk_psi5}$

56.5.2 Reset

The device has a single global asynchronous reset input to the module that resets the whole module bringing it to an inactive state upon its assertion. The user software must program the module registers to bring up the receiver operations.

56.6 Initialization information

56.6.1 Initialization



56.6.1.1 Sensor startup and initialization

After each power-on or under-voltage reset, the sensor performs an internal initialization, which is divided into three phases:

- Initialization Phase1: No data transmission.
- Initialization Phase 2: Transmission of type code and serial number of sensor.
- Initialization Phase 3: Transmission of “Sensor Ready” or “Sensor Defect” or other sensor specific data.

As this PSI5 implementation is targeted towards powertrain devices/sensors the standard initialization phase is modified and tuned for those applications. The comparison of the original scheme and enhanced schemes are shown in *Figure 1508*. *Figure 1508* also describes that the initialization content is the same as defined in V1.3, and the only modification is that it is transmitted using the SMC channel when a fast startup is required. “Fast Initialization Phase” below means that the sending of first sensor data is fast, but the sending of sensor initialization data will actually be much slower.

Figure 1508. Fast initialization phase

56.7 Design assumptions and limitations

56.7.1 Assumptions

- Slot Configuration Register would always be programmed with valid number of bits for frame configuration.
- There will be no Timing error bits (T) in async mode. Also, in this mode the IP waits indefinitely for the detection of a valid start sequence, hence the F bit (NFR) is not set in Async mode. Rest all of the errors are available (E, EM, and C).

56.7.2 Limitations

As this is a PSI5 receiver, designed primarily to only receive the PSI5/SMC data and store as it is into the RAM buffer. So, it would not be responsible neither to recognize the content of the received messages nor do any decision making based on the content. Similarly, for Command it would not recognize the content of command and would transmit as it is writing into corresponding DSR and reception of PSI5 messages would not in any way depend on the content of command as far as PSI receiver is concerned. Its the responsibility of SW to sequence the issue of commands across the PSI5 channels and thereby recognize the content of received message and infer it.

56.8 Miscellaneous descriptions

56.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels

Each PSI5 channel has the Channel Target Pulse Registers (CTPR) and Channel Initialize Pulse Register (CIPR). The CTPR defines the period of the internal sync pulse generation and the CIPR defines the initial offset time with respect to the sync pulse trigger. The sync pulse trigger can be generated from either the PSI5_GCR[CTC_GED] global bit or the PSI5_PCCR[CTC_ED] channel specific bit.

When staggering of the channels is required then the PSI5_GCR[CTC_GED] global bit is used as a common trigger for all the PSI5 channels in which PSI5_PCCR[CTC_GED_SEL] bit is set to 1. Setting this bit to 1 triggers the internal sync pulse generators of all the PSI5 channels and the trigger of each channel is then automatically staggered with respect to the other channel, depending on the value of the CIPR.

When the specific PSI5 channel is not to be kept as a part of staggered channels, then the channel-specific PSI5_PCCR[CTC_GED_SEL] bit has to be kept as 0. The channel in this case, has to be triggered locally by writing a 1 to the PSI5_PCCR[CTC_ED] of that specific channel. This triggers the internal Sync Pulse Generator of that specific channel without affecting other channels.

Following is the procedure for starting the internal Sync Pulse Generators:

- If in Normal mode, then stop and reset all Channel Trigger Counters (CTCs) by setting the global PSI5_GCR[CTC_GED] bit to 0 or the channel specific PSI5_PCCR[CTC_ED] to 0.
- Enter Config mode.
- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a “0” to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, refer to *Section 56.3.2.34: Counter Target Pulse Register (PSI5_CH0_CTPR)*, *Section 56.3.2.35: Counter Initialize Pulse Register (PSI5_CH0_CIPR)* and to *Section 56.4.3.4.5: Sync Pulse Trigger Generation*.

Figure 1509. CIPR and CTPR

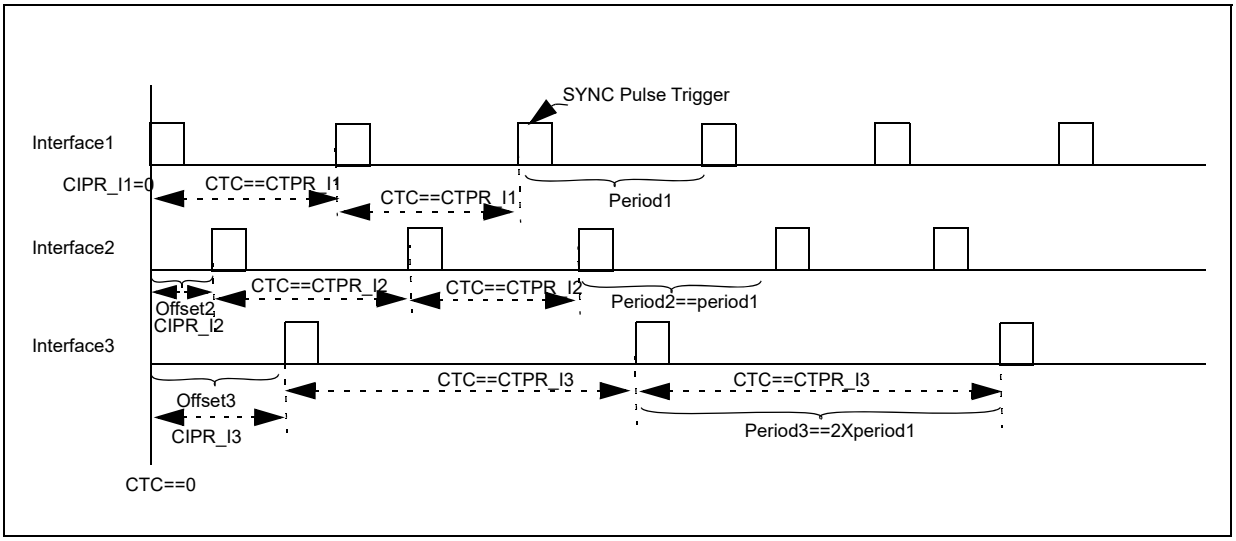


Figure 1509 shows the CIPR and the CTPR definition w.r.t the staggering of the channels. *Figure 1510* is a more detailed representation of these parameters along with the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

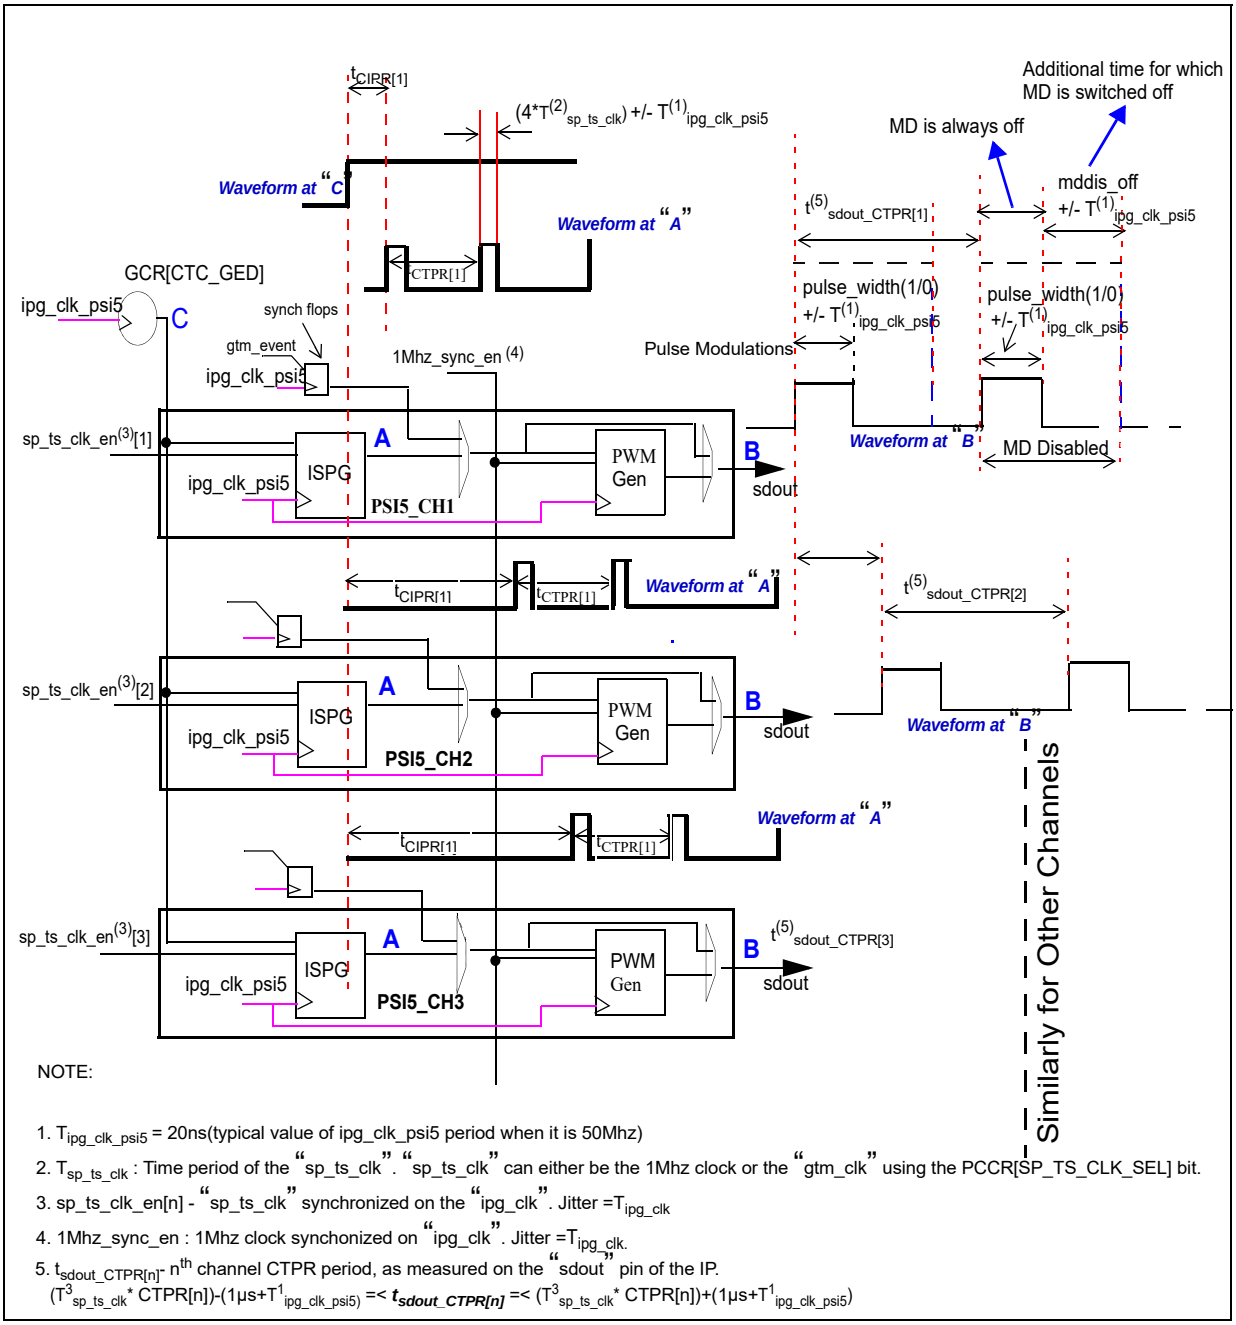
Figure 1510. Sync pulse generation parameters and Jitters



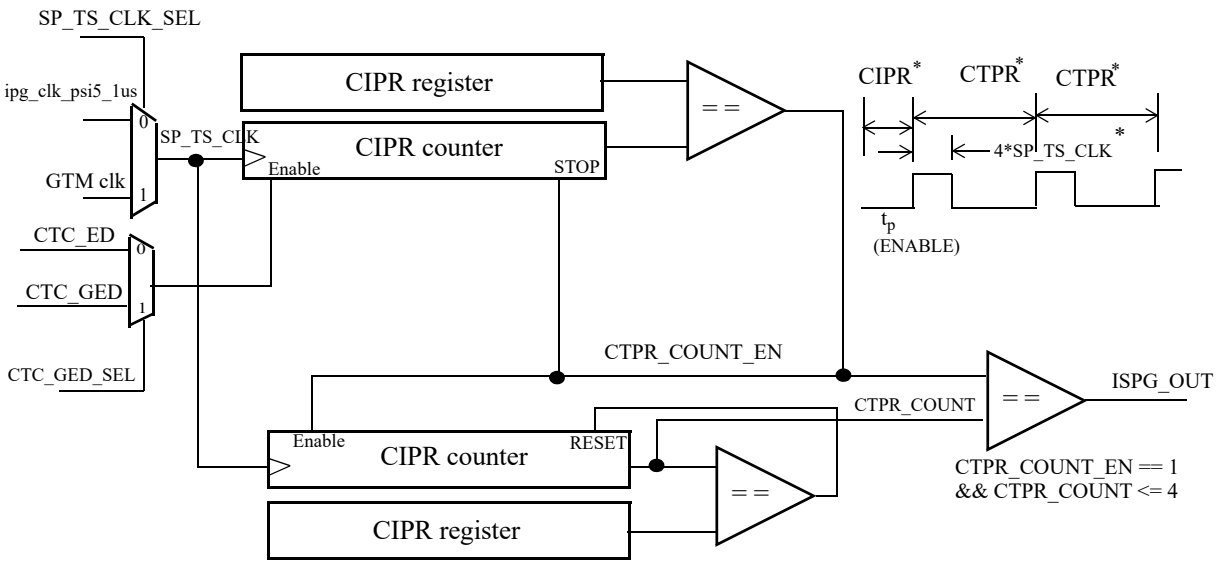


Figure 1510 shows the various jitters.

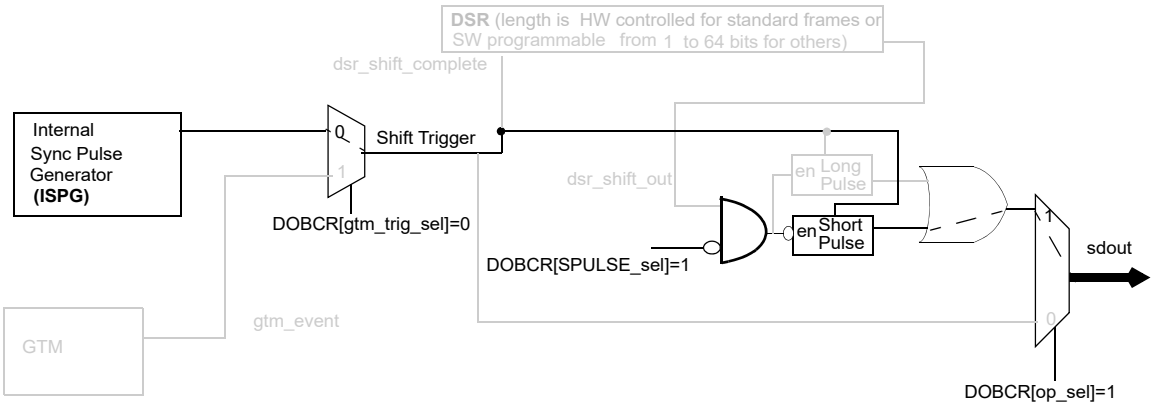
Figure 1511. ISPG (Internal Sync Pulse Generator) structure



* - For exact values and more details refer to *Figure 1510*

Note 1: All channels with CTC_GD selected will be enabled at the same time, enabling staggering of the ispg_out signals.
Note 2: This structure is replicated in each channel, with CTC_GED being a common signal to all channels.

56.8.3 Implementation of EI diagnostic register

Figure 1514. Implementation of EI diagnostic register

57 Peripheral Sensor Interface-Support module (PSI5-S)

57.1 Introduction

The PSI5 Support IP (PSI5-S) module is used to interface directly to a UART compatible PSI5 transceiver over a high speed UART link. The transceiver is required to implement a compliant PSI5 module for all vehicle applications as is currently defined in the PSI5 protocol specification V2.0.

PSI5 messages from sensors received by the transceiver are decomposed into UART bytes and sent to the PSI5-S which in turn reconstructs the PSI5 messages from the UART packet, and makes them available for the application in system RAM.

ECU-to-sensor commands are sent from the PSI5-S module to the transceiver, which in turn generates the appropriate logical 1's and 0's in the SYNC pulses sent on the bus.
The PSI5-S supports all command formats of the PSI5 V2.0 including the "tooth gap" method and "variable length" pulses.

At the system level, the PSI5-S supports one transceiver with up to seven PSI5 channels. Apart from these seven channels, there is an eighth channel available for special purposes, including direct communication with the transceiver and storage of corrupt messages.

Note: For details on PSI5-S system, refer to Figure 1559.

57.1.1 Overview

PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make PSI5 also suitable for many other automotive sensor applications. The development goal of PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented license free.

The main features of PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications.

The main features of the PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s or optional 189 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module can be configured to support the following PSI5 features:

- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

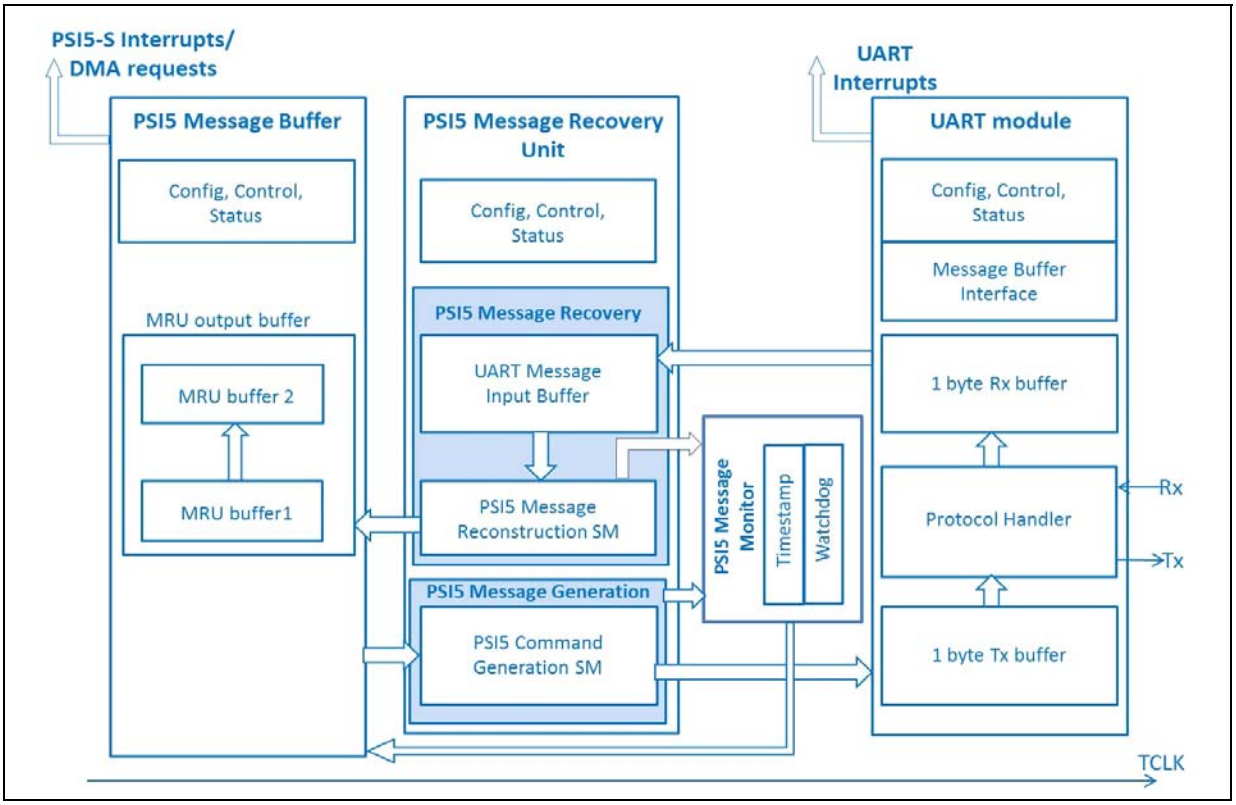
The PSI5-S module requires the physical and data link layer of the PSI5 to be implemented outside its interface. It also requires the PSI5 information to be embedded in the form of UART packet, from where it reconstructs the PSI5 message.

The module receives PSI5 message, from up to seven PSI5 channels each with up to six sequential frames. This is achieved via the external UART compliant transceiver. The PSI5 message in each of these frames are decomposed into three-to-six UART bytes (depending on PSI5 data payload) and streamed on a UART link at up to 6.25 Mbit/s to the PSI5-S module. In addition, via the PSI5-S interface, the application sends commands to the transceiver. The transceiver interprets them as either SYNC pulse commands (which will result in short, long or no SYNC pulses on the PSI5 bus), configuration commands (which will result in updates to the transceiver configuration) or diagnostic commands (which will result in the transceiver responding directly over the UART connection). In addition to the seven channels above there is an additional channel, known as Channel0, which is used for special purposes like storing the direct responses from the transceiver or storing the unrecoverable messages.

The PSI5-S consists of three main functional blocks.

1. UART front end: used as PSI5-S front end.
   When PSI5 functionality is not required then it is possible to use this as a standard UART (without LIN) also.
2. Message Recovery Unit: it consists of two state machines.
   – The first state machine interprets the input UART data stream and rebuilds the PSI5 message contained in the up to six UART bytes and also checks for the status of the correct reception of PSI5 message.
   – The second state machine sends SYNC pulse commands via the UART TxBuffer, to the external UART compliant transceiver, which in turn outputs SYNC pulses (short, long, or no SYNC pulse) on the PSI5 bus used to synchronize sensor responses in a bus configuration, and where required, also sends commands to sensors as defined in the PSI5 protocols V2.0.
3. PSI5 Message buffer & interface: It is composed of two MRU buffers, MRU buffer1 and MRU buffer2.
   Both buffers are collectively referred to as MRU output buffer. The MRU buffer1 is internal to the IP and not accessible from outside the IP. It is three word deep. MRU buffer2 is accessible to the application and is 4 word deep. MRU buffer2 can be read by the DMA interface, to transfer the stored PSI5 messages, to Channel specific mailboxes in system RAM directly.

Note: General description:



- *The location in system RAM where the messages are stored is referred to as the Mailbox. The mailbox is divided on the basis of channel and each channel is divided on the basis of slots on the PSI5 bus. Thus Mailbox1, location1 would mean Mailbox location for Channel1 and Slot No "1". This is also denoted by MBOX1, LOC1 or $MBOX_1$, LOC_1. This terminology would be followed in the subsequent sections of the doc.*
- *Each "location" of each mailbox channel is made up of 3x32 bits. The maximum size of each mailbox can be 6 "locations". There are 8 such mailboxes. For channels operating in asynchronous mode, the whole of the Mailbox would act like a ring buffer and all the 6 locations would be filled in that manner.*
- *Mailbox0 only has two locations MBOX0, LOC0 and MBOX0, LOC1. MBOX0, LOC0 is reserved for messages intended for Channel0 (used for transceiver specific messages) while*

MBOX0, LOC1 contain "unrecoverable" messages for any channel. Other 4 locations of the MBOX0 are reserved.

- *Also a "UART byte" would mean the "byte" that is received by the UART receiver. "UART packet" would mean the group of UART bytes from which the PSI5 message would be extracted. "PSI5 message" means the message contained in the MRU buffers which contains the actual PSI5 message along with the timestamp and the error status bits.*

Figure 1515 shows the block diagram of the PSI5-S module.

Figure 1515. PSI5-S digital interface block diagram

57.1.2 Features

- IPS interface for register read/write.
- Support for up to 7 PSI5 channels (Channel1 to Channel7) with each channel supporting up to 6 different Frame Streams (Slots). Each of the Frame Streams can be individually configured for Parity/CRC, payload Length, Synchronous/Asynchronous Operation, Timestamp Capture event, Timestamp A or Timestamp B selection.
- Additional Channel0 for special functions.
- Supports bidirectional full duplex operations, via the UART Rx and Tx links.
- Provision of Extended CRC (XCRC) to check the coherence of the UART packet that comprise the PSI5 message.
- Message Reconstruction Unit (MRU) buffer2 (consisting of 4, 32-bit words). Three of these words contain the PSI5 messages (PSI5 message payload, Message Status

flags, Time Stamp) and the fourth one contains the mailbox address to which the three PSI5 words need to be transferred.

- A 24-bit time stamp register, clocked with either the module clock or the GTM clock (gtm_trig). The time stamp appended to the PSI5 message in the MRU, can be configured to be, either the one that is captured when a new PSI5 message is detected, or the one that is captured when the Output ECU to Sensor command is transferred from the UART TX buffer to the UART Tx Shift register.
- IPS interface DMA support, for transferring the data in the MRU output buffer to system memory.
- Downstream Data Shift Register (DDSR) on per channel basis supporting the following:
  - Application can write the ECU to Sensor commands to the DDSR.
  - Supports automatic addition of the start bits/stuff bits /CRC calculation to the contents of DDSR.
  - Provision of resetting and rejecting the contents of DDSR at any stage of command transmission.
- Support for conversion of the logic levels contained in the DDSR, to UART commands to be sent to the transceiver.
- Provision of writing the Software calculated commands directly to the UART TX Buffer. This can be used for direct writing of the transceiver status or diagnostic commands, or both.
- Configurable UART message idle time counter, that indicates to the PSI5 MRU when an idle time at least as long as the configured length (number of bit times), has occurred on the Rx line.
- Provision of configuring the PSI5-S front-end as a standalone UART module, when the PSI5-S module is disabled. In this mode the module, does not have any relation with the PSI5 protocol.
- Support of up to 6.25 Mbit/s UART Rx Baud Rate.
- An output clock for the PSI5 transceiver UART interface.

57.1.3 PSI5-S global modes of operation

The PSI5-S module can be configured in 4 different global modes of operation. These are UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. These global modes can be entered by programming the PS_GLCR[GLOBAL_MODE] bits appropriately. *Figure 1516* shows the state transition diagram for these bits.

The PS_NORMAL, PS_CONFIG and PS_DISABLE are collectively referred to as the “PSI5-S” modes (refer to *Figure 1516*). Once the PS_GLCR[GLOBAL_MODE] bits are appropriately configured for the “PSI5-S” modes, the information that the intended mode of operation is fully achieved is reflected by the setting of the PS_GLSR[GL_MODETR_DONE] status bit. An interrupt can also be generated for this event, in case the PS_GLCR[GL_MODETR_DONE_EN] bit is set to “1”. Thus, only when PS_GLSR[GL_MODETR_DONE] goes to “1” it should be considered that the IP has entered the desired “PSI5-S” mode.

This bit is reset to “0” when the mode is changed from any of the PSI5-S modes to the UART_STDALONE mode and the corresponding interrupt is automatically deasserted.

Following are the descriptions of the different global modes.

57.1.3.1 Standalone UART mode (UART_STDALONE mode)

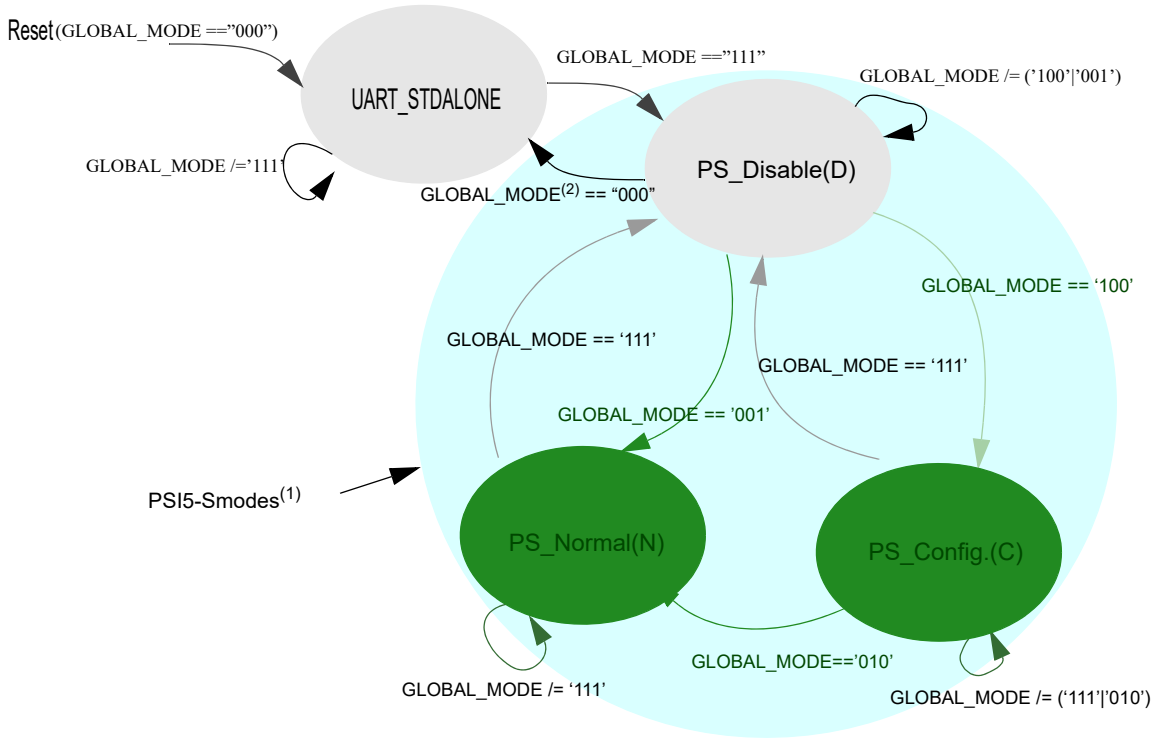
This is the default state after the module reset. In this mode, only the PS_GLCR[GLOBAL_MODE] register bits and the registers of the UART module are accessible for writing. This is the mode which is to be used when the PSI5-S front end has to be used as a standalone UART. This state indicates that the UART will now function as a standard UART and the PSI5-S core will be disabled.

57.1.3.2 Disable mode (PS_DISABLE)

PS_Disable mode in the PSI5-S reduces power consumption. In this mode the RX, TX and common time base counters are disabled for any operation. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1537*, for the details of these bits. Note that when entering PS_Disable mode from any other mode, the register contents are retained and are not changed. The timestamp counter is however reset when entering Disable mode.

In PS_Disable mode, only PS_GLCR[GLOBAL_MODE] register bits are accessible for read/write. Accessing any other register bits will generate transfer error.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of the PS_GLCR[GLOBAL_MODE] bits.



57.1.3.3 Configuration mode (PS_CONFIG mode)

In the configuration mode all PSI5-S global, channel specific configuration/control registers and UART registers can be written. The receiver and transmitter sub-blocks remain disabled in this mode. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1537*, for the details of these bits.

57.1.3.4 Normal mode (PS_NORMAL mode)

In PS_NORMAL mode, the receiver and the transmitter blocks become active, error handling is enabled, UART starts its operation and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5-S global and channel-specific configuration registers are locked for writing, although these registers can still be read. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1537* for the details of these bits. Note that there are still some register bits that can be written in this mode also (refer to the detailed register description).

Figure 1516. Operating modes

1. PSI5-S module can be configured in 4 different Global modes of operation. These are UART_STDALONE, PS_NORMAL, PS_CONFIG and PS_DISABLE. The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as “PSI5-S” modes.
2. PS_GLSR[GL_MODETR_DONE] status bit is reset to “0” when the transition occurs from PS_DISABLE to UART_STDALONE mode.

Table 1537. State transition

Present state	PS_GLCR (State variables)			Next state
	PS_GLCR[GLOBAL_MODE(2)]	PS_GLCR[GLOBAL_MODE(1)]	PS_GLCR[GLOBAL_MODE(0)]	
UART_STDALONE	1	1	1	PS_Disable
PS_Disable	0	0	0	UART_STDALONE
PS_Disable	0	0	1	PS_Normal
PS_Disable	1	0	0	PS_Config
PS_Config	1	1	1	PS_Disable
PS_Config	0	1	0	PS_Normal
PS_Normal	1	1	1	PS_Disable

57.1.4 PSI5-S system modes of operation

57.1.4.1 Stop mode

For PSI5-S modes:

In this mode, upon the STOP request from the system level the IP generates a system level acknowledgment with the information that the clocks to the IP can be switched off. The process of the same is as described below.

At the PSI5-S Rx side, as soon as stop mode request is received by the IP then the current PSI5 message under construction (in the internal PSI5 message extraction logic) is immediately saved to the MRU output buffer1. Thus the assertion of the stop mode acts like a “forced” flushing for the current PSI5 message completion. Depending on the state of the PSI5 message under construction, the resultant PSI5 message might or might not have errors. Any byte that is being received by the UART is henceforth rejected. The internal PSI5 message extraction logic goes back to an “idle” state and remains so till the STOP mode request remains asserted.

At the PSI5-S Tx side, on the reception of the stop mode request, the internal sync pulse generation counters are stopped immediately (DDSR trigger counters) and no further command bits are shifted onto the UART Tx side. The UART Tx completes the current byte that is being transmitted and enters the idle state. No further transmissions take place. On deassertion of the stop mode, once the clock restarts, the transmission of the commands resumes from where they had halted.

Once both the above processes are completed the IP generates acknowledgment for switching of the clocks to the PSI5-S IP. Also, refer to *Section 57.4.2.2: PSI5 “recoverable and unrecoverable” messages*.

For UART STDALONE mode, refer to *Chapter 59: LINFlexD*.

57.1.4.2 Debug mode

The IP enters this mode on system request. Any register can be read or written to by the debugger. The IP can enter the debug mode in addition to it being in any of the other modes (UART Standalone/Disable/Normal/Config). In this mode the hardware clearing of the register PS_WDGTSSR remains disabled and any read of this register has no effect on the contents of this register. Apart from this there is no other difference as to whether the IP is in debug mode or not in the debug mode of operation.

57.2 External signal description

Table 1538. External signal description

S.No	Name	Function	I/O	Pull-up
Signals to/from pads				
1.	ipp_ind_linrx	LINUART receive pin. Used for Receiving UART packets from transceiver which contain information to enable the rebuilding of the PSI5 message within the packet of between three and six UART bytes.	I	Active

Table 1538. External signal description (continued)

S.No	Name	Function	I/O	Pull-up
2.	ipp_do_lintx	LINUART transmit pin. Used for transmitting command bytes from TxFIFO to transceiver for generation of SYNC pulses (long, short or no) on the PSI5 bus or direct diagnostic/status commands for the transceiver itself.	O	Passive
3.	ipp_port_en_tx	LINUART transmission port enable: Connected to the enable pin of the pad which is to be used for “LINTX” functionality. When “1” it indicates that the IP is doing transmit of data.	O	Passive
4.	ipp_psi5_uart_tclk	Transceiver clock output, which drives the UART interface on the transceiver. The clock output frequency is configurable between 4 and 8 x UART baud rate on the interface between PSI5-S and transceiver. Frequency can be controlled at the system level through the Clock Generator Module (MC_CGM). The duty cycle of the transceiver clock is between 40% and 60%.	O	Passive

57.3 Memory map and register description

57.3.1 Memory map

Table 1539 shows the memory map.

0x0320	PSI5-S channel1 ECU to Sensor Downstream Data Shift register (PS_DDSR_L_CH7)	R	R/W[5]	R/W[5]	0x0000_0000	*Section 57.3.4.26*
0x0324–0x0330	Reserved					—

1. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot wherein writing a 1 causes an effect on the register bit while writing a 0 has no effect; a read always returning a 0”, D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable.
2. Locations from 0x0000 to 0x005C are for UART registers.
3. PS_NOUSE_REG: Stands for register NOT REQUIRED in PSI5-S modes. It will be required in UART STANDALONE mode.
4. Register has significance in UART STANDALONE mode. This document would only mention the bit field names in the corresponding register description. For detailed bit description and the functioning of this register in UART modes (sleep, init and normal) belonging to UART STANDALONE mode, refer to *Chapter 59: LINFlexD*.
5. Not all register bits are of this type (refer to the register bit description for more details).
6. Register Bits are automatically hardware cleared on read of any bit of this register.

57.3.2 Transfer error generation

The IP generates transfer error cases in a number of scenarios as detailed below:

1. Trying to write to any register in the PS_DISABLE mode (apart from the PS_GLCR and PS_GLSR) will result in the generation of the transfer error.
2. Trying to write to any “Read Only” register (those which have “R,R,R” in all the D,C,N columns in *Table 1539*) will generate a transfer error in any of the PS_DISABLE, PS_NORMAL and PS_CONFIG modes. Apart from the above “Read Only” registers, trying to write to any register bits outside there intended mode of operation (Normal/Config) would be ignored without the generation of any transfer error. For bit level operation and mode access of each register, refer to *Section 57.3.3* and *Section 57.3.4*.
3. Trying to access (R/W) any register space which is declared as reserved in *Table 1539* or which is unimplemented will generate a transfer error.
4. Reading of any register in any mode and if that register is NOT in unimplemented/reserved space, then a transfer error will not be generated.
5. Trying to write to any PSI5-S register (starting from locations 0x00B4, but apart from PS_GLCR and PS_GLSR) in the UART_STDALONE mode will generate a transfer error.
6. In UART Standalone mode the UART behaves as a standalone IP and for detailed transfer error cases in this mode, refer to *Chapter 59: LINFlexD*.

57.3.3 UART register configuration

This section contains information of the UART registers that are specifically required for correct functioning of the IP in the “PSI5-S” modes.

In order to operate the PSI5-S module, the UART configuration registers need to be programmed with appropriate values. The values that are required for different register fields are defined in the following register descriptions. Some bits have to be programmed with definite values of “1” or “0” only. This configuration has to be strictly followed for a predictable operation of the PSI5-S core. All these bits should be programmed in the PS_CONFIG mode before enabling the UART RX or the TX paths.

In the following UART register description “PS_NOUSE_BIT” against a bit name and bit description, means that the specific register bit is present in the UART module but it is NOT REQUIRED in the PSI5-S modes of operation. For correct operation in the PSI5-S modes, the corresponding register bit might be required to be programmed as “1” or a “0”; the same would be mentioned in the bit description.

Note that a bit with “PS_NOUSE_BIT” against its description would still be required in the UART STDALONE mode. For detailed information of the UART register bit functioning in the UART STDLONE mode, refer to the separate document describing the standalone LINUART module.There are some other register bits which do not have a “PS_NOUSE_BIT” against them. These can be programmed as required. A bit mentioned as “Reserved” would mean that neither it is available in the UART STANDLONE mode nor in the PSI5-S modes.

57.3.3.1 PSI5-S LIN control register 1 (PS_LINCR1)

The PS_LINCR1 register contains control bits used to configure features of the PSI5-S UART Front end.

Figure 1517. PSI5-S LIN control register 1 (PS_LINCR1)

Table 1540. PS_LINCR1 field descriptions

Field	Description
19 AUTOWU	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
25 SLFM	Self test mode 0 Self test mode disabled 1 Self test mode enabled To be used along with the LBKM bit. When this bit is set then in addition to the Loop Back mode; the “ipp_do_lintx” is driven to “1”.
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Programmed in PS_CONFIG mode. When set then the “ipp_do_lintx” output is internally looped back and connected to “ipp_ind_linrx” pin.
29 RBLM	PS_NOUSE_BIT Always program as 0 in PSI5-S modes.
30 SLEEP	PS_NOUSE_BIT **Note:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standalone mode. This bit is read as “1” in PS_DISABLE mode but is read as “0” in PS_NORMAL and PS_CONFIG mode.
31 INIT	PS_NOUSE_BIT **Note:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standalone mode. This bit is read as “0” in PS_DISABLE and PS_NORMAL mode, and “1” in PS_CONFIG mode.

57.3.3.2 PSI5-S LIN interrupt enable register (PS_LINIER)

Figure 1518. PSI5-S LIN interrupt enable register (PS_LINIER)

Table 1541. PS_LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
17 OCIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **Note:** This bit is also writable in PS_NORMAL mode.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (FEF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
26 WUIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **Note:** This bit is also writable in PS_NORMAL mode.

Table 1541. PS_LINIER field descriptions (continued)

Field	Description
28 TOIE	Timeout Interrupt Enable 0 No interrupt 1 Interrupt generation enabled. An interrupt is generated if this bit is set and the Timeout Flag (TO) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Data Received Flag (DRF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in PS_UARTSR is set. This interrupt can be used by the Application for debugging when it wants to read the byte that is under transmission. This byte can be read from the PS_BDRL[DATA_TX[0]] location. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.

57.3.3.3 PSI5-S LIN status register (PS_LINSR)

This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes.

Figure 1520. PSI5-S UART mode control register (PS_UARTCR)

Table 1543. PS_UARTCR field descriptions

Field	Description
0 MIS	PS_NOUSE_BIT Always program as “1” in PSI5-S modes.
1:3 CSP	Configurable Sample Point These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: **OSR / CSP**: 4 / 2, 3; 5 / 2, 3, 4; 6 / 3, 4, 5; 8 / NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6 and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.

Table 1543. PS_UARTCR field descriptions (continued)

Field	Description
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
12 PCE_Tx/ DTU	In PSI5-S mode Parity Control Enable for Tx path (In UART STANDLONE mode used to disable UART timeout, refer to *Chapter 59: LINFlexD* for more details): 1 Parity generation for Tx path enabled. 0 Parity generation for Tx path disabled. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[31] == 1. When programmed as “1” then a 1 bit additional parity bit is added to the transmitted 8 bits of UART data, so a total of 9 bits including parity are present between a start and a stop bit, in the transmitted data. When programmed as “0” then total of 8bits data is present between a start and a stop bit in the transmitted data.
13:14 SBUR	PS_NOUSE_BIT Always program as “00” in PSI5-S modes.
15 WLS	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
16:18 TDFL/TFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
19:21 RDFL/RFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
22 RFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
23 TFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
24 WL1	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
25 PC1	Parity Control {PC1, PC0} 00 Parity is Even for both the Rx/Tx paths. 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths. 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed only in the PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
26 RxEn	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when PS_UARTCR[31] == 1.

Table 1543. PS_UARTCR field descriptions (continued)

Field	Description
27 TxEn	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when PS_UARTCR[UART] == 1
28 PC0	Parity Control {PC1, PC0} 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
29 PCE_Rx	Receive Parity check enable. 1 Enable the parity checking on the Rx path 0 Disable the parity checking on the Rx path Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1. When programmed as “1” then a 1 bit additional parity bit is expected along with the received 8 bits of UART data, so a total of 9 bits including parity are expected between a start and a stop bit, in the received data. When programmed as “0” then total of 8bits data is expected between a start and a stop bit in the received data.
30 WL0	PS_NOUSE_BIT Always program as “1” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
31 UART	PS_NOUSE_BIT Always program as “1” in PSI5-S modes. Can be programmed in PS_CONFIG mode only.

Figure 1521. PSI5-S UART mode status register (PS_UARTSR)

Table 1544. PS_UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated on the UART interrupt lines if the SZIE bit in PS_LINIER is set.
17 OCF	PS_NOUSE_BIT Read Only Bit.
18:20 PE[3:1]	PS_NOUSE_BIT Read Only Bit.
21 PE0	Parity Error flag for Data0 byte These bits indicate if there is a Parity Error in the received byte. No interrupt is generated if this error occurs. 0 No parity error 1 Parity error in the corresponding received byte This flag is automatically cleared by hardware. The software can poll this flag for debugging purposes.
22 RMB	PS_NOUSE_BIT Read Only Bit.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). FEF is automatically cleared by hardware. An interrupt is generated if this bit is set and the FEIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and the previous byte has not yet been read from the UART Rx buffer due to some fault in PSI5-S core reading logic. It is automatically cleared by hardware. An interrupt is generated if this bit is set and the BOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	PS_NOUSE_BIT Read-only Bit.
27 RFNE	PS_NOUSE_BIT Read-only Bit.

Table 1544. PS_UARTSR field descriptions (continued)

Field	Description
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO is automatically cleared by hardware. An interrupt is generated if this bit is set and the TOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
29 DRF	Data Reception Completed Flag DRF is set by hardware in UART buffer mode and indicates that one byte has been received and is ready for being read. DRF is automatically cleared by hardware. An interrupt is generated if this bit is set and the DRIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
30 DTF	Data Transmission Completed Flag DTF is set by hardware in UART buffer mode and indicates that the current byte which was written to the PS_BDRL[0] location has been successfully transmitted by the UART. DTF is automatically cleared by hardware when a new byte transmission is started. An interrupt will be generated if the DTIE bit in PS_LINIER is set.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

57.3.3.6 PSI5-S LIN fractional baud rate register (PS_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Address: 0x0024 Access: User read/write

<tr><td>0xFFFFF</td><td>1048575</td></tr>
</table>
</td></tr>
</table>

Note: The UART baud rate is programmed in two registers: the LIN Integer Baud Rate register (PS_LINIBRR) and the LIN Fraction Baud Rate register (PS_LINFBRR). The baud rate registers can be programmed only during the PS_CONFIG mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

$Tx_{BR} = Rx_{BR}$ = ipg_baud_clk/(16 × LDIV) (when UARTCR[ROSE] == 0)

$Tx_{BR} = Rx_{BR}$ = ipg_baud_clk/UARTCR[OSR] x LINIBRR (when UARTCR[ROSE] == 1)

LDIV is an unsigned fixed point number which comprises of the mantissa and the fraction. The mantissa is coded into 20 bits of LINIBRR, and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled (UARTCR[ROSE] ==1) then PS_LINFBRR is not used. Hence LDIV contains only the integer part programmed in LINIBRR. Following are 2 examples for two different baud rate calculations.

Example 1:

With UARTCR[ROSE] = 0.

LDIV = 1041.67, ipg_baud_clk = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

$Tx_{BR} = Rx_{BR}$ = 80 MHz/ (16 x 1041,67) = 4.8 Kbit/s

Example 2:

When UARTCR[ROSE] = 1:

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, UARCR[OSR] = 4

$Tx_{BR} = Rx_{BR}$ = ipg_baud_clk/ (UART[OSR] × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

57.3.3.8 PSI5-S LIN control register 2 (PS_LINCR2)

This register includes control status bits related to buffer operations.

1. Register bit can be read in any mode, written only in PS_CONFIG mode.
2. Register bit can be written only by software in PS_CONFIG mode. Bit is always read 0 by software.

Figure 1527. PSI5-S global control register (PS_GCR)

Table 1550. PS_GCR field descriptions

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB: 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is the LSB bit (of DATA_TX in PS_BDRL register) 1 The first bit of transmitted data is MSB — in other words, first bit transmitted is the MSB bit (of DATA_TX in PS_BDRL register)
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB: 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (of DATA_RX in PS_BDRM register) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (of DATA_RX in PS_BDRM register)
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only). 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only). 0 Received data is not inverted 1 Received data is inverted
30 STOP	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
31 SR	Soft reset SR executes a soft reset of the UART controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0.

57.3.3.12 PSI5-S UART preset timeout register (PS_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed to monitor the idle state of the reception line. This register can be written by software any time.

Address: 0x0050 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1528. PSI5-S UART preset timeout register (PS_UARTPTO)

Table 1551. PS_UARTPTO field descriptions

Field	Description
20:31 PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. The register must be programmed to a value of “Idle Timeout required in terms of number of bits received” at that particular baud rate. The idle timeout is measured after the stop bit and measures the minimum amount of time (in terms of bits) for which the line stays high. Refer also to register UARTCTO.

57.3.3.13 PSI5-S UART current timeout register (PS_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (refer to *Section 57.3.3.12: PSI5-S UART preset timeout register (PS_UARTPTO)* to monitor the idle state of the reception line.

The timeout counter:

- Starts at zero and counts upward.
- Is clocked with baud clock frequency of Tx_{BR}/Rx_{BR}. Also refer to *Note: on page 2633*.
- Is automatically enabled when UARTCR[RXEN] = 1.

Note: Due to internal synchronization there is a delay between 4 to 6 clock cycles of “ipg_clk_ps”, for the internal counter’s value (which is clocked with baud frequency of Tx_{BR}/Rx_{BR}) to reflect on to UARTCTO.

UARTCTO is reset when:

- UARTCTO becomes equal to UARTPTO.
- Whenever UARTPTO is written.
- When the PSI5-S goes in PS_DISABLE mode.

Field	Description
31 DRE0	PS_NOUSE_BIT Always program with “0” in PSI5-S modes

57.3.3.16 PSI5-S UART Tx idle delay time (PS_PTD)

This register is used to add a programmable idle time between the data that is transmitted on the UART Tx line. The duration of this delay is programmable between 1 to 16 bit times.The programmable delay is such that when the normal ECU to Sensor communication (no direct command) is happening, then it comes into play between each byte of transmitted data. When the ECU to Sensor direct command is used then this delay comes into play between each direct command. The direct commands can be programmed as 1, 2 and 4 bytes depending on the PS_GLCR[DIRCMD_LEN] register. Refer to *Section 57.3.4.13: PSI5-S ECU to sensor direct command write register (PS_DIRCMD)* and *Section 57.3.4.1: PSI5-S global control register (PS_GLCR)*, for more details.

31 EN	IFD Enable 0 The IFD is active in the UART Tx path 1 The IFD is inactive

57.3.4 PSI5-S register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

PS_GLCR[GLOBAL_MODE] are the only register bits that can be written in the PS_DISABLE mode.

All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error.

57.3.4.1 PSI5-S global control register (PS_GLCR)

The Global Control Register (PS_GLCR) provides control functions for all the PSI5-S channels simultaneously.

Address: 0x00B4 Access: User read/write

Figure 1533. PSI5-S global control register (PS_GLCR)

Table 1556. PS_GLCR field descriptions

Field	Description
8:9 DIRCMD_LEN	Direct Command Length Register This defines the length of the Direct Command that is transferred to the UART Tx line. The Direct command is written to the PS_DIRCMD register in the format {DIRCMD_BYTE3, DIRCMD_BYTE2, DIRCMD_BYTE1, DIRCMD_BYTE0}.Following is the bit description: 00 1 byte command: 1 byte {DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx. Rest bytes of the PS_DIRCMD are ignored. 01 2 byte command: 2 bytes {DIRCMD_BYTE1, DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx without any idle time between DIRCMD_BYTE1 and DIRCMD_BYTE0. Rest bytes of the PS_DIRCMD are ignored. 10 4 byte command: 4 bytes 11 4 byte command: 4 bytes {DIRCMD_BYTE3, DIRCMD_BYTE2, DIRCMD_BYTE1, DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx line without any idle time between these bytes. The idle time between the commands is still governed by the PS_PTD register in the LINUART module. This register is also writable in the NORMAL mode.
11 IE_DIRCMD_RDY	Interrupt enable bit for DIRCMD_RDY 0 PS_GLCR[DIRCMD_RDY], when goes as “1”, does not generate any interrupt on the “ipi_ps_glbl” interrupt line. 1 PS_GLCR[DIRCMD_RDY], when goes as “1”, generates an interrupt on the “ipi_ps_glbl” interrupt line. **Note:** This bit is also writable in PS_NORMAL mode.
13 DEBUG_EN	Debug enable bit 0 The IP does not enter the debug mode when a request is made to the IP for entering into the debug mode. It continues its normal operation. 1 The IP enters the debug mode immediately, as soon as a request is made to the IP for entering into the debug mode. For debug mode operation, refer to *Section 57.1.4.2: Debug mode*.
16 GL_DDSR_TRIG	This is the global shift trigger of all the DDSRs of each channel. When the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] == 1, only then is this bit effective, else this bit has no effect. 1 The shift triggers of all the DDSR’s start synchronously. 0 Shift triggers of all the DDSR registers are halted (default state). If bit is cleared during runtime, PS_DDTRIG_PERR and PS_DDTRIG_OFFR counters are reset. **Note:** If bit is subsequently set after being cleared, then the counters will restart and the offsets in PS_DDTRIG_PERR and PS_DDTRIG_OFFR registers will be applied again. This bit is also writable in PS_NORMAL mode.
17 GL_MODETR_ DONE_EN	Interrupt enable for PS_GLSR[GL_MODETR_DONE] bit 1 Generates the interrupt when PS_GLSR[GL_MODETR_DONE] bit is set. 0 No interrupt is generated on setting of the PS_GLSR[GL_MODETR_DONE] bit. **Note:** This bit is also writable in all modes (PSI5-S and UART_NORMAL).

Table 1556. PS_GLCR field descriptions (continued)

Field	Description
18 MRU_ERR_EN	Enables the interrupt for MRU overwrite when the unread contents of MRU Buffer1 are overwritten by a new message. 0 MRU overwrite error is not enabled. 1 MRU overwrite error is enabled. **Note:** This bit is also writable in ps_normal mode.
19 TSCS_B	This bit controls the selection of clock input to timestamp counter B, either by the external periodic clock or by the GTM module. 1 gtm_trig is selected as the clock. 0 External clock (ipg_clk_ps_ts) is selected.
20 TSCS_A	This bit controls the selection of clock input to timestamp counter A, either by the external periodic clock or by the GTM module. 1 gtm_trig is selected as the clock. 0 External clock (ipg_clk_ps_ts) is selected.
21 CLR_CNTR_B	This bit will reset timestamp counter B when PS_GLCR[CLRTSCNT_G_L] is NOT set. 1 Timestamp counter B is reset. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode.
22 CLR_CNTR_A	This bit will reset timestamp counter A when PS_GLCR[CLRTSCNT_G_L] is NOT set. 1 Timestamp counter A is reset. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode.
23 CLRTSCNT_G	This bit controls the global clearing of the timestamp counters A and B when CLRTSCNT_G_L == 1. When CLRTSCNT_G_L == 0 then this bit has no effect. 1 Both timestamp counters are cleared at the same time. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode.
24 CLRTSCNT_G_L	This bit control whether the timestamp counters counter A and B are cleared simultaneously or independently: 0 Timestamp counters A and B are cleared independently. When PS_GLCR[CLR_CNTR_A] == 1 timestamp counter A is cleared. When PS_GLCR[CLR_CNTR_B]== 1 timestamp counter B is cleared. 1 Both timestamp counters are cleared simultaneously as soon as CLRTSCNT_G == 1.
25 TSCNT_EN_B	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G_L] is not set. 0 Timestamp counter A not enabled. 1 Timestamp counter B is enabled. **Note:** This bit is also writable in ps_normal mode.
26 TSCNT_EN_A	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G_L] is not set. 0 Timestamp counter A not enabled. 1 Timestamp counter A is enabled. **Note:** This bit is also writable in ps_normal mode.

Table 1556. PS_GLCR field descriptions (continued)

Field	Description
27 TSCNTEN_G	This bit controls the global trigger of the timestamp counters A and B when TSCNTEN_G_L == 1. When TSCNTEN_G_L == 0 then this bit has no effect. 0 Both timestamp counters are disabled simultaneously. 1 Both timestamp counters start simultaneously. **Note:** This bit is also writable in ps_normal mode.
28 TSCNTEN_G_L	This bit control whether the timestamp counters counter A and B are started simultaneously or independently. 0 Timestamp counters A and B are started independently. When PS_GLCR[TSCNT_A_EN] == 1 timestamp counter A starts When PS_GLCR[TSCNT_B_EN] == 1 timestamp counter B starts. 1 Both timestamp counters are triggered simultaneously as soon as TSCNTEN_G == 1.
29:31 GLOBAL_MODE	These are the bits which decide Global Mode of the IP. There are 4 modes, UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. For details of modes related to GLOBAL_MODE bit setting, refer to *Table 1537: State transition*. **Note:** These bits are writable in all modes (PSI5-S and UART_STANDALONE).

57.3.4.2 PSI5-S global status register (PS_GLSR)

Address: 0x00B8 Access: User read/write

Figure 1534. PSI5-S global status register (PS_GLSR)

Table 1557. PS_GLSR field descriptions

Field	Description
11 DIRCMD_RDY	Bit used to indicate the “Ready for Direct Command write” status: 0 Direct Command that is written to the PS_DIRCMD register is currently under processing. Any further command written to the PS_DIRCMD register would be rejected without any information. 1 The PS_DIRCMD register is empty and the application can write the direct ECU to sensor transceiver command to the PS_DIRCMD register. Once the command is written to the PS_DIRCMD, then a “w1c” to this register should be done so that the command written to the PS_DIRCMD register is queued for UART transmission with the highest priority. When the command has been transferred from the register to the UART, then this bit goes as “1”. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1” then this event generates an interrupt on the ipi_ps_glbl line. **Note:** This bit is also writeable in the PS_NORMAL mode.
17 GL_MODETR_DONE	This bit indicates, as to when the global mode transitions, as programmed by PS_GLCR[GLOBAL_MODE] have actually been accomplished: 1 The global mode as programmed in the PS_GLCR[GLOBAL_MODE] have been accomplished. 0 The intended global mode, as programmed in the PS_GLCR[GLOBAL_MODE] register bits, is under processing. **Note:** This bit is cleared by w1c. The bit is also writable in PS_NORMAL and PS_DISABLE mode. This bit is reset to “0” when the mode is changed from PS_DISABLE to the UART_STDALONE mode.
18 MRU_ERR	This bit shows whether unread MRU buffer1 contents have been overwritten by a new message: 1 Overwrite occurred. 0 No overwrite occurred. **Note:** This bit is cleared by w1c. The bit is also writable in PS_NORMAL mode.
26:28 FID	Points to the frame whose data in MRU buffer 1 was overwritten.
29:31 CHID	Points to the channel whose data in MRU buffer 1 was overwritten.

57.3.4.3 PSI5-S channel base address register (PS_CH_BASE_ADDR)

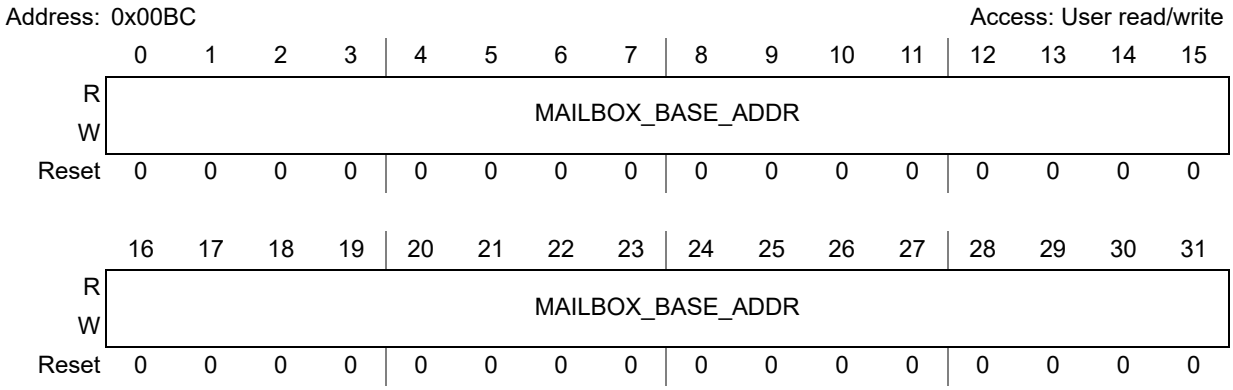

Figure 1535. PSI5-S channel base address register (PS_CH_BASE_ADDR)

Table 1558. PS_CH_BASE_ADDR field descriptions

Field	Description
0:31 MAILBOX_BASE_ADDR	This register will provide the base address of the mailbox in the system RAM.This value needs to be programmed by the software.

57.3.4.4 PSI5-S MRU output buffer 2 register 0 (PS_MRU_BUF2_REG0)

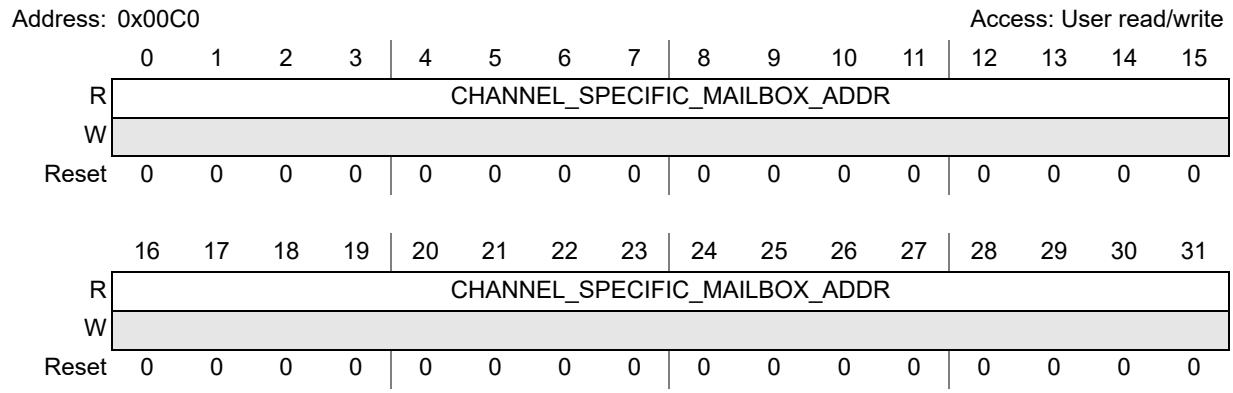

Figure 1536. PSI5-S MRU output buffer 2 register 0 (PS_MRU_BUF2_REG0)

Table 1559. PS_MRU_BUF2_REG0 field descriptions

Field	Description
0:31 CHANNEL_SPECIFIC_MAILBOX_ADDR	This register will provide the channel specific mailbox address corresponding to channel and slot for which data has been received.This value is computed by the IP based on the PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] and FID, CID. Following is the formula used to calculate this address: – For messages with CID==0 in the header byte, destined for Channel0 location0, value is: PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] – For “unrecoverable” messages destined for Channel0,location1, value is: PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]+0xC – For other messages with CID = 1 to 7 the value can be calculated as: (PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] + (6*4*3(MSG_CH_ID)+(MSG_FRAME_ID)*4*3)) When using the DMA for reading the MRU buffer, this register forms the Access1 of the DMA transfer.

57.3.4.5 PSI5-S MRU output buffer 2 register 1 (PS_MRU_BUF2_REG1)

Figure 1537. PSI5-S MRU output buffer 2 register 1 (PS_MRU_BUF2_REG1)

Table 1560. PS_MRU_BUF2_REG1 field descriptions

Field	Description
0:3 DCI	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM.
5 R_UVL_ERR	Message underflow It is set when less than three UART bytes are received in the UART packet. In case of XCRC error the message is treated as unrecoverable and written in mail box location1 of channel 0. 1 Error occurred 0 No error occurred Refer to *Section 57.4.2.1: PSI5 message extraction*, for more details.
6 N_ERR	Indicates that the number of UART bytes in the received UART packet does not match the number specified in Channel Configuration Register A indicated by CID and FID that is the number of UART bytes does not match the value programmed in PS_MSGA_CH_{CID}[F_{FID}_bytes]. Also, refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)*. 1 Error occurred 0 No error occurred Refer to *Section 57.4.2.1: PSI5 message extraction*, for more details.
7:9 CHID	Indicates Channel id of PSI5 message present in the UART header byte.
10:12 FID	Indicates Frame ID of PSI5 message present in the UART header byte.
13 R_OVL_ERR	Message overflow.It is set when more than six UART bytes are received in the UART packet.The message may be recoverable (XCRC_ERR == 0) or unrecoverable (XCRC_ERR==1). Refer to *Section 57.4.2.1: PSI5 message extraction*, for more details. 1 Error occurred 0 No error occurred

Table 1560. PS_MRU_BUF2_REG1 field descriptions (continued)

Field	Description
14 F_WD_ERR	Frame watchdog error in the received PSI5 message In case there is no XCRC error in the received message, then this bit will be the same as the PS_WDGTSSR[F_WD_ERR[CID]] bit, where CID is the channel ID of the received PSI5 message. In case the received PSI5 message has an XCRC error then this bit will be the logical OR of all the PS_WDGTSSR[F_WD_ERR[CHn]] bits that is in this case it will be "PS_WDGTSSR[F_WD_ERR[1]] OR PS_WDGTSSR[F_WD_ERR[2]] OR....PS_WDGTSSR[F_WD_ERR[7]]". Refer to *Section 57.4.5: PSI5-S watchdog operation*, *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* and *Section 57.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*, for more details. 1 Error occurred 0 No error occurred **Note:** Whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set, PS_WDGTSSR (which is a hardware clearing register) should always be read. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective "CID", whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID.This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit.
15 SCI_O_ERR	UART overrun error has occurred in at least one UART byte of the received UART packet, due to which some UART byte has been lost. 1 Error occurred 0 No error occurred
16 SCI_F_ERR	UART framing error has occurred in the current received UART packet. 1 Error occurred 0 No error occurred
17 SCI_P_ERR	UART message parity error has occurred in at least one UART byte of the received UART packet. 1 Error occurred 0 No error occurred
18 HD_ERR	This bit is set when any of the ERR[1:0] is "1" and indicates a transceiver error. 1 Error occurred 0 No error occurred
19:20 ERR	Transceiver error flags received in the Message header byte of the UART packet indicated by CID and FID.
21 CRC_ERR/ P_ERR	Indicates whether "PSI5 message" crc_err or the parity error in the PSI5 message indicated by CID and FID has occurred. The Parity is taken as even for PSI5 calculation: 1 Indicates crc_error/Parity Error has occurred 0 No crc_error/parity error has occurred **Note:** This bit always remains "0" for messages having CID and FID both as "0".
22:24 CRC	Contains the received CRC or Parity Bits of the PSI5 message, of indicated by CID and FID.

Table 1560. PS_MRU_BUF2_REG1 field descriptions (continued)

Field	Description
25 XCRC_ERR	Indicates xcrc_err in the received UART packet: 1 Indicates xcrc_error occurred 0 No xcrc_error occurred
26:31 XCRC	This is the value of XCRC received in the last six bits of the UART byte, which occurs just before the information of a “new UART packet received” has been generated. Refer to *Section 57.4.1: PSI5-S UART message structure* and *Section 57.4.2.5: PSI5-S XCRC handling*, for more details.

Figure 1540. PSI5-S mbox status IRQ (PS_MBOX_SR_IRQ)

Table 1563. PS_MBOX_SR_IRQ field descriptions

Field	Description
24 MBOX_CH7	When set it Indicates at least one message in mailbox 7 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH7[*F(0-5)_READ*] bits that is MBOX_CH7 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel7 are cleared.
25 MBOX_CH6	When set it Indicates at least one message in mailbox 6 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH6[*F(0-5)_READ*] bits that is MBOX_CH6 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel6 are cleared.
26 MBOX_CH5	When set it Indicates at least one message in mailbox 5 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH5[*F(0-5)_READ*] bits that is MBOX_CH5 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel5 are cleared.
27 MBOX_CH4	When set it Indicates at least one message in mailbox 4 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH4[*F(0-5)_READ*] bits that is MBOX_CH4 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel4 are cleared.
28 MBOX_CH3	When set it Indicates at least one message in mailbox 3 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH3[*F(0-5)_READ*] bits that is MBOX_CH3 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel3 are cleared.
29 MBOX_CH2	When set it Indicates at least one message in mailbox 2 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH2[*F(0-5)_READ*] bits that is MBOX_CH2 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel2 are cleared.

Table 1563. PS_MBOX_SR_IRQ field descriptions (continued)

Field	Description
30 MBOX_CH1	When set it Indicates at least one message in mailbox 1is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH1[*F(0-5)_READ*] bits that is MBOX_CH1 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel1 are cleared.
31 MBOX_CH0	When set it Indicates at least one message in mailbox 0is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH0[*F(0-1)_READ*] bits that is MBOX_CH0 = F0_READ OR F1_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel0 are cleared.

Note: Also refer to Figure 1573: IRQ[n] interrupts, for bit fields details.

Figure 1541. PSI5-S error status IRQ (PS_ERR_SR_IRQ)

Table 1564. PS_ERR_SR_IRQ field descriptions

Field	Description
22 R_UVL_ERR	When set indicates that message underflow error (number of UART bytes received are less than 3) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_UVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_UVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
23 N_ERR	When set indicates that N_ERR (Number of UART bytes are not equal to PS_MSGA_CHn[Fn_byte]) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[N_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[N_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
24 R_OVL_ERR	When set indicates that message Overflow error (number of UART bytes received have exceeded 6) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_OVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_OVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
25 F_WD_ERR	When set indicates that Frame Watchdog error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[F_WD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[F_WD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
26 SCI_O_ERR	When set indicates that UART Overrun error (from the UART side) is present in the message currently present in MRU buf2. When “1”, then this bit indicates that some UART byte belonging to the concerned UART packet, has been overwritten by another UART byte and is lost. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_O_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_O_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.

Table 1564. PS_ERR_SR_IRQ field descriptions (continued)

Field	Description
27 SCI_F_ERR	When set indicates that UART Framing error is present in the message currently present in MRU buf2. If this bit is set then it indicates to the application that the synchronization of the UART module is lost and any subsequent UART bytes received will be error prone. In this case the application is required to reset the UART module by using the PS_GCR[SR] bit. Subsequently it should restart the transmission. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_F_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_F_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
28 SCI_P_ERR	When set indicates that UART parity error is present in the message currently present in MRU buf2. This bit will be set when there is a parity error in any UART byte using which the concerned UART packet was formed. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
29 HD_ERR	When set indicates that Header error (E0/E1) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[HD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[HD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
30 CRC_ERR/P_ERR	When set indicates that PSI5 CRC/Parity error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **Note:** This bit always remains “0” for messages having CID and FID both as “0”.
31 XCRC_ERR	When set indicates that XCRC error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[XCRC_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[XCRC_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.

Note: Also refer to Figure 1573: IRQ[n] interrupts, for bit fields details.

If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.

Figure 1544. PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)

Table 1567. PS_WDGTSSR bit field details

Field	Description
0:6 F_WD_ERR_STATUS	F_WD_ERR_STATUS[7:1] These bits give the watchdog error status for the watchdog of each corresponding channel. Thus F_WD_ERR_STATUS[1] will give the watchdog error status for watchdog of channel1. Similarly F_WD_ERR_STATUS[2] will give the watchdog error status for watchdog of channel2 and so on till F_WD_ERR_STATUS[7], which gives the watchdog error status for watchdog of channel7. As soon as the watchdog of the corresponding channel has a watchdog overrun error, the error status is latched in the corresponding bits of this register. **Note:** PS_WDGTSSR is a hardware cleared register. These bits are automatically cleared by the hardware when PS_WDGTSSR is read by the application. This register should ALWAYS be read whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective “CID” whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID.This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit.
8:31 WDGTS_STATUS	Timestamp value of that specific channel, the timestamp of which is captured when the watchdog error of that specific channel has occurred. This register always contains the timestamp value corresponding to the last occurring Watch Dog error. If due to bad programming watchdog error of more than one channel happen simultaneously then this register contains the timestamp value of the highest channel. For each channel, whether Timestamp A or B is captured depends on the value of PS_MSGA_CHn[TIMESTAMP_A_B_SEL] register bit. **Note:** These bits are automatically cleared by the hardware when PS_WDGTSSR is read by the application.

Note: All bits of PS_WDGTSSR register are self clearing on read. This implies that in case this register is read by the application before the corresponding PS_WDGTSSR[F_WD_ERR_STATUS[CHn]] has had a chance to be sent in the next upcoming PSI5 message, then this bit would be sent as a "0" in this upcoming PSI5 message.

57.3.4.13 PSI5-S ECU to sensor direct command write register (PS_DIRCMD)

Address: 0x012C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DIRCMD_BYTE3								DIRCMD_BYTE2							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	DIRCMD_BYTE1								DIRCMD_BYTE0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1545. PSI5-S ECU to sensor direct command write register (PS_DIRCMD)

Table 1568. PS_DIRCMD field descriptions

Field	Description
0:7 DIRCMD_BYTE3	Byte3 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1".
8:15 DIRCMD_BYTE2	Byte2 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1".
16:23 DIRCMD_BYTE1	Byte1 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1".
24:31 DIRCMD_BYTE0	Byte0 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1".

Note: A "w1c" should be done on the PS_GLSR[DIRCMD_RDY] so that the command written on the PS_DIRCMD register is queued for transmission on the UART TX line. As soon as any ongoing transmission on the UART TX is finished, the PS_DIRCMD starts being transmitted

on the UART Tx line. When PS_GCR[TDFBM] = 0, then the bits on the UART Tx line are shifted in the following sequence "DIRCMD_BYTE0[0], DIRCMD_BYTE0[1]....DIRCMD_BYTE3[0]....DIRCMD_BYTE3[7]" with DIRCMD_BYTE0[0] being shifted first.

57.3.4.14 PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)

Figure 1546. PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)

Table 1569. PS_MSGA_CH0 field descriptions

Field	Description
21:23 F0_BYTE	Number of UART bytes comprising one UART packet. Applicable only to special messages having CID = 0 in their Message Header. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled and a message with the corresponding frame ID is not expected to occur. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
26 TIME_STAMP_A_B_SEL	Whether the Timestamp corresponding to timestamp counter A or B, is appended to messages targeted for Channel0. 0 Timestamp counter A 1 Timestamp counter B
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel.Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 Timestamp buffer is cleared. This bit is one shot and is always read as "0". **Note:** This bit is also writable in PS_NORMAL mode.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value "0" or is refreshed on a timestamp "capture event". 0 Timestamp buffer maintains value "0". 1 Timestamp buffer responds to a "capture event" and captures the respective timestamp value.

57.3.4.15 PSI5-S channel 0 message configuration register B (PS_MSGB_CH0)

Figure 1547. PSI5-S channel 0 message configuration register B (PS_MSGB_CH0)

Table 1570. PS_MSGB_CH0 field descriptions

Field	Description
27:31 F0_payload	Number of bits in payload region of the message (only for channels having CID as “0” in the message header). This channel is always asynchronous. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

57.3.4.16 PSI5-S mailbox status register channel 0 (PS_MBOX_SR_CH0)

Address: 0x0178 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1548. PSI5-S mailbox status register channel 0 (PS_MBOX_SR_CH0)

Table 1571. PS_MBOX_SR_CH0 field descriptions

Field	Description
26 F1_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC1) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC1) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when an unrecoverable message (with the CID = 0 and FID=1) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
27 F1_OV	1 Indicates that there is an unread message stored in MBOX0, LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX0, LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode.
28 F1_READ	MBOX0, LOC1 is reserved for any unrecoverable message (XCRC_ERR has occurred or it is an "illegal message"). It can correspond to any channel from 1 to 7. 1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX0, LOC1 by the DMA. 0 No unread message in MBOX0.LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode.
29 F0_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC0) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC0) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when a transceiver message (with the CID = 0 and FID=0) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.

Table 1571. PS_MBOX_SR_CH0 field descriptions (continued)

Field	Description
30 F0_OV	1 Indicates that there is an unread message stored in MBOX0, LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX0, LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode.
31 F0_READ	MBOX0, LOC0 is reserved for a transceiver message. 1 It indicates that the message that has just been read from PS_MRU_BUF2 will be stored in MBOX0, LOC0 by the DMA. 0 No unread message in MBOX0, LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode.

57.3.4.17 PSI5-S channel message configuration register A (PS_MSGA_CHn)

Address: 0x0190 + [n-1]*0x3C (n=1 to 7) Access: User read/write

Figure 1549. PSI5-S channel message configuration register A (PS_MSGA_CHn)

Table 1572. PS_MSGA_CHn field descriptions

Field	Description
0 L_PC_EN	Selects whether the parity/CRC selection for a PSI5 message is to be controlled globally on a channel basis (through the G_PC bits) or locally on a per frame basis (through the L_PC[frame] bits). 0 Parity/CRC option controlled globally through the G_PC bit. 1 Parity/CRC option controlled locally through the L_PC[frame] bits individually for message of each frame.
1:3 F5_BYTE	Number of bytes in UART packet for message corresponding to frame 5. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F5_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
4 L_PC5	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame5. 1 CRC selected for PSI5 message for frame5.
5:7 F4_BYTE	Number of bytes in UART packet for message corresponding to frame 4. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F4_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
8 L_PC4	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame4. 1 CRC selected for PSI5 message for frame4.
9:11 F3_BYTE	Number of bytes in UART packet for message corresponding to frame 3. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F3_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
12 L_PC3	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame3. 1 CRC selected for PSI5 message for frame3.
13:15 F2_BYTE	Number of bytes in UART packet for message corresponding to frame 2. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F2_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
16L_PC2	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame2. 1 CRC selected for PSI5 message for frame2.

Table 1572. PS_MSGA_CHn field descriptions (continued)

Field	Description
17:19 F1_BYTE	Number of bytes in UART packet for message corresponding to frame 1. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F1_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
20 L_PC1	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message. 0 Parity selected for message for frame1. 1 CRC selected for PSI5 message for frame1.
21:23 F0_BYTE	Number of bytes in UART packet for message corresponding to frame 0. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F0_payload] is immaterial. Refer to note in *Section 57.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
24 L_PC0	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message. 0 Parity selected for message for frame0. 1 CRC selected for PSI5 message for frame0.
25 MODE	This bit selects the operating modes between sync and async for the channel. 1 Asynchronous. 0 Synchronous.
26 TIME_STAMP_A_B_SEL	Decides whether timestamp counter A or B value is captured in the local timestamp buffer, whenever a “capture event” occurs. 0 Timestamp counter A. 1 Timestamp counter B.
27 TMSG_TCMD	Whether the timestamp is recorded when the message is received or when the channel command is moved from the TxFIFO to the UART Tx register (emulates a sync pulse) 1 Timestamp recorded based on message header byte received. 0 Timestamp recorded based on “emulated” sync pulse.
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel.Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 Timestamp buffer is cleared. This bit is one shot and is always read as “0”. **Note:** This bit is also writable in PS_NORMAL mode.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value “0” or is refreshed on a timestamp “capture event”. 0 Timestamp buffer maintains value “0”. 1 Timestamp buffer responds to a “capture event” and captures the respective timestamp value.

Table 1572. PS_MSGA_CHn field descriptions (continued)

Field	Description
30 G_PC	This bit globally selects the Parity or the CRC option for all the Frames of that particular channel provided L_PC_EN is set “0”. 0 Parity option selected globally for messages of all frames. 1 CRC option selected globally for messages of all frames.
31 CH_EN	PSI5 Channel Enable. This bit decides if the IP takes the data belonging to the specific channel as “legal” or “illegal”. 0 Concerned PSI5 channel is disabled. Any data occurring with a CID value of a disabled channel is treated as an “illegal message” and send to Channel 0 unrecoverable message area ($MBOX_0$, LOC_1). 1 Concerned PSI5 channel is enabled.Any data occurring with a CID value of an enabled channel can either be treated as “legal” or “illegal”. Refer to *Section 57.4.2.1: PSI5 message extraction* for the definition of legal and illegal messages. Legal messages are sent to $MBOX_{CID}$, LOC_{FID} while illegal messages are sent to $MBOX_0$, BOX_0, LOC_1.

57.3.4.18 PSI5-S channel message configuration register B (PS_MSGB_CHn)

Address: 0x0194 + [n-1]*0x3C (n=1 to 7) Access: User read/write

Figure 1550. PSI5-S channel message configuration register B (PS_MSGB_CHn)

Table 1573. PS_MSGB_CHn field descriptions

Field	Description
2:6 F5_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 5. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
7:11 F4_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 4. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Table 1573. PS_MSGB_CHn field descriptions (continued)

Field	Description
12;16 F3_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 3. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
17:21 F2_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 2. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
22:26 F1_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 1. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
27:31 F0_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 0. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28. This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Note: The IP expects legal values to be programmed for Fn_byte field. If this is not followed then the IP reprogrammed the registers with default values. Whenever the value of "Fn_byte" field becomes 1 or 2 it is defaulted to 3 and value of 7 is defaulted to 6. This updation happens once the IP enters the PS_NORMAL mode.

In addition to the above, the following checks are also performed.

By default the IP will expect that there is coherence between the expected number of bytes calculated through the "minUARTbytes" and the number of bytes in the "Fn_byte" field. Refer to Figure 1560: PSI5-S packet structure for definition of "minUARTbytes". If there is no coherence (that is the above two calculations do not match) then the IP does the following recalculation:

When Programmed Fn_byte > "minUARTbytes", then the IP will expect that the additional extra bytes would be stuffed with 0s from the transceiver. Rest of the checking will be done as described in Section 57.4.2.2: PSI5 "recoverable and unrecoverable" messages.

When Fn_byte < "minUARTbytes" then the "Fn_bytes" is internally "increased" such that the expanded "Fn_bytes" is now equal to minUARTbytes". Refer to Figure 1560: PSI5-S packet structure for definition of "minUARTbytes". Using this expanded "Fn_bytes" value the message that would be arriving is analyzed. This would mean that no data bits are lost. Rest of the checking will be done as described in Section 57.4.2.2: PSI5 "recoverable and unrecoverable" messages.

The "recalculated" Fn_byte field is automatically updated by the IP once the IP enters the NORMAL mode of operation. For the subsequent occurrence in the document, all references to "Fn_byte" would mean the recalculated value of "Fn_byte".

57.3.4.19 PSI5-S mailbox status register channel (PS_MBOX_SR_CHn)

Figure 1551. PSI5-S mailbox status register channel (PS_MBOX_SR_CHn)

Table 1574. PS_MBOX_SR_CHn field descriptions

Field	Description
14 F5_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC5) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC5) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=5) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writeable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
15 F5_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC5 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writable in ps_normal mode.
16 F5_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC5. 0 No unread message in MBOX[n], LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writable in ps_normal mode.

Table 1574. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
17 F4_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC4) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC4) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=4) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
18 F4_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC4 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode.
19 F4_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC4. 0 No unread message in MBOX[n], LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode.
20 F3_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC3) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC3) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=3) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
21 F3_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC3 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode.
22 F3_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC3 by the DMA. 0 No unread message in MBOX[n], LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode.

Table 1574. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
23 F2_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC2) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC2) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=2) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit fields details.
24 F2_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC2 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode.
25 F2_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC2. 0 No unread message in MBOX[n], LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode.
26 F1_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC1) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC1) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=1) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
27 F1_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode.
28 F1_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC1. 0 No unread message in MBOX[n], LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode.

Table 1574. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
29 F0_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC0) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC0) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=0) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1573: IRQ[n] interrupts*, for bit field details.
30 F0_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode.
31 F0_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC0. 0 No unread message in MBOX[n], LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode.

57.3.4.20 PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)

Address: 0x01A0 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1552. PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)

Table 1575. PS_WD_CFGR_CHn field descriptions

Field	Description
4 WDRST	Resets watchdog counter for the channel This bit will reset the watchdog counter and the counter will be reloaded with the value of WD_TO and automatically start counting again. **Note:** It is also writable in PS_NORMAL mode.
5 WDCS	This will select either GTM or the module clock for watchdog counter of the channel. See *Figure 1576: Clock distribution in PSI5-S*. 0 ipg_clk_ps_wd clock. 1 gtm_trig is selected as the clock.
6 WDEN	The watchdog counter for each channel can be started, stopped. 1 Watchdog counter started. 0 Watchdog counter stopped. It maintains its value. **Note:** This bit is also writable in PS_NORMAL mode.
8:31 WD_TO	This indicates the watchdog time out value. The watchdog generates an overrun error, in case the watchdog is not refreshed before the watchdog counter reached the WD_TO value. The Watchdog is refreshed in a different manner depending on whether the PSI5-S channel is in asynchronous mode or synchronous mode as described below: In Asynchronous mode: As soon as the IP enters the PS_NORMAL mode the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled then the counter starts immediately. Whether the WD has to be “refreshed (re-loaded)” or “not to be refreshed” is analyzed when the XCRC is calculated. In case the XCRC is correct the watchdog is re-loaded (It is not STOPPED), else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In case of watchdog overrun error the counter is refreshed. In Synchronous mode: As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled then the counter starts immediately. Thereby it is re-loaded, either on the occurrence of a sync pulse or the watchdog overrun error. In case the event for this load is the Sync Pulse then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured (enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FFID_byte] is not equal to “0”. The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured“, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered. In both the above modes, the watchdog can be always refreshed using a software reload. **Note:** The watchdog counter is enabled ONLY if the channel is enabled.

57.3.4.21 PSI5-S DDSR trigger offset register channel (PS_DDTRIG_OFFR_CHn)

Address: 0x01A4 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1553. PSI5-S DDSR trigger offset register channel (PS_DDTRIG_OFFR_CHn)

Table 1576. PS_DDTRIG_OFFR_CHn field descriptions

Field	Description
16:31 DDTRIG_OFFR	These bits configure the delay between the “shift trigger” of the various DDSRs across different channels. The value in this register governs the delay after which the specific DDSR would be triggered once the Global Shift trigger (PS_GLCR[GL_DDSR_TRIG]) is written to “1” and the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] is set to “1” for that channel. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register.

57.3.4.22 PSI5-S DDSR trigger period register channel (PS_DDTRIG_PERR_CHn)

Address: 0x01A8 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1554. PSI5-S DDSR trigger period register channel (PS_DDTRIG_PERR_CHn)

Table 1577. PS_DDTRIG_PERR_CHn field descriptions

Field	Description
16:31 DDTRIG_PERR	These bits configure the “shift trigger” period for the DDSR of that specific channel. The value in this register governs the period with which the data for the DDSR of that particular channel would be shifted out. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register. **Note:** This register should be programmed to be greater than or equal to 2.

57.3.4.23 PSI5-S ECU to sensor control register (PS_E2SCR_CHn)

Address: 0x01AC + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1555. PSI5-S ECU to sensor control register (PS_E2SCR_CHn)

Table 1578. PS_E2SCR_CHn field descriptions

Field	Description
1:5 CMD	Bits for the ECU-to-sensor “CMD” format. They refer to the command send to the UART Tx logic, when a “1” is shifted from the DDSR register.
7:11 ACMD	Bits for the ECU-to-sensor “ACMD” format. They refer to the command send to the UART Tx logic, when a “0” is shifted from the DDSR register.

Table 1578. PS_E2SCR_CHn field descriptions (continued)

Field	Description
14 CH_TRIG	This controls that the DDSR of the specific channel is triggered locally. This bit controls the shifting when PS_E2SCR_CHn[GL_TRIG_SEL] is 0. 1 Start the “shift trigger” of the DDSR. 0 Stop the DDSR from shifting the commands. The counters corresponding to DDTRIG_PERR and the DDTRIG_OFFR are reset. **Note:** This bit is also writable in PS_NORMAL mode.
15 GL_TRIG_SEL	This bit controls whether the DDSR shift trigger is a global trigger or a local channel trigger. 1 The DDSR shift trigger is a global trigger dependent on PS_GLCR[GL_DDSR_TRIG]. 0 The DDSR shift trigger is a local channel trigger dependent on the bit CH_TRIG.
16 DEFAULT_SYNC	Decides the value to which the DDSR should default to when PS_E2SSR_CHn[DDSR_RDY] == 1. When PS_E2SSR_CHn[DDSR_RDY] == 1 then the default shift (whether it is CMD or ACMD) is based on the value of this bit.
17 DDSR_SHIFT_SEL	DDSR Shift Selection This is used to select the shift trigger for the DDSR registers. 0 The shift trigger is from internal DDSR counters which are clocked from either the gtm_trig or the ipg_clk_ps_ddtrig. 1 The input signal gtm_trig directly acts as the shift trigger of the DDSR registers. See *Figure 1576: Clock distribution in PSI5-S* for more details.
18 DDSR_CLR	Used for rejecting the contents of the DDSR register. As soon as this bit is written to “1” the contents of DDSR are immediately rejected and defaulted to “0” after the completion of the current ACMD or the CMD transmission. PS_E2SSR_CHn[DDSR_RDY] goes to 1 and value of PS_E2SCR_CHn[DEFAULT_SYNC] starts getting shifted. This bit is one shot (W1S). **Note:** This bit is also writable in PS_NORMAL mode.
19 DDSR_CLK_SEL	Selects which clock clocks shift logic of the DDSR, for shifting the bits for command transmission. 0 ipg_clk_ps_ddtrig clock. 1 gtm_trig is selected as the clock.
20 CMDTR_SW_CTRL	This bit decides that once the command is ready for transmission (indicated by the setting PS_E2SSR_CHn[CMDPR_BZY] to 1), then when should the actual transmission start: 0 The actual transmission of command remains suspended, even though the command is ready in the DDSR. 1 The command transmission starts once the PS_E2SSR_CHn[CMDPR_BZY] becomes 1, and the internal shift logic is available. **Note:** This bit is also writable in PS_NORMAL mode.

Table 1579. PS_E2SSR_CHn field descriptions

Field	Description
22 SYNCHRO_OVF	This bit gets set whenever due to any reason (like too less DDTRIG period), sync pulse of a channel comes before the previous sync pulse of the same channel has actually shifted its data. It can be used to detect sync pulse overflow. If PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to “1” then this can also be used to generate an interrupt on the ipi_ps_e2s_ch[n] line where “n” is the specific channel number. 1 Synch Pulse overflow has occurred for the specific channel. 0 No synch pulse overflow has occurred in the specific channel.
24 CMDTR_NWRT	Status of Command written to the DDSR: 1 Command written to the DDSR is rejected as an attempt to write to it has been made when DDSR_RDY == 0. 0 Command written to the DDSR has been accepted for processing.

Table 1579. PS_E2SSR_CHn field descriptions (continued)

Field	Description
25 CMDPR_BZY	Command Processing Busy Status This bit along with the DDSR_RDY bit can be used to check the status of the command that is being processed in the DDSR. 1 DDSR is ready with the processed command complete with CRC/start bits/stuff bits.The transmission of the same would start if PS_E2SCR_CHn[CMDTR_SW_CTRL] == 1. For this status DDSR_RDY should also be read as “0”. 0 DDSR is busy with command processing. For this status DDSR_RDY should also be read as “0”. Note that when DDSR_RDY goes to “1” then this bit goes to “0”. So it represents the above status conditions ONLY when DDSR_RDY is “0”.
26 DDSR_RDY	Status for DDSR getting empty and ready for receiving new command. 1 DDSR is empty and ready for receiving a new command. 0 DDSR is not ready and is busy with either the command processing or the command transmission.

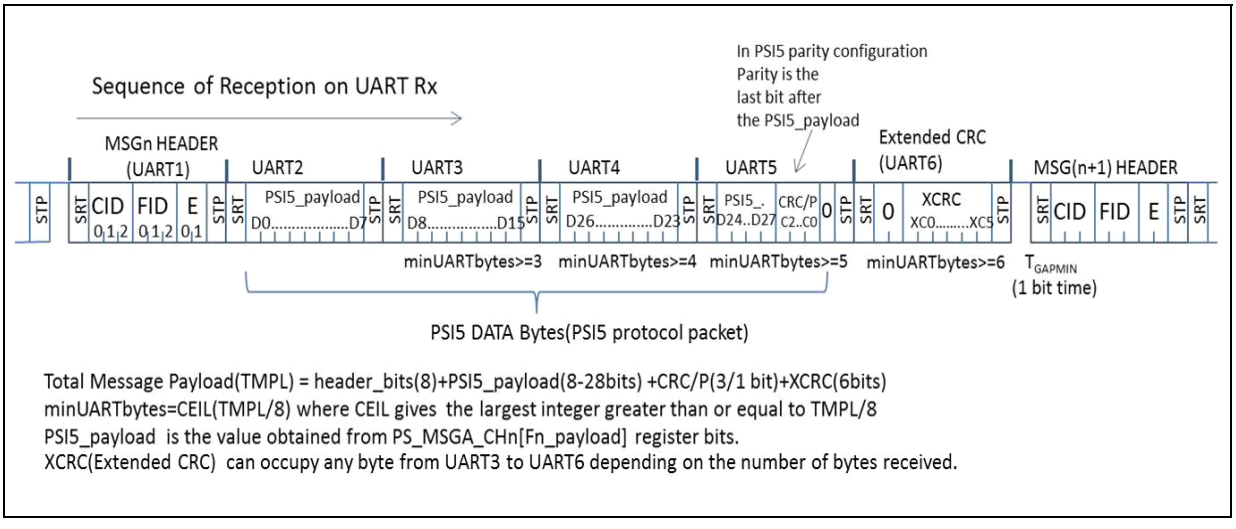
Table 1581. PS_DDSR_L_CHn field descriptions

Field	Description
0:7 DDSR_L1	8 bits of the DDSR_L that can only be read by the Application. These 8 bits are automatically updated by the hardware. They can be read by the software to check for the processed command after the command is written to the DDSR by the application, the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to “1”.
8:31 DDSR_L0	Lower 24 bits of the DDSR register that are written by the Application as well as updated by the hardware once the command processing is over. Though all the 24 bits can be written by the software, yet only those number of bits as governed by PS_E2SCR_CHn[CMD_TYPE] are actually taken for processing. This register can be read by the software to check for the processed command, after the command is written to the DDSR by the application, the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to “1”. **Note:** These bits are also writable in the PS_NORMAL mode.

57.4 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The UART compatible transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. *Figure 1559* shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1559. System setup (peripheral sensor connected to device)



ECU (Electronic Control Unit) is comprised of PSI5-S digital interface and the UART compatible PSI5 transceiver (present externally). The PSI5-S digital interface communicates with the PSI5 Transceiver though the UART interface as shown in *Figure 1559*. When conducting the Sensor To ECU communication, the external transceiver converts the sensor data to the UART packet format before sending it to the PSI5-S module. The IP extracts the PSI5 Frames from the input UART Packet.

57.4.1 PSI5-S UART message structure

The transceiver sends a UART message packet consisting of between three to six UART bytes which contains information to allow rebuilding of the PSI5 message as well as the message itself and has a CRC which protects the complete packet (XCRC).

Each byte is made up of one start bit, eight data bits and one stop bit - no parity is included in the UART byte. *Figure 1560* shows the PSI5-S UART packet structure.

Figure 1560. PSI5-S packet structure

The UART packet is made up of the following:

- MSGnHEADER: This is the message header byte which includes the indication of which channel the PSI5 message was received on (3-bit CID), the slot on that channel in which the message was received (3-bit FID) and transceiver error indication bits (2-bit E).
- PSI5 DATA bytes: Minimum one, maximum four, depending on the data payload region of the PSI5 message (8 - 28 bits) and whether parity (1-bit) or CRC (3-bit) is configured for the PSI5 message. In the above example shown in *Figure 1560* it is taken as 28 bits and 4 UART bytes are shown (UART2-UART5). Messages having CID and FID both as “0s” do not have the CRC/Parity field in them. Such messages only have the message header, payload and the XCRC fields.
- XCRC- 6-bits: This is the extended CRC which protects the UART packet. Note that any bits between the end of the PSI5 message payload and the XCRC are ‘stuffed’ with ‘0’s. This can also be seen in *Figure 1560*. For details about XCRC handling, refer to *Section 57.4.2.5*.
- Example to calculate the minUARTbytes (for messages NOT having CID and FID both as 0):
  - Fn_payload = 14
    with PSI5 CRC option: TMPL = 8+14+3+6=31, minUARTbytes=CEIL(3.8)=4
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:13], CRC[2:1]),
    UART4(CRC[0],0,XCRC[0:5])
  - Fn-payload = 13
    with PSI5 Parity option: TMPL = 8+13+1+6=28, minUARTbytes=CEIL(3.5)=4
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:12],Paritybit,00),
    UART4(00,XCRC[0:5]).

Note: The “0” stuffing between the parity bit and the XCRC. The XCRC is always in the last 6 bits of the last byte.

- Example to calculate the minUARTbytes (for messages having CID and FID both as 0):
  - F0_payload = 8
    TMPL = 8+8+0+6=22, minUARTbytes=CEIL(2.75)=3
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(00,XCRC[0:5]).
  - F0_payload = 10
    TMPL = 8+10+0+6=24, minUARTbytes=CEIL(3)=3
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:9],XCRC[0:5])

57.4.2 PSI5 received message handling

The PSI5 message (UART Type) received from sensors (through the external UART Transceiver) is handled internally to the PSI5-S IP by three separated parts:

- PSI5 message extraction:

  This decides when a UART packet has been received with the correct header byte, and then how to extract the information from this UART packet form a complete PSI5 message.
- PSI5 “recoverable” and “unrecoverable messages”:

  This differentiates the PSI5 messages received above, into “recoverable” and “unrecoverable” messages.
- PSI5 message storage and Mailbox transfer:

  This ensures the transfer of the PSI5 message to the correct location in the system RAM, once the PSI5 message has been correctly differentiated into “recoverable” and “unrecoverable” messages.

Following sections detail the above 3 parts.

57.4.2.1 PSI5 message extraction

Once a UART start bit is detected after the idle timeout (the idle time between message packets on the UART interface, that is the number of bit times between message packets in the range of at least 1 to 16, configurable in the UART module through the PS_UARTPTO register) has occurred, the UART bytes are subsequently sampled. They are being received by an internal state machine in the MRU, which checks for the formation of a complete UART packet, its coherence and extraction of the PSI5 message from the UART packet. Also, refer to *Figure 1561* for further understanding of this section.Each UART packet that is received can be considered as “recoverable” or “unrecoverable”. Demarcation between the two is explained subsequently. Following are the sequence of steps performed as each UART byte is being received:

1. There is a 6 byte UART message input buffer into which the UART bytes from the UART Rx register are written as they are received. A 3-bit UART message counter is incremented on the reception of each byte in UART message packet that is each UART byte received between idle time counter indications.
2. All the subsequent UART bytes in the UART packet are stored internally till any of the following events occurs:
   - UART Timeout that is bus idle time is detected.
   - Framing Error from the UART.
   - Number of UART bytes that are received as reported through the UART message counter described in *1.* above exceed 6.
   - STOP mode request mode is asserted. Refer to *Section 57.1.4.1*, for further details.
3. As soon as any of the events described in *2.* above occur, it is assumed that a complete UART packet has been received. The XCRC is then calculated immediately on the received UART packet. Refer to *Section 57.4.2.5*, for details about XCRC. If there is an XCRC error the message is assumed to be “unrecoverable” and it is sent to

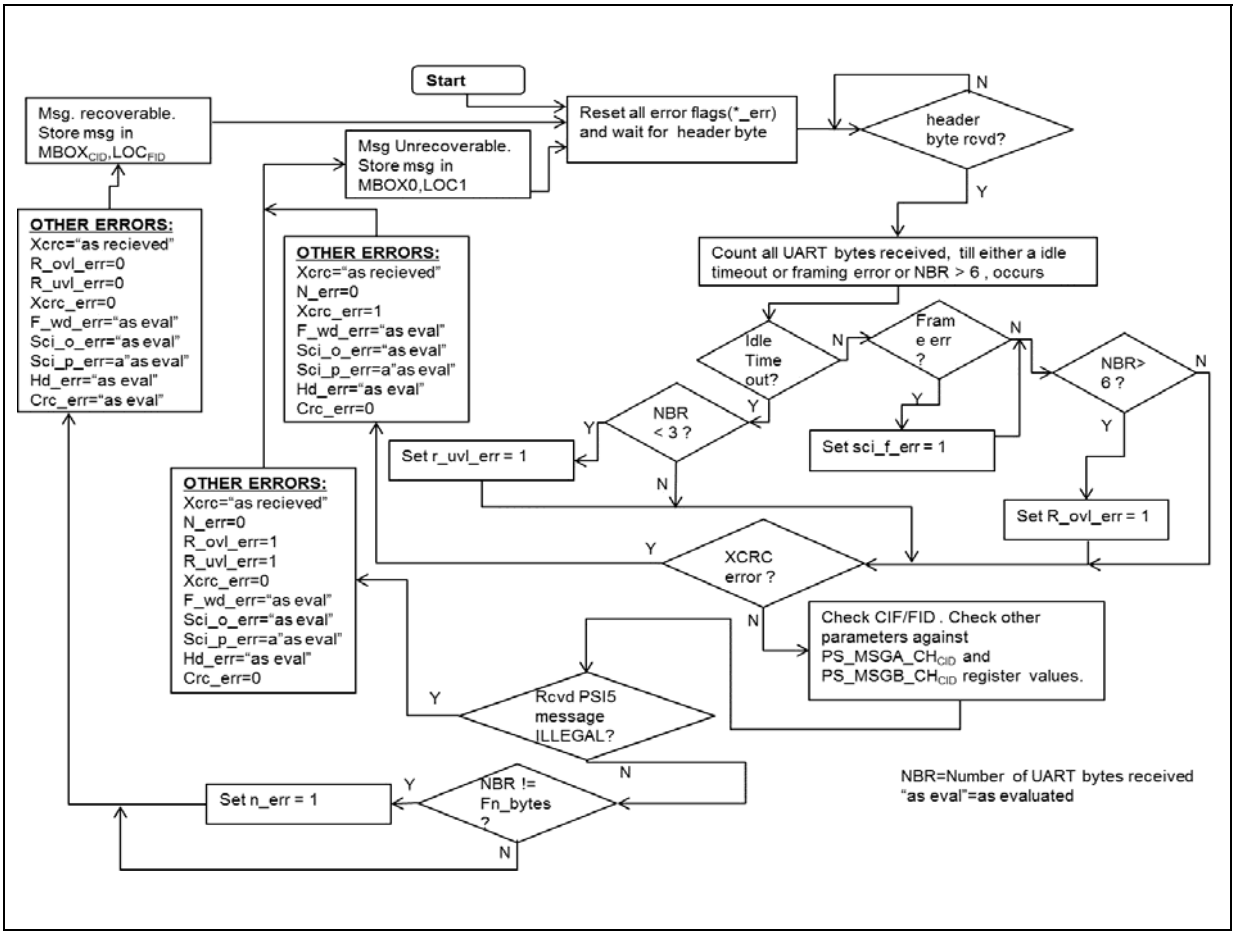
$MBOX_0$, LOC_1.The timestamp of the message is captured as is described in *Section 57.4.4*.The watchdog error is captured as is described in *Section 57.4.5*.

4. If there is NO XCRC error, then the CID and FID are extracted from the header byte, and the configured length of the message is determined from the configuration in PSI5 Channel*n* Message Configuration Register A. Following steps are performed.
   - The FID and the CID from the header byte is transferred directly to the PSI5 Frame status word.
   - The transceiver error flags (E0, E1) are transferred directly to the PSI5 Frame status word.
   - The message is then analyzed to see whether it is “LEGAL” or “ILLEGAL.
   - Following are the conditions for a “LEGAL” message:
     When the CID and the FID of the received message are both “0s” and PS_MSGA_CH0[F0_byte] is NOT “0” OR
     When the data of an Asynchronous Enabled channel is received with FID = 0 and $PS_MSGA_CH_{CID}$[F0_byte] is NOT “0” OR
     When the data of a Synchronous Enabled channel is received with legal FIDs (0 to 5) and if the received FID is such that the corresponding $PS_MSGA_CH_{CID}[F_{FID}_byte]$ is NOT 0.
   - Any received message that does not satisfy the above condition is considered as “ILLEGAL”. Illegal Messages are also treated as “unrecoverable” messages and are sent to $MBOX_0$, LOC_1.
     Example can be a message with CID as 0 but FID as 1(illegal because Channel0 is asynchronous and can only have FID equal to 0 messages) or a message received for an enabled synchronous channel but having an FID equal to 7 (illegal because FID as 7 is not a legal Frame ID).
   - The timestamp of a Legal/Illegal message is captured as is described in *Section 57.4.4*. The watchdog error is captured as is described in *Section 57.4.5*.
   - The number of UART bytes received in the UART message packet is compared with the number specified in Message Configuration Register A for the channel indicated by CID and FID in the header byte. If the number of bytes indicated by the message counter does not match $PS_MSGA_CH_{CID}[F_{FID}_byte]$ field, then the status bit N_Err within the PSI5 Frame status word is set. The above “number of bytes received” check is not carried out for an “illegal message”.
5. The PSI5 message payload is checked using the PSI5 CRC or parity as per the configuration. Whether the CRC or parity check is correct or not, the PSI5 message payload is written to the PSI5 Sensor Data word and the CRC or parity is written to the PSI5 Frame Status word. Note that the messages which have CID and FID both as “0”, are not checked for CRC or parity error. The CRC/Parity error status bits remain “0” for such messages.This above check is NOT done for “illegal messages”.

57.4.2.2 PSI5 “recoverable and unrecoverable” messages

Based on *Section 57.4.2.1: PSI5 message extraction*, a message is considered “unrecoverable”, if the XCRC is incorrect or it is an “illegal message”, else the message is considered “recoverable”. “Unrecoverable” message indicates that an error has been detected during the assembling phase of the UART packet that is during the formation of the UART packet from the individual UART bytes. “Unrecoverable” messages are always stored in PSI5 mailbox $MBOX_0$, LOC_1 in system RAM. “Recoverable” messages are always stored in the Mailbox location pointed out by the CIDn and the corresponding FID fields.

Figure 1561 describes the treatment of the “Recoverable” and “Unrecoverable” messages. It also details the setting of the various error flags. The various cases for a new PSI5 message reception are:



- Idle Timeout occurrence
- Framing Error occurrence

  As soon as a framing error has occurred, all the UART packets sampled till that instance are assembled to form a PSI5 packet and are transferred to the MRU buffer. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.
- Number of UART bytes received exceed 6

  In this case any UART bytes received after the 6th byte, are totally rejected by the internal PSI5-S state machine. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.
- STOP mode entry

  Refer to *Section 57.1.4.1*. Stop mode entry causes the flushing of the internal PSI5 message buffer and this event is treated like new message completion. Exiting from the stop mode resets the state machine and it becomes ready to respond to the next UART packet. The next UART packet is taken as the header byte of a new PSI5 message.The stop mode, as an event for a new PSI5 message formation is not shown in *Figure 1561*.

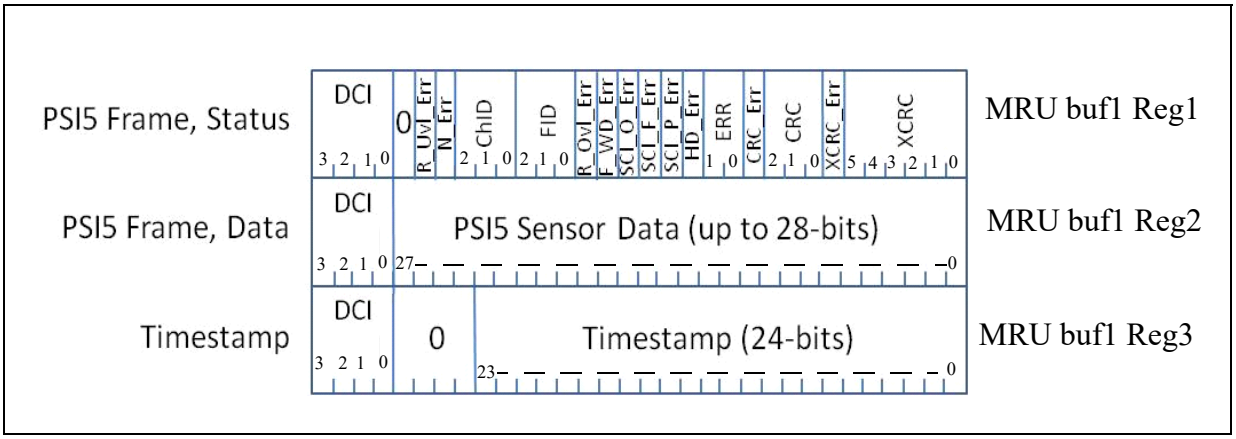
Figure 1561. PSI5-S message handling and error flags

Once the message has been correctly deciphered as “Recoverable” or “Unrecoverable” and the various error flags have been set then the Message is finally transferred to the MRU buf2. Once the corresponding message has been read from the MRU buf2 the bits in the “PS_MBOX_SR_CH[n]” register are set appropriately. This aids the application to correctly read the concerned message from the Mailbox. *Section 57.4.2.3* describes the PSI5 Message Storage and detection in detail.

57.4.2.3 PSI5 message storage and mailbox transfer

Once the message has been correctly deciphered as “recoverable” or “unrecoverable” and the various status bits are set, it is then transferred to the MRU output buffer. The MRU output buffer is a 2 stage buffer differentiated as MRU Buf1 and MRU Buf2. The MRU buf1 is composed of 3, 32 bit registers while the MRU buf2 is composed of 4, 32bit registers. *Figure 1562* shows the structure of MRU buf1. It is composed of three internal registers. These registers are not in the addressable space of the IP. When the internal state machine has correctly decoded the PSI5 message, it is transferred to MRU buffer1. It serves to hold the PSI5 message until it is transferred to MRU buf2.

Figure 1562. MRU buf1 structure



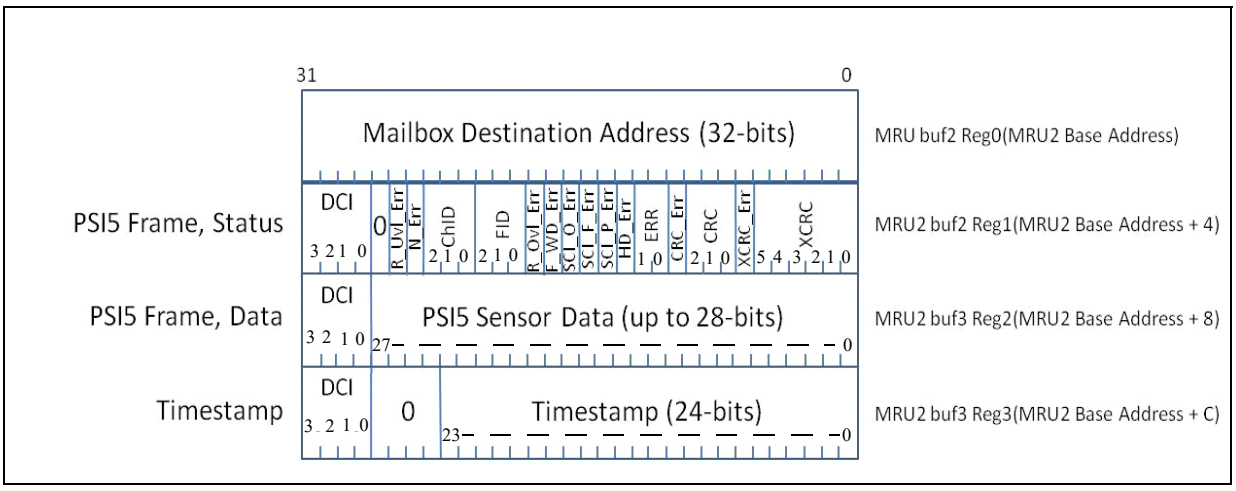


Figure 1563 shows the structure of MRU buf2. MRU buf2 has one extra location as compared to MRU buf1. This extra location (MRU buf2 Reg0) contains the address of the Mailbox location, where the message contained in the rest of the three locations of MRU buffer2 is to be placed. This specific MRU buf2 structure aids the DMA to perform linked scatter-gather data transfer from the IP. The extra location in the MRU buf2 is automatically updated by the hardware and provides the destination address for the message. This destination is the Mailbox Address at which the message (stored in MRU buf2 (Reg1-Reg3) is to be transferred by the DMA. This destination address is calculated by the IP based on ChID in the message header (or ChID0 in the case of an unrecoverable message), the FID in the message header and Base address of the mailbox in system RAM (provided by CH_BASE_ADDR) register.

Figure 1563. MRU buf2 structure

MRU buf2 is in the addressable space of the IP and is read by the DMA when the corresponding DMA request is asserted. The PSI5 message is transferred from the MRU buf1 to the MRU buf2 only when the MRU buf2 has been read completely by the DMA, that is all the 4 locations of the MRU buffer2 have been read by the DMA, for the corresponding PSI5 message.

Following are the sequence of operations that are performed, before the message in MRU buf2, gets ready to be accessed by the DMA:

1. The IP decodes the message as detailed in *Section 57.4.2.1: PSI5 message extraction* and *Section 57.4.2.2: PSI5 "recoverable and unrecoverable" messages*.
2. The corresponding message is available in MRU buf1 along with the various status bits latched internally in the IP. Externally, no interrupt is generated and neither are any status bit updated, when the message is transferred to MRU buf1.When the message is transferred to MRU buf1 a 3 bit DCI (data consistency indicator is added). The DCI is a 3-bit counter that is counted on a reception of each new message in MRU buf1.
3. The IP checks whether MRU buf2 is empty. If it is empty, then the MRU buf1 "Reg1 to Reg3" contents are transferred to the MRU buf2 "Reg1 to Reg3". The corresponding interrupts (except the Message Read from MRU) are also asserted based on the Interrupt Enable settings. Based on the PSI_CH_BASE_ADDR, the CID, FID values and whether an "unrecoverable message" has been received, the IP calculates the contents of MRU buf2 Reg0 register.
   - If CID == 0 then the "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0, LOC0.
   - If "unrecoverable message" is received then "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0, LOC1.
   - In all other cases "MRU buf2 Reg0" contains the Mailbox location corresponding to the $MBOX_{CID}$, LOC_{FID}.
4. Once the calculations in "*3.*" are done, the IP asserts the DMA request for Access 1. In DMA Access 1, the DMA reads the first location (MRU buf2 Reg0) of the MRU buf2. This single 32-bit access writes the content of MRU buf2 Reg0 into the destination address for the DMA channel performing the second access (Access 2). Access 2 is initiated by the DMA once the Access1 transfer is complete. Access 2 is composed of 3, 32-bit accesses of MRU buf2 and it writes the reconstructed PSI5 message along with its status and timestamp to the mailbox, starting at the destination address provided by Access 1.In Access2 the DMA reads the MRU buf2 Reg1, Reg2 and Reg3 in that order.
5. The application can read the PS_MBOX_SR_CH[n] register to get an indication to which mailbox location (or locations) the DMA would transfer the message. Note that "DMA transfer complete" bit/interrupt of the DMA indicates to the application, that the message read by the DMA from the IP has actually been written to the Mailbox.
6. The application should clear the corresponding "Fn_read" bits in the PS_MBOX_SR_CH[n] register once the application has read the corresponding message from the Mailbox. If a PSI5 message gets written to a Mailbox location, with "Fn_read" bit still set at the time at which the DMA has started the Acces1, then the corresponding "Fn_OV" bits are set in the PS_MBOX_SR_CH[n] register.
7. Reference to "*3.*" above, if the MRU buf2 has a pending message and the MRU buf1 also has a message that is ready to be transferred to the MRU buf2 and then a new message gets ready to be written to MRU buf1, then the previous message in MRU buf1 gets overwritten by the new message. The MRU overwrite interrupt is also generated with the setting of the corresponding register bit in the PS_GLSR register. PS_GLSR register contains the CID and the FID of the message that got overwritten by the new message in MRU buf1.
8. When writing an unrecoverable message to the PSI5 mailbox CID0, with the XCRC_ERR bit set, the timestamp that will be used will be the one which is captured at the time XCRC_ERR bit is set. When the unrecoverable message is due to an "illegal message", then the timestamp used would be the one which is captured on the

reception of any message that is always captured at the end of the header byte of every message.

9. In Asynchronous mode, FID will always be configured to be “0” and the module will use the PSI5 Mailbox for the channel (identified by CID in header) as a ring buffer, incrementing the destination address for each message received and saving up to the last six messages received. The bits of the PS_MBOX_SR_CH[n] register will still indicate the status of each location of the Ring Buffer. The software has to still clear the six bits of this register when it reads the Mailbox location else the overwrite bits would be set in the PS_MBOX_SR_CH[n] register. The message identification mechanism allows software to identify the latest message received.

57.4.2.4 PSI5-S data payload CRC recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1564. CRC calculation scheme

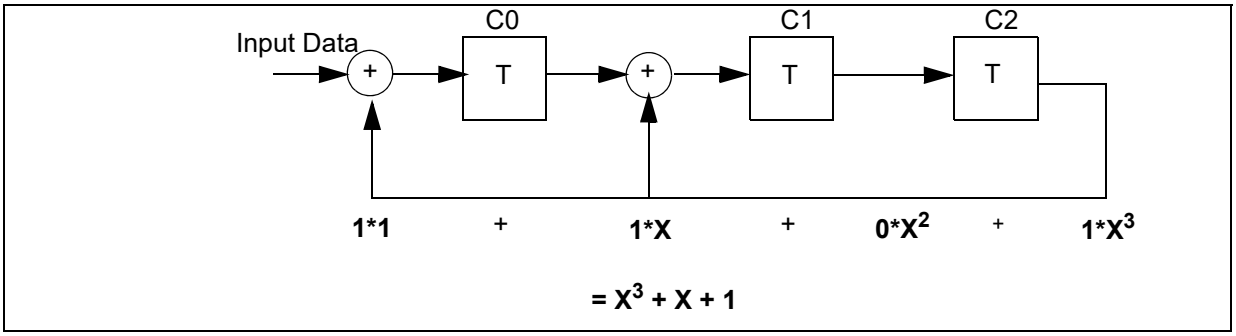

Table 1582. CRC calculation (at transmitter side)

Sensor data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1583. Transmitted and received sensor data

Transmitted sensor data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1583. Transmitted and received sensor data (continued)

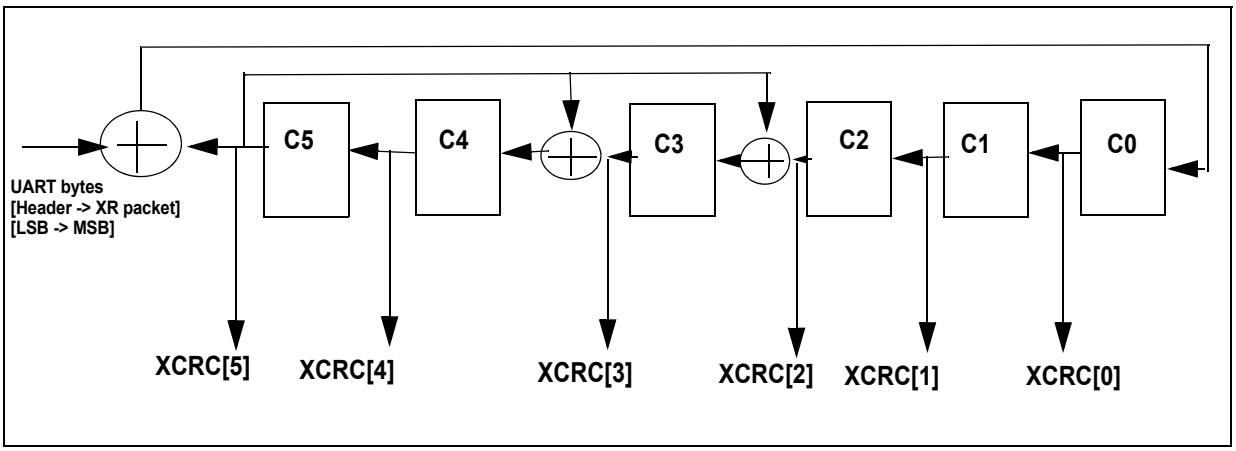
Received sensor data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1584. CRC re-calculation (at receiver side)

Sensor data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.



57.4.2.5 PSI5-S XCRC handling

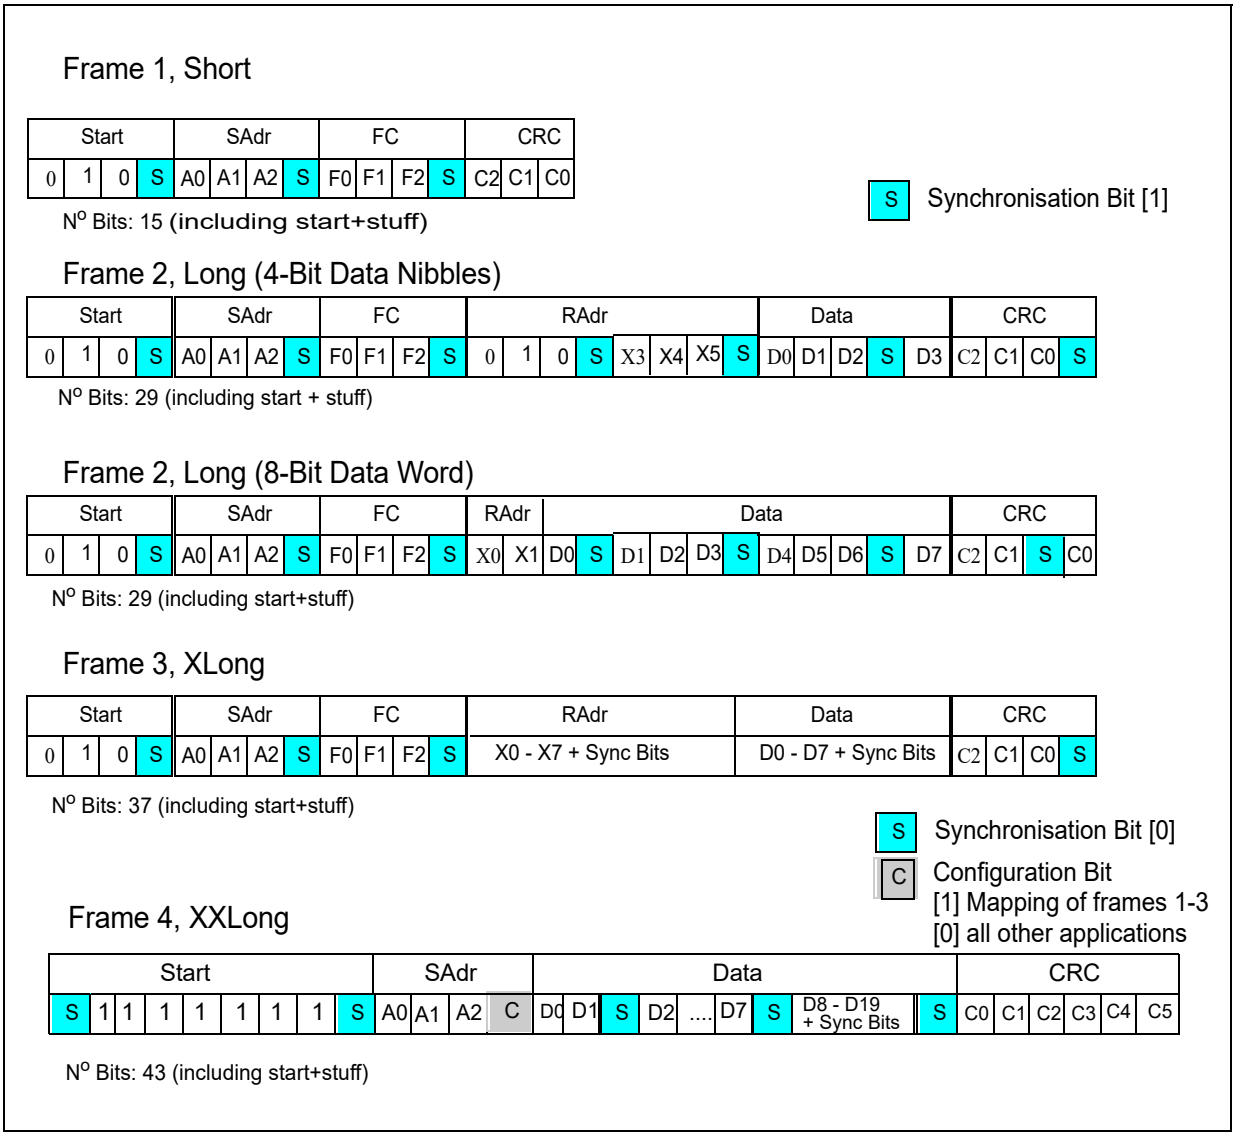
The XCRC calculation is triggered on any of the following events (which also indicate the reception of a new UART packet):

- UART idle timeout
- number of UART bytes exceed 6
- UART Framing error
- STOP mode assertion (refer to *Section 57.1.4.1*)

When any of the above events occur, the internal XCRC calculator becomes active. Each UART byte that is received, passes through the XCRC calculator on a bit by bit basis, starting from the header byte to the expected XCRC byte. The XCRC is assumed to be the last 6 bits of the last UART byte that is received before the occurence of any of the above events. *Figure 1565* shows the XCRC calculation algorithm.

Figure 1565. XCRC calculation

The UART bytes are shifted starting from the received header to data packets to the XCRC packet. Each of these UART bytes is shifted LSB first into this XCRC calculator. Once all the



bytes as denoted by the Fn bytes have been received and the Fnth packet (XCRC) has been shifted completely through this XCRC calculator and if XCRC[5:0] is equal to “0” then it denotes that the XCRC check has passed else there is an XCRC error and the XCRC_ERR bit is set.

The CRC polynomial used is “x6+x4+x3+1” with a binary initialization value of XCRC[5:0] = “010101”.

57.4.3 ECU-to-sensor communication

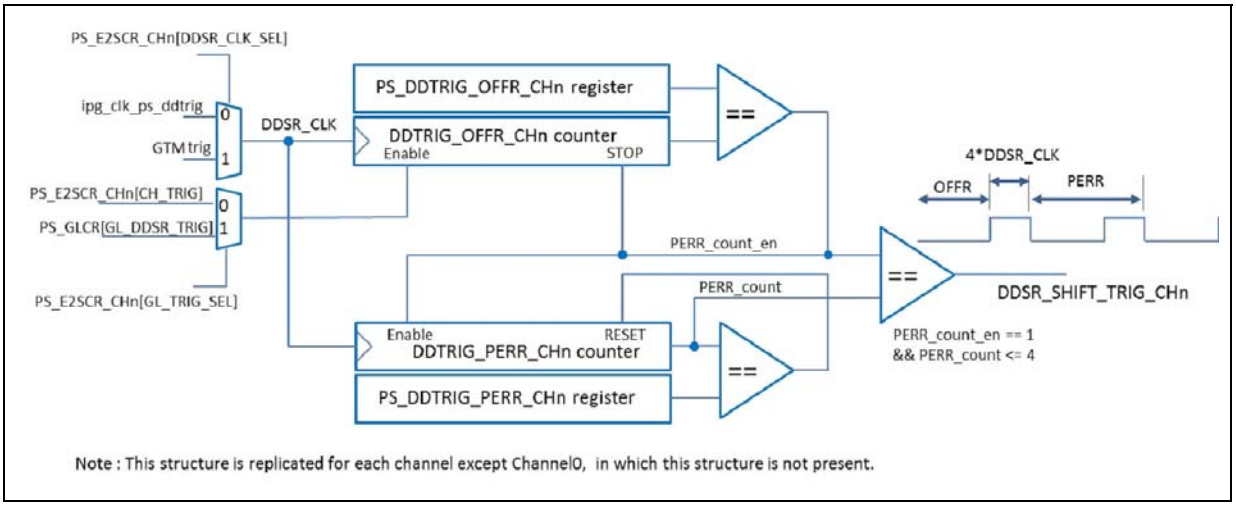
The IP send the commands for the ECU to Sensor communication in terms of UART bytes. It expects the external transceiver to correctly interpret the commands and then generate the appropriate logic 0 or logic 1 on the PSI5 bus. Following are the various PSI5-S ECU to Sensor commands supported by the IP, as shown in *Figure 1566*.

Figure 1566. Standard frame formats supported

- Short: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “C2,C1,C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes and “C2-C0” is the CRC. Refer to *Figure 1566* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, ”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]...PS_DDSR[5], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- Long (4bit Data Nibble): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,X2”, S, “X3,X4,X5, S, “D0,D1,D2”, S,“D3,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1566* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X5, D0...D3, ”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[15], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- Long (8bit Data Word): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,D0”, S, “D1,D2,D3, S, “D4,D4,D6”, S,“D7,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X1” is the Range Address, “D0-D7” is the data and “C2-C0” is the CRC. Refer to *Figure 1566* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X1, D0...D7, ”000”] with “A0” being given first and “0” as

the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.

– When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[15], 000) with PS_DDSR[0] being fed first in the CRC calculator.



- X-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,X2”, S, “X3,X4,X5”, S, “X6,X7,D0”, S, “D1,D2,D3”, S, “D4,D5,D6”, S,“D7,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1566* for the frame structure.
  – The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  – The transmitter extends the data bits by three zeros (as MSBs).
  – The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X7, D0...D7, ”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  – When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]...PS_DDSR[21], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- XX-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - “011111110”, “A0,A1,A2”, “C”, “D0,D1”, S, “D2,D3,D4” D5,D6,D7, S, “D8,D9,D10,D11,D12,D13”, S,“D14,D15,D16,D17,D18,D19”, S, “C0,C1,C2,C3,C4,C5” where “011111110” is the start sequence “S” is the stuff bit(0), A0-A2 is the sensor address, “C” is the configuration bit, “D0-D19” is the data and “C0-C5” is the CRC. Refer to *Figure 1566* for the frame structure.
  – The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0).
  – The transmitter extends the data bits by six zeros (as MSBs).
  – The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, D0...D19, ”000000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  – When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[23], 000000) with PS_DDSR[0] being fed first in the CRC calculator.

57.4.3.1 PSI5-S ECU to sensor command handling

The ECU-to-Sensor commands can be written to the PSI5 IP in two ways:

1. Direct writing for the special Transceiver commands: This can be used by the software to directly write the transceiver/diagnostic commands without using the internal sync pulse generators. Following procedure should be adopted for this:
   a) Application configures the PS_GLCR[DIRCMD_LEN] register for deciding the length of the direct command that is to be written. The length can be 1, 2 or 4 bytes.
   b) Application will check for the status flag PS_GLSR[DIRCMD_RDY]. A “1” here would mean that the PS_DIRCMD register is empty and ready to accept the Direct write command. Trying to write to PS_DIRCMD while DIRCMD_RDY is “0”, will be rejected without any information. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1” then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line, whenever the PS_GLSR[DIRCMD_RDY] bit goes to “1”.
   c) The application then writes the Direct Command to the PS_DIRCMD register. Depending on the PS_GLCR[DIRCMD_LEN] register, only the specific bytes are considered for transmission. Other bytes are ignored.
   d) A “w1c” to the PS_GLSR[DIRCMD_RDY] bit would queue the above direct command for UART transmission with the highest priority; and thereafter as soon as any pending current transmission is complete, the internal state machine would start the transfer of this direct command to the UART Tx line. All other channels would internally buffer their pending DDSR transmission and resume only once the above transmission is over.
   e) Once the Direct transmission is complete the PS_GLSR[DIRCMD_RDY] status bit would go to “1” and if the corresponding interrupt is enabled in the PS_GLCR register, then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line.
2. Writing to the DDSR (Downstream Data Shift Register): In this case the application writes the basic command to the DDSR_L and the IP will add the start bits/start condition/CRC/stuff bits before sending this command to the UART Tx FIFO. Following are the details:
   – There is one DDSR per channel. The default value of DDSR is dependent on the PS_E2SCR_CHn[CMD_TYPE] value. DDSR is composed of two sub registers DDSR_H (Higher) and DDSR_L (Lower). The application can only write to DDSR_L. The number of bits that can be written in the DDSR_L is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] bit values. Note that Channel0 does not have any DDSR, as it does not support any ECU-to-Sensor communication.
   – The “shift trigger” of the DDSR is governed by the values programmed in the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register and the frequency of ipg_clk_ps_ddtrig clock.
   – Once the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n are correctly programmed and each channel is programmed to respond to the selected shift trigger (local trigger or global trigger is decided via the bit PS_E2SCR_CHn[GL_TRIG_SEL]) the software has to write to the Global DDSR trigger bit, PS_GLCR[GL_DDSR_TRIG] or the PS_E2CR[CH_TRIG] bit, so as to synchronously start the DDSR triggers of each channel or locally start the DDSR shift triggers of each channel. The DDSR trigger logic gets the trigger signal immediately but it responds after a delay as programmed in the PS_DDTRIG_OFFR_CH[n] register. The shift trigger period is governed by the value programed in the PS_DDTRIG_PERR_CH[n] register. Refer to *Figure 1567* for the structure of the logic that generates the internal DDSR shift triggers.

Figure 1567. DDSR internal shift trigger generator

- The number of bits of DDSR_L that can be written by the application, is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] value.
- When PS_E2SSR_CHn[DDSR_RDY] == 1, then it indicates that the DDSR is empty and is ready to accept a new command. If the PS_E2SCR_CHn[DDSR_RDY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- Attempting to write to DDSR while PS_E2SSR_CHn[DDSR_RDY] == 0 results in the rejection of the new command and setting of the PS_E2SSR_CHn[CMD_NWRT] bit. If the PS_E2SCR_CHn[CMDTR_NWRT_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- The application then writes the command to the PS_DDSR_L and does a “w1c” to the PS_E2SCR_CHn[DDSR_RDY]. This indicates to the internal logic that the command is now ready for further processing. The clock that is used for shifting the contents of the DDSR can be configured through the PS_E2SCR_CHn[DDSR_CLK_SEL] register.
- Depending on the value of PS_E2SCR_CHn[CMD_TYPE], the internal logic adds the start bits/start condition/CRC/bit stuffing and updates the DDSR with the complete command, ready for transmission.
- Once this happens the PS_E2SSR_CHn[CMDPR_BZY] becomes “1”. If the PS_E2SCR_CHn[CMDPR_BZY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line. If PS_E2SCR_CHn[CMDTR_SW_CTRL] == 0 then the application can check the final value of the command in DDSR, that would actually be transmitted.Once the checking is complete it can put the PS_E2SCR_CHn[CMDTR_SW_CTRL] to “1”, to start the actual transmission. By default PS_E2SCR_CHn[CMDTR_SW_CTRL] is set to “1”. Note that the start condition is not a part of the DDSR and its transmission is dependent on the value of the PS_E2SCR_CHn[CMD_TYPE] and is automatically taken care by the IP.
- Each bit of the command in DDSR, if it is “1”, results in PS_E2SCR_CHn[CMD] being transferred to the UARTTX buffer or if it is “0” results in PS_E2SCR_CHn[ACMD] being transmitted to the UART-TX buffer. The “CMD” and the “ACMD” governs as to how the transceiver has to respond when it receives these values. These will specify to the transceiver whether it should send

a short or long SYNC pulse on the PSI5 bus when the application wishes to write to the sensors.

– Once the complete command has been transmitted, the PS_E2SSR_CHn[DDSR_RDY] goes to “1” while PS_E2SSR_CHn[CMDPR_BZY] goes to “0.

– Once the PS_E2SSR_CHn[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE].

– When PS_E2SSR_CHn[DDSR_RDY] == 1, then it is possible to abort the current transmission by doing a “W1C” of the PS_E2SCR_CHn[DDSR_CLR] bit. As soon as this is done the DDSR is reset to “0”, PS_E2SSR_CHn[DDSR_RDY] goes to “1” while PS_E2SSR_CHn[CMDPR_BZY] goes to “0”. Once the PS_E2SSR_CHn[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE]. Note that doing this “W1C” does not have any effect on the CMD/ACMD transmission that is already under progress in the UART.

Figure 1568. PS_DDSR sensor command (Ex: XXLong frame)

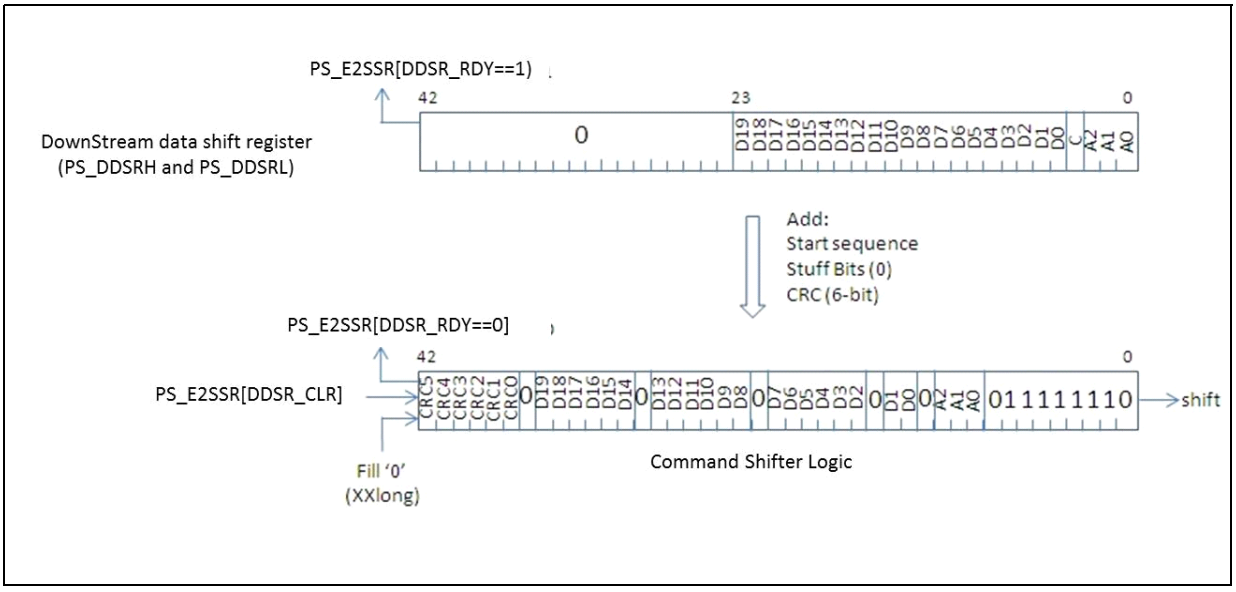


Figure 1569. PS_DDSR sensor command (Ex: PSI5 long format)

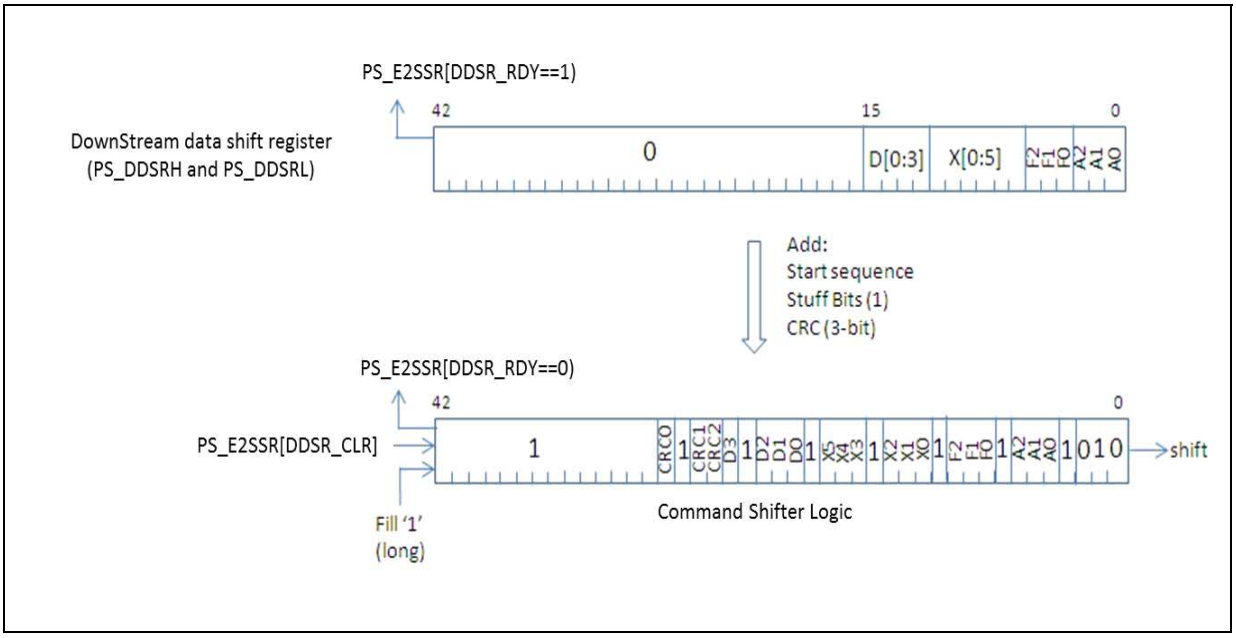

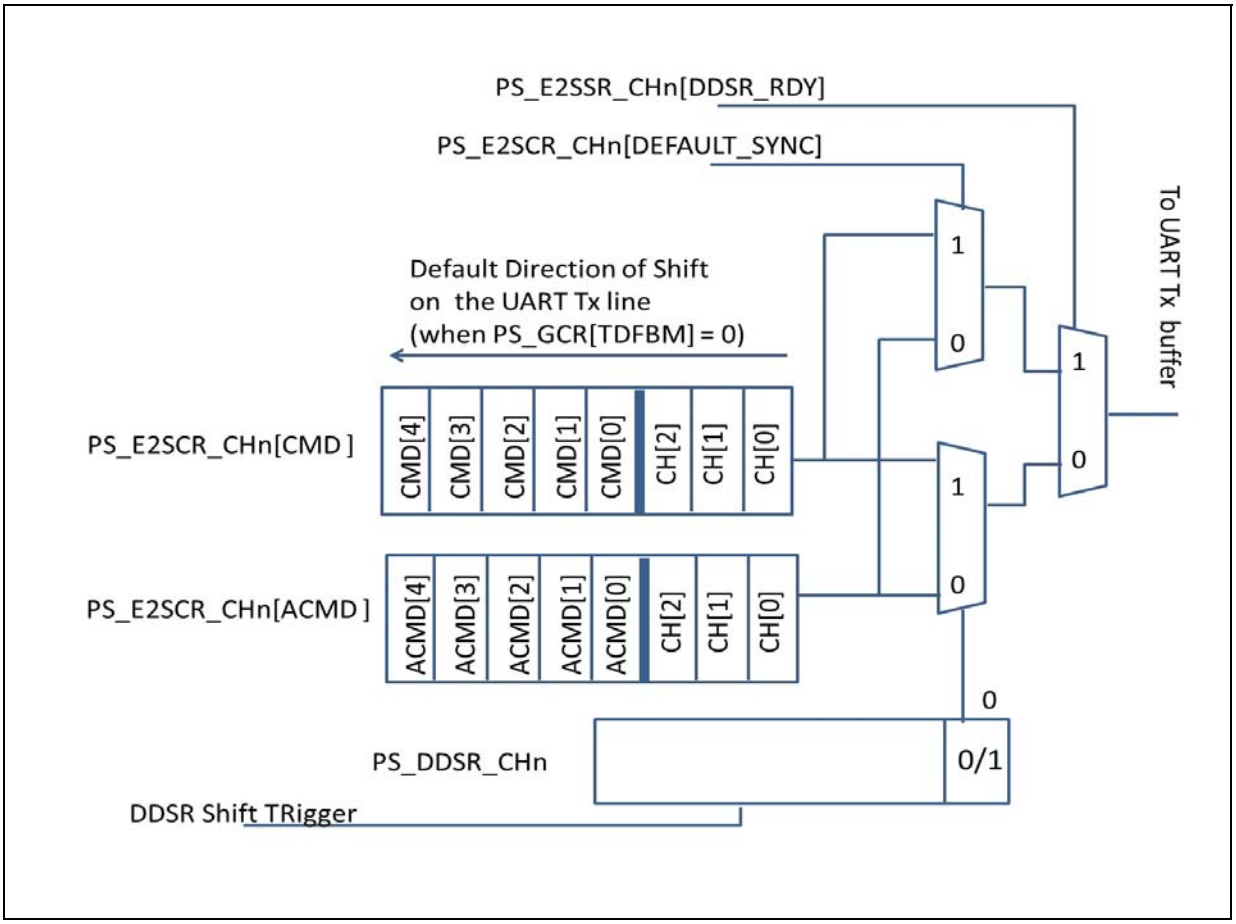

Figure 1570. CMD and ACMD

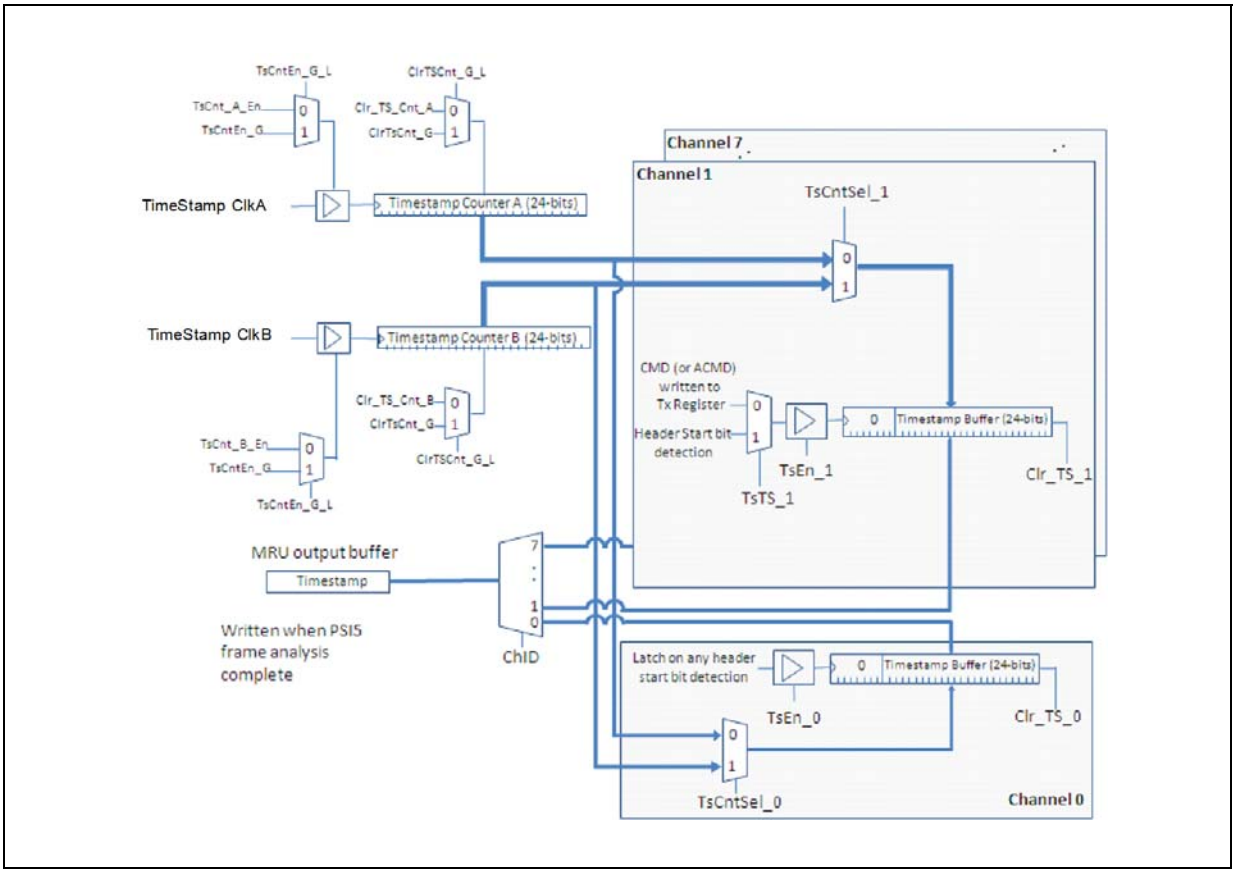
- The logic for processing the DDSR contents is shared among all the 7 channels. It has to be ensured by the software to correctly program the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register contents so that the none of the bits in the command get missed. Also since "*1.*" is possible, it is up to the application to ensure that the UART TX_BUFFER does not remain busy to the extent that some particular DDSR bit does not get the chance to be shifted out before it gets overwritten by some new DDSR bit.
- The approximate maximum time, beginning from when PS_E2SSR_CHn[DDSR_RDY] is made "0", to the time when the command is available for transmission is less than 1us, provided no other channel has an active command processing ongoing.If commands are written to multiple DDSR registers one after the other, then the time after which the particular channel will again get an access will increase. Note that the irrespective of the sequence in which the PS_E2SSR_CHn[DDSR_RDY] of the channels are cleared, the channels are always searched in a round robin fashion for the status of the respective DDSR_RDY bits. When the internal sequencer find the respective DDSR_RDY as "0" it starts the processing of the corresponding DDSR. The sequencer always goes as Channel1 -> Channel2 -> Channel3...Channel7 -> Channel1...
- The logic that shifts each bit of the DDSRs of each channel is shared among all the channels. When the shift trigger of a particular DDSR is received and if the UART TX Buffer is empty then the particular command bit is transmitted to the UART TX by the appropriate CMD/ACMD. It is possible that at one point of time, CMD/ACMD of more than one channel are pending to be transmitted to the UART TX. In this case the channel with a higher channel number will be given a priority. Thus if channel2 and channel1, both have a pending CMD/ACMD shift, then channel2 would be the first to get an access. Each pending channel would queue up for transmission. It can be ensured by the software that the internal shift triggers generated through the PS_DDTRIG_PERR_CHn and PS_DDTRIG_OFFR_CHn registers are correctly spaced so that all the channels get immediate access to transmit their DDSR bits.
- If a command bit that is desired to be shifted encounters more than one shift triggers (because it did not get shifted on the previous shift trigger) then the PS_E2SSR_CHn[SYNCHRO_OVF] bit gets set, to indicate synchronization overflow. An interrupt can also be generated if the PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to 1. In general, if the if PS_DDTRIG_PERR is programmed to be greater than 500us (which is a practical PSI5 sync pulse period) then it would be ensured that the bits are correctly transmitted even if all the channels simultaneously transmit their command bits.

57.4.4 Timestamp



The IP provides for two global 24-bit timestamp counters. Each can be clocked by either the module clock or the GTM trigger. The two timestamp counters are detailed as Timestamp Counter A and B (refer to *Figure 1571*). Following are the details:

1. Each channel has an internal Timestamp buffer that can be configured to capture either the TS counter A or B when it encounters the "capture event". Provided there is no XCRC error in the message, then this Timestamp buffer is appended to the message

when it is written to MRU buf1. When there is an XCRC error in the message, then Channel0 timestamp is appended (See "7.").

2. The "captured event" for the timestamp buffer of each channel can either be when a "a valid message header is detected" or when "a Command (or Alternate Command) is moved from the UART Tx Buffer to the UART Tx shift register" corresponding to the channel for which this command is being shifted to the UART.
3. The Timestamp Buffer can be enabled or disabled through the PS_MSGA_CHn[TSBUF_EN] bit. When the Timestamp buffer is disabled then it no longer responds to "capture events" and always contains the value "0".
4. It is possible to reset each Timestamp buffer by using the PS_MSGA_CHn[TSBUF_CLR] bit. As soon as this bit is written to "1" the Timestamp buffer is reset to all "0s" and it remains in this state till it encounters a "capture event".
5. In the case when the reception of message is chosen as the trigger, the time stamp will be captured immediately after the header byte of the UART message packet has been received.
6. In the case when the move of CMD or ACMD from the internal UART Tx Buffer to the UART Tx shift register in the UART module is chosen as the trigger, the timestamp for the intended channel (indicated in the CIDn fields of CMD or ACMD) is valid for all frames received on a channel between moves of CMD or ACMD from the UART Tx Buffer to the UART Tx Register (that is for a PSI5 SYNC period).
7. When a XCRC error is detected in any message then the timestamp that is appended with the message is the Channel0 timestamp which is captured at the time when XCRC_ERR has been detected.
8. For "illegal messages", the timestamp value that is captured is the Channel0 Timestamp value, which is captured whenever "a valid message header for that illegal message is detected". Note that the definition of a "legal" or a "illegal" message applies to a PSI5 message only when the concerned UART packet has no XCRC error.
9. In addition to the timestamp buffers described in "1.", there is a separate timestamp capture that occurs in case of a watchdog error. This timestamp is captured in the PS_WDGTSSR[WDGTS_STATUS] bits. The Timestamp A or B (as programmed in the PS_MSGA_CHn[TIMESTAMP_A_B_SEL]) is captured as soon as the watchdog overrun error occurs for that channel. Refer to *Section 57.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*, for more details.

Figure 1571. Timestamp capture

57.4.5 PSI5-S watchdog operation

The IP provides a watchdog to keep track of a number of reception parameters. The watchdog counter is a 24 bit down counter. Each channel, except Channel0, contains a watchdog counter. The refresh event for the watchdog is automatically chosen depending on whether the channels mode is synchronous or asynchronous. The watchdog timeout value can be configured in the “WD_TO” bits in the PS_WD_CFGR_CH[n] register. The refresh event for the watchdog are different in the synchronous and asynchronous modes as mentioned below:

- In Asynchronous mode:

  As soon as the IP enters the PS_NORMAL mode the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled then the counter starts immediately. Whether the WD has to be “refreshed (re-loaded)” or “not to be refreshed” is analyzed when the XCRC is calculated. In case the XCRC is correct the watchdog is re-loaded (It is not STOPPED), else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In case of watchdog overrun error the counter is refreshed.

- In Synchronous mode:

  As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled then the counter starts immediately. Thereby it is re-loaded, either on the occurrence of a sync pulse or the watchdog overrun error. In case the event for this

load is the Sync Pulse then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured (enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FID_byte] is not equal to “0”. The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured“, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered.

In both the above modes, the watchdog is always refreshed on the occurrence of Watchdog overrun error (F_WD_ERR) or a software reload. Also refer to *Section 57.3.4.20: PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)*.

The watchdog can be started in the NORMAL mode by writing a “1” to the WDEN bit in the PSI5_WD_CFGR_CH[n]. If the watchdog counter is not refreshed by its event and the watchdog counter becomes equal to “0”; the F_WD_ERR flag is set in the PSI5_IRQ_ERR_SR register and the same is also reflected in the PS_MRU_BUF2_REG1 register. An interrupt can also be generated on any of the “ipi_ps_irq[irq_n]” lines depending on the configuration. Note that writing a “0” to WDEN bit disables the watchdog checking mechanism.*Figure 1572* shows the watchdog counter.

Figure 1572. Watchdog counter

As soon as the watchdog overrun error for a particular channel occurs, the status of the watchdog error is immediately latched in the register described in *Section 57.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*. This watchdog error status (PS_WDGTSSR[F_WD_ERR_STATUS[CHn]]) is also sent to the MRU registers (as F_WD_ERR) as shown in the PSI5 frame status word (shown in *Figure 1562* and *Figure 1563*). However this information is sent in the next upcoming PSI5 message packet that occurs for that particular channel, provided this upcoming PSI5 message has no XCRC error. In case the upcoming UART packet has an XCRC error then the Frame watchdog error field in this PSI5 message packet is the “OR” of the F_WD_ERR

status of all the channels that is OR of all the fields of PS_WDGTSSR[F_WD_ERR_STATUS] bits.

57.4.6 Interrupt handling

Following are the various interrupt signals that represent the various events:

1. PSI5-S general interrupt request (Status flags in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ)/ipi_ps_irq[irq_n] where irq_n = 0 to 7 and denotes the irq number.

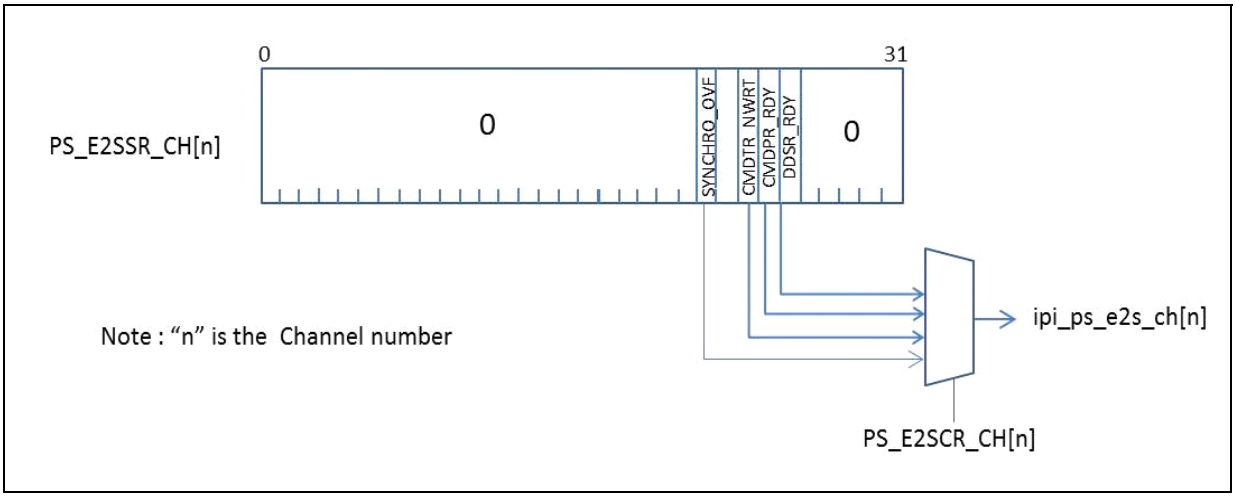
   There are 8 such interrupts in the IP. Each of these “irq” lines can be configured to respond to any or all of the following events:

   – At least one message of the specific channel has been read by the DMA from the MRU buffer (The interrupt is configurable to respond to any channel through the corresponding PS_MBOX_SEL_IRQ[irq_n] register)
   – When there is a XCRC error in a new packet that is transferred to MRU buffer2 OR
   – When there is a CRC or parity error in a new packet that is transferred to MRU buffer2 OR
   – When the watchdog Error has been detected in the message just written to MRU buf2 OR
   – When the message header has been detected with transceiver error flags OR
   – When the PSI5 state machine detects in the UART, the message parity error, the overflow error or the framing error and the corresponding frame is transferred to MRU buffer 2
   – When the “R_OVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
   – When the “R_UVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
   – When the number of bytes received does not match the expected Fn bytes (N_ERR == 1)

   Each of the “ipi_ps_irq[irq_n]” lines can be configured to be asserted on any of the above events by correctly programming the registers PS_MBOX_SEL_IRQ[irq_n] and PS_ERR_SEL_IRQ[irq_n].

   This interrupt is cleared when the corresponding bits in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ are cleared. It is assumed that one event would not be mapped on more than one “irq” lines. If the same event is mapped on more than one “irq” lines then clearing the corresponding status bit in the PS_MBOX_SR_IRQ or PS_ERR_SR_IRQ will clear all the interrupt requests related to that same event.*Figure 1573* shows the interrupt structure for IRQ interrupts.

Figure 1573. IRQ[n] interrupts



2. PSI5-S ECU-to-Sensor interrupt (Status Flags in PSI5_E2SSR)/ipi_ps_e2s_ch[n] where n = 1 to 7.

   This interrupt is used for the ECU to Sensor Communications and is generated in the following cases:

   – When the DDSR is empty and is ready to accept a new command new from the application. In this case the PS_E2SSR_CHn[DDSR_RDY] bit is set to "1".
   – When the DDSR is still busy (PS_E2SSR_CHn[DDSR_RDY] bit is set to "0") and the application attempts to write a new command to the DDSR. The new command is rejected and the PS_E2SSR_CHn[CMD_NWRT] bit is set to "1".
   – When the command that is written to the DDSR has finished calculating the CRC/stuff bits/start bits and is ready for transmission the PS_E2SSR_CHn[CMDPR_BZY] goes to "1" leading to the generation of this interrupt.
   – When there is a synchronization overflow in a particular channel (the same data bit encounters 2 sync pulses without getting a chance to shift), then the bit PS_E2SSR_CHn[SYNCHRO_OVF] is set to "1".

Figure 1574. ECU to sensor interrupts

3. Global interrupt (Status Flags in PS_GLSR) /ipi_ps_glbl.

   This interrupt is a single interrupt for the whole IP and is generated in the following cases:

   – When the DMA has not completed reading the MRU buffer2; simultaneously there is a pending data in MRU buffer1 that needs to be offloaded to the MRU buffer2 and a new message comes, that overwrites the contents of MRU buffer 1. The channel ID and the Frame ID of the overwritten message can be read from the PS_GLSR registers.

   – When there is any change in the "PSI5-S" global modes of the IP. Thus it is asserted during the following transitions UART_STDALONE to PS_DISABLE, PS_DISABLE to PS_CONFIG, PS_DISABLE to PS_NORMAL and PS_CONFIG to PS_NORMAL. Assertion of this interrupt indicates that the desired mode has been accomplished by the IP.

   – When the "DIRCMD_RDY" bit in the PS_GLSR is set to "1", indicating that PS_DIRCMD register is ready to accept a new Direct Command write from the CPU.

Figure 1575. Global interrupts

57.5 PSI5-S clock and reset

Figure 1576. Clock distribution in PSI5-S

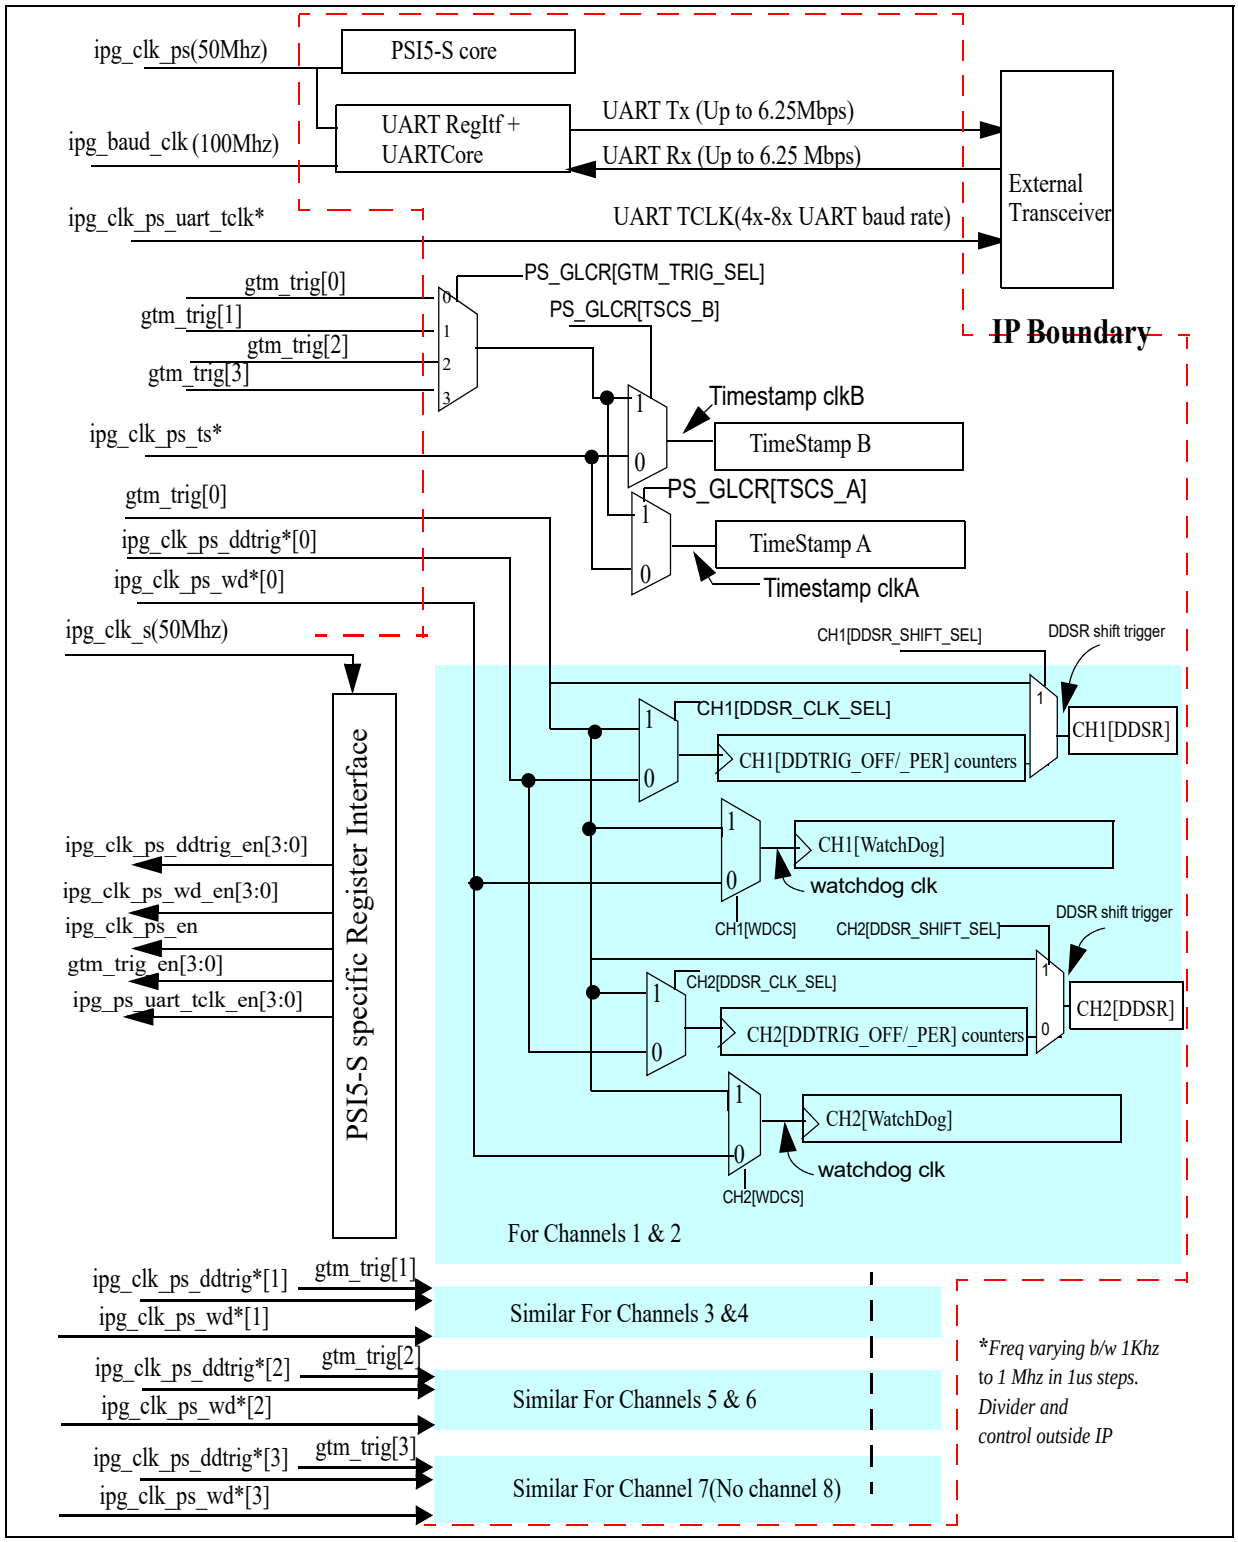


Figure 1576 shows the clocking scheme for the PSI5-S IP. It also shows the distribution of various clocks on the basis of channels.

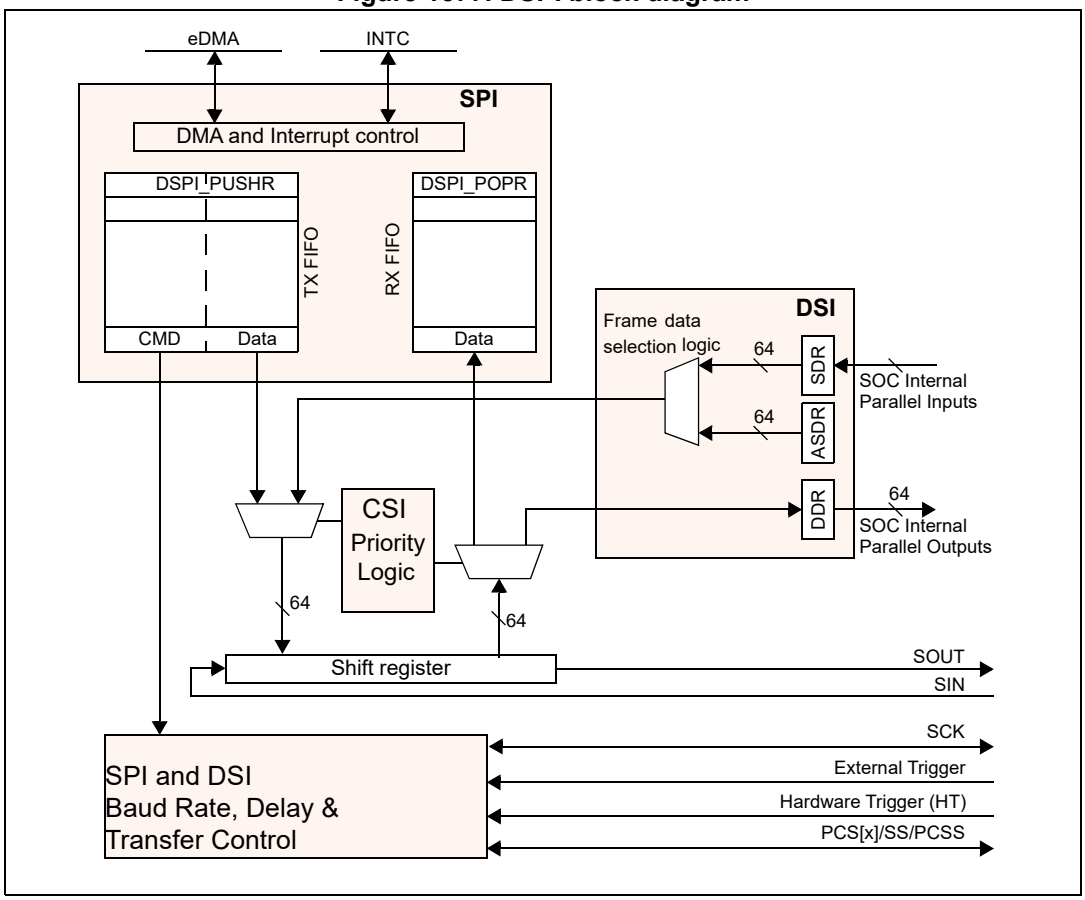
The divider and the control of clock “ipg_clk_ps_ts”, “ipg_clk_ps_wd” and “ipg_clk_ps_ddtrig” are outside the IP. The various clock enables are also controlled by the IP. When the IP enters the disable mode it deasserts all the clock enables from the IP. However the clock enables are deasserted only when once the PS_DISABLE mode entry interrupt has been received and the PS_GLSR[GL_MODETR_DONE_EN] bit has been cleared.

For the safe operation of the UART module, the following relation should be satisfied between “ipg_baud_clk” and “ipg_clk_ps”:

ipg_baud_clk > *ipg_clk_ps* > ipg_baud_clk/3

58 Deserial Serial Peripheral Interface (DSPI)

58.1 Introduction



The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note: For the chip-specific implementation details of the instances of this module, refer to the Device Configuration chapter.

58.1.1 Block diagram

Figure 1577 provides the block diagram of this module.

Figure 1577. DSPI block diagram

58.1.2 Features

The DSPI supports the following features:

- Full-duplex, four-wire synchronous transfers.
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection.
- Buffered transmit operation with 4-entry TX FIFO buffer.
- Buffered receive operation with 4-entry RX FIFO buffer.
- Asynchronous clocking scheme for Register and Protocol interfaces.
- Individual TX and RX FIFOs disabling for low-latency updates to SPI queues.
- Visibility inside TX and RX FIFOs for debugging.
- Programmable transfer attributes on a per-frame basis:
  - 8 transfer attribute registers along with 8 extended transfer attribute registers
  - Serial clock with programmable polarity and phase
  - Various programmable delays
  - programmable serial frame size of 4 to 64 bits, expandable by software control. SPI frames longer than 32 bits are supported using the continuous selection format
  - Continuously held chip select capability
  - Parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer.
- Deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer.
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End Of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame Complete (TCF)
  - Transfers due from current Command frame Complete (CMDTCF)
  - Transfer of current SPI frame Complete (SPITCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
  - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line.
- Modified SPI transfer formats for communication with slower peripheral devices.
- Power-saving architectural features: support for stop mode

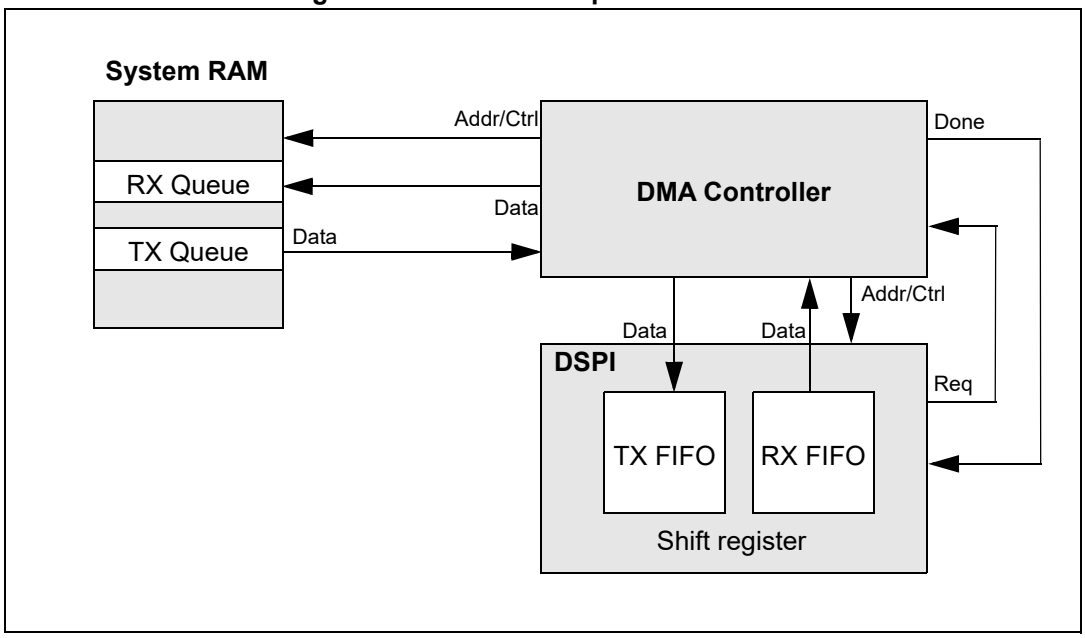
The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
  - DSPI memory-mapped register
  - Parallel input signals
  - Programmable selection of source data on bit basis.
- Deserialized data provided as:
  - Parallel output signals
  - Bits in a memory-mapped register
- Interrupt conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
  - Transfer of current DSI frame complete (DSITCF)
  - DSI parity error (DPEF)
- DMA request support for following conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
- Transfer initiation conditions:
  - Continuous
  - Change in data
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics.
- Continuous serial communications clock.

DSPI supports a combination of SPI and DSI modes of operation (Combined Serial Interface (CSI)) for the downstream Micro Second Channel in either Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration (configurable by software). Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is performed at frame boundaries.
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame.
- Separate interrupts for frame completion from SPI and DSI.

58.1.3 DSPI configurations



The DSPI module can operate in SPI configuration as well as in DSI, and CSI configuration. Refer to the relevant section in the “Communication interfaces” section of the “Device Configuration” chapter.

58.1.3.1 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. *Figure 1578* shows a system example with DMA, DSPI and external queues in system RAM.

Figure 1578. DSPI with queues and DMA

58.1.3.2 DSI configuration

In the DSI configuration the DSPI serializes up to 64 parallel input signals or register bits. The DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

TSB mode provides the Micro Second downstream Channel support (MSC), serializing from 4 to 64 parallel input signals or register bits. Refer to *Section 58.4.9: Timed Serial Bus (TSB)*.

58.1.3.3 CSI configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in *Section 58.4.10: Interleaved TSB (ITSB) Mode*.

58.1.4 Modes of operation

The DSPI modes of operation that can be divided into two categories:

- Module-specific modes
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes
  - External Stop mode
  - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

58.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

58.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI/DSI bus masters In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

58.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

58.1.4.4 External Stop mode

External Stop mode is used for MCU power management; the DSPI supports the Peripheral Bus Stop mode mechanism.

Upon a request to enter External Stop mode:

- In Master mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary, it signals that the protocol clock to the DSPI module may be shut off.
- In Slave mode, a request to enter External Stop mode must be run after the last clock cycle or Low-power mode is not entered.

58.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

58.2 DSPI signal description

This section provides the DSPI signals description.

Table 1585 lists the signals that may connect off chip depending on device implementation.

Table 1585. DSPI signal description

Signal	Description	I/O
PCS0/ SS	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[3:1]	Master mode: Peripheral Chip Select 1–3 Slave mode: Unused	O
PCS4	Master mode: Peripheral Chip Select 4	O
PCS5/ PCSS	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[7:6]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O

58.2.1 PCS0/$\overline{SS}$ — Peripheral Chip Select/Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low $\overline{SS}$ signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

58.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

58.2.3 PCS4 — Peripheral Chip Select 4

In master mode, PCS4 is a Peripheral Chip Select output signal.

58.2.4 PCS5/$\overline{PCSS}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

58.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

58.2.6 SIN — Serial Input

SIN is a serial data input signal.

58.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

58.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

58.3 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPI_POPR also results in a transfer error.

Table 1586. DSPI memory map

Offset (hex)	Register name	Width (in bits)	Access	Reset value	Location

58.3.1 DSPI Module Configuration Register (DSPI_MCR)

The DSPI_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Figure 1579. DSPI Module Configuration Register (DSPI_MCR)

Table 1587. DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2:3 DCONF	DSPI Configuration Selects the DSPI configuration. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. MTFE should not be set in ITSB Mode as Microsecond Channel upstream operation is not supported. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS[5]/PCSS is used as the Peripheral Chip Select[5] signal (PCS[5]). 1 PCS[5]/PCSS is used as an active-low PCS Strobe signal (PCSS).
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer generating the overflow is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8:15 PCSIS[7:0]	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.

Table 1587. DSPI_MCR field descriptions (continued)

Field	Description
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI, putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is 1. MDIS should be set to '0' in Slave Mode as a slave does not control master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes TX FIFO and CMD FIFO. Writing a '1' to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.
21 CLR_RXF	Clear RX FIFO Flushes RX FIFO. Writing a '1' to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22:23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
28 XSPI	Extended SPI Mode Enables use of CTARE (Command and Transfer Attribute Register Extended) registers, which allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled, allowing the user to send multiple Data Frames in a single Command Frame. When MCR[DIS_TXF] is asserted, Extended SPI Mode cannot be used to transmit SPI frames over 16 bits in size. 0 Normal SPI Mode. Up to 16-bit Frames. Command Cycling is not available. 1 Extended SPI Mode. Up to 32-bit SPI Frames. Command Cycling Enabled.

Table 1587. DSPI_MCR field descriptions (continued)

Field	Description
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of "After SCK (t_{ASC})" and "PCS to SCK (t_{CSC})" delays when operating in Continuous PCS mode. The individual delay masks are selected via PUSHR[PE_MASC] and PUSHR{PP_MCSC]. The firmware should select appropriate masks when providing continuous frames via the PUSHR. This masking is not available if Continuous SCK mode is enabled. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers. **Note:** HALT bit starts/stops the internal state machine. All the other MCR bits must be set to their expected value before releasing HALT bit. If one MCR bit needs to be changed in running state, HALT bit must be set first.

58.3.2 Hardware Configuration Register (DSPI_HCR)

Hardware Configuration Register provides particular implementation details about the module, that is number of Receive and Transmit FIFO entries, number of CTAR registers and if DSI features are implemented in the module or not. It is read only register. A write to this register will generate a Transfer Error.

Note: The reset bits in the HCR are set by the configuration parameters.

Table 1588. DSPI_HCR field descriptions

Field	Description
0 DSI	DSI features are implemented for the module. 0 DSI features are not implemented, DSI registers do not exist. 1 DSI features are implemented
1 PISR	PISR0-3 and parallel inputs frame positions selection logic (DSI Muxing Logic) are implemented for the module. 0 PISR0-3 registers are not implemented. 1 PISR0-3 registers are implemented.
2 DSI64	DSI features in 64 bit mode are implemented for the module. 0 DSI features for 64 bit mode are not implemented; related registers do not exist. 1 DSI features for 64 bit mode are implemented
3 PISR_EX	PISR4-7 and parallel inputs frame positions selection logic (DSI 64 bit Muxing Logic) are implemented for the module. 0 PISR4-7 registers are not implemented. 1 PISR4-7 registers are implemented.
4 XSPI	Extended SPI Mode feature is implemented for the module. 0 Extended SPI Mode is not implemented. 1 Extended SPI Mode is implemented.
5:7 CTAR	Maximum implemented CTAR register number.
8:11 TXFR	Maximum implemented TXFR register number.
12:15 RXFR	Maximum implemented RXFR register number.
16:19 CMDFR	Maximum implemented command FIFO number.
20 MSTR_MODE	Master Mode implementation is enabled
21 SLV_MODE	Slave Mode implementation is enabled
22 TSB_EN	TSB Mode implementation is enabled
23 ITSB_EN	Interleaved TSB Mode implementation is enabled

58.3.3 DSPI Transfer Count Register (DSPI_TCR)

DSPI_TCR has an SPI transfer counter to assist in queue management.

Do not write the TCR when the DSPI is in the Running state.

Address: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1581. DSPI Transfer Count Register (DSPI_TCR)

Table 1589. DSPI_TCR field descriptions

Field	Description
0:15 SPI_TCNT	SPI Transfer Counter The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. A value written to SPI_TCNT presets the counter to that value. The Transfer Counter wraps around; incrementing past 65535 resets the counter to zero.

58.3.4 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTARs are used to define different transfer attributes:

- In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays.
- In slave mode, a subset of the bitfields in CTAR0 and CTAR1 set the slave transfer attributes.

Do not write to the CTARs while the DSPI is in the Running state.

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 1582. DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

Table 1590. DSPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate. (Master mode only) Doubles the baud rate of the Serial Communications Clock (SCK). It halves the Baud Rate division ratio, supporting faster frequencies and odd division ratios for the Serial Communications Clock (SCK). When DBR is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in *Table 1591*. Refer to the BR field description in this table for details on how to compute the baud rate. Refer to *Table 1591* for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid value for the number of bits to be transmitted for any mode is 4.There is a constraint on the minimum allowable Frame size, which depends on the register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. Min. Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol Clock Frequency f_r = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by (PBR x BR) / (1 + DBR) The minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'f_p' can be equal to, less than or greater than 'f_r' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is used in 64-bit mode, then DSICR0[FMSZ4] also comes into picture while switching PCS assertion control.
5 CPOL	Clock Polarity. (Master and Slave mode) Selects the inactive state of the Serial Communications Clock (SCK). Devices must have identical clock polarities for successful communication between serial devices. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.

Table 1590. DSPI_CTAR*n* field descriptions (continued)

Field	Description
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, this bit is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First. Specifies whether the LSB or MSB of the frame is transferred first. In TSB mode, this bit should comply with the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8:9 PCSSCK	PCS to SCK Delay Prescaler. Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. Refer to the CSSCK field description in this table for calculating the PCS to SCK Delay. Refer to *Section 58.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, PCSSCK has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10:11 PASC	After SCK Delay Prescaler. Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. Refer to the ASC field description in this table for calculating the After SCK Delay. Refer to *Section 58.4.5.3: After SCK delay (tASC)* for more details. In TSB mode, PASC has no effect. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12:13 PDT	Delay after Transfer Prescaler. (Master mode only) Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In TSB mode, the PDT field defines two MSB bits of the Delay after Transfer. Refer to the DT field description for calculating the Delay after Transfer. Refer to *Section 58.4.5.4: Delay after transfer (tDT)* for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.

Table 1590. DSPI_CTAR*n* field descriptions (continued)

Field	Description
14:15 PBR	Baud Rate Prescaler. (Master mode only) Selects the prescaler value for the baud rate. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. Refer to the BR field description in this table for calculating the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16:19 CSSCK	PCS to SCK Delay Scaler. (Master mode only) Selects the scaler value for the PCS to SCK delay. PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period calculated by: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$ *Table 1592* lists the delay scaler values. Refer to *Section 58.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, the field has no effect.
20:23 ASC	After SCK Delay Scaler. (Master mode only) Selects the scaler value for the After SCK Delay. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period calculated by: $t_{ASC} = (1/f_P) \times PASC \times ASC$ *Table 1592* lists the delay scaler values. Refer to *Section 58.4.5.3: After SCK delay (tASC)* for more details.
24:27 DT	Delay After Transfer Scaler (Master mode only) Selects the Delay after Transfer Scaler. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period. The Delay after Transfer is a multiple of the protocol clock period calculated by: $t_{DT} = (1/f_P) \times PDT \times DT$ *Table 1592* lists the delay scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer to *Section 58.4.5.2: PCS to SCK delay (tCSC)* for more details.
28:31 BR	Baud Rate Scaler. (Master mode only) Selects the scaler value for the baud rate. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is calculated by: SCK baud rate = $(f_P/PBR) \times [(1+DBR)/BR]$ *Table 1593* lists the baud rate scaler values.

Table 1591. DSPI SCK duty cycle

58.3.5 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 1583. DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

Table 1594. DSPI_CTAR*n*_SLAVE field descriptions

Field	Description
0:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ5	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1.

58.3.6 DSPI Status Register (DSPI_SR)

The status register contains DSPI status bits and interrupt/DMA request event flag bits.

Software can clear most of the flag bits in the SR by writing a '1' to them (w1c). Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Figure 1584. DSPI Status Register (DSPI_SR)

Table 1595. DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag. Indicates that all bits in a frame have been shifted out. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status. Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2 SPITCF	SPI Frame Transfer Complete Flag. Similar to TCF but only asserted on SPI frame transmission completion in CSI Mode This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag. Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.

Table 1595. DSPI_SR field descriptions (continued)

Field	Description
4 TFUF	Transmit FIFO Underflow Flag. Indicates an underflow condition in the TX FIFO. Transmit underflow is detected only for DSPI blocks in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. Similar to TCF but only asserted on DSI frame transmission completion in CSI Mode. This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer to *Section 58.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*. This bit is valid only when DSPI_MCR[XSPI] is enabled. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9 DPEF	DSI Parity Error Flag. Indicates that a DSI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.

Table 1595. DSPI_SR field descriptions (continued)

Field	Description
10 SPEF	SPI Parity Error Flag. Indicates that a SPI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits. Indicates that a DSI frame has been received with bits selected by DIMR with active polarity, defined by the DPIR. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag. Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Transmit FIFO Invalid Write Flag. Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag. Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a ‘1’ to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16:19 TXCTR	TX FIFO Counter. Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20:23 TXNXTPTR	Transmit Next Pointer. Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.

Table 1595. DSPI_SR field descriptions (continued)

Field	Description
24:27 RXCTR	RX FIFO Counter. Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28:31 POPNXTPTR	Pop Next Pointer. Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

58.3.7 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

The DSPI_RSER controls DMA and interrupt requests.

Do not write to the RSER while the DSPI is in the Running state.

Table 1596. DSPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable. Enables TCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the Status register to generate a request. DSPI_RSER[CMDFFF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled. 1 Enabled.

Table 1596. DSPI_RSER field descriptions (continued)

Field	Description
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. Enables SPITCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. Enables DSITCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the status register to generate a request. DSPI_RSER[TFFF_DIRS] toggles between either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. DSPI_SR[TFFF] flag and DSPI_RSER[TFFF_RE] must be set. 0 Interrupt requests. 1 DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the status register to generate an interrupt requests. 0 Disabled. 1 Enabled.

Table 1596. DSPI_RSER field descriptions (continued)

Field	Description
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the status register to generate a request. DSPIRSER[RFDF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled 1 Enabled
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[RFDF] flag and DSPI_RSER[RFDF_RE] must be set. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO FIll DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[CMDFFF] flag and DSPI_RSER[CMDFFF_RE] must be set. 0 Interrupt request. 1 DMA request.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[DDIF] flag and DSPI_RSER[DDIF_RE] must be set. 0 Interrupt request. 1 DMA request.

58.3.8 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.
- The CMD FIFO for writes to the Command field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

When Extended SPI Mode is not enabled (MCR[XSPI] = 0):

- TX FIFO and CMD FIFO must be filled simultaneously.
- Writes must be given to both Data and Command fields of PUSHR for every PUSHR operation.
- TX FIFO and CMD FIFO can be considered a single 32-bit FIFO.

When Extended SPI Mode is enabled (MCR[XSPI] = 1):

- TX FIFO and CMD FIFO can be written independently.
- A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register do not update the FIFO. Reads during Module disable mode return the last PUSHR write performed when Module was enabled.

Address: 0x0034 Access: User read/write

Figure 1586. DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

Table 1597. DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable. (SPI master mode) Continuous Selection Format enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame as EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1:3 CTAS	Clock and Transfer Attributes Select. Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI slave mode, CTAR0 is used. Refer to the Device Configuration chapter to determine how many CTARs this device has. Do not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7

Table 1597. DSPI_PUSHR field descriptions (continued)

Field	Description
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. DSPI_SR[EOQF] is set at the end of the transfer. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter. Clears the SPI_TCNT field in the Transfer Count register. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame causes this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE: This bit enables parity bit transmission and parity reception check for the SPI frame. MASC: The current frame has the “after SCK” delay masked if this bit is asserted. Refer to *Section 58.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE: No parity bit included/checked. MASC: t_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE: Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC: t_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP: controls the polarity of the parity bit transmitted and checked. MCSC: The next frame has the “PCS to SCK” delay masked if this bit is asserted. Refer to *Section 58.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP: Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC: t_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP: Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC: t_{CSC} delay is masked in the next frame.
8:15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16:31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command

58.3.9 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Field	Description
0:31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

58.3.11 DSPI Transmit FIFO Registers (DSPI_TXFR*n*)

TXFR*n* provide visibility into the TX FIFO for debugging purposes.

Each read-only register is an entry in the TX FIFO. Reading the TXFR*n* registers does not alter the state of the TX FIFO.

Reading DSPI_TXFR*n* registers is invalid for a DSPI Master when used in Extended SPI (XSPI) mode.

Address: 0x003C + *n**0x4 (*n* = 0 to 3) Access: User read-only

Field	Description
0:15 TXCMD_TXDATA	Transmit Command or Transmit Data In master mode, the TXCMD field sets the transfer attributes for the SPI data. In slave mode, the TXDATA contains 16 MSB bits of the SPI data to be shifted out.
16:31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

58.3.12 DSPI Receive FIFO Registers (DSPI_RXFR*n*)

RXFR*n* provide visibility into the RX FIFO for debugging purposes.

Each read-only register is an entry in the RX FIFO. Reading the RXFR*n* registers does not alter the state of the RX FIFO.

MCR[MDIS] must be 0 when RXFR is read.

Address: 0x007C + *n**0x4 (*n* = 0 to 3) Access: User read-only

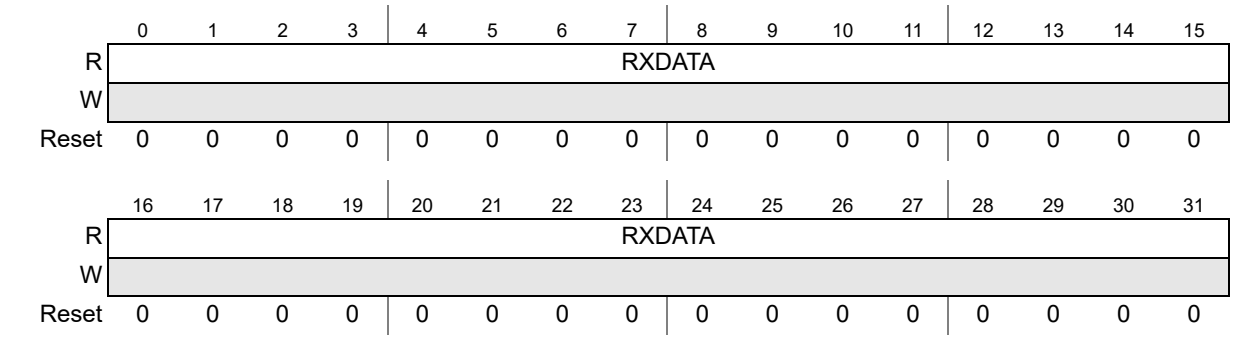

Figure 1590. DSPI Receive FIFO Registers (DSPI_RXFR*n*)

Field	Description
0:31 RXDATA	Receive Data Contains the received SPI data.

58.3.13 DSPI DSI Configuration Register 0 (DSPI_DSICR0)

DSICR0 selects various attributes associated with DSI and CSI Configurations.

Do not write to the DSICR0 while the DSPI is in the Running state.

Address: 0x00BC Access: User read/write

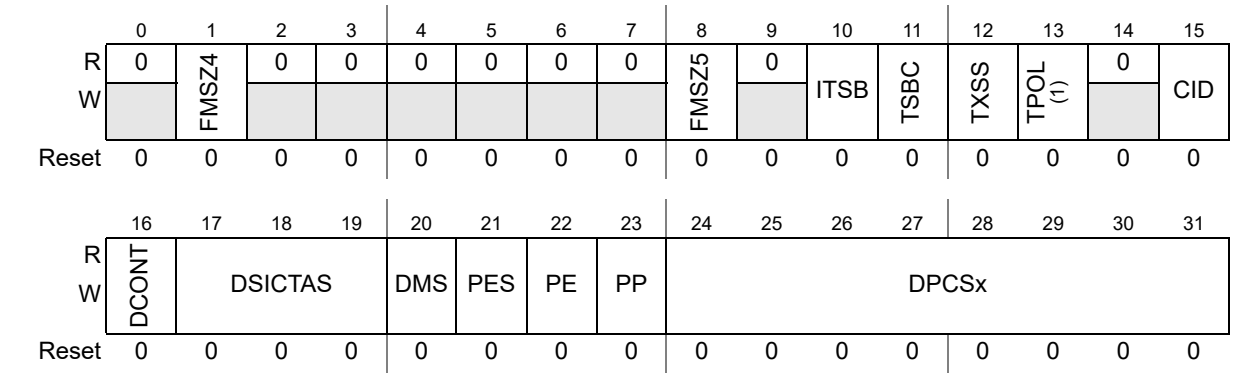

Figure 1591. DSPI DSI Configuration Register 0 (DSPI_DSICR0)

1. This bit is reserved if the device does not have a hardware trigger input signal (HT).

Table 1602. DSPI_DSICR0 field descriptions

Field	Description
1 FMSZ4	MSB of the frame size in master mode when DSI is used in 32-bit mode. If the bit is set, 16 is added to the frame size, as defined by the CTAR*n*[FMSZ] field. The CTAR*n* register is selected by the DSICTAS field.
8 FMSZ5	MSB of the frame size in master mode when DSI is used in 64-bit mode. If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ4], CTAR*n*[FMSZ]} fields. The CTAR*n* register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit is {DSICR0[FMSZ5], DSICR0[FMSZ4], CTAR*n*[FMSZ]}. This field is only valid when DSICR1[DSI64] is enabled.
10 ITSB	Interleaved TSB mode. Enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are sent when either the previous transmission was an SPI frame or the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. ITSB mode requires DSICR0[TSBC] set and should be written only when MCR[HALT] is asserted. If ITSB bit is set without setting DSICR0[TSBC], DSPI operates in Normal Mode depending on MCR[DCONF] bit. Refer to *Section 58.4.10: Interleaved TSB (ITSB) Mode* for more details. 0 Disabled. 1 Enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows up to 64-bit data to be used. It also allows t_{DT} to be programmable. 0 Disabled. 1 Enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either: a) data from host software written to the DSPI DSI Alternate Serialization Data Register (ASDR1/0), or b) parallel input pin states latched into the DSPI DSI Serialization Data Register (SDR1/0). 0 SDR source. 1 ASDR source.
15 CID	Change In Data Transfer Enable When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. Do not enable CID when DCONT is enabled. 0 Disabled. 1 Enabled.

Table 1602. DSPI_DSICR0 field descriptions (continued)

Field	Description
16 DCONT	DSI Continuous Peripheral Chip Select Enable (DSI Master mode only) Enables the PCS signals to remain asserted between transfers. When the TSBC bit is set, DCONT has no effect. Do not enable DCONT when CID is enabled. 0 PCS signals return to inactive. 1 PCS signals remain asserted.
17:19 DSICTAS	DSI Clock and Transfer Attributes Select (DSI Master mode only) Selects the CTAR which provides transfer attributes for DSI frames. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop Stops DSI frame transmissions if DDIF flag is set in the status register. 0 Disabled. 1 Enabled.
21 PES	Parity Error Stop Stops DSI operation if a parity error occurred in the received DSI frame. 0 Disabled. 1 Enabled.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of ‘1’ bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of ‘1’ bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24:31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

58.3.14 DSPI DSI Serialization Data Register 0 (DSPI_SDR0)

Read-only SDR0 contains the states of the 32 LSB parallel input signals.

The states of these signals are latched into the SDR0 on the rising edge of every protocol clock.

When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

When DSICR1[DSI64E] is set, SDR1 is the MSB half and SDR0 is the LSB half of the 64-bit SDR.

Field	Description
0:31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals.

58.3.15 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized.

When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames.

Writes to the ASDR0 take effect on the next frame boundary.

When DSICR1[DSI64E] is set, ASDR1 is the MSB half and ASDR0 is the LSB half of the 64-bit ASDR.

Figure 1596. DSPI DSI Configuration Register 1 (DSPI_DSICR1)

Table 1607. DSPI_DSICR1 field descriptions

Field	Description
2:7 TSBCNT[5:0]	Timed Serial Bus Operation Count TSBCNT defines the length of the data frame When TSBC is set. The TSBCNT field valid value is from 3 to 63. The TSBCNT field selects the number of data bits to be shifted out during a transfer in TSB mode. Number of data bits in data frame = TSBCNT + 1.
13 DSI64E	DSI 64-bit Mode Enable Allows serialization and deserialization of Data frames up to 64 bits in size. The extended registers DSPI_SDR1, DSPI_ASDR1, DSPI_COMPR1, DSPI_DDR1, DSPI_SSR1, DSPI_PISR4-7, DSPI_DIMR1, DSPI_DPIR1 are valid in this mode. 0 Disabled. DSI Mode operates in the default 32-bit configuration 1 Enabled. DSI Mode operates in 64-bit configuration

Table 1607. DSPI_DSICR1 field descriptions (continued)

Field	Description
14 DSE1	Data Select Enable 1 When DSICR0[TBSC] bit is set, the DSE1 bit enables insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTAR*n* register, selected by the DSICR0[DSICTAS] field. If DSICR1[DSI64] is enabled, then the insertion bit position is defined by concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields. The TSBCNT field value must be greater than the FMSZ field value plus one for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When DSICR0[TSBC] bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the Data frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16:23 TRGPRD	Internal Trigger Period for the ITSB mode. When DSICR0[TRG] bit is cleared and ITSB Mode is enabled, this field determines the trigger period for the internal trigger in number of baud rate clock cycles. The trigger period should be calculated as: Trigger Period = 64 bits (DSI frame maximum size) + 2 selection bits (maximum) + t_{PF} (passive frame time) When DSICR1[DSI64E] is disabled, DSI frame maximum size is 32. Refer CTAR[FMSZ] field for minimum frame size allowed. Refer to Interleaved TSB (ITSB) Mode for more details. 0 – 4 These values are invalid since minimum Command frame size is 5. (that is 1 selection bit + minimum frame size which is 4) 5 – 255 Number of baud rate clock cycles to be used as the trigger period. The trigger period implemented is equal to TRGPRD + 1.
24:31 DPCS1_x	DSI Peripheral Chip Select 0–7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

58.3.19 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0.

Each bit in the SSR0 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR0 register value has no effect.

When DSICR1[DSI64E] is set, SSR1 is the MSB half and SSR0 is the LSB half of the 64-bit SSR.

Address: 0x00D4 Access: User read/write

Figure 1597. DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

Table 1608. DSPI_SSR0 field descriptions

Field	Description
0:31 SS	Source Select Select the serialization source for the 32 LSB of DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

58.3.20 DSPI DSI Parallel Input Select Register 0 (DSPI_PISR0)

PISR0–3 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 if DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–3 only preselect the parallel input pins. The final selection to the transmitted frame is made with the DSPI_SSR1/0 register bits or the DSICR0[TXSS] bit.

When DSICR1[DSI64E] is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins).

58.3.24 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

DIMR0 selects bits in the 32 LSB of received DSI frame to be checked to generate the DDI interrupt.

When DSICR1[DSI64E] is set, DIMR1 is the MSB half and DIMR0 is the LSB half of the 64-bit DIMR.

Address: 0x00E8 Access: User read/write

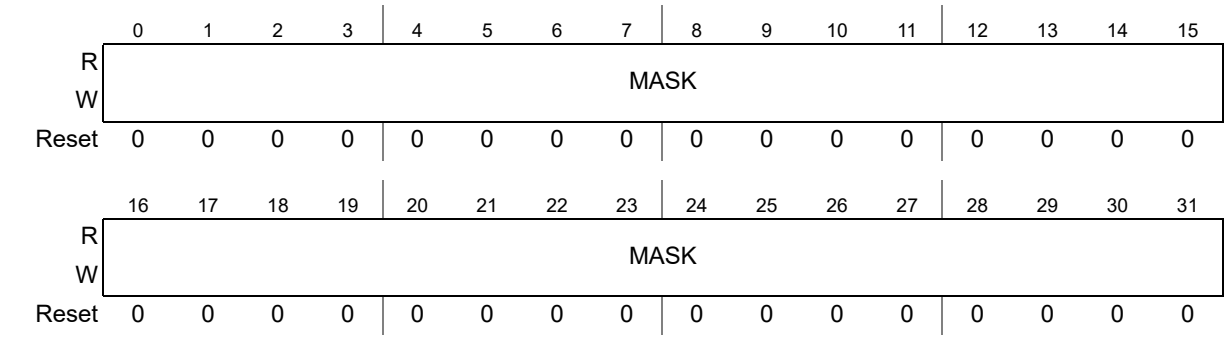

Figure 1602. DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

Table 1613. DSPI_DIMR0 field descriptions

Field	Description
0:31 MASK	Mask 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame produces a DDI interrupt if the data bit matches the configured polarity.

58.3.25 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

DPIR0 defines which data bit value in the 32 LSB of received DSI frame generates the DDI interrupt.

When DSICR1[DSI64E] is set, DPIR1 is the MSB half and DPIR0 is the LSB half of the 64-bit DPIR.

Address: 0x00EC Access: User read/write

Field	Description
0:31 DP	Data Polarity 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

58.3.26 DSPI DSI Serialization Data Register 1 (DSPI_SDR1)

Read-only SDR1 contains the states of the 32 MSB parallel input signals.

The states of these signals are latched into the SDR1 on the rising edge of every protocol clock.

When DSICR0[TXSS] is cleared, the data in SDR1 and SDR0 is the source of the DSI frames.

The concatenation of {DSPI_SDR1, DSPI_SDR0} provides the 64-bit data to be serialized.

This register is valid only when DSICR1[DSI64E] is set.

Address: 0x00F0 Access: User read-only

Field	Description
0:31 SER_DATA	Serialized Data

58.3.27 DSPI DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized.

When DSICR0[TXSS] is set, the data in ASDR1 and ASDR0 is the source of the DSI frames.

Writes to the ASDR1 take effect on the next frame boundary.

The concatenation of {DSPI_ASDR1, DSPI_ASDR0} provides the 64-bit alternate serialization data.

This register is valid only when DSICR1[DSI64E] is enabled.

58.3.28 DSPI DSI Transmit Comparison Register 1 (DSPI_COMPR1)

Read-only COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data.

The upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift register.

The concatenation of {DSPI_COMPR1, DSPI_COMPR0} provides the 64-bit transmit comparison data.

This register is valid only when DSICR1[DSI64E] is enabled.

58.3.30 DSPI DSI Serialization Source Select Register 1 (DSPI_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and from SDR1.

Each bit in the SSR1 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR1 register value has no effect.

The concatenation of {DSPI_SSR1, DSPI_SSR0} provides the 64-bit Serialization Source Select value.

This register is valid only when DSICR1[DSI64E] is enabled.

Table 1619. DSPI_SSR field descriptions

Field	Description
0:31 SS	Source Select 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR1 register

58.3.31 DSPI DSI Parallel Input Select Register 4 (DSPI_PISR4)

PISR4–7 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 when DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–7 only preselect the parallel input pins. The final selection to the transmitted frame is made with the SSR0 and SSR1 register bits or the DSICR0[TXSS] bit.

When 64-bit DSI mode is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins). If DSICR1[DSI64E] is disabled, then DSPI_PISR4-7 registers are invalid.

58.3.35 DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1)

DIMR1 selects bits from the 32 MSB in the received 64-bit DSI frame to be checked to generate the DDI interrupt.

The concatenation of {DSPI_DIMR1, DSPI_DIMR0} provides the 64-bit Deserialized Data Interrupt Mask value.

This register is valid only when DSICR1[DSI64E] is enabled.

58.3.37 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame.

These registers are valid only when DSPI_MCR[XSPI] is set.

When the DSPI is configured as:

- an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.
- an SPI bus slave, the CTARE0 register is used.

Figure 1615. DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

Table 1626. DSPI_CTARE*n* field descriptions

Field	Description
15 FMSZE	Frame Size Extended This field concatenated with DSPI_CTAR[FMSZ] defines the frame size of the SPI frames to be transmitted. Frame size is the concatenation of {DSPI_CTAR[FMSZ], DSPI_CTARE[FMSZE]} + 1. 0 Default Mode. Up to 16-bit SPI frames can be transferred. 1 Up to 32-bit SPI frames can be transferred. Each frame transfer is a result of 2 TX FIFO Pops.
21:31 DTCP	Data Transfer Count Preload This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame that selected this DSPI_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

58.3.38 DSPI Status Register Extended (DSPI_SREX)

The DSPI_SREX contains status fields that reflect the DSPI status and indicate the occurrence of events.

This register is not writable.

Address: 0x013C Access: User read-only

Figure 1616. DSPI Status Register Extended (DSPI_SREX)

Table 1627. DSPI_SREX field descriptions

Field	Description
24:27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28:31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

58.4 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations:

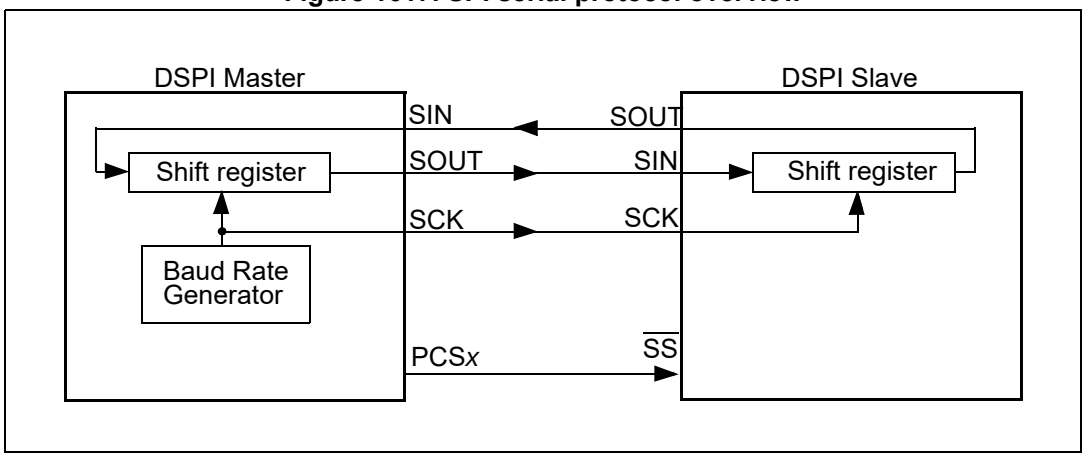
- SPI Configuration in which the DSPI operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes and deserializes parallel input/output signals or bits from memory-mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI Configuration. Refer to *Section 58.3.1: DSPI Module Configuration Register (DSPI_MCR)* for the DSPI configuration values.

The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows CTAR selection on a frame by frame basis by setting a field in the SPI command. Extended SPI Mode (DSPI_MCR[XSPI]) further allows the usage of CTARE*n* (CTAR*n* Extended) registers to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates which CTAR is used for the data transfer.

Refer to *Section 58.3.4: DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTARn)* for information on CTARs fields.



Refer to *Section 58.3.37: DSPI Clock and Transfer Attributes Register Extended (DSPI_CTAREn)* for information on CTAREs fields.

Typical master to slave connections are shown in *Figure 1617*.

When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave: the data that was in the master shift register is now in the shift register of the slave, and vice versa.

At the end of a transfer, the TCF bit in the Status register is set to indicate a completed transfer.

Figure 1617. SPI serial protocol overview

Generally, more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in *Section 58.4.6: Transfer formats*.

The transfer rate and delay settings are described in *Section 58.4.5: DSPI baud rate and clock delay generation*.

58.4.1 Start and Stop of DSPI transfers

The DSPI has two operating states that are independent of DSPI configuration:

- STOPPED is the default DSPI state: no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results.
- RUNNING is the state when serial transfers take place.

DSPI_SR[TXRXS] indicates what state the DSPI in (‘1’ = RUNNING state).

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

58.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The SPI frames can be 32 bits long.

The DSPI is in SPI Configuration when the DCONF field in the MCR is 0b00.

The host CPU or a DMA controller transfers the SPI data from memory external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer.

Received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI.

The FIFO buffers operation is described in:

- *Section 58.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*,
- *Section 58.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*,
- *Section 58.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism*.

The interrupt and DMA request conditions are described in *Section 58.4.12: Interrupts/DMA requests*.

The SPI Configuration supports two block-specific modes:

- Master mode: the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry.
- Slave mode: the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

58.4.2.1 Master mode

In SPI Master mode, the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals.

The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields.

The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin.

In SPI Master mode, each SPI frame to be transmitted has a command associated with it for transfer attribute control on a frame-by-frame basis.

In Extended SPI Master mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. Extended SPI Mode allows for larger frame sizes of up to 32 bits.

58.4.2.2 Slave mode

In SPI slave mode, the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers.

Certain transfer attributes such as clock polarity, clock phase and frame size must be set in CTAR0 and CTARE0 for successful communication with an SPI master. The data is shifted out with MSB first; shifting out of LSB is not supported in this mode.

58.4.2.3 FIFO Disable operation

The FIFO Disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO.

The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled.

The Transmit and Receive side of the FIFOs are disabled separately:

- MCR[DIS_TXF] disables TX FIFO and CMD FIFO.
  - TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in the status register and the extended status register behave as if there is a one-entry FIFO.
  - The contents of the TXFR registers and TXNXTPTR and CMDNXTPTR are undefined.
- MCR[DIS_RXF] bit disables the RX FIFO.
  - The RFDF, RFOF and RXCTR fields in the status register behave as if there is a one-entry FIFO.
  - The contents of the RXFR registers and POPNXTPTR are undefined.

The FIFO Disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

58.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission.

The TX FIFO holds 4 words, each consisting of SPI data that is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR).

The number of entries in the TX FIFO is device-specific.

TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. This field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

58.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set.When TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete, the TFFF bit is cleared. Writing a ‘1’ to the TFFF bit also clears it. The DSPI ignores attempts to push data to a full TX FIFO; the state of the TX FIFO does not change and no error condition is indicated.

The TFFF can generate a DMA request or an interrupt request. Refer to *Section 58.4.12.2: Transmit FIFO Fill interrupt or DMA request* for details.

58.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled and the frame size of SPI Data to be transmitted is more than 16 bits, then two Data entries are popped from TX FIFO simultaneously and transferred to the shift register. The first of the two popped entries forms the 16 LSB bits of the SPI frame. Such an operation also causes TX FIFO Counter to decrement by two.

At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a ‘1’ to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave’s DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave’s SR is set. Refer to *Section 58.4.12.9: Transmit FIFO Underflow interrupt request* for details.

58.4.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific.

SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPI_MCR[XSPI]) is disabled:

- The TX FIFO and CMD FIFO must be filled together as every CMDFIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled:

- The TX FIFO and CMD FIFO can be filled independently as every CMDFIFO entry can have multiple TXFIFO entries attached to it.
- The CTARE[DTCP] field decides the number of SPI Data Frames of size {FMSZE, FMSZ} to be transmitted using the current Command Entry. FMSZ and FMSZE fields are given in the CTAR/CTARE registers respectively, pointed by the CTAS field in the Command frame.
- The amount of time a command entry is in use is known as a Command Cycle. The busy flag DSPI_SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO entry is used during the next command cycle. This field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

58.4.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin.

The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific.

SPI data is added to the RX FIFO on completion of a transfer when the received data in the shift register is transferred into the RX FIFO.

SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the status register points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR = 2 means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

58.4.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register.

While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the status register is set to indicating an overflow condition. Consequently:

- If the DSPI_MCR[ROOE] bit is set, the incoming data is shifted in to the shift register.
- If the DSPI_MCR[ROOE] bit is cleared, the incoming data is ignored.

58.4.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one.

Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data read from the empty RX FIFO is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the status register is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete, or by writing a ‘1’ to it.

58.4.3 Deserial Serial Interface (DSI) configuration

The DSI Configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in *Section 58.4.6: Transfer formats*. The received serial frames are converted to a parallel form (deserialized) and placed on the parallel output signals or in the DSPI_DDR. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR1/0).

The DSI frames can be from 4 to 32 bits, or 64 bits when DSICR1[DSI64E] is enabled.

58.4.3.1 DSI master mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions (described in *Section 58.4.3.5: DSI transfer initiation control*) that can initiate a transfer:

- Continuous.
- Change in data.
- Trigger signal.
- Trigger signal combined with a change in data.

Transfer attributes are set during initialization. DSICR0[DSICTAS] field determines which of the DSPI_CTARs will control the transfer attributes.

58.4.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers.

Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1.

The data is shifted out with MSB first.

58.4.3.3 DSI serialization

The DSI configuration from 4 to 16 bits can be serialized using two different sources selected by DSICR0[TXSS]:

- DSPI DSI Serialization Data Register (DSPI_SDR1/0). The DSPI_SDR0 holds the latest 32 parallel input signal values which is sampled at every rising edge of the protocol clock.
  When DSICR1[DSI64E] is enabled, 64-bit DSI frames are supported and hence DSPI_SDR1 holds the 32 MSB parallel input signal values which is sampled at every rising edge of the protocol clock.
- DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0). The DSPI_ASDR1/0 registers are written by host software and used as an alternate source of serialized data. DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled.

The DSPI has to sample the (SDR/ASDR) inputs before it transmits a DSI frame. Due to the asynchronous clock structure within DSPI, the sampling of inputs come under Register Clock domain whereas DSI frame transmission logic lies in Protocol Clock domain. Hence the sampled data (from ASDR1/0 or SDR1/0) must be synchronized into the Protocol Domain before being loaded into the Shift register for transmission.

To prevent Clock Domain clocking issues, SDR/ASDR inputs should not change while they are being sampled into the Protocol Domain. This is assured in the following manner:

- For the ASDR0 and ASDR1 inputs:
  - The initial write performed on ASDR register causes the 32-bit ASDR input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain.
  - Once synchronized, the lock is removed and the next ASDR write triggers this process again. If a write is performed on ASDR while the lock is asserted, this is processed as soon as the previous synchronization process completes and the lock is de-asserted. If multiple writes are performed on ASDR when lock is asserted after the first write, only the last value is considered for synchronization once the lock is de-asserted.
- For the SDR0 and SDR1 inputs:
  - The process is the same as ASDR with the only difference being that SDR inputs are delayed internally by a single clock to detect a change in the SDR input pins.

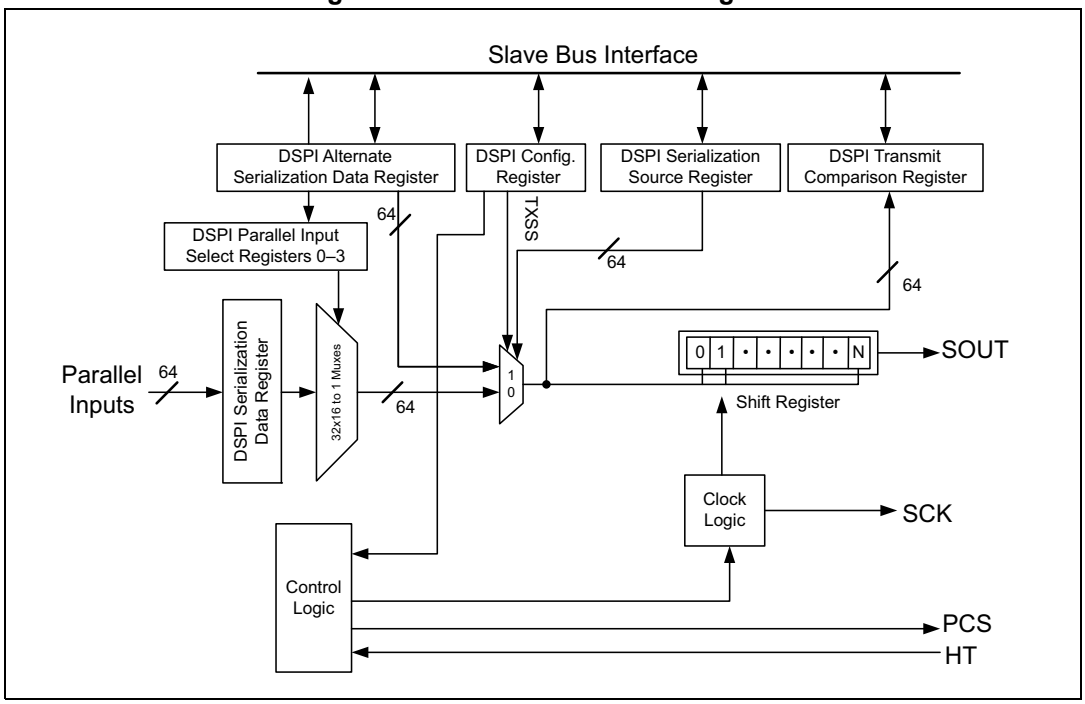
Note: If SDR0 and SDR1 inputs are both changed at the same time instant, then the synchronization logic ensures that both SDR0 and SDR1 contribute to the same DSI frame.

Once the synchronization process for a particular Deserial input begins, it takes up to five Register clock periods and five Protocol clock periods before the synchronization process for the next Deserial input can begin. Hence the writes performed on ASDR0/1 and SDR0/1 are constrained with this timing.

The DSPI_PISR0–3 registers (DSPI_PISR0–7 registers if DSICR1[DSI64E] is enabled) allow changing of the relative position of the parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent parallel inputs by writing IPS*n* fields. The IPS*n* field is treated as a 4-bit integer number, representing numbers from -8 to 7. The parallel input pin number, selected by IPS*n* field is defined by the sum of the IPS*n* field number (*n*) and the IPS*n* field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result. When DSICR1[DSI64E] is enabled, if the above operation result is negative, the number 64 should be added. If the result is higher than 64, 64 should be subtracted from the result.

For example, IPS0, set to minus 1 (binary 1111), preselects parallel input 31 to 0 position in the transmitted frame. (This preselects parallel input 63 to 0 position in the transmitted frame when DSICR1[DSI64E] is set).

IPS6, set to 3 (binary 0011), preselects parallel input 9 to be bit number 6 in the transmitted frame, while the value minus 2 (1110) preselects parallel input 4.



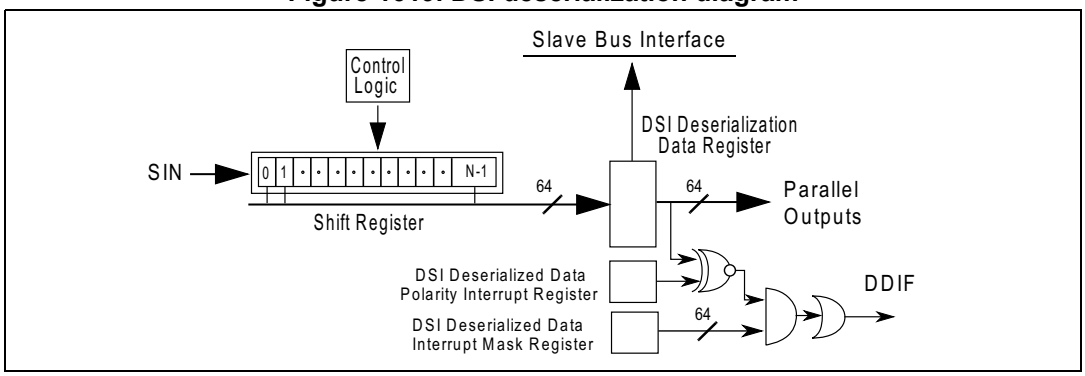
IPS31, set to minus 8 (binary 1000), preselects parallel input 23 to be bit number 31 in the transmitted frame.

The parallel input pin state to be transmitted should be selected by TXSS or DSPI_SSR1/0 registers and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR1/0 registers provide additional way of creating the frame for transmission. Each bit from this register is ORed with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR1/0 and DSPI_ASDR1/0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. The control field may come from DSPI_ASDR1/0 registers set by the CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMPR1/0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. *Figure 1618* shows the DSI serialization logic.

Figure 1618. DSI serialization diagram



58.4.3.4 DSI deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR1/0). This register presents the deserialized data as parallel output signal values. The DSPI_DDR1/0 is memory-mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR1/0), bit-wise ANDed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR1/0) and the results ORed to produce DDIF flag in the DSPI_SR. Which in turn can cause DDIF interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] and/or stop DSI frame transmissions if DSICR0[DMS] bit is set. *Figure 1619* shows the DSI Deserialization logic.

Figure 1619. DSI deserialization diagram

58.4.3.5 DSI transfer initiation control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0 register. *Table 1628* lists the four transfer initiation conditions.

Table 1628. DSI data transfer initiation control

DSPI_DSICR0 bits		Transfer initiation control
TRRE	CID	
0	0	Continuous
0	1	Change in Data
1	0	Triggered
1	1	Triggered or Change in Data

58.4.3.5.1 Continuous control

For continuous control, a new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

58.4.3.5.2 Change in data control

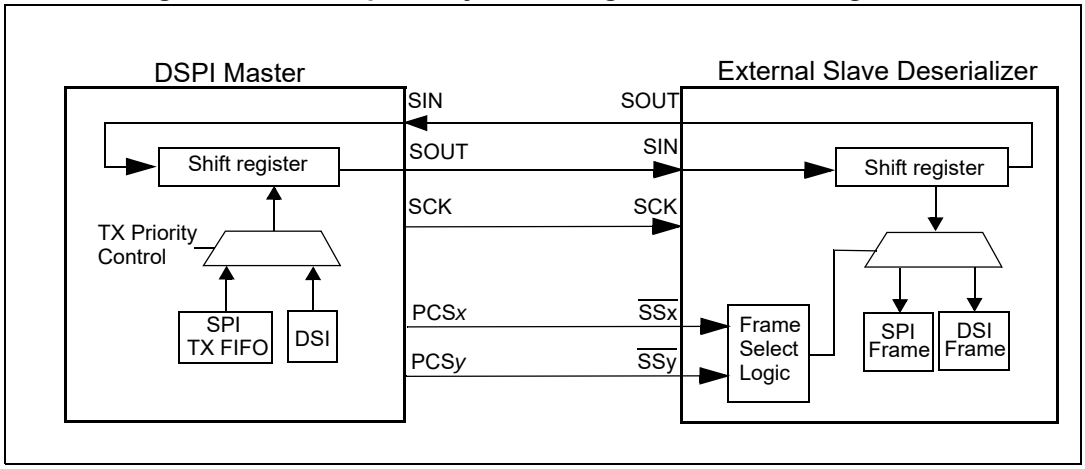
For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_COMPR1/0. When the data selected for the transfer from the DSPI_SDR1/0 and DSPI_ASDR1/0 registers is different from the data in the DSPI_COMPR1/0 a new DSI frame is transmitted.

58.4.3.5.3 Change in data control

For change in data control, initiation of a transfer is controlled by the detection of a change in data to be serialized.

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1; since the following statement then holds true:

Once slave select is asserted, there is a very small window (of up to three module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occurs, the next frame to be transmitted would be loaded into the shift register. Since it is not feasible that such a write is initiated and completed within this short span of time, the data transmitted by DSPI slave would lag by one data frame.



58.4.4 Combined Serial Interface (CSI) configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis.

CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the parallel output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the

DSPI_MCR is 0b10. *Figure 1620* shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

Figure 1620. Example of System using DSPI in CSI Configuration

In CSI Configuration, the DSPI transfers DSI data based on *Section 58.4.3.5: DSI transfer initiation control*. When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTARs associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy.

The CSI Configuration is only supported in master mode.

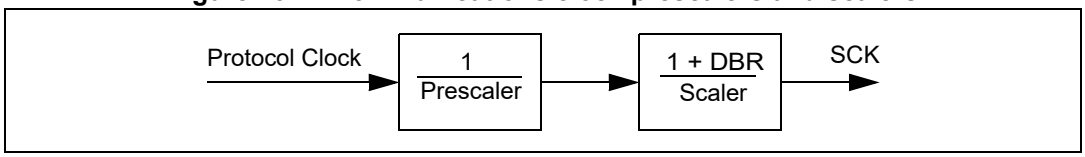
Data returned from the external slave while a DSI frame is transferred is placed on the parallel output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

58.4.4.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR selected by the DSICR0[DSICTAS] field.

The parallel inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR) on the rising edge of every protocol clock and serialized based on the transfer initiation control settings in the DSPI_DSICR1/0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty), they have priority over DSI data and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR1/0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.



58.4.4.2 CSI deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR1/0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred, the returned frames are deserialized and latched into the DSPI_DDR1/0. When SPI frames are transferred, the returned frames are deserialized and written to the RX FIFO.

58.4.5 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. *Figure 1621* shows conceptually how the SCK signal is generated.

Figure 1621. Communications clock prescalers and scalers

58.4.5.1 Baud rate generator

The baud rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. *Table 1629* shows an example of how to compute the baud rate.

Table 1629. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note: The clock frequencies mentioned in Table 1629 are given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

58.4.5.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. The PCSSCK and CSSCK fields in the CTAR*n* registers select the PCS to SCK delay by the formula in the CSSCK field description. *Table 1630* shows an example of how to compute the PCS to SCK delay.

Table 1630. PCS to SCK delay computation example

f_P	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1630 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

58.4.5.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. The PASC and ASC fields in the CTAR*n* registers select the After SCK delay by the formula in the ASC field description. *Table 1631* shows an example of how to compute the After SCK delay.

Table 1631. After SCK delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1631 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

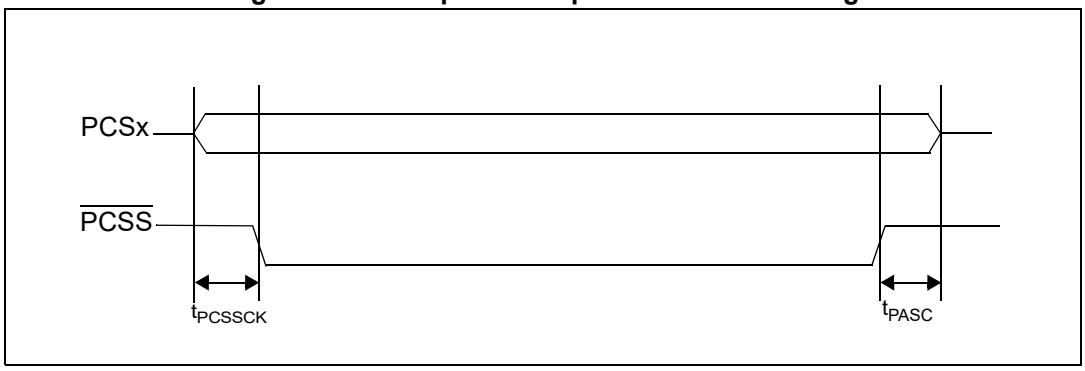
58.4.5.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. The PDT and DT fields in the CTAR*n* registers select the Delay after Transfer by the formula in the DT field description. *Table 1632* shows an example of how to compute the delay after transfer.

Table 1632. Delay after transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

Note: The clock frequency mentioned in Table 1632 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.



When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode, the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. Refer to detailed information on *Section 58.4.9: Timed Serial Bus (TSB)*.

58.4.5.5 Peripheral Chip Select Strobe Enable ($\overline{PCSS}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs, thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, $\overline{PCSS}$ provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4]and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. *Figure 1622* shows the timing of the $\overline{PCSS}$ signal relative to PCS signals.

Figure 1622. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

Equation 86

$$t_{PCSSCK} = \frac{1}{f_P} \times PCSSCK$$

At the end of the transfer the delay between $\overline{PCSS}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

Equation 87

$$t_{PASC} = \frac{1}{f_P} \times PASC$$

Table 1633 shows an example of how to compute the t_{PCSSCK} delay.

Table 1633. Peripheral Chip Select Strobe Assert Computation Example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

Table 1634 shows an example of how to compute the t_{PASC} delay.

Table 1634. Peripheral Chip Select Strobe Negate Computation Example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK or TSB mode are enabled.

Note: The clock frequency mentioned in the preceding Table 1633 and Table 1634 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

58.4.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTAR*n*) select the polarity and phase of the serial clock, SCK.

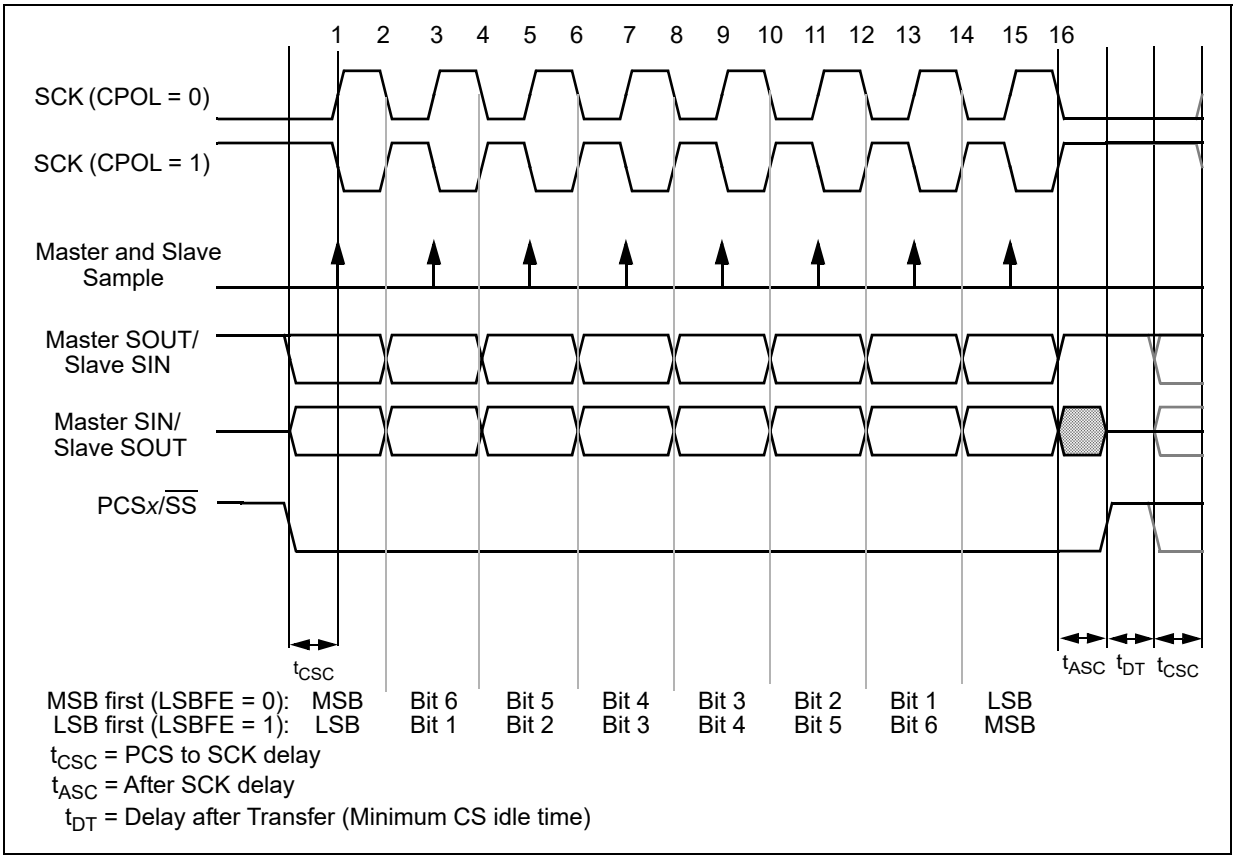
- CPOL: selects the idle state polarity of the SCK.
- CPHA: selects if the data on SOUT is valid before or on the first SCK edge.

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

In DSI slave mode, only CTAR1 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0.
- Classic SPI with CPHA = 1.
- Modified Transfer format with CPHA = 0.
- Modified Transfer format with CPHA = 1.



A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. Refer to *Section 58.4.6.5: Continuous Selection Format* for details.

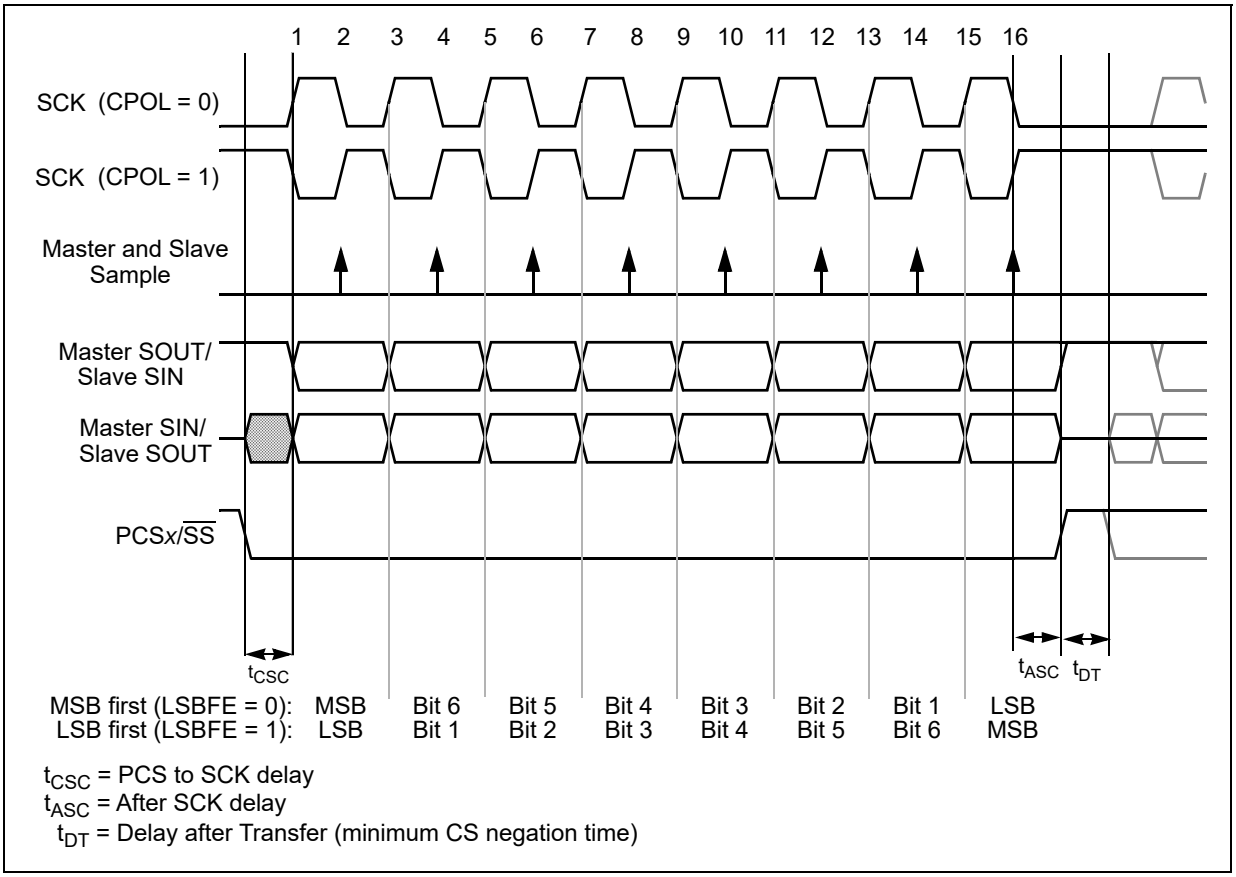
58.4.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in *Figure 1623* is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 1623. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals.

At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals.



For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

58.4.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in *Figure 1624* is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 1624. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave.

After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins.

For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

58.4.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave

mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_sl} – data hold time on slave data input
- t_p – protocol clock period

Figure 1625 shows the modified transfer format for CPHA = 0 and f_p/f_{sck} = 4{s}. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked “SOUT of Ext Slave”, presents regular SPI slave serial output.
- Signal, marked “SOUT of DSPI Slave”, presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according to DSPI master CPHA programming.

Note: In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

Note: When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

Figure 1625. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)

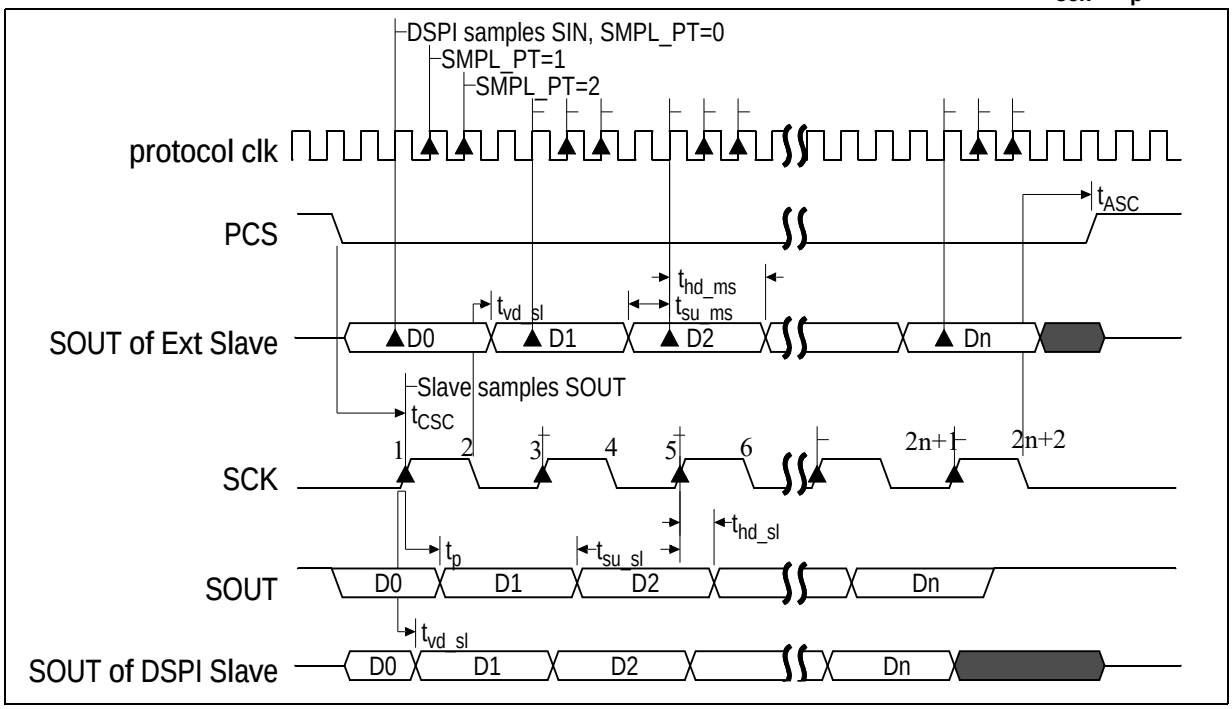


Figure 1626. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

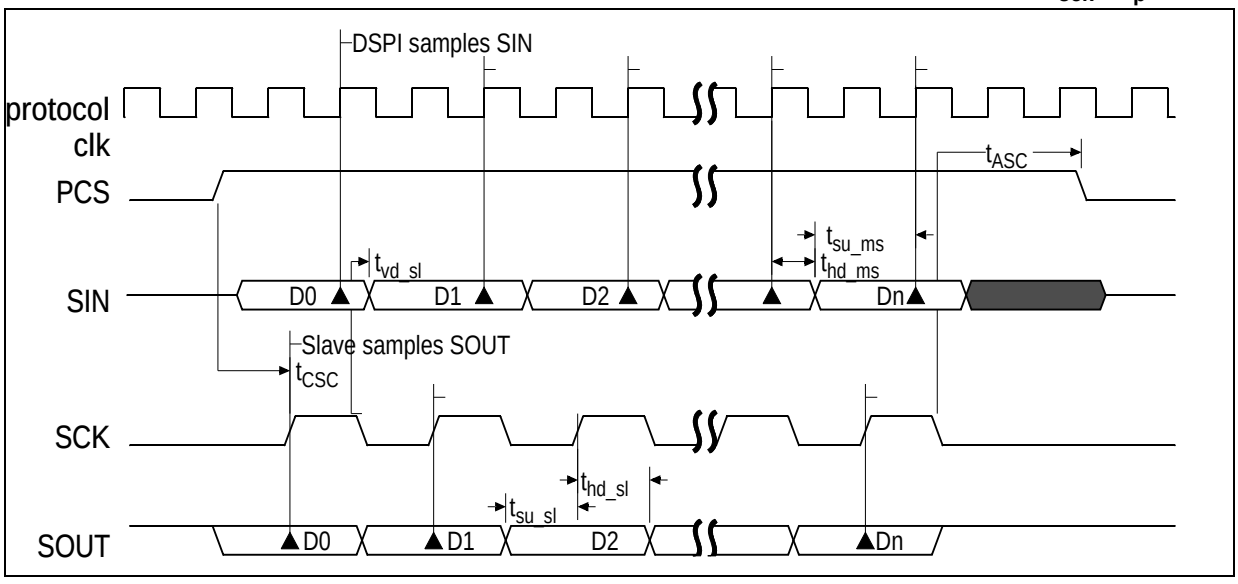

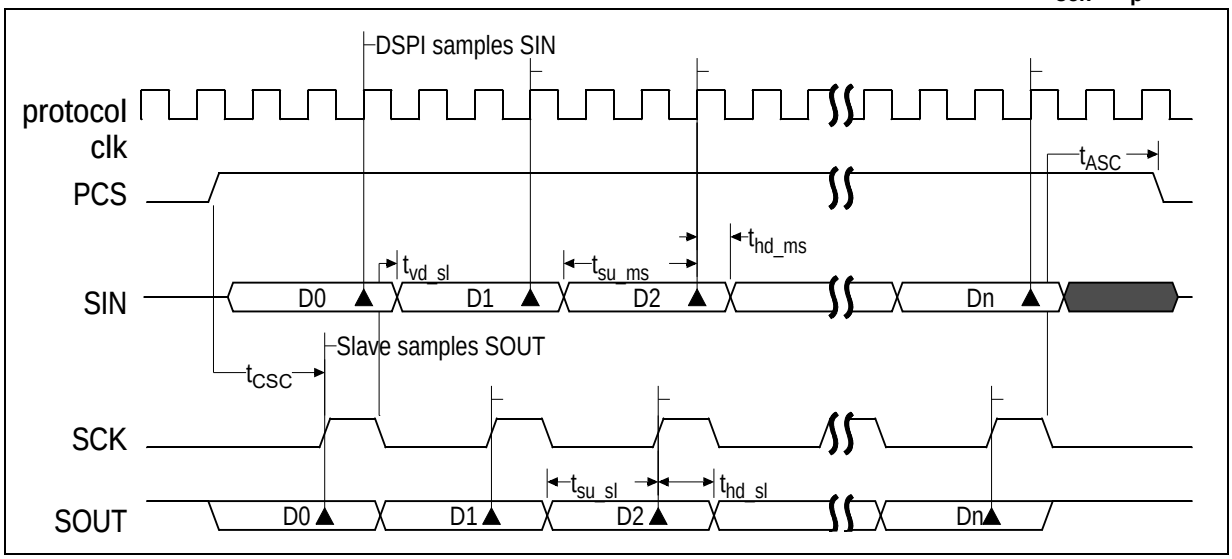

Figure 1627. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

58.4.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. The SCK to PCS delay must be greater than or equal to half of the SCK period.

Figure 1628. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)

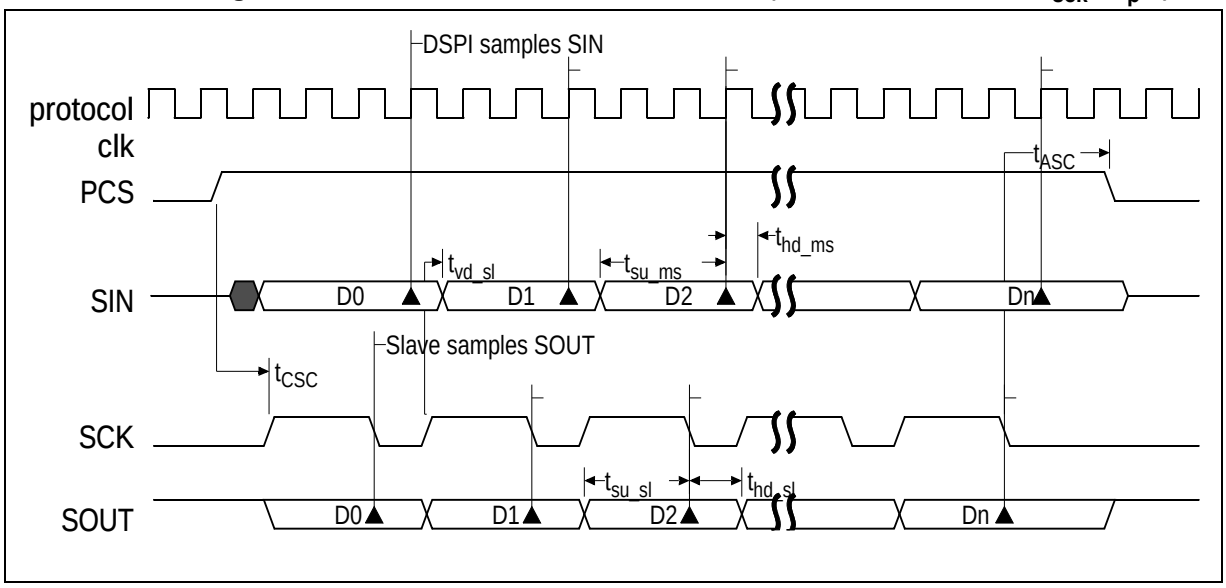

Figure 1629. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

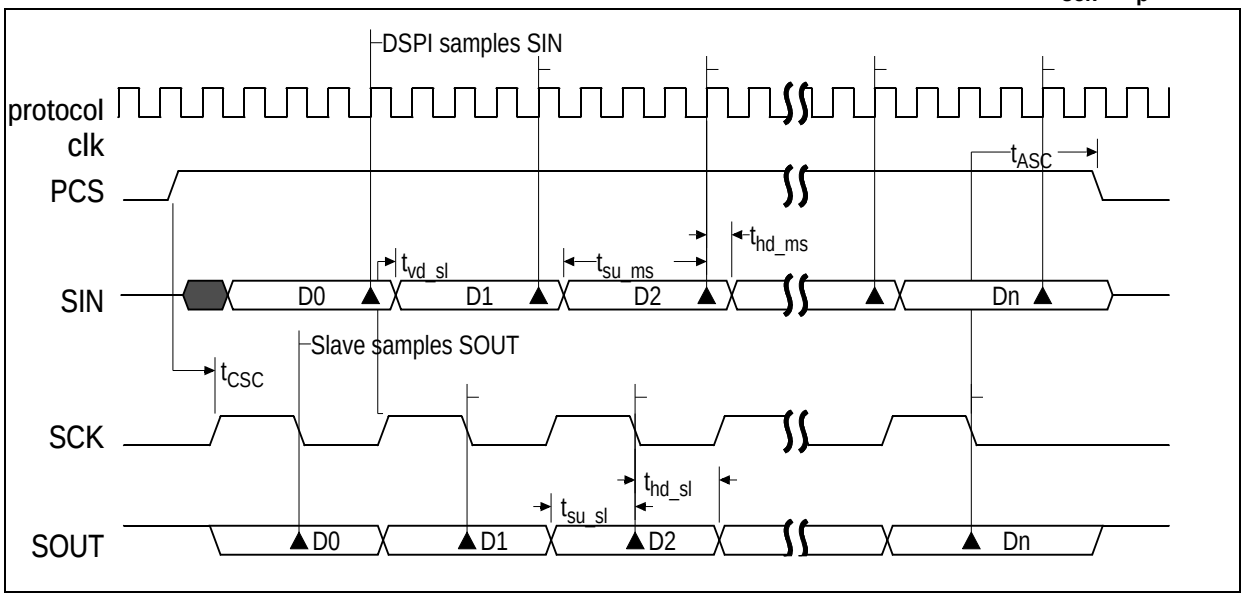

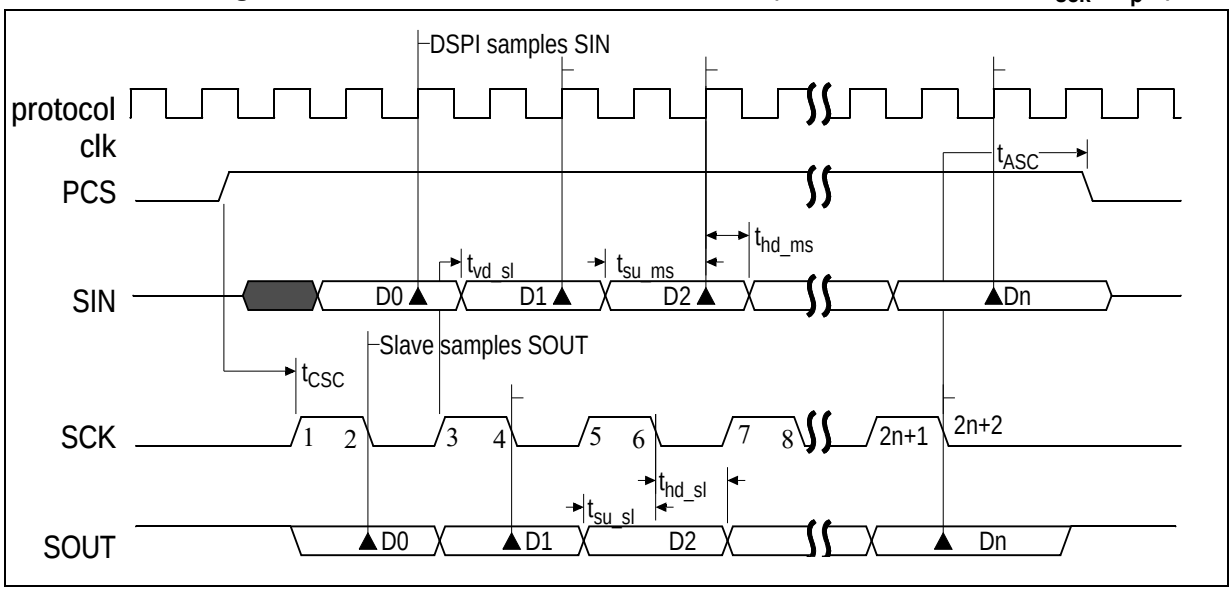

Figure 1630. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

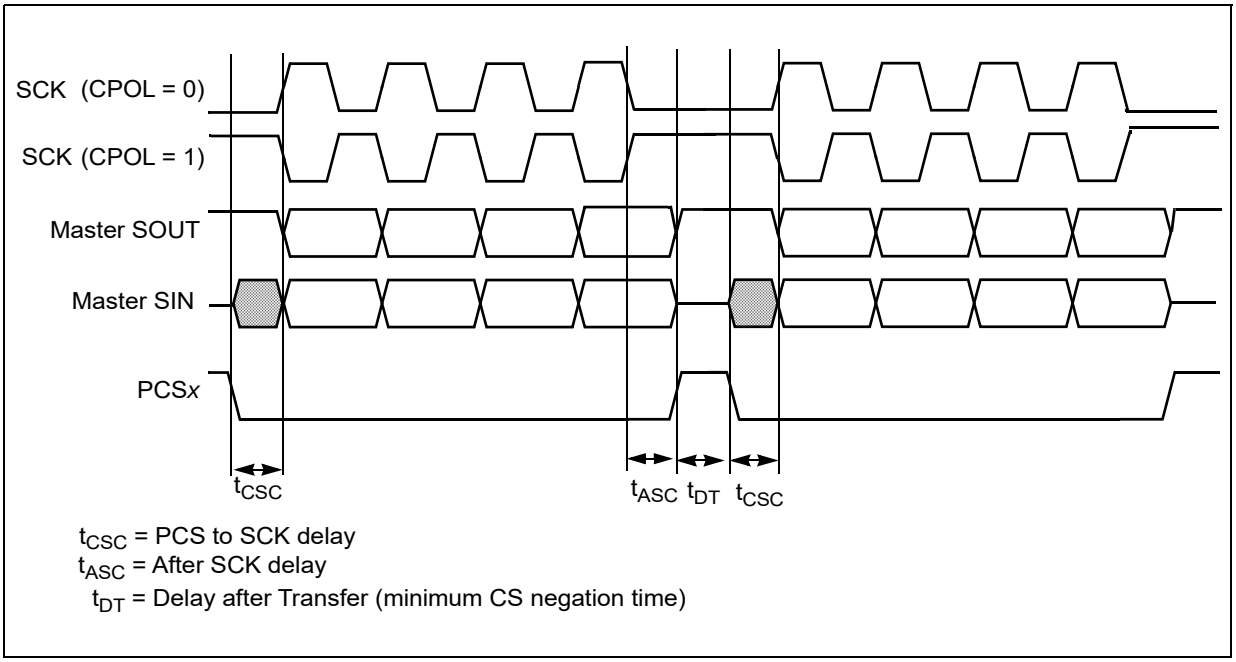
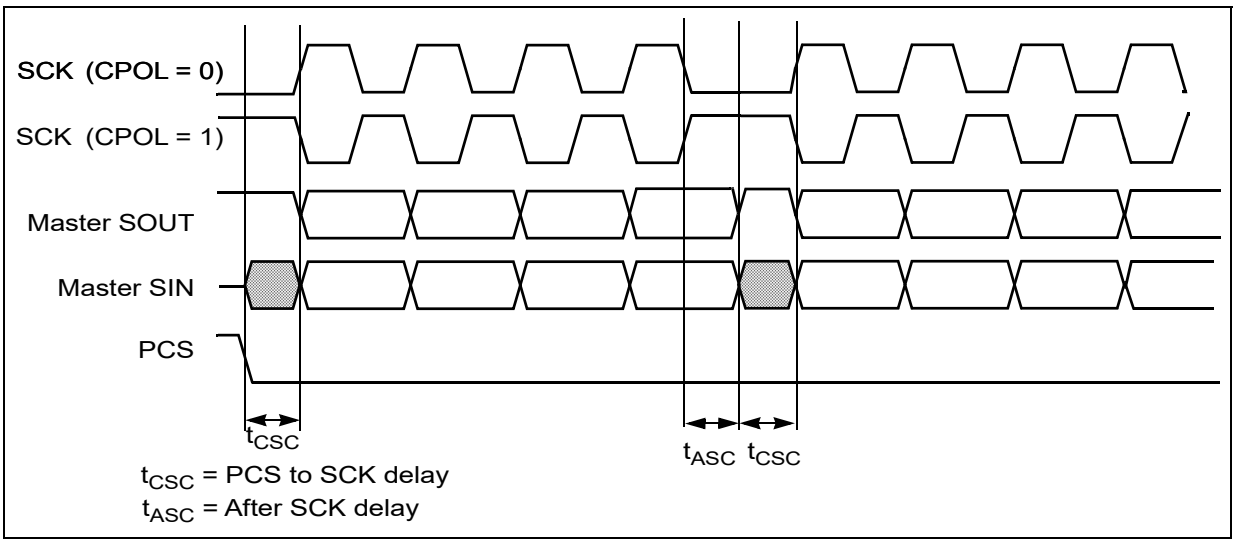


58.4.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI Configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.

The behavior of the PCS signals in the two configurations is identical so only SPI Configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select



signals are selected by the PCSIS*n* bits in the MCR. The timing diagram in *Figure 1631* is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 1631. Example of non-continuous format (CPHA = 1, CONT = 0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. *Figure 1632* shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 1632. Example of continuous transfer (CPHA = 1, CONT = 1)

When using DSPI with continuous selection follow these rules:

- All transmit commands must have the same PCS*n* bits programming.
- The CTARs selected by transmit commands must be programed with the same transfer attributes. Only FMSZ field can be programed differently in these CTARs.
- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit de-asserted (in master mode) and the user software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCS*n* at end of transmission of last frame.
- The PUSHR[CONT]/DSICR0[DCONT] bits must be de-asserted before asserting MCR[HALT] bit (in master mode). This ensures that the PCS*n* signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCS*n* signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

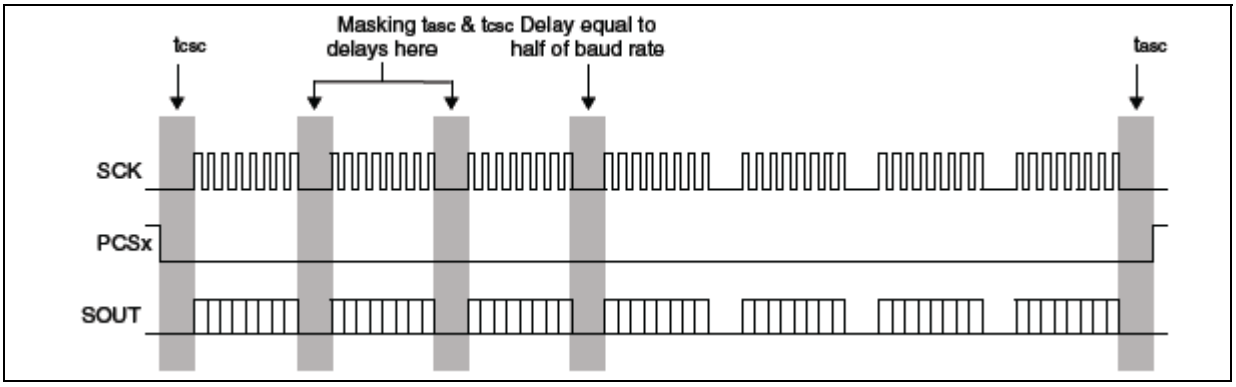
Note: You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

Note: When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

58.4.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

Note: The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.



The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR. When this bit is asserted, MASC and MCSC bits of the PUSHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

Figure 1633 shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

Figure 1633. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

58.4.7 Continuous Serial Communications Clock

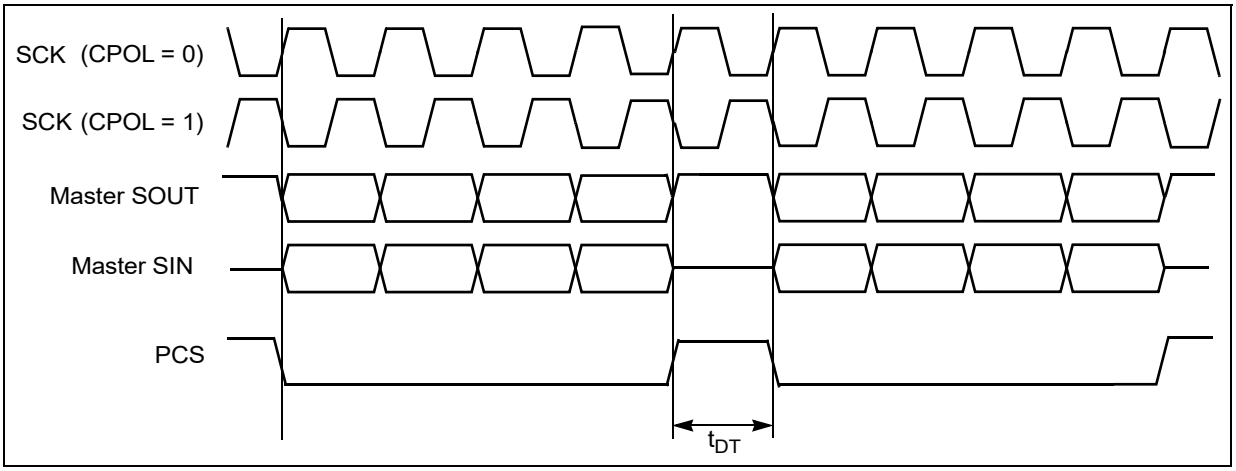
The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
  - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
  - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.



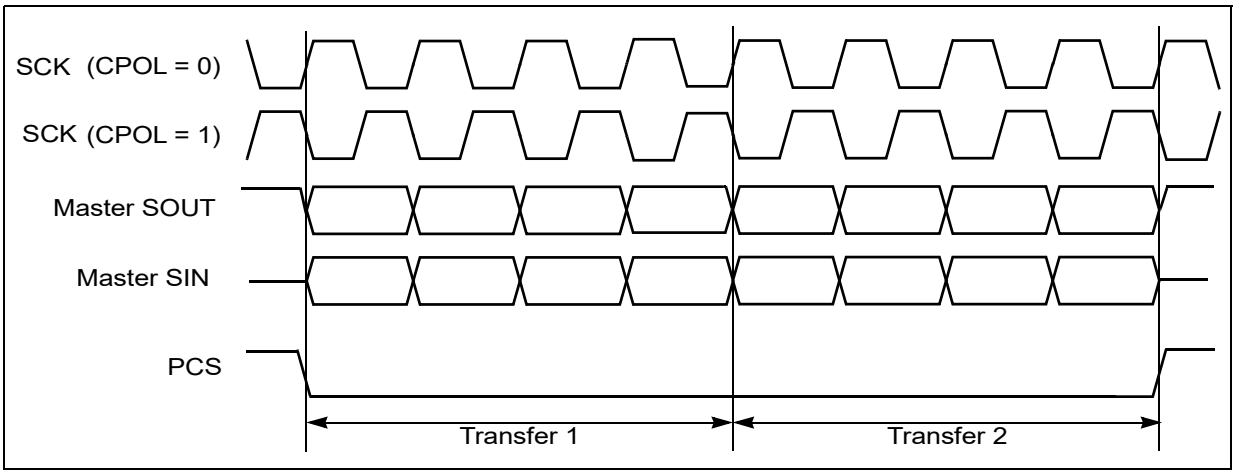
It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles.

Figure 1634 is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note: When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 1634. Continuous SCK timing diagram (CONT = 0)



If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with

PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to *Section 58.4.1: Start and Stop of DSPI transfers*).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

Figure 1635 shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 1635. Continuous SCK Timing Diagram (CONT = 1)

58.4.8 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

58.4.9 Timed Serial Bus (TSB)

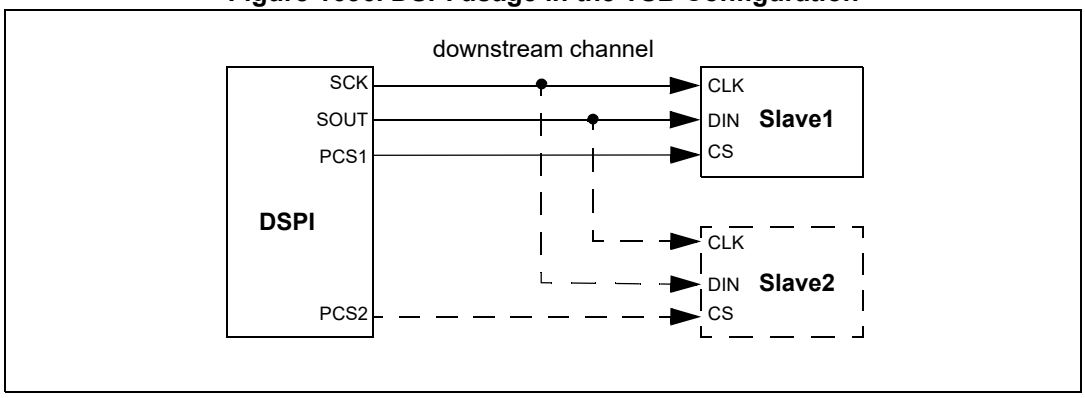
The DSPI can be programed in Timed Serial Bus configuration by setting DSICR0[TSBC] bit. Refer to *Section 58.3.13: DSPI DSI Configuration Register 0 (DSPI_DSICR0)* for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the device.

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

Figure 1636 shows the signals used in the TSB interface.



In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0), written by the host software,
- parallel input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR1/0).

DSICR0[TXSS] bit or DSPI_SSR1/0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

Figure 1636. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTAR*n* PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

Figure 1637. TSB Downstream Frames

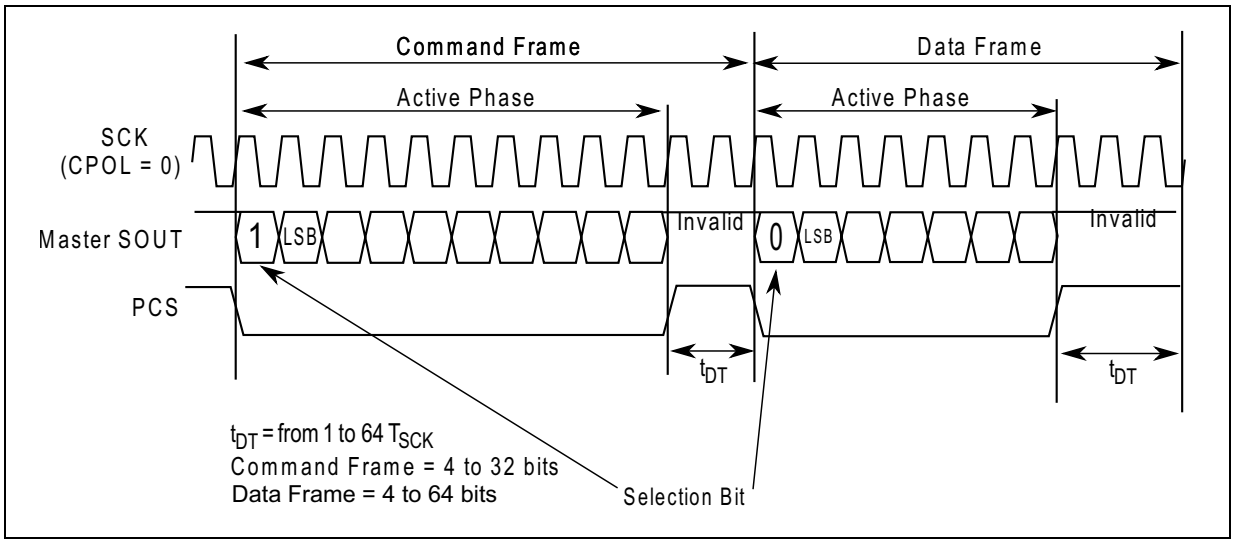


Figure 1637 shows two types of MSC downstream frames: command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit '0' indicates a data frame
- The selection bit '1' indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR1/0 or ASDR1/0 registers and up to two zero selection bits. Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSE*n* bit set increases the data frame size by one bit.

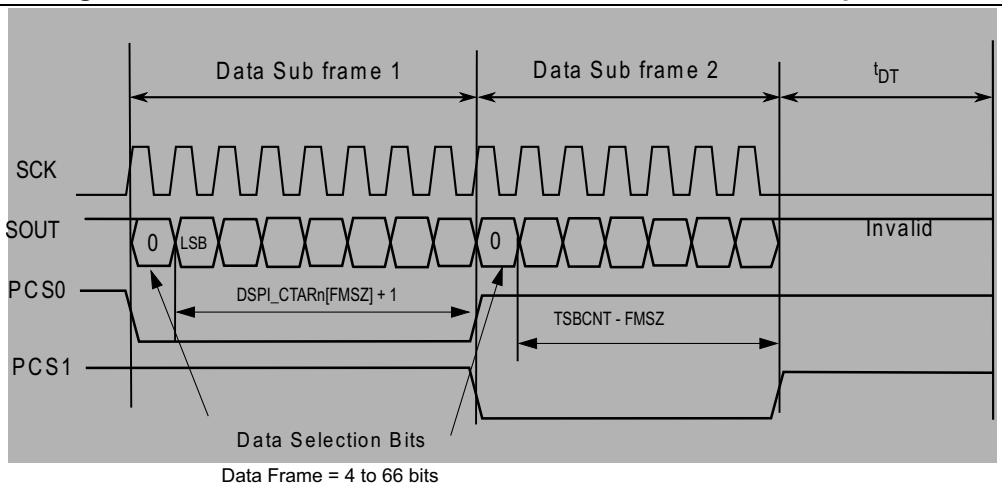
To comply with MSC specification, set DSPI_CTAR*n*[LSBFE] to transmit least significant bit first.

Regardless of the LSBFE bit setting, the data frame selection bits, if enabled, are always transmitted first, before the corresponding data subframes.

58.4.9.1 MSC Dual Receiver Support with PCS Switchover

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switchover occurs, is defined by FMSZ field of the DSPI_CTAR*n* register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Note: When using Dual receiver support, it must be ensured that the number of bits to be transmitted to each slave must be at least 4.



Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switchover occurs at the driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switchover if enabled.

The Data Frame with PCS switchover is shown in *Figure 1638*.

Figure 1638. TSB Data Frame Format for MSC Dual Receiver Operation

58.4.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB in all aspects except for the differences mentioned in *Table 1635*. In the Interleaved TSB or ITSB mode, frame transmission is governed by the following rules:

- Transmission of frames is executed on a periodic trigger that is generated internally to the DSPI. The trigger period is calculated as follows:
  - Trigger Period = 64 bits (maximum data frame size) + 2 selection bits (maximum bits in data frame) + t_{PT}

    t_{PT} is the passive frame time or dead time inserted to have constant trigger period.
  - The user software shall configure the trigger period and trigger source.
- If the previously transmitted frame was a SPI frame or the TX FIFO (or CMD FIFO) is empty, the frame transmitted on subsequent trigger will always be a DSI frame.
- If the previously transmitted frame was not a SPI frame and the TX_FIFO (and CMD FIFO) is not empty, the frame transmitted on subsequent trigger will always be a SPI frame.

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) in such a way to prevent back to back SPI frames. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits cannot be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

Table 1635 lists the differences between the TSB and ITSB modes.

Table 1635. Differences between TSB and ITSB modes

Mode attribute	TSB mode	ITSB mode
Frame priority	Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Frame selection bit	Selection bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Frame transmission	Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Periodically triggered transmission (that is frames are transmitted continuously on every trigger).
Frame gap	Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is inserted automatically as the whole operation is based on a periodic trigger. If a frame has less than 64-bits to be transmitted, dead or passive time is automatically inserted by waiting for the next trigger pulse. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In TSB and ITSB mode, separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI. MSC dual receiver support with PCS switchover is also supported in ITSB mode. Refer to *Section 58.4.9.1: MSC Dual Receiver Support with PCS Switchover* for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the ITSB mode features listed in the table above.

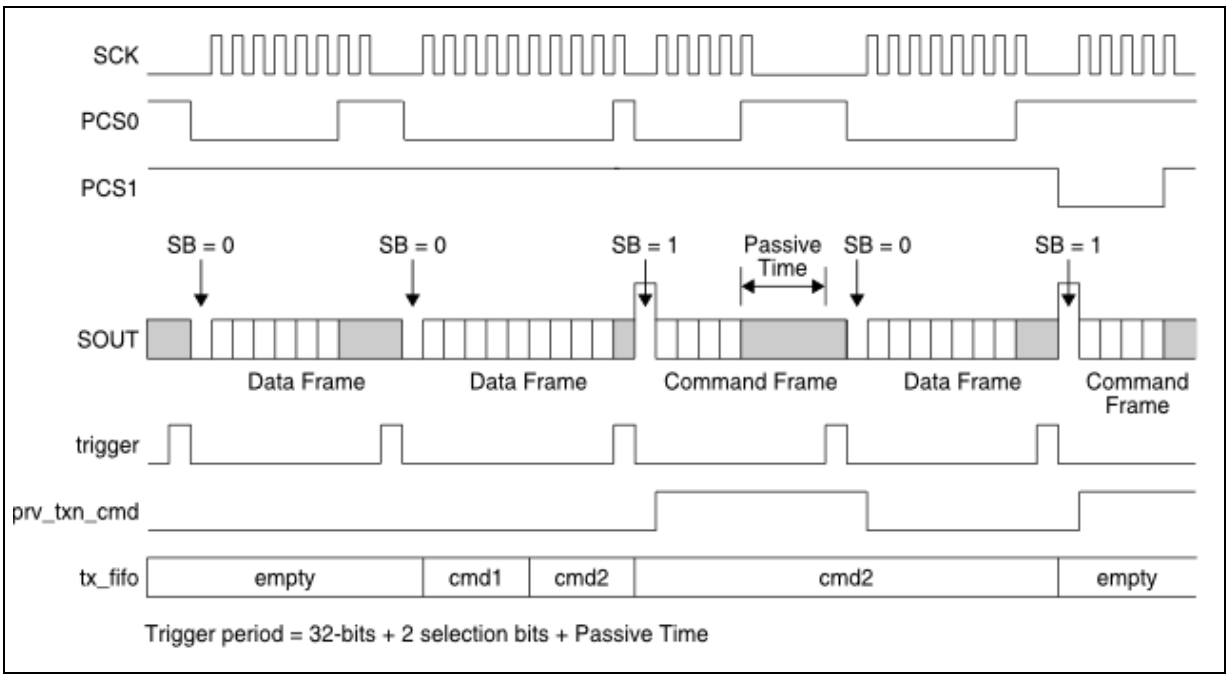
58.4.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame completion (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in *Section 58.4.10: Interleaved TSB (ITSB) Mode*.

58.4.10.2 Using ITSB mode for MSC downstream channel



MSC Downstream Channel uses two types of frames: command frames and data frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- If command frame has less bits than data frame, a gap is inserted to ensure next data frame starts at known reference time.
- In dual MSC ASIC, some bits of the data frame (which can be up to 64 bits) goes to first ASIC and remainder bits to second ASIC.
- In dual MSC ASIC, if a command frame is sent to one ASIC, it must not change the timing of the next data frame.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (Refer to *Section 58.4.10.1: Configuring DSPI for ITSB mode*), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in *Section 58.4.4: Combined Serial Interface (CSI) configuration*.

Figure 1639 shows a sample MSC Downstream transmission using the ITSB mode.

Figure 1639. Sample MSC downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, since there are no command frames, a data frame is transmitted: to send a command frame at the start of operation, the user software must program a command frame in the TX_FIFO before enabling DSPI (MCR[HALT] = 0).
- The second trigger sets off the transmission of another data frame.
- Between the second and third trigger, two command frames are pushed into the TX_FIFO.
- At third trigger, a command frame is transmitted as the TX_FIFO is not empty: since only 16 bits or less are transmitted, no transmission happens till next trigger. This is marked as the “Passive Time”. The passive time is added in all frames after frame transmission completes and until next trigger pulse is detected.
- At fourth trigger, since the previous transmission was a command frame, a data frame is transmitted.
- At fifth trigger, since one command frame is pending in TX_FIFO and last transmitted frame was not a command frame, a command frame is transmitted.
- At sixth trigger (not shown), the process continues.

58.4.11 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

58.4.11.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines the polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

58.4.11.2 Parity for DSI frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode, the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation, clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

58.4.12 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. *Table 1636* lists these conditions.

Table 1636. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
DSI Transfer Complete	DSITCF	Yes	—
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—
DSI Parity Error	DPEF	Yes	—
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

58.4.12.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note: This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

58.4.12.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[TFFF] flag clears automatically when DMA is used to fill TXFIFO.

Note: To clear SR[TFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

Wait until SR[TFFF] = 1

Write data to PUSHR using CPU.

Clear SR[TFFF] by writing a '1' to its location. If TXFIFO is not full, this flag will not clear.

58.4.12.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note: SR[CMDFFF] flag clears automatically when DMA is used to fill CMD FIFO.

Note: To clear SR[CMDFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

Wait until SR[CMDFFF] = 1

Write data to Command field of PUSHR using CPU.

Clear SR[CMDFFF] by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.

58.4.12.4 Transmit FIFO Invalid Write interrupt request

The Transfer Fifo Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered

invalid until a Command Entry becomes available. The Transfer Fifo Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

58.4.12.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

58.4.12.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

58.4.12.7 SPI Transfer Complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

58.4.12.8 DSI Transfer Complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

58.4.12.9 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

58.4.12.10 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[RFDF] flag clears automatically when DMA is used to fill RXFIFO.

Note: To clear SR[RFDF] when not using DMA, follow these steps for every POP performed using CPU to drain RXFIFO:

Wait until SR[RFDF] = 1

Read data from POPR using CPU.

Clear SR[RFDF] by writing a ‘1’ to its location. If RXFIFO is not empty, this flag will not clear.

Note: Clearing SR[RFDF] by writing a ‘1’ to its location after performing MCR[CLR_RXF], will not happen if RXFIFO is not empty because the data from shift register can be transfered just after clear operation is performed.

58.4.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

58.4.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

58.4.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

58.4.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR1/0 data, masked with DSPI_DIMR1/0, has been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

58.4.13 Power saving features

The DSPI supports the following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

Note: When in Slave Mode, the module can only be put in Low Power Modes (such as STOP and HALT) once the Master module has transitioned to the Low Power Mode as well.

58.4.13.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter External Stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

If a DSPI block is configured in Slave mode, External Stop mode requests must be run after the last clock cycle or Low-power mode is not entered.

58.4.13.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting the MDIS bit in the MCR. The module disable mode can also be initiated by hardware.

When the MDIS bit is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.

If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible.

Certain read or write operations have a different effect when the DSPI is in the module disable mode:

- Reading the RX FIFO Pop register does not change the state of the RX FIFO.
- Writing to the FIFO Push register does not change the state of the TX FIFO or CMD FIFO.
- Clearing of the FIFOs has no effect.
- Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect.
- All status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect.
- Writing to the TCR during module disable mode has no effect.
- Interrupt and DMA request signals cannot be cleared.

58.5 Initialization/application information

This section describes how to initialize the DSPI module.

58.5.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI Configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a ‘1’ to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a ‘1’ to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

58.5.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a ‘1’ to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

58.5.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

58.5.4 Baud rate settings

Table 1637 shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

Table 1637. Baud rate values (bps)

Baud Rate scaler values (DSPI*n*_CTAR[BR])	Baud rate divider prescaler values (DSPI*n*_CTAR[PBR])			
	2	**3**	**5**	**7**
2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
64	781 kHz	521 kHz	312 kHz	223 kHz
128	391 kHz	260 kHz	156 kHz	112 kHz
256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

58.5.5 Delay settings

Table 1638 shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

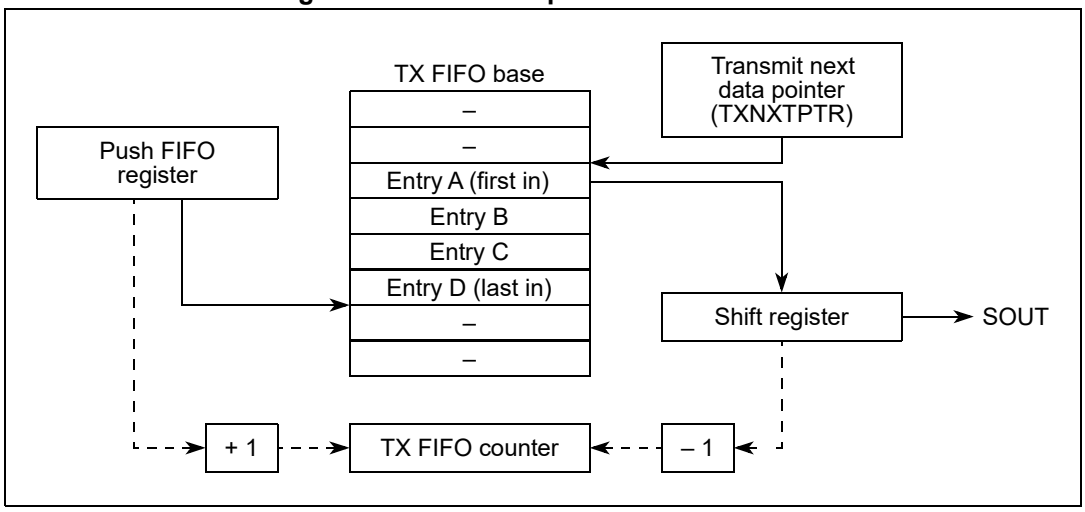
Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 1638. Delay values

		Delay prescaler values (DSPI*n*_CTAR[PBR])			
		1	**3**	**5**	**7**
Delay scaler values	**2**	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

58.5.6 Calculation of FIFO pointer addresses



Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped.

- For TX FIFO, the first-in pointer is the Transmit Next Pointer (TXNXTPTR).
- For CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR).
- For RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR).

Figure 1640 illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts are applicable to the CMD FIFO and RX FIFO.

Refer to *Section 58.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*, *Section 58.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* and *Section 58.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism* for details on the FIFO operation.

Figure 1640. TX FIFO pointers and counter

58.5.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

Equation 88

$$First-inEntryAddress = TXFIFOBase + (4 \times TXNXTPTR)$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

Equation 89

$$Last-inEntryAddress = TXFIFOBase + 4 \times (TXCTR + TXNXTPTR - 1) \bmod (TXFIFOdepth)$$

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXTPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

58.5.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

Equation 90

$$First-inEntryAddress = CMDFIFOBase + (4 \times CMDNXTPTR)$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

Equation 91

$$Last-inEntryAddress = CMDFIFOBase + 4 \times (CMDCTR + CMDNXTPTR - 1) mod(CMDFIFOdepth)$$

CMD FIFO Base – Base address of CMD FIFO
CMDCTR – CMD FIFO Counter
CMDNXTPTR – Command Next Pointer
CMD FIFO Depth – Command FIFO depth, implementation specific

58.5.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

Equation 92

$$First-inEntryAddress = RXFIFOBase + (4 \times POPNXTPTR)$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

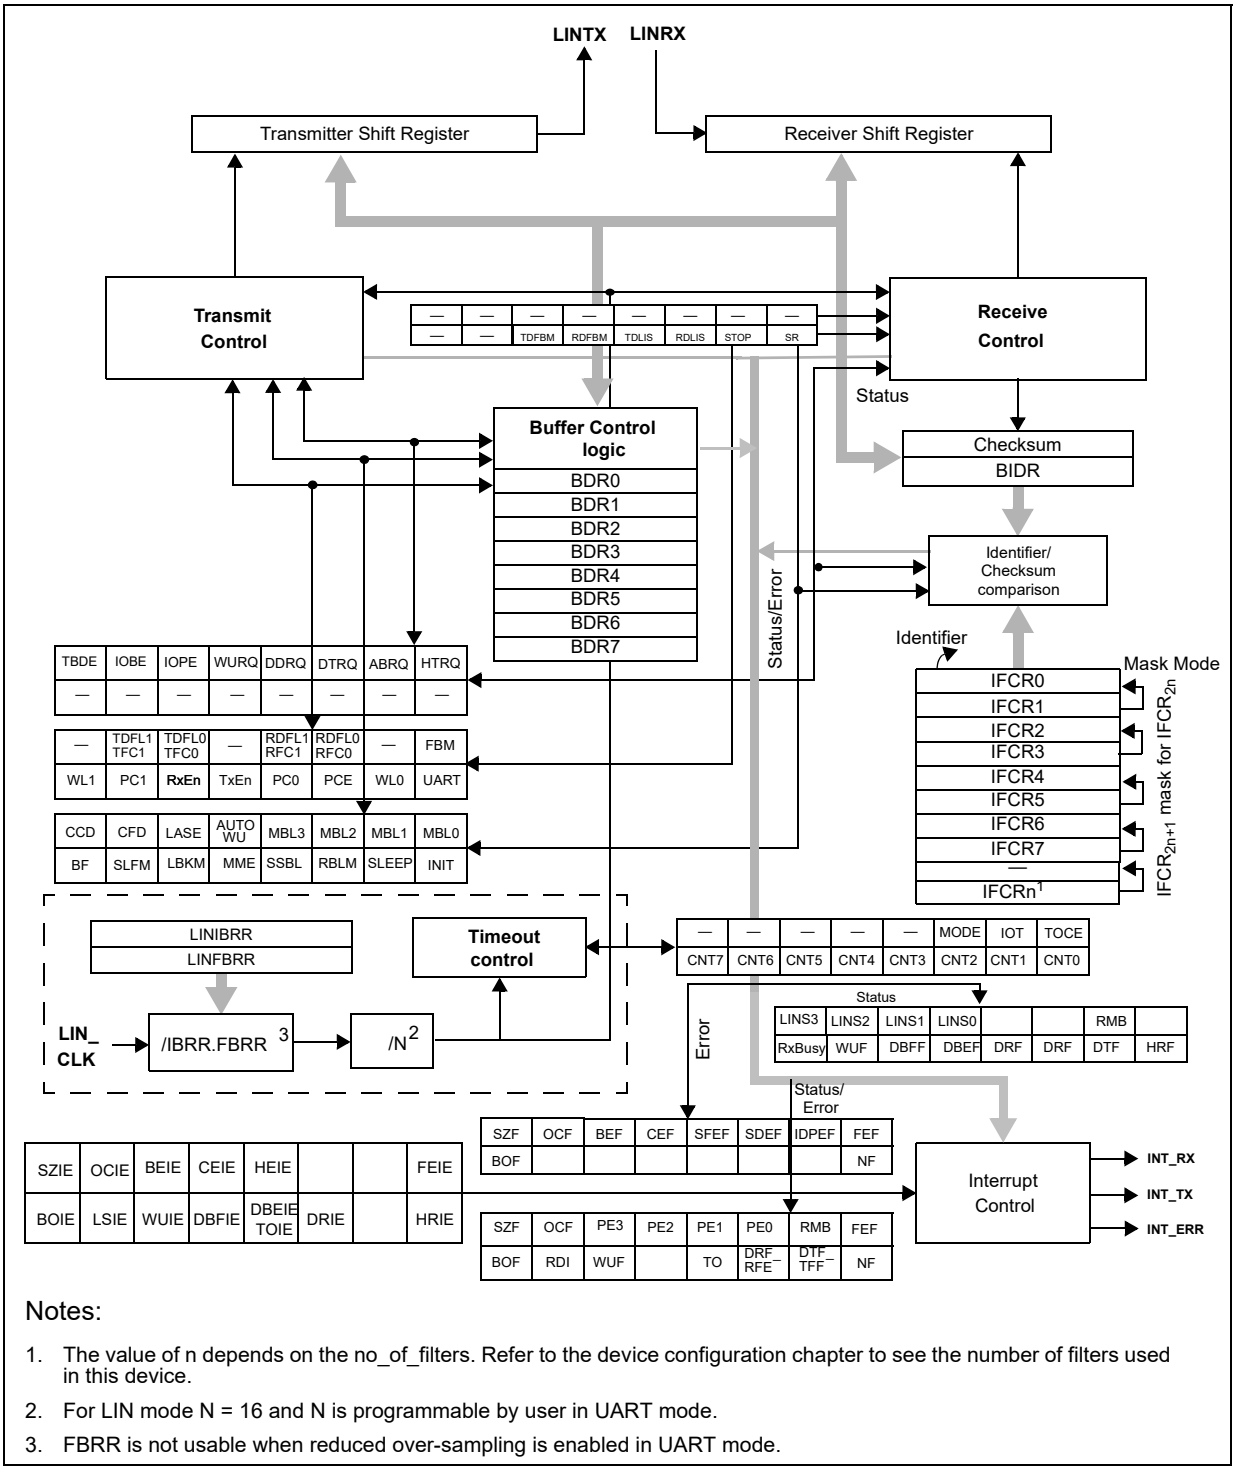
Equation 93

$$Last-inEntryAddress = RXFIFOBase + 4 \times (RXCTR + POPNXTPTR - 1) mod(RXFIFOdepth)$$

RX FIFO Base – Base address of RX FIFO
RXCTR – RX FIFO counter
POPNXTPTR – Pop Next Pointer
RX FIFO Depth – Receive FIFO depth, implementation specific

59 LINFlexD

59.1 Introduction



The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 1641. Block diagram

Notes:

1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.
2. For LIN mode N = 16 and N is programmable by user in UART mode.
3. FBRR is not usable when reduced over-sampling is enabled in UART mode.

59.2 Main features

LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

59.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK $\geq$ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)

59.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers (refer to *Section 59.3.2.8: Baud rate generation*)
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate (BR) <= LIN_CLK/16
  - 16 times oversampling
  - 3:1 majority voting
- For LIN_CLK/16 < BR <= LIN_CLK/8
  - OSR = 8
  - 3:1 majority voting
- For LIN_CLK/8 < BR <= LIN_CLK/4
  - OSR = 4,5,6
  - 1:1 voting

59.2.3 Standard features

DMA2x bus interface.

59.3 Functional description

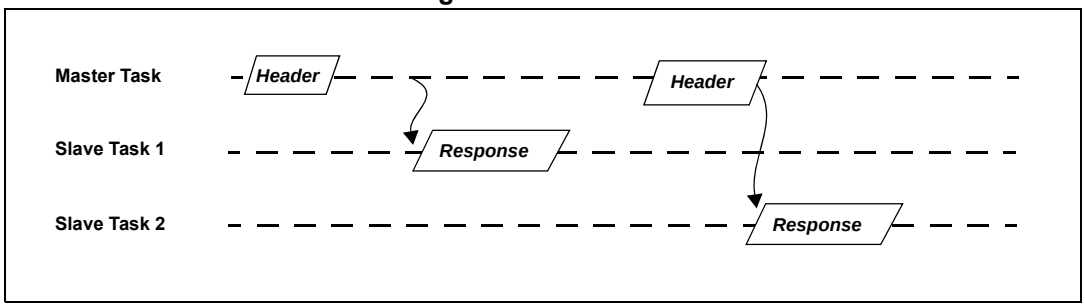
59.3.1 LIN protocol

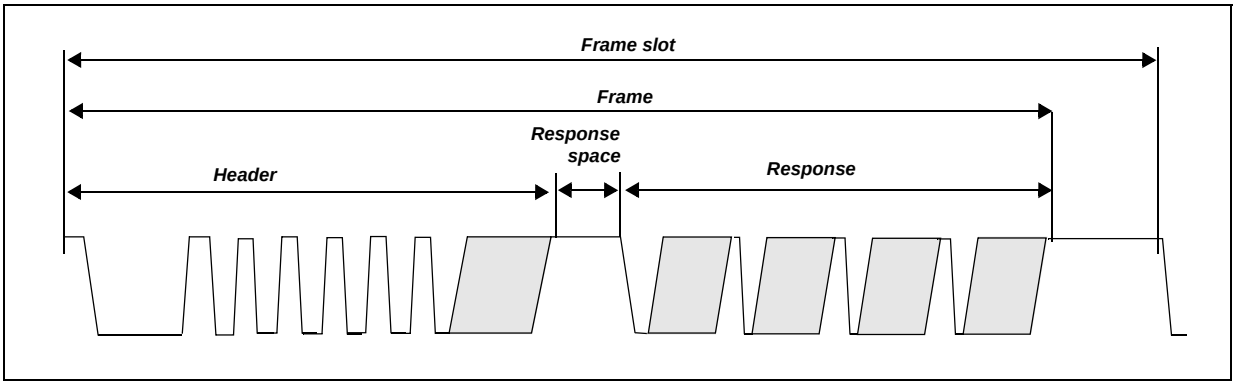
The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task - all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

59.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 1642. Frames





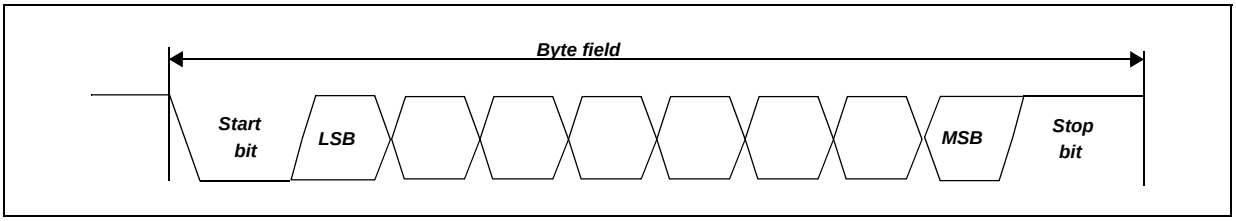


Figure 1643. Structure of LIN frame

59.3.1.2 Data field

Each byte is transmitted as shown in *Figure 1644*. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

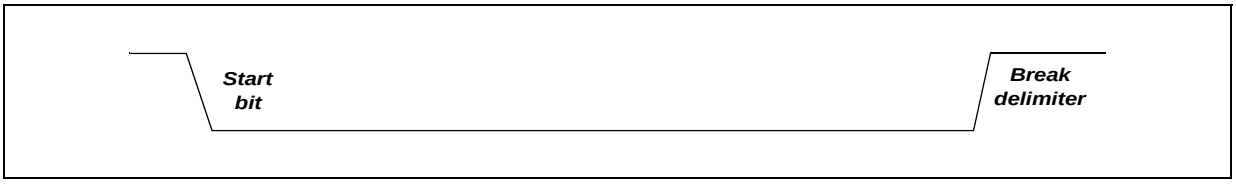

Figure 1644. Structure of byte field

59.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in *Figure 1645*. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

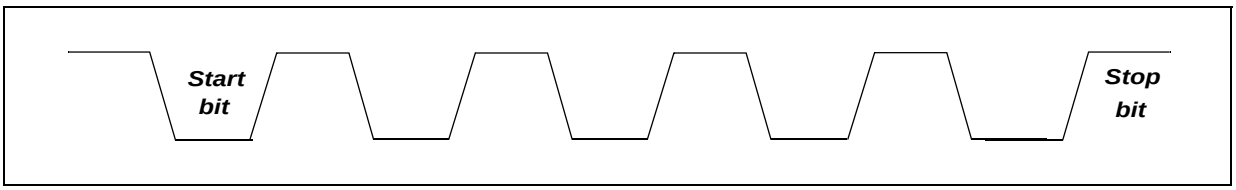

Figure 1645. Break field

59.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

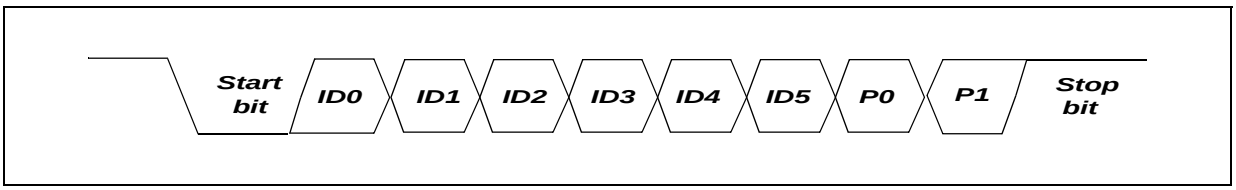

Figure 1646. Sync byte field

59.3.1.5 Identifier

The Identifier field consists of two sub fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 1647. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

59.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it used for communication with LIN 2.0 slaves.

59.3.2 LINFlexD features

59.3.2.1 Operating modes

The LINFlexD has three operating modes: Initialization, Normal, and Sleep modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

59.3.2.1.1 Initialization mode (INIT)

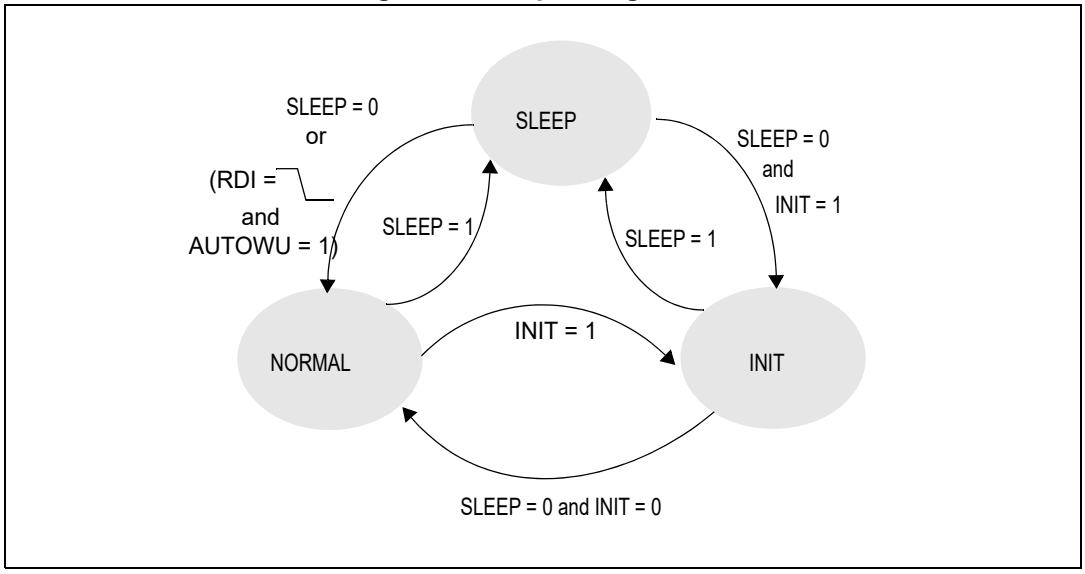
To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. Set up the baud rate registers
2. Reset the UART bit
3. Select the mode (Master or Slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

59.3.2.1.2 Normal mode (NM)



Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

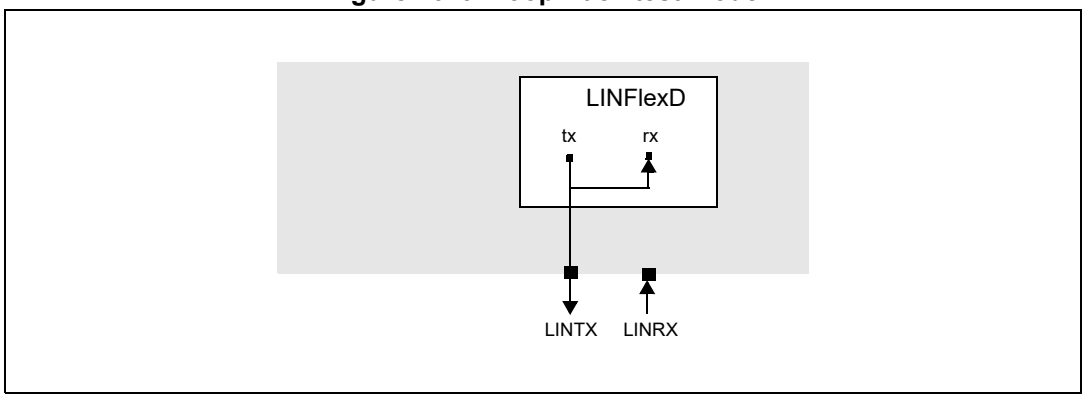
59.3.2.1.3 Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to *Section 59.3.2.10: Wakeup management*.

Figure 1648. Operating modes

59.3.2.2 Test mode



59.3.2.2.1 Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and

Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

Figure 1649. Loop Back test mode

59.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

59.3.2.3.1 Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

59.3.2.3.2 Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

59.3.2.3.3 Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

59.3.2.3.4 Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

59.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

59.3.2.4.1 Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

59.3.2.4.2 Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

59.3.2.5 Errors

59.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- That the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,

  or

- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

   If there is an inconsistent Sync Field error, it means that:

   D > 14.0625%

   If there is no error, it means that:

   D < 14.84375%

   If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 0)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

1. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

59.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles. Bit error is not checked during break field transmission.

Example 1

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In

this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

59.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

59.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINIER.

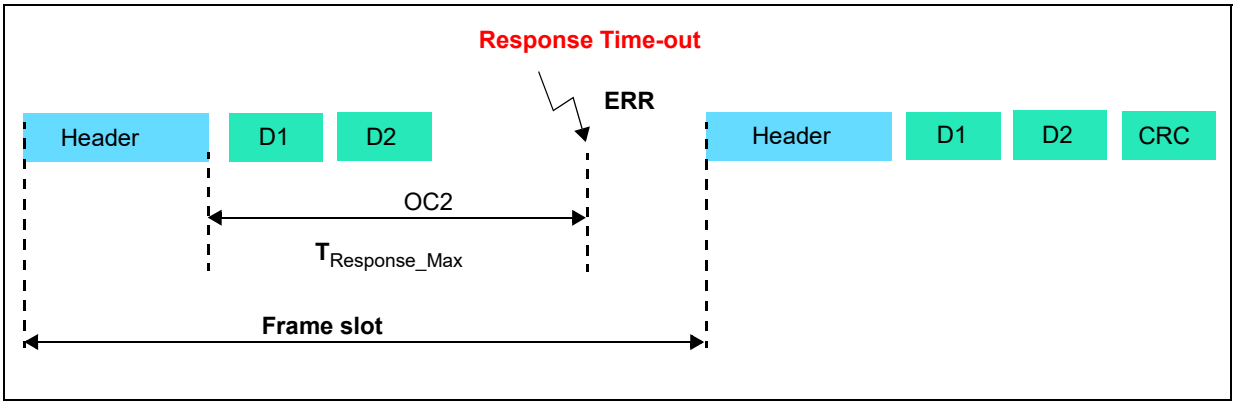
59.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

59.3.2.5.6 Timeout error

Figure 1650. Incomplete response (for example, missing checksum)



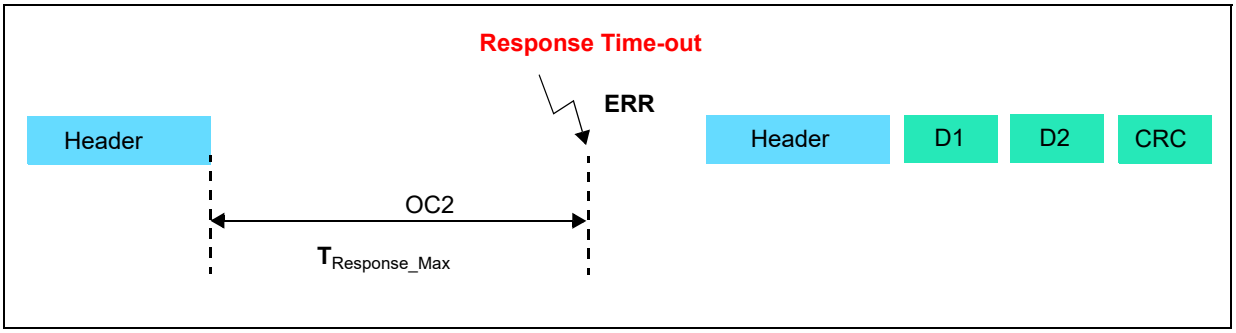


Figure 1651. No response

Header timeout mechanism

- Master mode
  - ocr_2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further ocr_2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the ocr_2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the ocr_2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, ocr_2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = 1.4 × (9 × 10 bit time) and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:

    At the end of the ID, ocr_2 is loaded with 36 (maximum possible response space)

    At the end of the first_data_byte it is reloaded again according to DFL

    Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length).
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

    Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit.
  - If the counter starts after 11 Tbit, the HTO value is 56 – 11 = 45 Tbit

    The reset value of HTO is 45 and this register can only be programmed in slave mode.

    As response space is now included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

    The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

59.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th, and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (refer to *Section 59.4.2.4: LIN Error Status Register (LINESR)*).

59.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a

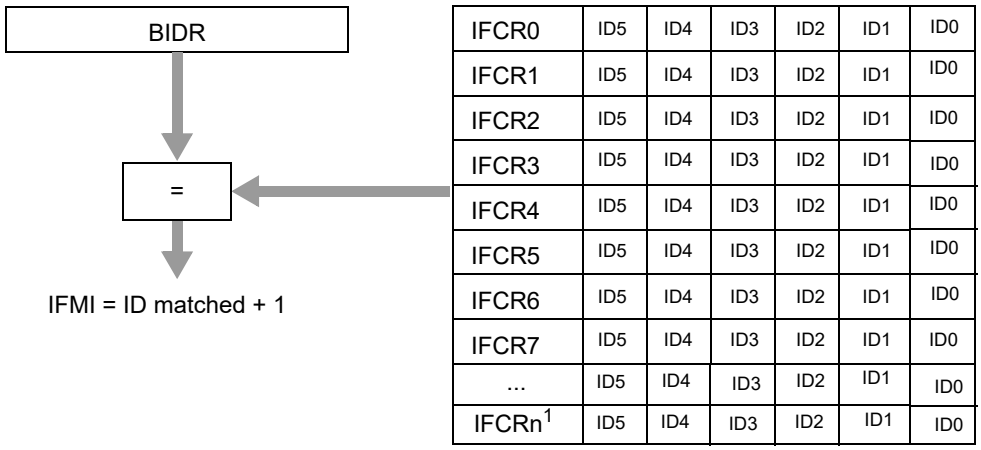
filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

59.3.2.6.1 Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2*n* and 2*n*+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2*n* or IFCR2*n*+1 (if the corresponding FACT bit is set).

59.3.2.6.2 Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2*n* is the filter and 2*n*+1 acts as a mask for it. The FACT bit for filter 2*n*+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.



If there is a match of identifier with the *m*th filter in any mode, then *m*+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note: If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.

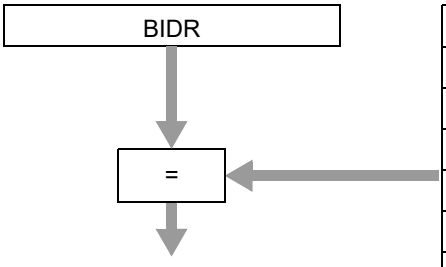


Figure 1652. Identifier List mode

59.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 1639. 10-bit-shift-register sample register

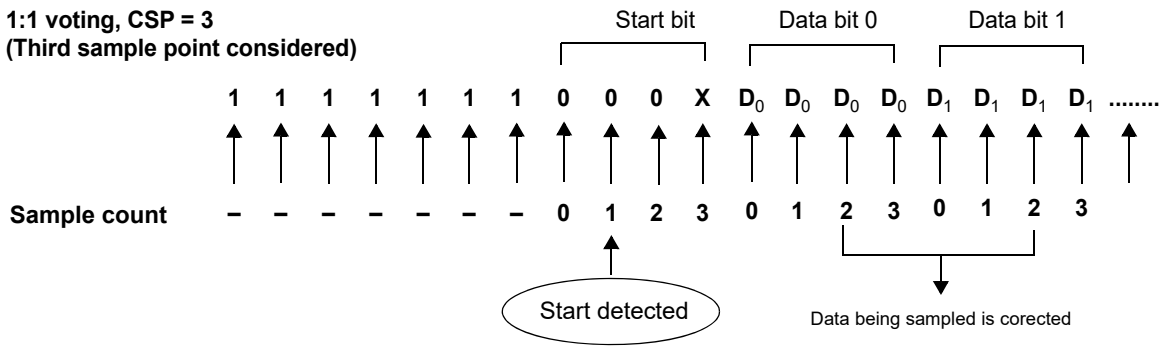
Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x(1)	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: due to sampling during transition of the bit, the bit value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. So ‘x’ refers to an indeterministic value.

59.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to *Table 1639* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘0’ (2 or more), then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.



59.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to *Table 1639* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘1’ (2 or more), then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

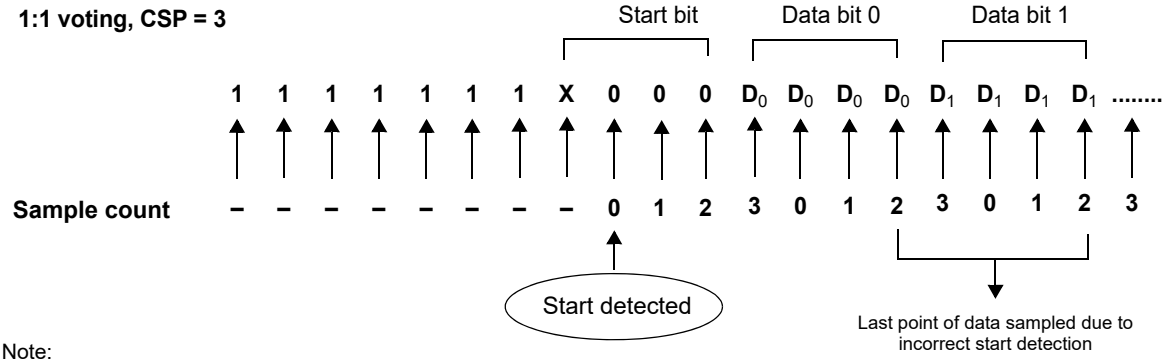


Figure 1654. Start detection and sampling for over sampling rate = 4 (Case 1)

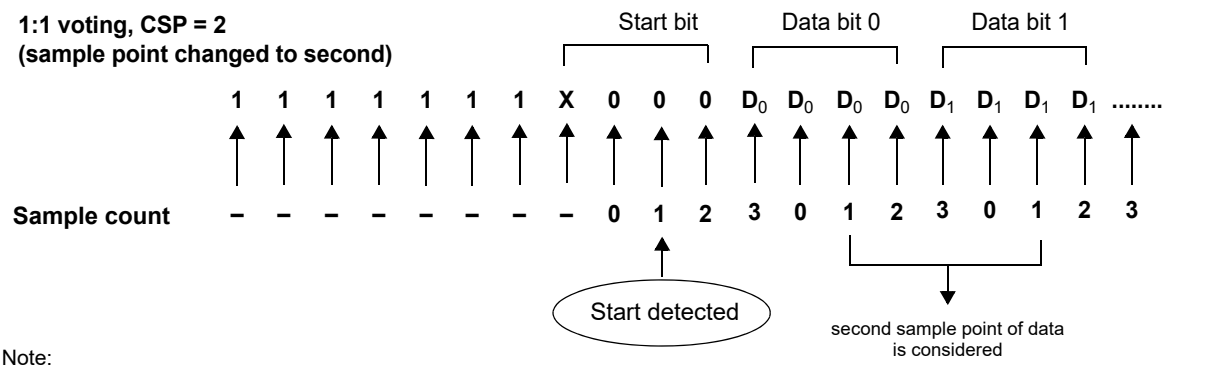
Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.Therefore ‘X’ refers to a indeterministic value.

Figure 1655. Start detection and sampling for over sampling rate = 4 (Case 2a)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two resulting in the following situation:

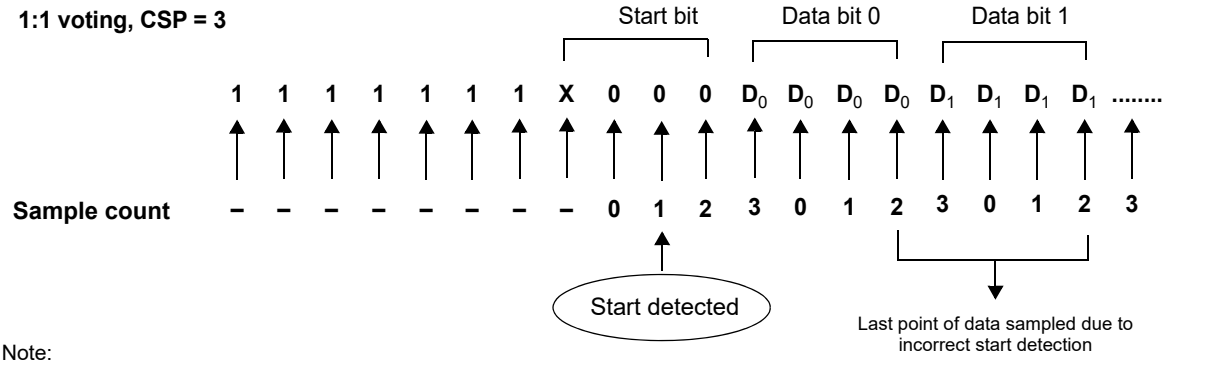


Figure 1656. Start detection and sampling for over sampling rate = 4 (Case 2b)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

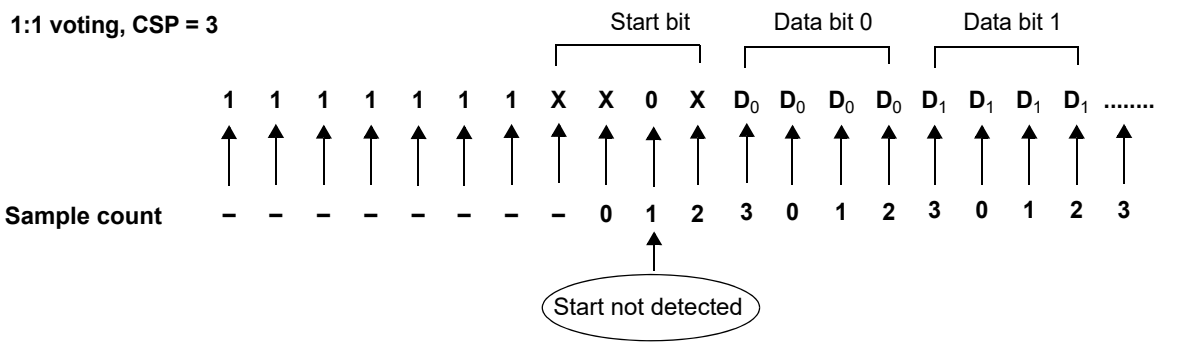

Figure 1657. Start detection and sampling for over sampling rate = 4 (Case 3)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

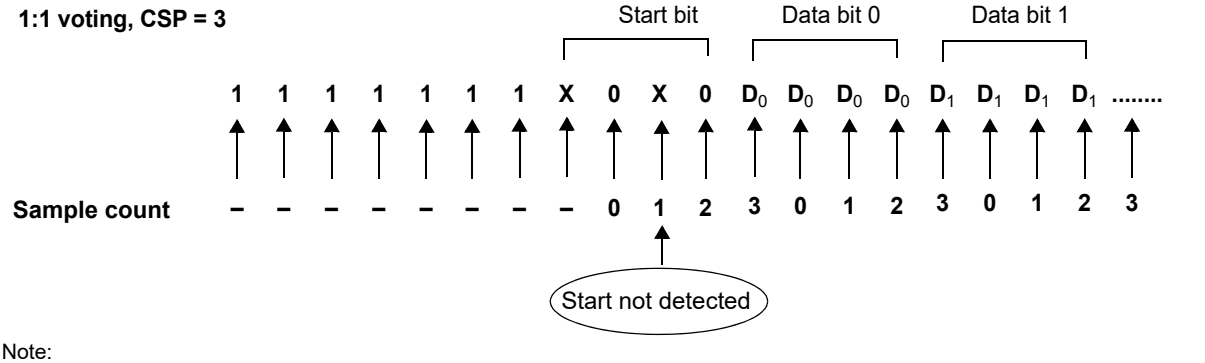

Figure 1658. Start detection and sampling for over sampling rate = 4 (Case 4)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

Figure 1659. Start detection and sampling for over sampling rate = 4 (Case 5)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

59.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Equation 94 **Tx = Rx = LIN_CLK / (16 × LDIV)**

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled LINFBRR is not used and LDIV contains only the integer part of LINIBRR.

Example 2

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Baud rate = 80 MHz/(16 x 1041,67) = 4.8 Kbit/s

Example 3

When ROSE = 1 (Only for UART mode):

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, OSR = 4

Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

Note: Due to design constraints the maximum baud rate achievable is 25 Mbit/s.

The relationship "(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK" should be maintained)

59.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

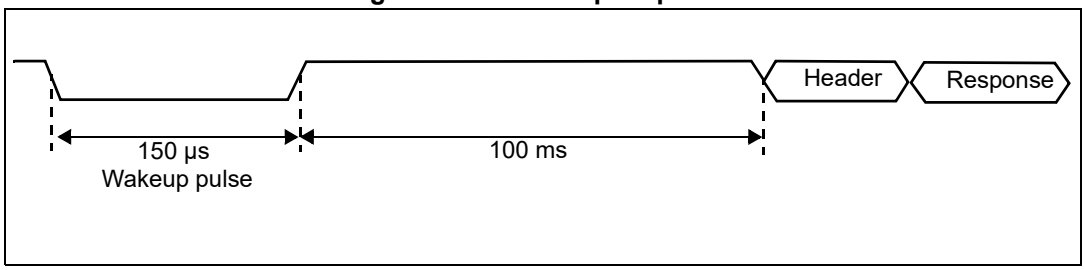
When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

59.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.



1. AUTOWU = 1

   On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.

2. AUTOWU = 0

   On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 1660. Wakeup sequence

59.3.2.11 Use case and limitations

In LIN mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

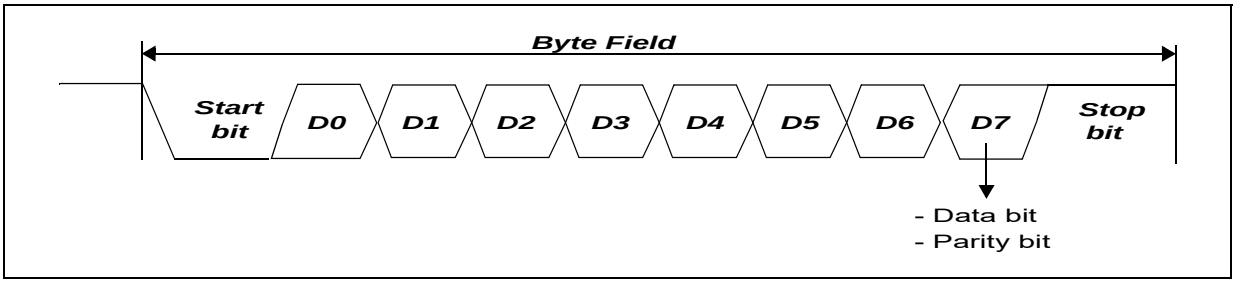
59.3.3 Timer

There is an 8-bit counter which has different behavior in different modes.

In Output Compare Mode (LINTCSR[MODE]= 1): This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has soft reset the LIN IP through GCR [SR] bit to get reset the output compare flag (LINESR[OCF]).

In LIN mode: The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

59.3.4 UART mode



The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames,16-bit frames,17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

59.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

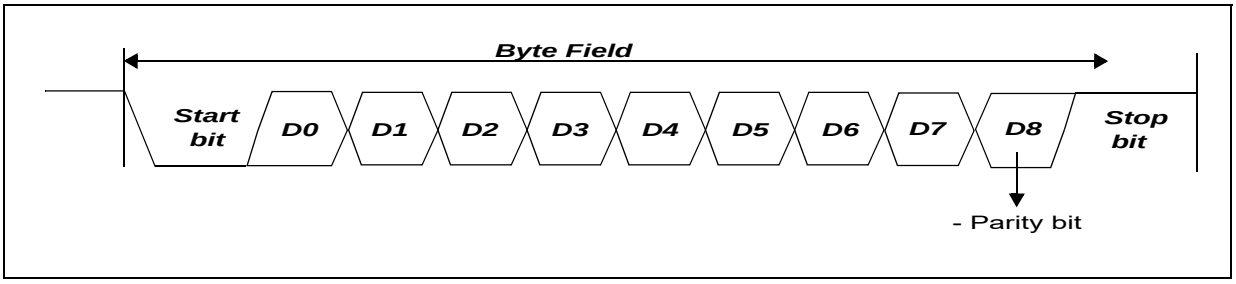


Figure 1661. UART mode 8-bit data frame

59.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

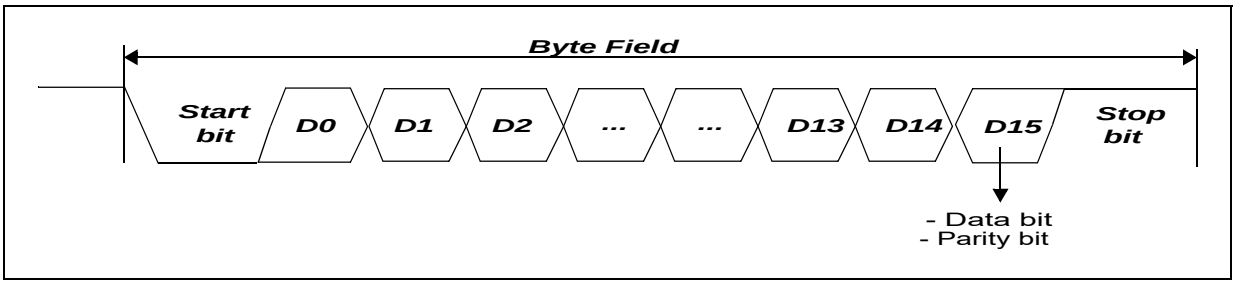

Figure 1662. UART mode 9-bit data frame

59.3.4.3 16-bit data frames

The 16th bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

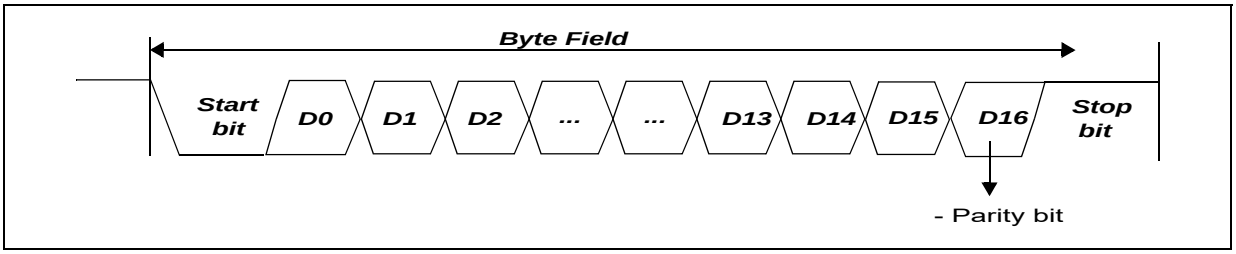

Figure 1663. UART mode 16-bit data frame

59.3.4.4 17-bit frames

The 17th bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

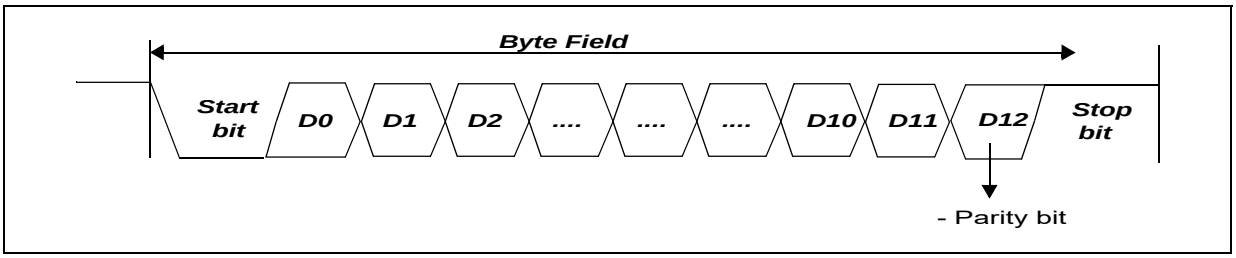

Figure 1664. UART mode 17-bit data frame

59.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

Figure 1665. UART mode 13-bit data frame

59.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in *Figure 1666*.

Figure 1666. Structure of 8-byte buffer

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1.

The same applies for reception.

59.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Invalid writes to BDRL which generates IPS transfer error, also triggers data transmission at the same time.

When the FIFO is full, a read to DATA0 of BDRM reflects the content of DATA3 in BDRL. Proper functionality of the IP is not affected by this.

Table 1640. BDRL access in UART mode

IPS operation(1)	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

59.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 1641. BDRM access in UART mode

IPS operation(1)	Register (2)	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
   Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.
2. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.

Note: If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the

reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.

If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.

If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.

If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.

If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.

When WLS bit = 1, BDRM access depends on WL bit setting.

When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.

In UART FIFO mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

59.3.5 DMA interface

59.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

59.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in *Table 1642* and *Table 1643*.

Table 1642. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: 1 8 bytes: normal frames 1 64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full

Table 1642. LINFlexD control/status fields description (continued)

Register	Field	Level	Description

DMATXE[2**TX_CH_NUM](1)		High	DMA Tx channel enable (read/write)
			In UART or LIN master mode only channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1.
			DMATXE[x] = 0b → TX channel x disabled
			DMATXE[x] = 1b → TX channel x enabled

DMARXE[2**RX_CH_NUM](1)		High	DMA Rx channel enable (read/write)
			In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1.
			DMARXE[x] = 0b → RX channel x disabled
			DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation

Table 1643. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the Tranfer Control Descriptors (TCDs) referred to in this document are described in *Table 1644*.

Table 1644. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.

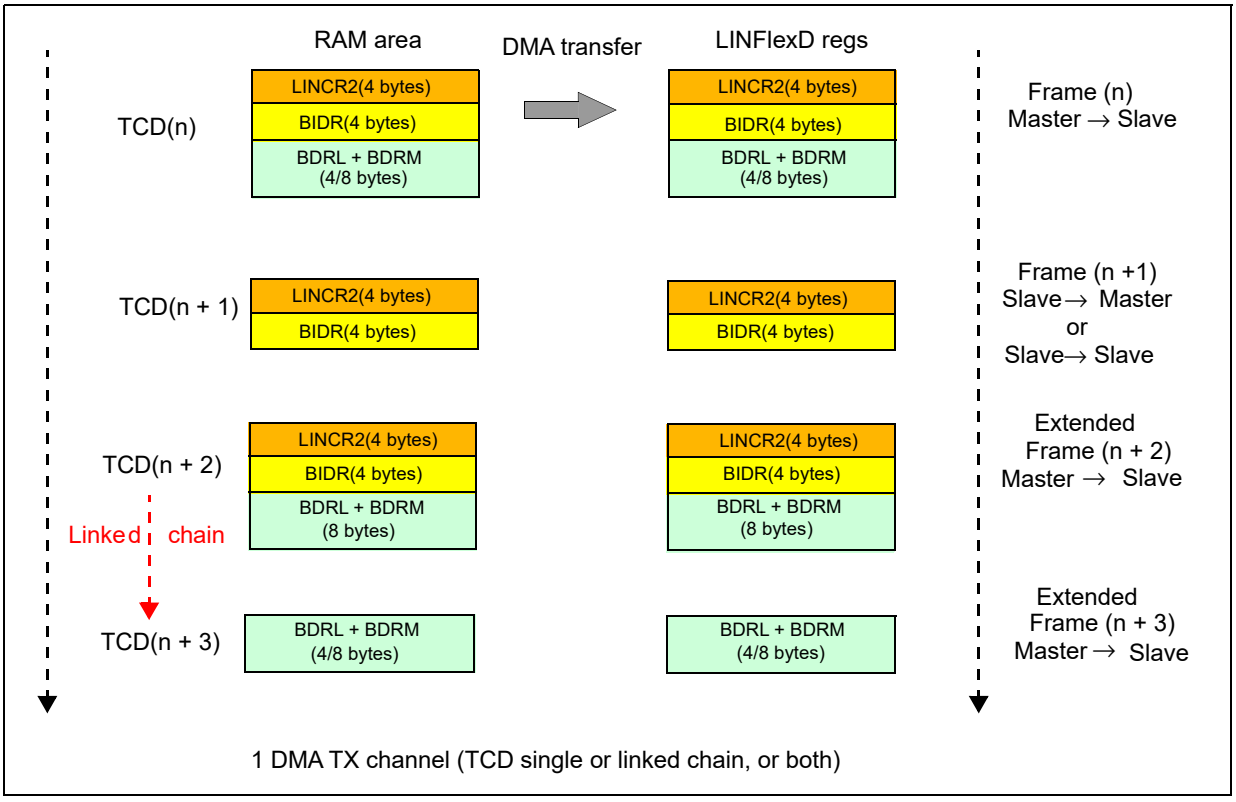

Table 1644. TCD control fields description (continued)

TCD field	Level	Description
SSIZE[2:0]	—	Source data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

59.3.5.3 Master node: TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1667*.

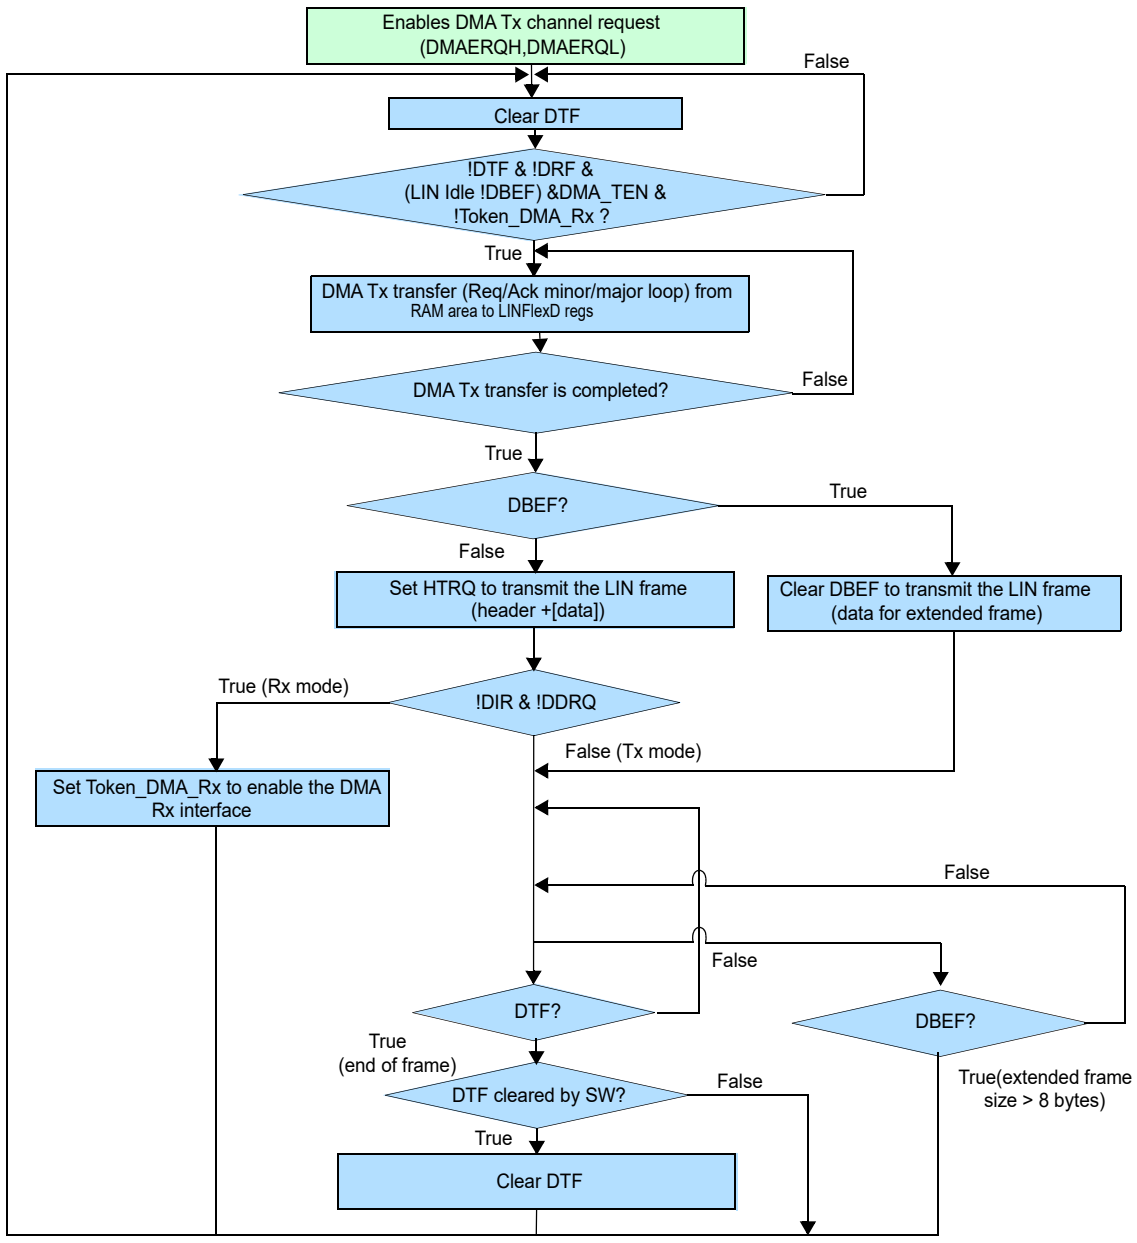
Figure 1667. Master node: TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

Table 1645 provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 1645. Master node: Tx mode - Register setting



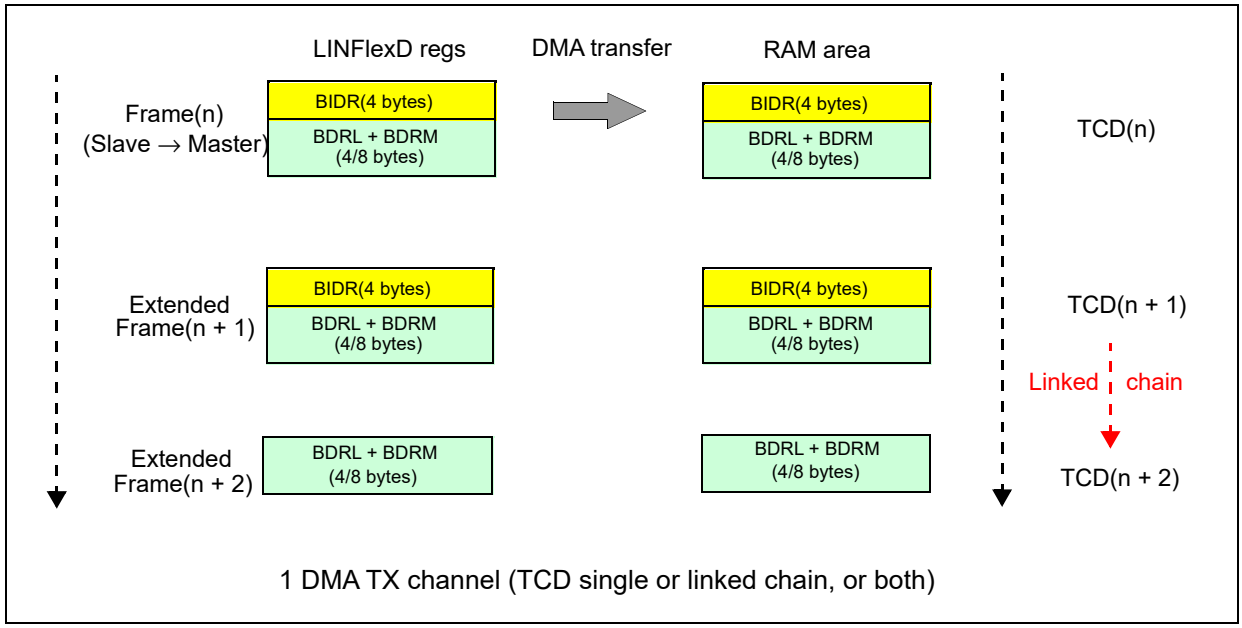
LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in *Figure 1668*. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in *Table 1646*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1646. TCD setting: Master node -Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1668. Master node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

59.3.5.4 Master node: RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1669*.

Figure 1669. Master node: RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in *Figure 1670*. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in *Table 1647*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

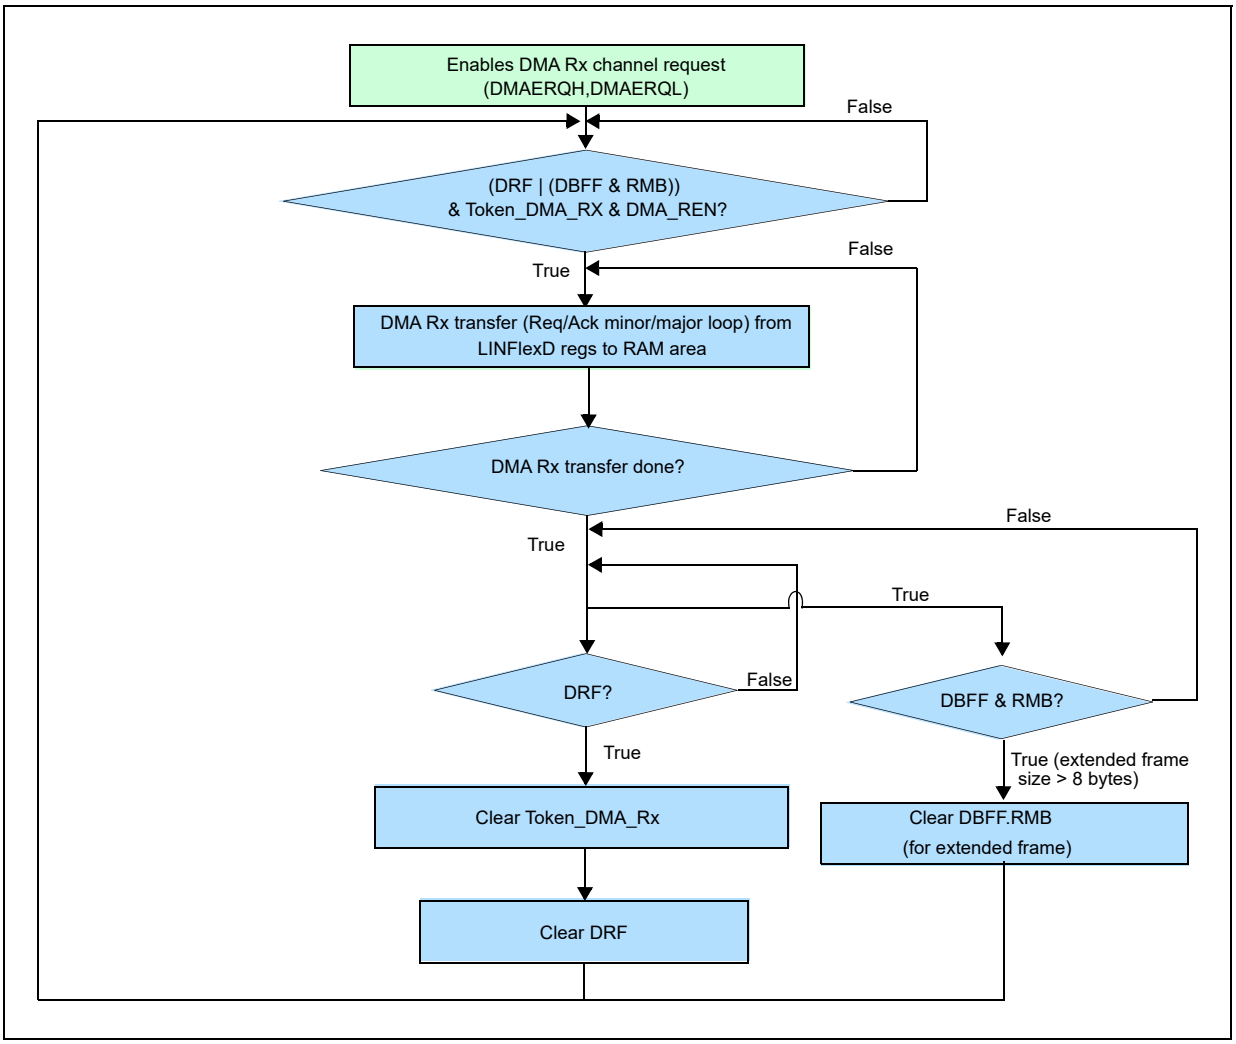


Table 1647. TCD setting: Master node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 1647. TCD setting: Master node - Rx mode (continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

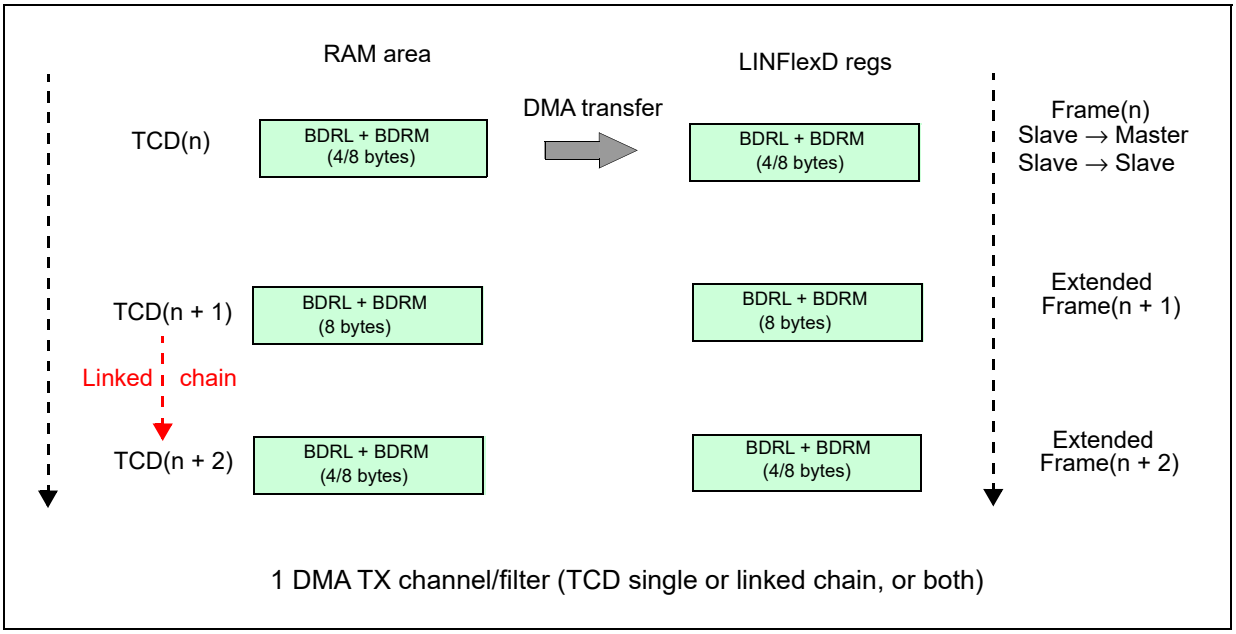

Figure 1670. Master node — DMA Rx FSM (concept scheme)

59.3.5.5 Slave node: TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1671*.

Figure 1671. Slave node — TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1648*.

Table 1648. Slave node: Tx mode - Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in *Figure 1672*. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1649*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

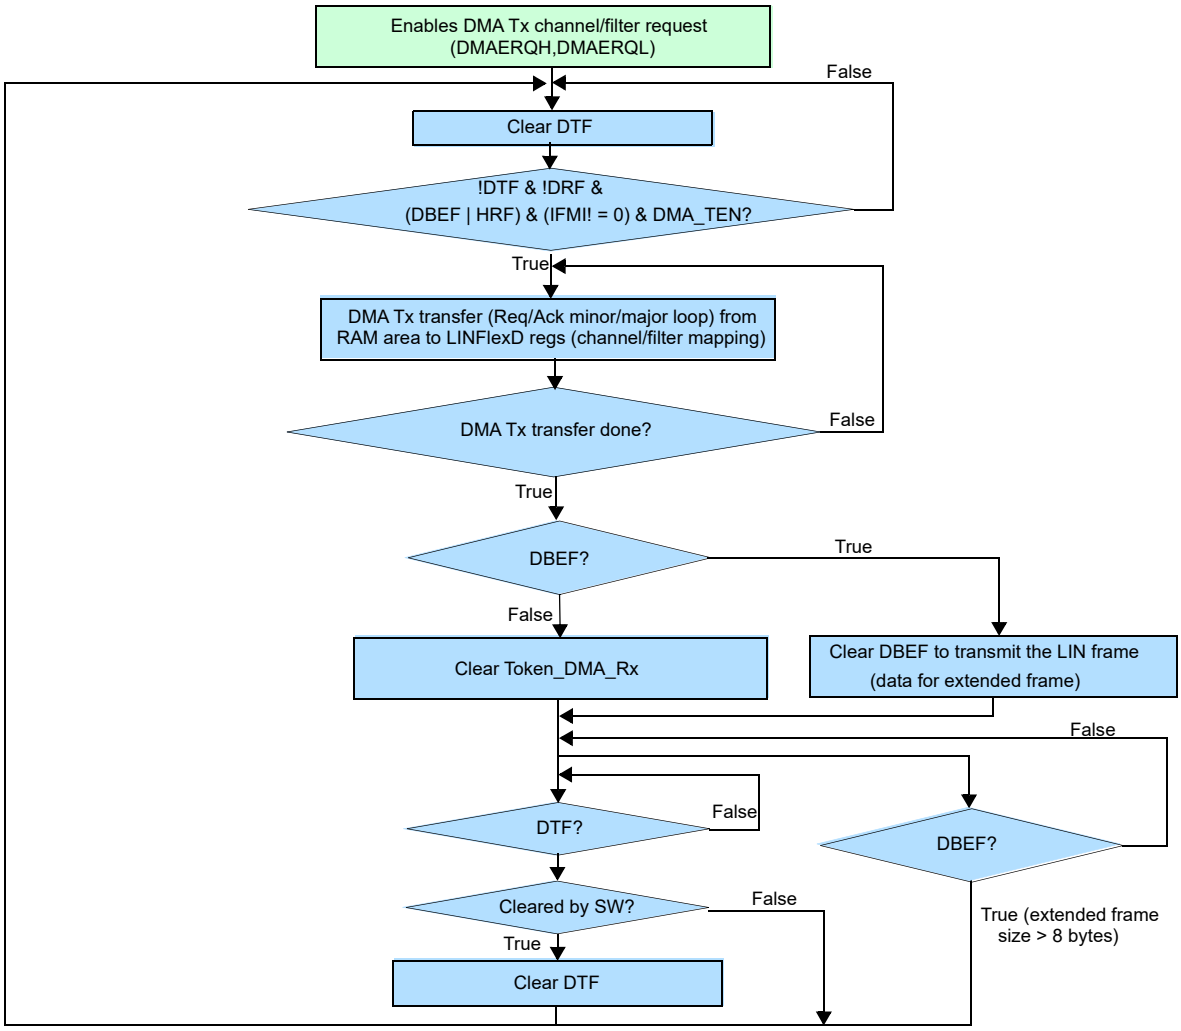

Table 1649. TCD setting: Slave node - Tx mode

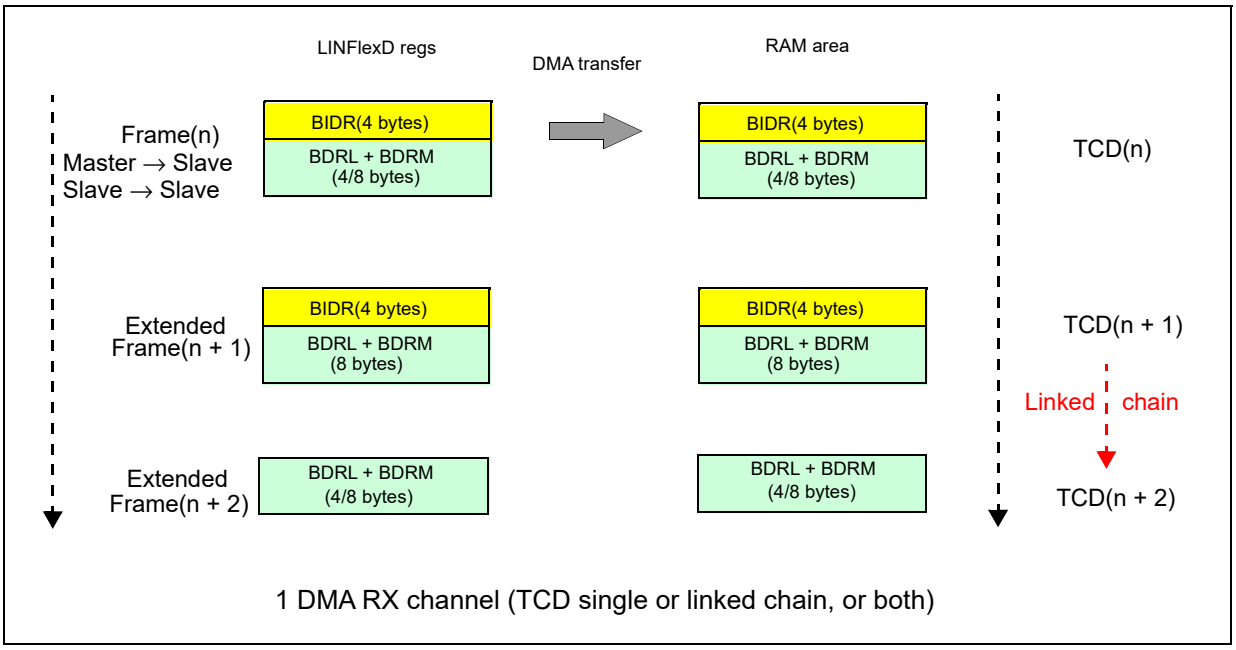
TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 1649. TCD setting: Slave node - Tx mode (continued)

TCD field	Value	Description
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1672. Slave node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

59.3.5.6 Slave node: RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1673*.

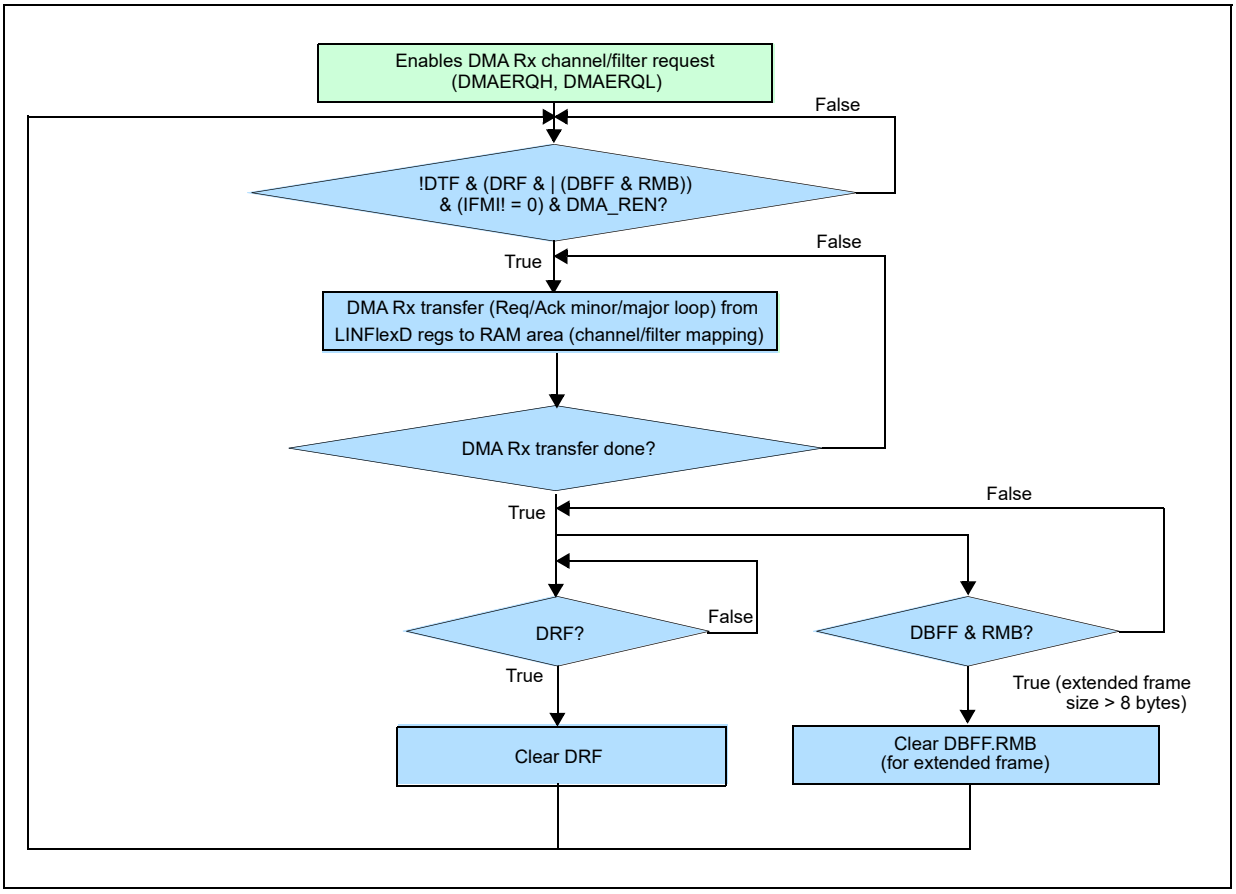
Figure 1673. Slave node: RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1650*.

Table 1650. Slave node: Rx mode - Register setting



LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in *Figure 1674*. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1651*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1651. TCD setting: Slave node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

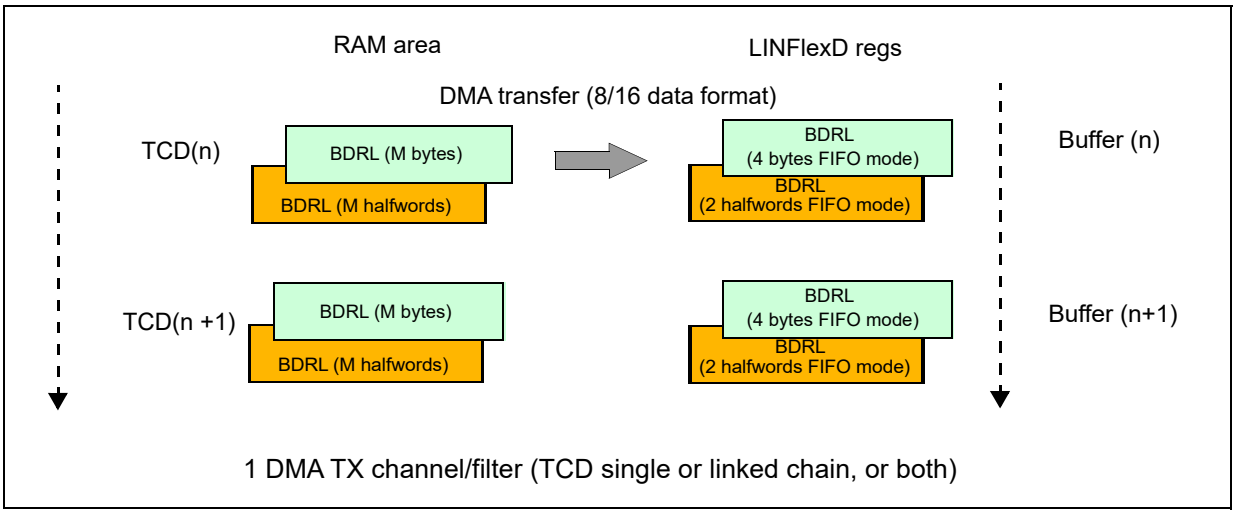


Figure 1674. Slave node — DMA Rx FSM (concept scheme)

59.3.5.7 UART: TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1675*.

Figure 1675. UART: TX memory map

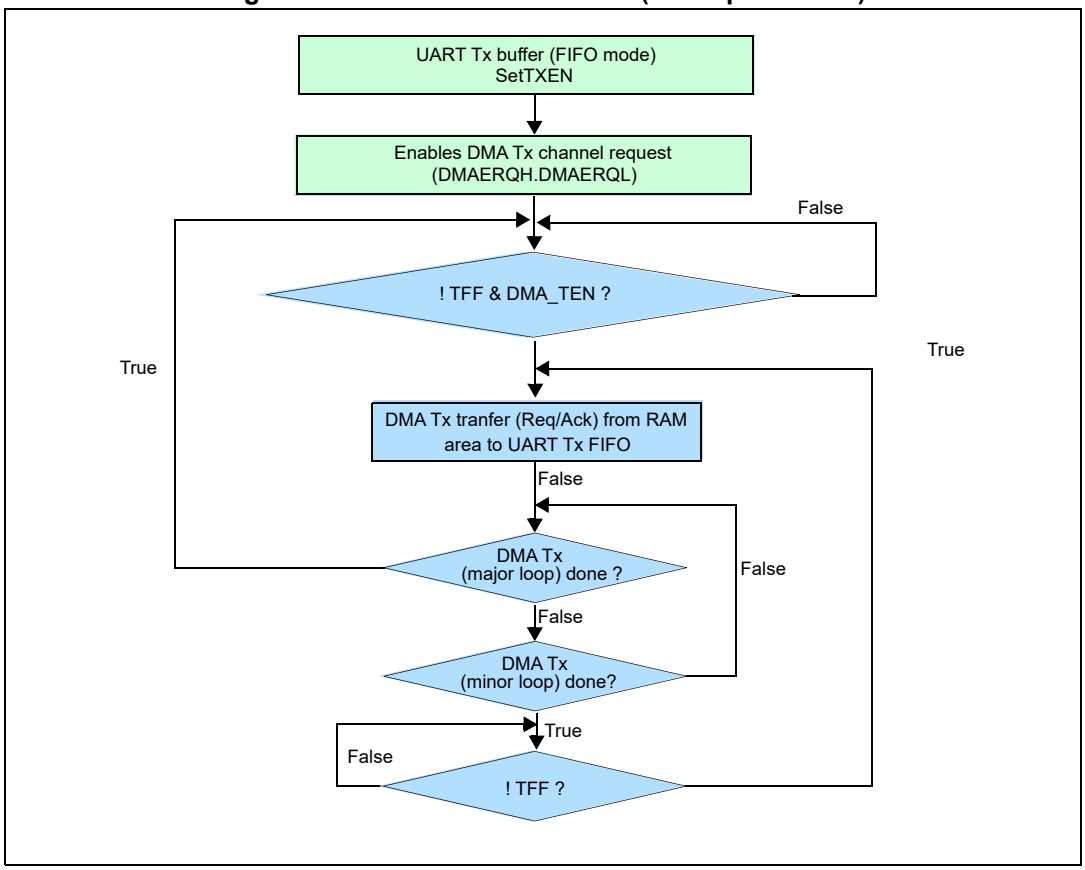
The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.



The concept FSM to control the DMA Tx interface is given in *Figure 1676*. DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in *Table 1652*. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 1652. TCD setting: UART - Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	-M	-M × 2	—
DADDR[31:0](1)	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

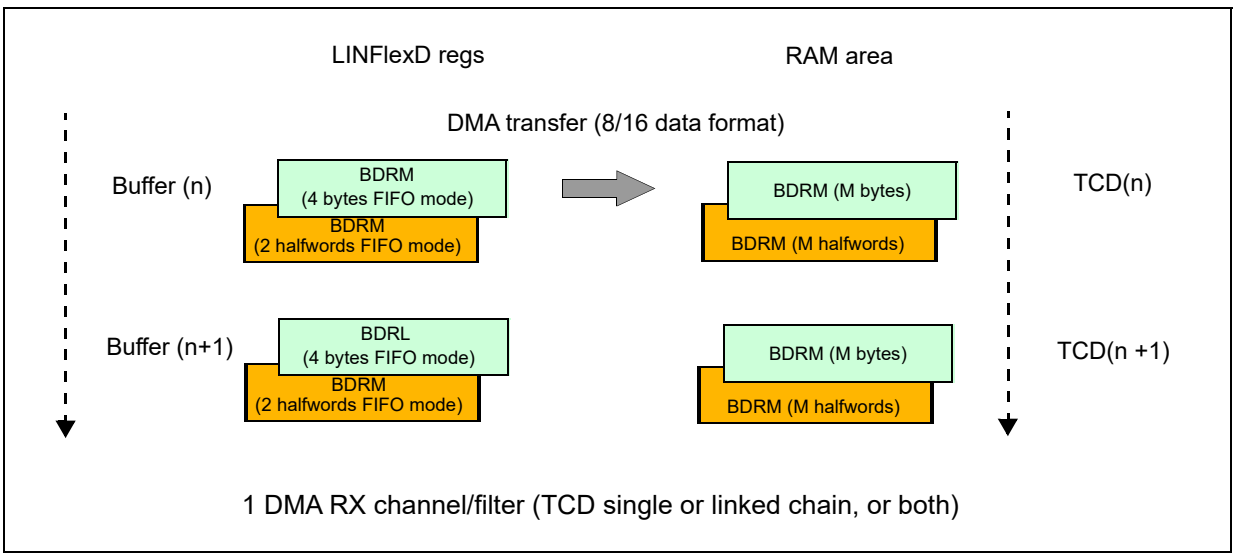


Figure 1676. UART: DMA Tx FSM (concept scheme)

59.3.5.8 UART: RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Table 1653*.

Figure 1677. UART: RX memory map

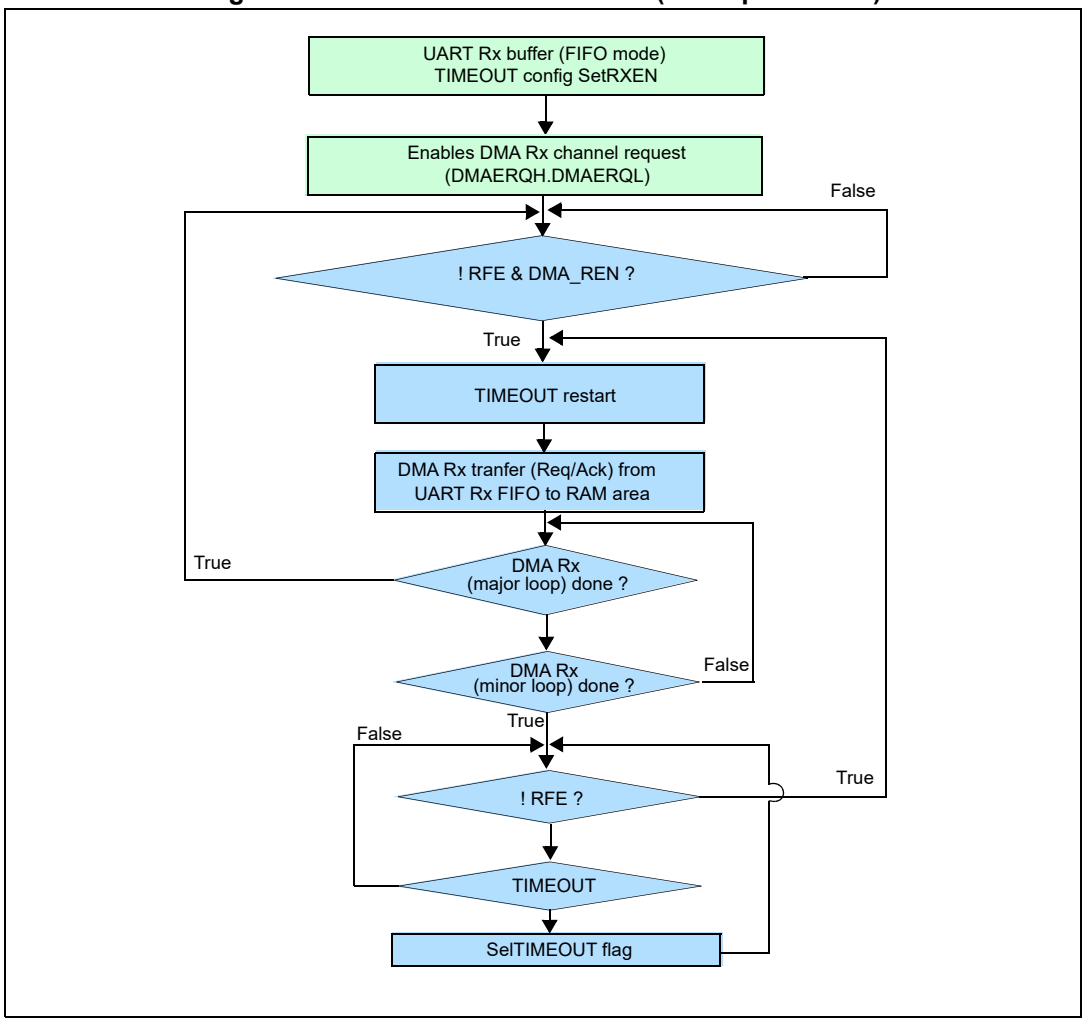
The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.



The concept FSM to control the DMA Rx interface is given in *Figure 1678*. DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 1653. TCD setting: UART - Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0](1)	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	-M	-M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 1678. UART — DMA Rx FSM (concept scheme)

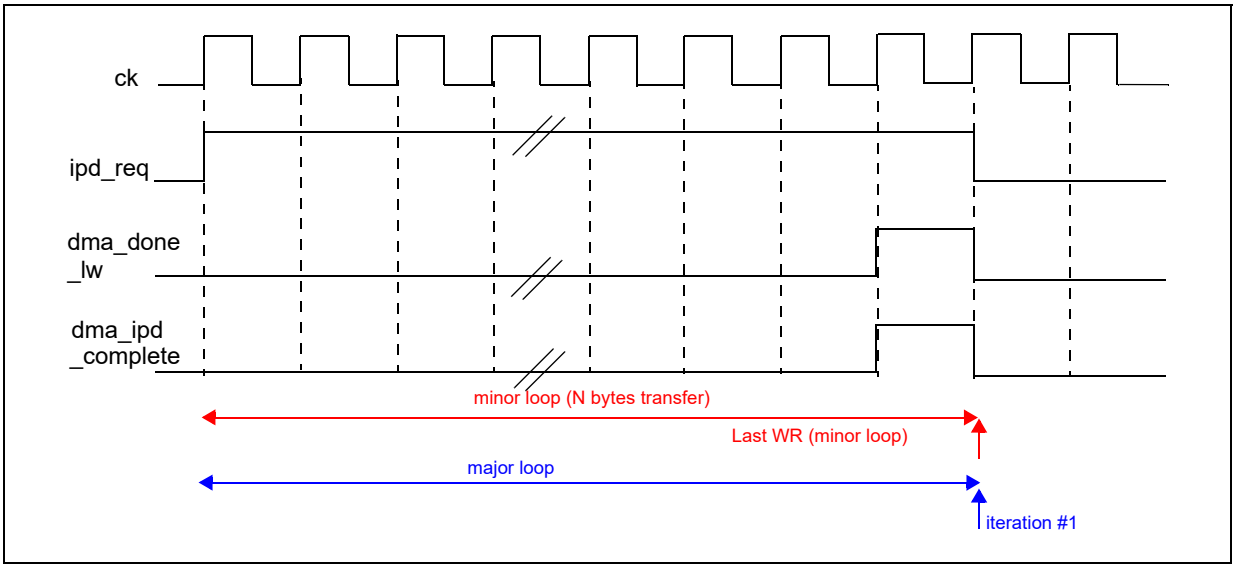
59.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- ipd_req
  - DMA peripheral request, asserted until the DMA transfer has been completed.
- dma_done_lw
  - DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected.
- dma_ipd_complete
  - DMA major loop finished. It is asserted for one cycle after the data phase of the last write.
- dma_ipd_ack, dma_ipd_done
  - Unused in this implementation.

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 1679. DMA interface (major loop — single iteration)



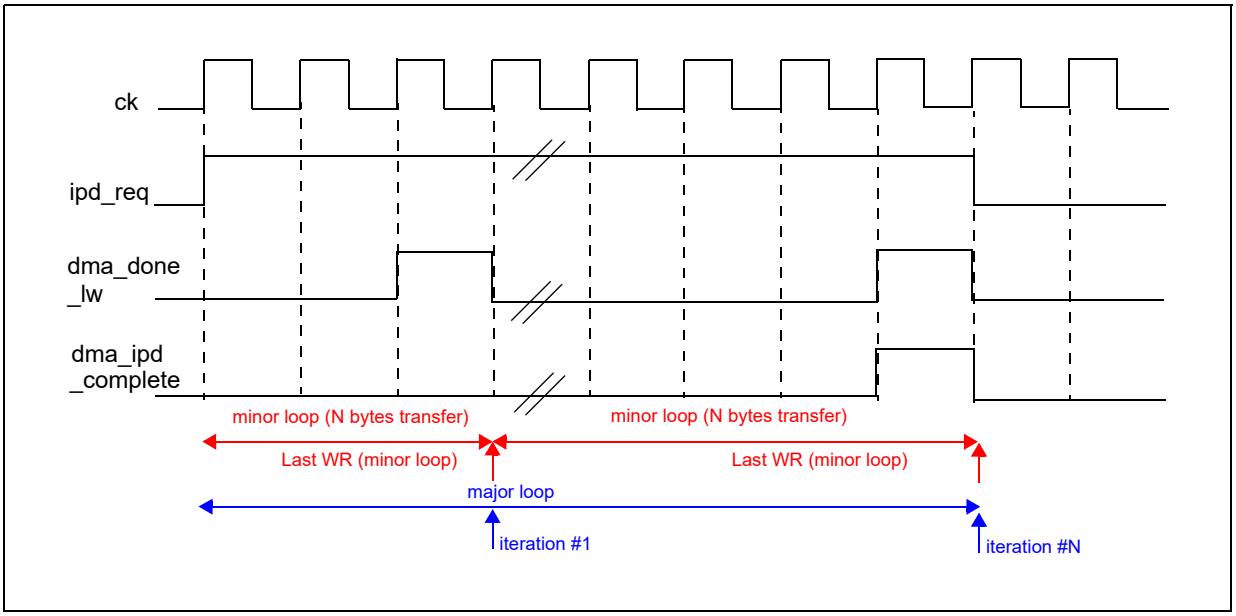


Figure 1680. DMA interface (major loop — N iteration)

59.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA

channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

59.4 Memory map and register description

Note: Refer to the LINFlexD configuration section of the Device Configuration chapter for registers implementation per LINFlexD instance.

59.4.1 Memory map

Table 1654 shows the LINFlexD memory map.

Note: In Master mode, the registers IFCR0–IFCR15 are not present.

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in bus transfer error.

59.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format.
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

59.4.2.1 LIN Control Register 1 (LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

Address: 0x0000 Access: User read/write

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1(2)	0	0	1	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When slave = 0, this field reads '1' and cannot be programmed.

Figure 1681. LIN Control Register 1 (LINCR1)

Table 1655. LINCR1 field descriptions

Field	Description
16 CCD	Calculation disable 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read-only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).

Table 1655. LINCR1 field descriptions (continued)

Field	Description
19 AUTOWU	Auto Wakeup 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.
20:23 MBL[3:0]	Master Break Length These bits choose the length of the Sync break to be generated by the master. 0x0 10-bit break length 0x1 11-bit break length 0x2 12-bit break length 0x3 13-bit break length 0x4 14-bit break length 0x5 15-bit break length 0x6 16-bit break length 0x7 17-bit break length 0x8 18-bit break length 0x9 19-bit break length 0xA 20-bit break length 0xB 21-bit break length 0xC 22-bit break length 0xD 23-bit break length 0xE 36-bit (cooling) break length 0xF 50-bit break length These bits can be programmed in Initialization mode only. They are read-only in Normal mode.
24 BF	By-pass filter 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter This bit can be programmed during Initialization mode only. Note: If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.
25	Reserved
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to *Section 59.3.2.2*. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. If generic *slave* = 0, then this bit will read a ‘1’ always, and cannot be programmed.

Table 1655. LINCR1 field descriptions (continued)

Field	Description
28 SSBL	Slave Mode Sync Break Length 0 11-bit break length 1 10-bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

Figure 1682. LIN Interrupt enable register (LINIER)

Table 1656. LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **Note:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.

Table 1656. LINIER field descriptions (continued)

Field	Description
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE_TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

59.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0x0008 Access: User read/write

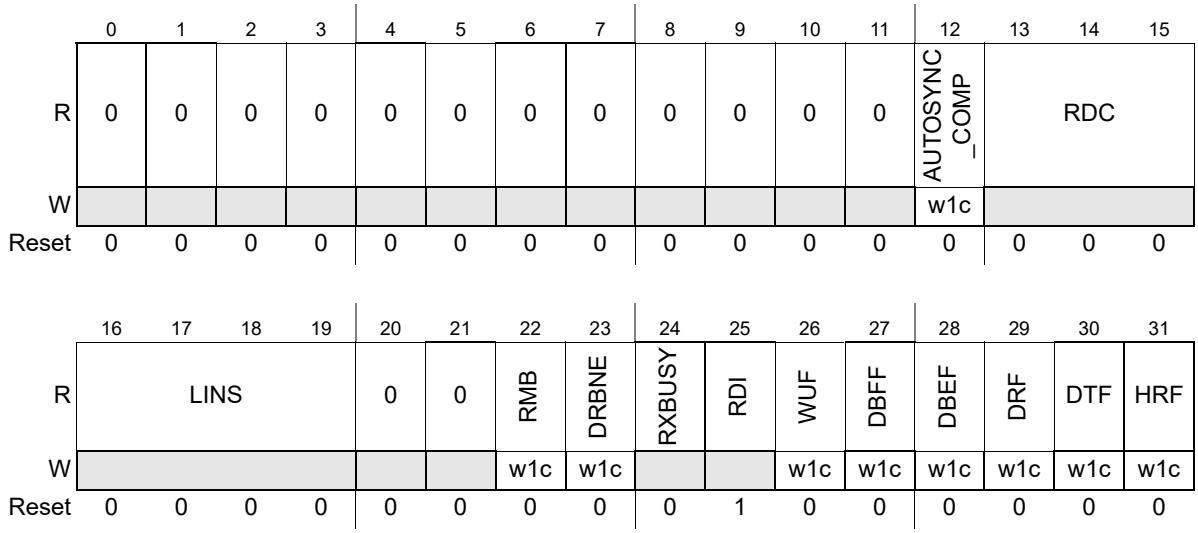

Figure 1683. LIN Status Register (LINSR)

Table 1657. LINSR field descriptions

Field	Description
12 AUTOSYNC_COMP	Autosynchronization Completed This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers should be read in autosynchronization mode.
13:15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 1657. LINSR field descriptions (continued)

Field	Description
16:19 LINS	LIN state 0x0 Sleep mode LINFlexD is in Sleep mode to save power consumption. 0x1 Init 0x2 Idle This mode is entered when: SLEEP bit and INIT bit are reset by software, Wakeup pulse has been received on RX pin (AUTOWU set), Previous frame transmission/reception has been completed/aborted. 0x3 Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0x4 Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0x5 Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0x6 Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0x7 Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 0x8 Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 0x9 Checksum Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXBUSY	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.

Table 1657. LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **Note:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin and when: The slave is in Sleep mode The master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next eight bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: All filters are inactive and Bypass filter (BF) bit is set No match in any filter and Bypass filter (BF) bit is set TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

Figure 1684. LIN error status register (LINESR)

Refer to *Section 59.3.2.5: Errors* for detailed description of all errors.

Table 1658. LINESR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

Table 1658. LINESR field descriptions (continued)

Field	Description
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **Note:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

59.4.2.5 UART Mode Control Register (UARTCR)

Address: 0x0010 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS(1)	CSP(1)			OSR(1)				ROSE(1)	NEF(1)(2)			DTU_PCETX(1)	SBUR(1)		WLS(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TDFL_TFC(2)			RDFL_RFC(3)			RFBM(1)	TFBM(1)	WL1(1)	PC1(1)	RXEN	TXEN	PC0(1)	PCE(1)	WL0(1)	UART(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When TFBM = 0, the field is read/write; when TFBM = 1, the field is read-only.
3. When RFBM = 0, the field is read/write; when RFBM = 1, the field is read-only.

Figure 1685. UART Mode Control Register (UARTCR)

Table 1659. UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 1 UARTCTO monitors the idle state of the reception line. 0 UARTCTO monitors the number of bits to be received. The default value of this bit is 0.
1:3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: – OSR 4: CSP 2, 3 – OSR 5: CSP 2, 3, 4 – OSR 6: CSP 3, 4, 5 – OSR 8: CSP NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received (num_of_frames). When num_of_frames equals NEF, Disable Timeout is set and num_of_frames gets reset to zero, restarting the timer and enabling the timeout again.
13:14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.

Table 1659. UARTCR field descriptions (continued)

Field	Description
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.
16:18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL_TFC defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL_TFC is a read/write field. TDFL_TFC[2] is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL_TFC = x01 or TDFL_TFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes TDFL_TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TDFL_TFCx is a read-only field available for debug purposes. 000 empty 001 1-byte 010 2-bytes 011 3-bytes 100 4-bytes Others: Reserved **Note:** TDFL_TFC can be programmed and are significative only when the UART bit is set.
19:21 RDFL_RFC	Reception Data Field Length/RX FIFO Counter RDFL_RFC defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL_RFC is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL_RFC = x01 or RDFL_RFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes RDFL_RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RDFL_RFCx is a read-only field available for debug purposes. 000 Empty 001 1-byte 010 2-bytes/1.5 byte in case of WLS bit setting 011 3-bytes 100 4-bytes/2×1.5 byte in case of WLS bit setting Others: Reserved RDFL_RFC can be programmed and are significative only when the UART bit is set. **Note:** In buffer mode, RDFL_RFC should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.

Table 1659. UARTCR field descriptions (continued)

Field	Description
22 RFBM	RFBM Rx FIFO/Buffer mode 0 Rx Buffer mode enabled 1 Rx FIFO mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx FIFO/Buffer mode 0 Tx Buffer mode enabled 1 Tx FIFO mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
26 RXEN	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TXEN	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
29 PCE	Parity Control Enable 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.

Table 1659. UARTCR field descriptions (continued)

Field	Description
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

59.4.2.6 UART Mode Status Register (UARTSR)

Address: 0x0014 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

W	w1c	w1c	w1c				w1c	w1c	w1c	w1c	w1c		w1c			w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. When RFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when RFBM = 1, the field is read-only.
2. When TFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when TFBM = 1, the field is read-only.

Figure 1686. UART Mode Status Register (UARTSR)

Table 1660. UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. For Baud rate above 1 Mbit/s, this flag is not usable.
18:21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. PE[i] (where i = 0,1,2 or 3) can be equal to: 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **Note:** Parity is checked only after a complete frame is received. When WL bits = 10 or 11, either PE[0] or PE[2] is only set. – When PE[0] is set, it indicates Parity error in either first or second byte received. – When PE[2] is set, it indicates Parity error in either third or fourth byte received.
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table 1660. UARTSR field descriptions (continued)

Field	Description
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software.The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF_RFE	Data Reception Completed Flag/Rx FIFO Empty Flag DRF_RFE is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF_RFE should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF_RFE bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF_RFE is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DRF_RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. DRF_RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF_TFF	Data Transmission Completed Flag/TX FIFO Full Flag DTF_TFF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF_TFF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DTF_TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. DTF_TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

59.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Address: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	MODE(1)	IOT(1)	TOCE	CNT							
W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.

Figure 1687. LIN Time-Out Control Status Register (LINTCSR)

Table 1661. LINTCSR field descriptions

Field	Description
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event This feature is applicable only when MODE bit in LINTCSR is cleared.
23 TOCE	Time-out counter enable 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24:31 CNT	Counter Value These bits reflect the value of a free-running counter used for timeout. **Note:** For proper functionality of this counter, LINIBRR should be greater than or equal to 5. This counter increments once in every bit duration, as per the programmed bit rate. The counter starts as soon as the IP comes out of reset and increments based on the slowest baud rate possible (LINIBRR = FFFFFh), until the user programs LINIBRR and LINFBRR with the desired values.

59.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the count value in LINTOCR register. This register is writable by software only in Output Compare Mode.

Address: 0x001C Access: User read/write

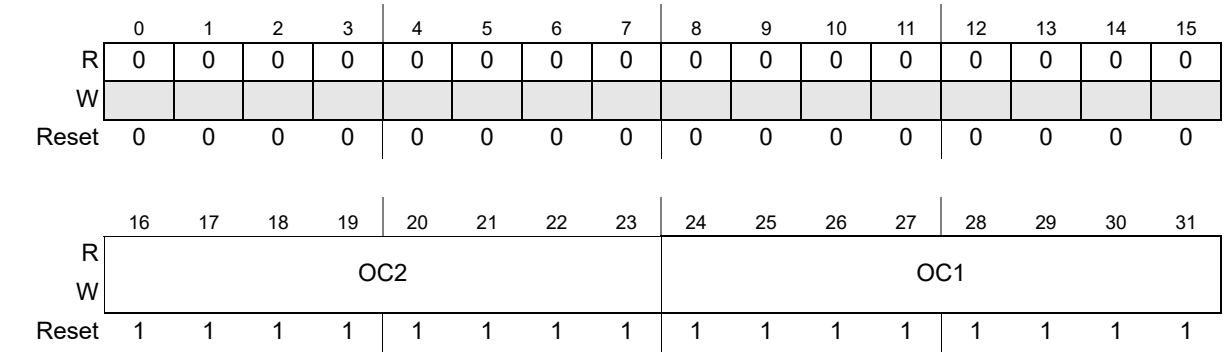

Figure 1688. LIN Output Compare Register (LINOCR)

Table 1662. LINOCR field descriptions

Field	Description
16:23 OC2	Output compare value 2 When MODE bit = 0 in LINTCSR register: This field is loaded by HW, with response timeout calculated based on RTO value in LINTOCR register and CNT value in LINTCSR register. When MODE bit = 1 in LINTCSR register: This field can be used as output compare register, up to bit rates of 1 Mbit/s.
24:31 OC1	Output compare value 1 When MODE bit = 0 in LINTCSR register: This field is loaded by HW, with header timeout calculated based on HTO value in LINTOCR register and CNT value in LINTCSR register. When MODE bit = 1 in LINTCSR register: This field can be used as output compare register, up to bit rates of 1 Mbit/s. **Note:** OC1 field can be used as output compare register only in LIN slave mode.

59.4.2.9 LIN Time-Out Control Register (LINTOCR)

Address: 0x0020 Access: User read/write

1. This reset value is valid only in Master mode (slave = 0).

Figure 1689. LIN Time-Out Control Register (LINTOCR)

Table 1663. LINTOCR field descriptions

Field	Description
20:23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0xE = 14, corresponding to $T_{Response_Maximum} = 1.4 * T_{Response_Nominal}$
25:31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is 0x2C = 45, corresponding to $T_{Header_Maximum}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 0x1C = 28 (1.4 × 10 bits of sync + 1.4 × 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

59.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0x0024 Access: User read/write

Figure 1692. LIN Checksum Field Register (LINCFR)

Table 1666. LINCFR field descriptions

Field	Description
24:31 CF	Checksum bits When the LINCR1[CCD] bit is reset these bits are read-only and are calculated by hardware. When the LINCR1[CCD] bit is set, these bits can be written by software.

LINCR1[CFD]	LINCR1[CCD]	LINCHKSUM Read/write	Checksum sent
1	1	read/write	None
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

59.4.2.13 LIN Control Register 2 (LINCR2)

This register includes control status bits related to buffer operations.

Address: 0x0030 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TBDE(1)	IOBE(1)	IOPE(1)	WURQ(2)	DDRQ(2)	DTRQ(2)	ABRQ(2)	HTRQ(2)	0	0	0	0	0	0	0	0
W																
Reset	0	1	0(3)/1	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in Initialization mode.
2. This field can be read/set by software.
3. When slave = 0, reset value is '0' and the this field cannot be programmed.

Figure 1693. LIN Control Register 2 (LINCR2)

Table 1667. LINCR2 field descriptions

Field	Description
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **Note:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.

59.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0x0034 Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1694. Buffer Identifier Register (BIDR)

Table 1668. BIDR field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1 **Note:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copies them in the BDRs 1 LINFlexD transmits the data from the BDRs
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = ‘1’).

59.4.2.15 Buffer Data Register Least Significant (BDRL)

This register is a part of an 8-byte data buffer.

Address: 0x0038 Access: User read/write

R W	FACT(1)															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.

Figure 1697. Identifier Filter Enable Register (IFER)

Table 1671. IFER field descriptions

Field	Description
16:31 FACT	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. 1. In Identifier mask mode, FACT (2*n*+1) have no effect on the corresponding filters as they act as mask for the Identifier 2*n*. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **Note:** Refer to device configuration chapter to see the number of filters used in the device.

59.4.2.18 Identifier Filter Match Index (IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address: 0x0044 Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

2. Refer to the Device Configuration chapter to see the number of filters used in this device.

Figure 1701. Identifier Filter Control Register (IFCR2n+1)

Table 1675. IFCR2*n*+1 field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity.

59.4.2.22 Global Control Register (GCR)

This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

Address: 0x8C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. This field is read 0 by software.

Figure 1702. Global Control Register (GCR)

Table 1676. GCR field descriptions

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. 0 The first bit of received data is LSB – in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB – in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. 0 Received data is not inverted 1 Received data is inverted

Table 1676. GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. The following register fields are reset by SR: LINSR: All fields except RXbusy and AUTOSYNC_COMP LINESR: All fields LINTCSR: Only CNT[0:7] UARTSR: All fields except RFE and TFFt UARTCR: Only TFC and RFC UARTCTO: All fields

59.4.2.23 UART Preset Timeout Register (UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

Address: 0x8C + 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	0	0	0	PTO											
W																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

Figure 1703. UART Preset Timeout Register (UARTPTO)

Table 1677. UARTPTO field descriptions

Field	Description
20:31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A value of 0, 1 or 2 is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer to the UARTCTO register.

59.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (refer to *Section 59.4.2.23*) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

*Note: Due to this synchronisation, UARTCTO reflects the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) which was present on it, before 4 to 6 clock cycles of PBRIDGEx_CLK.*

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO-1
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

Address: 0x8C + 0x08 Access: User read

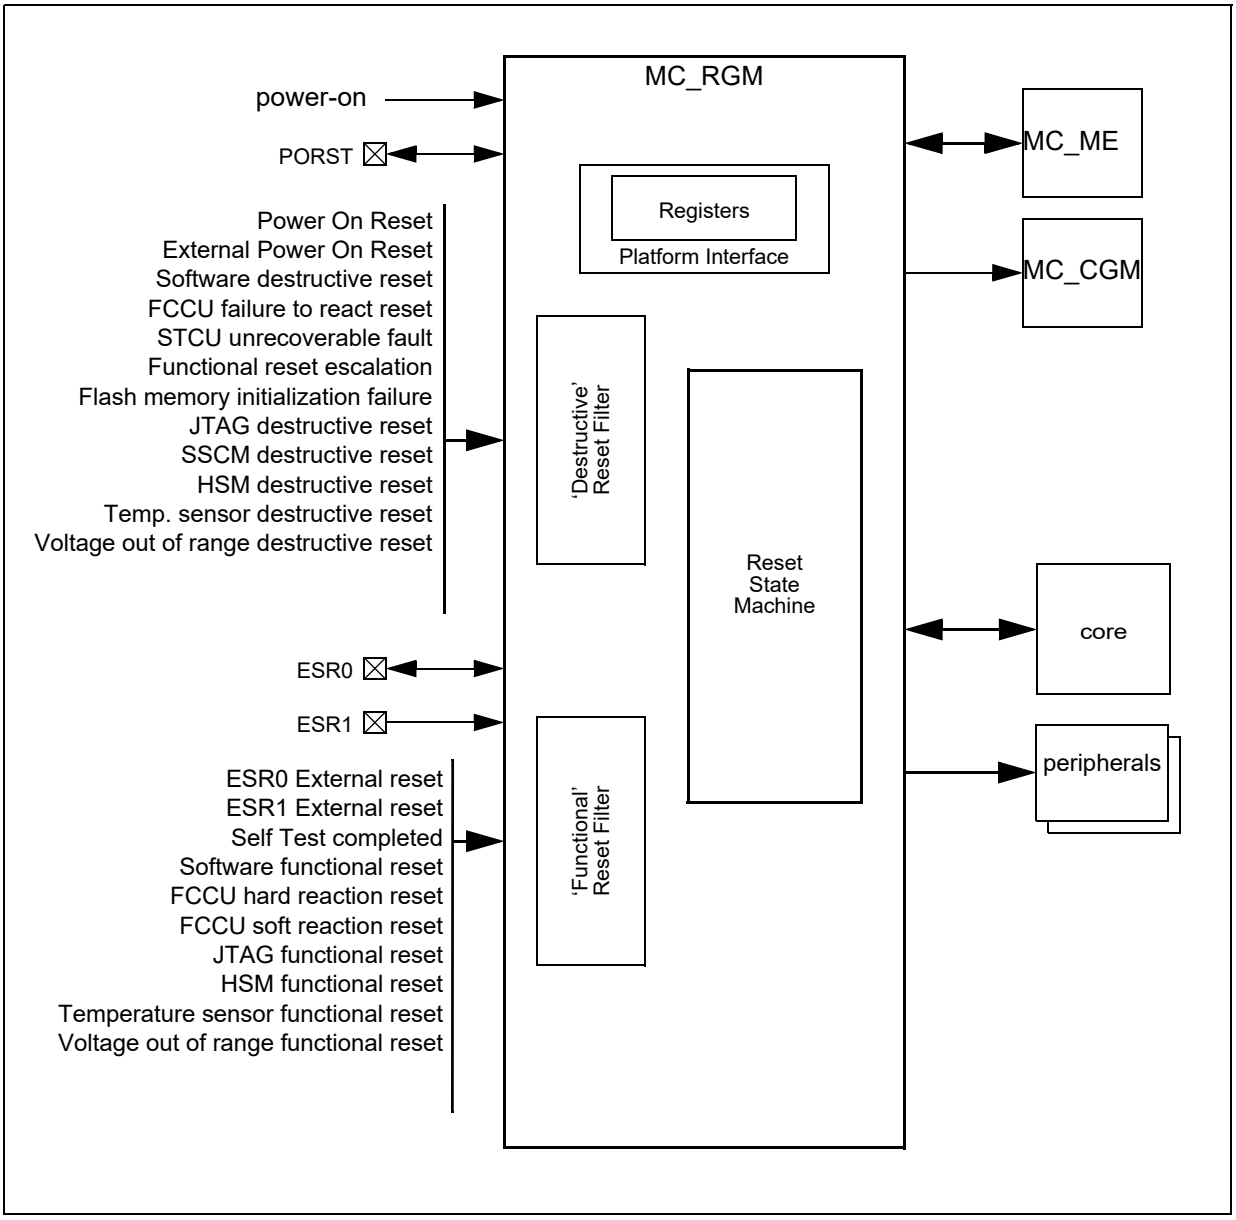
60 Reset Generation Module (MC_RGM)

60.1 Introduction



This chapter describes the MC_RGM module.

60.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

Figure 1734 shows the MC_RGM block diagram.

Figure 1734. MC_RGM block diagram

60.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to SAFE mode or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration
- boot mode capture on ESR0 deassertion

60.1.3 Reset sources

The different reset sources are organized into two families: ‘destructive’ and ‘functional’.

- A ‘destructive’ reset source is associated with an event related to a critical, usually hardware, error or dysfunction. When a ‘destructive’ reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software ‘destructive’ reset and external power-on reset cases, which do preserve the system memory content if the chip is not configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Destructive’ resets are:
  - Power On Reset
  - External Power On Reset
  - Software destructive reset
  - FCCU failure to react reset
  - STCU unrecoverable fault
  - Functional reset escalation
  - Flash memory initialization failure
  - JTAG destructive reset
  - SSCM destructive reset
  - HSM destructive reset
  - Temperature sensor destructive reset
  - Voltage out of range destructive reset
- A ‘functional’ reset source is associated with an event related to a less-critical, usually non-hardware, error or dysfunction. When a ‘functional’ reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Functional’ resets are:
  - ESR0 External reset
  - ESR1 External reset
  - Self Test completed
  - Software functional reset
  - FCCU hard reaction reset
  - FCCU soft reaction reset
  - JTAG functional reset
  - HSM functional reset
  - Temperature sensor functional reset
  - Voltage out of range functional reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (the PHASE*n* states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to

the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (see *Section 60.3.1.2: 'Destructive' Event Reset Disable Register (RGM_DERD)* and *Section 60.3.1.3: 'Destructive' Event Alternate Request Register (RGM_DEAR)* for 'destructive' resets and *Section 60.3.1.6: 'Functional' Event Reset Disable Register (RGM_FERD)* and *Section 60.3.1.7: 'Functional' Event Alternate Request Register (RGM_FEAR)* for 'functional' resets).

60.2 External signal description

The MC_RGM interfaces to the bidirectional reset pin ESR0.

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

60.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

60.3.1.1 ‘Destructive’ Event Status Register (RGM_DES)

This register contains the status of the ‘destructive’ reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing ‘1’.

This register is reset only on power-on.

27 F_FFRR	Flag for FCCU failure to react reset 0 No FCCU failure to react reset event has occurred since the last clear. 1 A FCCU failure to react reset event has occurred.
28 F_SOFT_DEST	Flag for software ‘destructive’ reset 0 No software ‘destructive’ reset event has occurred since the last clear. 1 A software ‘destructive’ reset event has occurred.
30 F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred
31 F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

60.3.1.2 ‘Destructive’ Event Reset Disable Register (RGM_DERD)

This register provides dedicated bits to disable particular ‘destructive’ reset sources. When a ‘destructive’ reset source is disabled, the associated ‘destructive’ event will trigger either a SAFE mode request or an interrupt request (see *Section 60.3.1.3: ‘Destructive’ Event Alternate Request Register (RGM_DEAR)*). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a ‘destructive’ or power-on reset.

This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x010 Access: User read, Supervisor read/write, Test read/write

Table 1684. RGM_DERD field descriptions (continued)

Field	Description
30 D_PORST	Disable external power-on reset 0 An external power-on reset event triggers a reset sequence 1 An external power-on reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR.AR_PORST
31 D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

60.3.1.3 'Destructive' Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a 'destructive' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Table 1686. RGM_DBRE field descriptions

Field	Description
7 BE_VOR_DEST	Bidirectional Reset Enable for voltage out of range 'destructive' reset 0 ESR0_B is asserted on a voltage out of range 'destructive' reset event.
8 BE_TSR_DEST	Bidirectional Reset Enable for temperature sensor 'destructive' reset 0 ESR0_B is asserted on a temperature sensor 'destructive' reset event if the reset is enabled.
16 BE_HSM_DEST	Bidirectional Reset Enable for HSM 'destructive' reset request 0 ESR0_B is asserted on a HSM 'destructive' reset request event.
17 BE_SSCM_DEST	Bidirectional Reset Enable for SSCM 'destructive' reset request 0 ESR0_B is asserted on a SSCM 'destructive' reset request event.
21 BE_JTAG_DEST	Bidirectional Reset Enable for JTAG 'destructive' reset request 0 ESR0_B is asserted on a JTAG 'destructive' reset request event. 1 ESR0_B is not asserted on a JTAG 'destructive' reset request event.
22 BE_FIF	Bidirectional Reset Enable for flash memory initialization failure 0 ESR0_B is asserted on a flash memory initialization failure event.
23 BE_EDR	Bidirectional Reset Enable for 'functional' reset escalation 0 ESR0_B is asserted on a 'functional' reset escalation event.
26 BE_SUF	Bidirectional Reset Enable for STCU2 unrecoverable fault 0 ESR0_B is asserted on a STCU2 unrecoverable fault event.
27 BE_FFRR	Bidirectional Reset Enable for FCCU failure to react reset 0 ESR0_B is asserted on a FCCU failure to react reset event.

Table 1686. RGM_DBRE field descriptions (continued)

Field	Description
28 BE_SOFT_DEST	Bidirectional Reset Enable for software ‘destructive’ reset 0 ESR0_B is asserted on a software ‘destructive’ reset event.
30 BE_PORST	Bidirectional Reset Enable for external power-on reset 0 ESR0_B is asserted on an external power-on reset event if the reset is enabled.
31 BE_POR	Bidirectional Reset Enable for power-on reset 0 ESR0_B is asserted on a power-on reset event.

60.3.1.5 ‘Functional’ Event Status Register (RGM_FES)

This register contains the status of the ‘functional’ reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing ‘1’ if the triggering event has already been cleared at the source.

This register is reset only on power-on.

Note: If a ‘functional’ reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.

26 F_FCCU_HARD	Flag for FCCU hard reaction reset 0 No FCCU hard reaction reset event has occurred since either the last clear or the last power-on reset assertion. 1 A FCCU hard reaction reset event has occurred.
28 F_SOFT_FUNC	Flag for software ‘functional’ reset 0 No software ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion. 1 A software ‘functional’ reset event has occurred.
29 F_ST_DONE	Flag for self test completed 0 No self test completed event has occurred since either the last clear or the last power-on reset assertion. 1 A self test completed event has occurred.
30 F_ESR1	Flag for ESR1 External Reset 0 No ESR1 external reset event has occurred since either the last clear or the last power-on reset assertion. 1 An ESR1 external reset event has occurred.
31 F_ESR0	Flag for ESR0 External Reset 0 No ESR0 external reset event has occurred since either the last clear or the last power-on reset assertion. 1 An ESR0 external reset event has occurred.

60.3.1.6 ‘Functional’ Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable ‘functional’ reset sources.When a ‘functional’ reset source is disabled, the associated ‘functional’ event will trigger either a SAFE mode request or an interrupt request (see *Section 60.3.1.7: ‘Functional’ Event Alternate Request*

Register (RGM_FEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any ‘destructive’ reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x310 Access: User read, Supervisor read/write, Test read/write

31 D_ESR0	Disable ESR0 External Reset 0 An ESR0 external reset event triggers a reset sequence

60.3.1.7 ‘Functional’ Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a ‘functional’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x320 Access: User read, Supervisor read/write, Test read/write

60.3.1.8 ‘Functional’ Bidirectional Reset Enable Register (RGM_FBRE)

This register enables the generation of an external reset on ‘functional’ reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x330 Access: User read, Supervisor read/write, Test read/write

29 BE_ST_DONE	Bidirectional Reset Enable for self test completed 0 ESR0_B is asserted on a self test completed event
30 BE_ESR1	Bidirectional Reset Enable for ESR1 External Reset 0 ESR0_B is asserted on an ESR1 external reset event if the reset is enabled 1 ESR0_B is not asserted on an ESR1 external reset event
31 BE_ESR0	Bidirectional Reset Enable for ESR0 External Reset 0 ESR0_B is asserted on an ESR0 external reset event if the reset is enabled

60.3.1.9 ‘Functional’ Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence will be done when a ‘functional’ reset sequence is triggered. The ‘functional’ reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

Note: This could be useful for fast reset sequence, for example to skip flash memory reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x340 Access: User read, Supervisor read/write, Test read/write

60.3.1.10 'Functional' Reset Escalation Threshold Register (RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See *Section 60.4.6: 'Functional' reset escalation* for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Address: 0x604 Access: User read, Supervisor read/write, Test read/write

Field	Description
4:7 FRET	'Functional' Reset Escalation Threshold 0000 'Functional' reset escalation function disabled 0001 Number of 'functional' reset events before escalation to destructive reset ... 1111 Number of 'functional' reset events before escalation to destructive reset

60.3.1.11 'Destructive' Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for 'destructive' reset escalation keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the 'destructive' reset software escalation function. Writing any value to this register will reset the 'destructive' reset counter. See *Section 60.4.7: 'Destructive' reset escalation*, for details on the 'destructive' reset escalation function.

This register is reset only on power-on.

Address: 0x608 Access: User read, Supervisor read/write, Test read/write

60.3.1.12 External Reset Output Extension Control Register (RGM_EROEC)

This register controls the assertion of the ESR0_B pin after the reset sequence has completed. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. The register bit is cleared on write '1'.

Clearing the EROEC bit will cause the MC_RGM to stop asserting the ESR0_B pin within two 16 MHz internal RC oscillator clock cycles. The ESR0_B pin cannot be asserted by writing to this register.

This register also provides the current value sampled on ESR0 via the ERIS bit. This is useful for software to poll if, for example, ESR0_B is used in the system to synchronize the application software with an external event.

This register is reset only on power-on.

Address: 0x60C Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7

Field	Description
10 LINFLEXD_14_RST	LINFLEXD_14 reset Writing a '1' to this bit resets the LINFLEXD_14 peripheral. Writing a '0' to this bit releases the reset to the LINFLEXD_14 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_0_CTR_RST	CAN_RAM_SUB_0_CTR reset It is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_0_CTR_RST bit Writing a '1' to this bit resets the CAN_RAM_SUB_0_CTR peripheral. Writing a '0' to this bit releases the reset to the CAN_RAM_SUB_0_CTR peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 M_TTCAN_0_SUB_0_RST	M_TTCAN_0_SUB_0 reset Writing a '1' to this bit resets the M_TTCAN_0_SUB_0 peripheral. Writing a '0' to this bit releases the reset to the M_TTCAN_0_SUB_0 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 M_CAN_1_SUB_0_RST	M_CAN_1_SUB_0 reset Writing a '1' to this bit resets the M_CAN_1_SUB_0 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 M_CAN_2_SUB_0_RST	M_CAN_2_SUB_0 reset Writing a '1' to this bit resets the M_CAN_2_SUB_0 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_2_SUB_0 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 M_CAN_3_SUB_0_RST	M_CAN_3_SUB_0 reset Writing a '1' to this bit resets the M_CAN_3_SUB_0 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_3_SUB_0 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

60.3.1.16 Peripheral Reset Register 3 (RGM_PRST3)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See *Table 1698* for details.

Address: 0x61C Access: User read, Supervisor read/write, Test read/write

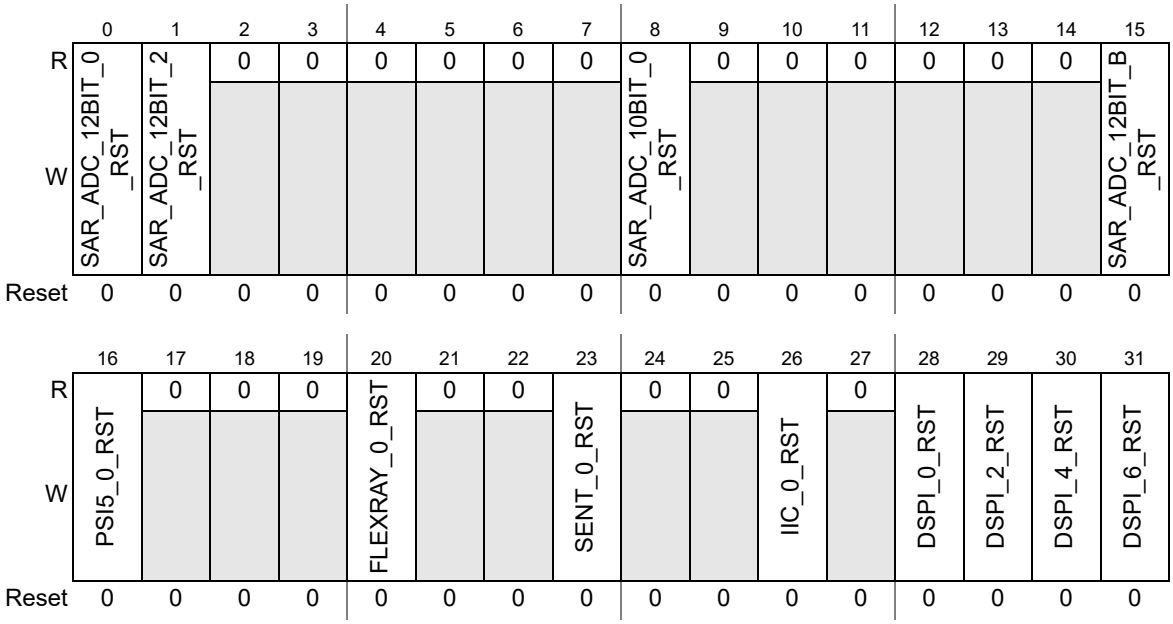

Figure 1750. Peripheral Reset Register 3 (RGM_PRST3)

Table 1698. RGM_PRST3 register field descriptions

Field	Description
0 SAR_ADC_12BIT_0_RST	SAR_ADC_12BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_12BIT_0_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 SAR_ADC_12BIT_2_RST	SAR_ADC_12BIT_2 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_2 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_12BIT_2_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1698. RGM_PRST3 register field descriptions (continued)

Field	Description
8 SAR_ADC_10BIT_0_RST	SAR_ADC_10BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_10BIT_0_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 SAR_ADC_12BIT_B_RST	SAR_ADC_12BIT_B reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_B peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_B peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_12BIT_B_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 PSI5_0_RST	PSI5_0 reset Writing a ‘1’ to this bit resets the PSI5_0 peripheral. Writing a ‘0’ to this bit releases the reset to the PSI5_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
20 FLEXRAY_0_RST	FLEXRAY_0 reset Writing a ‘1’ to this bit resets the FLEXRAY_0 peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXRAY_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 SENT_0_RST	SENT_0 reset Writing a ‘1’ to this bit resets the SENT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SENT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 IIC_0_RST	IIC_0 reset Writing a ‘1’ to this bit resets the IIC_0 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1698. RGM_PRST3 register field descriptions (continued)

Field	Description
28 DSPI_0_RST	DSPI_0 reset Writing a ‘1’ to this bit resets the DSPI_0 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_2_RST	DSPI_2 reset Writing a ‘1’ to this bit resets the DSPI_2 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 DSPI_4_RST	DSPI_4 reset Writing a ‘1’ to this bit resets the DSPI_4 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 DSPI_6_RST	DSPI_6 reset Writing a ‘1’ to this bit resets the DSPI_6 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_6 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

60.3.1.17 Peripheral Reset Register 4 (RGM_PRST4)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See *Table 1699* for details.

Address: 0x620 Access: User read, Supervisor read/write, Test read/write

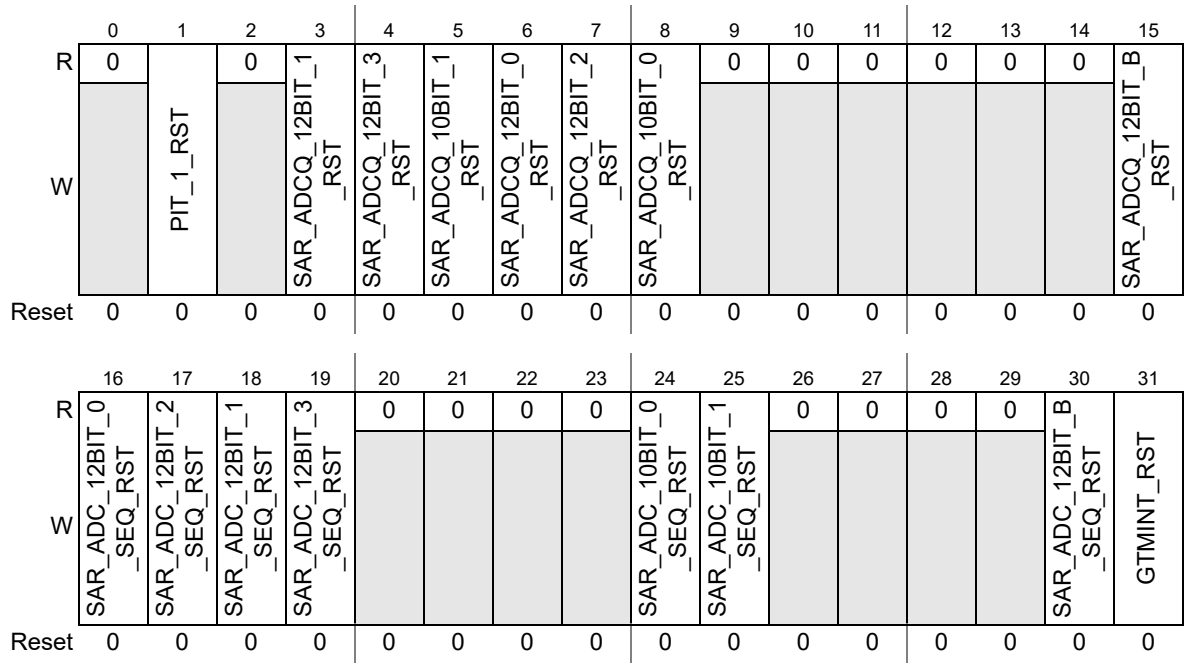

Figure 1751. Peripheral Reset Register 4 (RGM_PRST4)

Table 1699. RGM_PRST4 register field descriptions

Field	Description
1 PIT_1_RST	PIT_1 reset Writing a ‘1’ to this bit resets the PIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the PIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
3 SAR_ADCQ_12BIT_1_RST	SAR_ADCQ_12BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_12BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_12BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 SAR_ADCQ_12BIT_3_RST	SAR_ADCQ_12BIT_3 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_12BIT_3 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_12BIT_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1699. RGM_PRST4 register field descriptions (continued)

Field	Description
5 SAR_ADCQ_10BIT_1_RST	SAR_ADCQ_10BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_10BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_10BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 SAR_ADCQ_12BIT_0_RST	SAR_ADCQ_12BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_12BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_12BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
7 SAR_ADCQ_12BIT_2_RST	SAR_ADCQ_12BIT_2 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_12BIT_2 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_12BIT_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 SAR_ADCQ_10BIT_0_RST	SAR_ADCQ_10BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADCQ_10BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_10BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 SAR_ADCQ_12BIT_B_RST	SAR_ADCQ_12BIT_B reset Writing a ‘1’ to this bit resets the SAR_ADCQ_12BIT_B peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADCQ_12BIT_B peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 SAR_ADC_12BIT_0_SEQ_RST	SAR_ADC_12BIT_0_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_0_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_0_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
17 SAR_ADC_12BIT_2_SEQ_RST	SAR_ADC_12BIT_2_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_2_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_2_SEQ p ripheral if the bit’s current value is ‘1’, otherwise it has no effect.0 No forced reset of peripheral 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1699. RGM_PRST4 register field descriptions (continued)

Field	Description
18 SAR_ADC_12BIT_1_SEQ_RST	SAR_ADC_12BIT_1_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_1_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_1_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
19 SAR_ADC_12BIT_3_SEQ_RST	SAR_ADC_12BIT_3_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_3_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_3_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
24 SAR_ADC_10BIT_0_SEQ_RST	SAR_ADC_10BIT_0_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_0_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_0_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
25 SAR_ADC_10BIT_1_SEQ_RST	SAR_ADC_10BIT_1_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_1_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_1_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 SAR_ADC_12BIT_B_SEQ_RST	SAR_ADC_12BIT_B_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_B_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_B_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 GTMINT_RST	GTMINT reset Writing a ‘1’ to this bit resets the GTMINT peripheral. Writing a ‘0’ to this bit releases the reset to the GTMINT peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

60.3.1.18 Peripheral Reset Register 5 (RGM_PRST5)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See *Table 1700* for details.

Address: 0x624 Access: User read, Supervisor read/write, Test read/write

Figure 1752. Peripheral Reset Register 5 (RGM_PRST5)

Table 1700. RGM_PRST5 register field descriptions

Field	Description
3 SD_ADC_1_RST	SD_ADC_1 reset Writing a ‘1’ to this bit resets the SD_ADC_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SD_ADC_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 SD_ADC_3_RST	SD_ADC_3 reset Writing a ‘1’ to this bit resets the SD_ADC_3 peripheral. Writing a ‘0’ to this bit releases the reset to the SD_ADC_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
5 SD_ADC_5_RST	SD_ADC_5 reset Writing a ‘1’ to this bit resets the SD_ADC_5 peripheral. Writing a ‘0’ to this bit releases the reset to the SD_ADC_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
22 FCCU_RST	FCCU reset Writing a ‘1’ to this bit resets the FCCU peripheral. Writing a ‘0’ to this bit releases the reset to the FCCU peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1700. RGM_PRST5 register field descriptions (continued)

Field	Description
25 CRC_1_RST	CRC_1 reset Writing a '1' to this bit resets the CRC_1 peripheral. Writing a '0' to this bit releases the reset to the CRC_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 DMAMUX_5_3_1_RST	DMAMUX_5_3_1 reset Writing a '1' to this bit resets the DMAMUX_5_3_1 peripheral. Writing a '0' to this bit releases the reset to the DMAMUX_5_3_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

60.3.1.19 Peripheral Reset Register 6 (RGM_PRST6)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See *Table 1701* for details.

Address: 0x628 Access: User read, Supervisor read/write, Test read/write

Table 1701. RGM_PRST6 register field descriptions

Field	Description
0 DSPI_9_RST	DSPI_9 reset Writing a ‘1’ to this bit resets the DSPI_9 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_9 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
3 LINFLEXD_1_RST	LINFLEXD_1 reset Writing a ‘1’ to this bit resets the LINFLEXD_1 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 LINFLEXD_3_RST	LINFLEXD_3 reset Writing a ‘1’ to this bit resets the LINFLEXD_3 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
10 LINFLEXD_15_RST	LINFLEXD_15 reset Writing a ‘1’ to this bit resets the LINFLEXD_15 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_15 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_1 _CTR_RST	CAN_RAM_SUB_1_CTR reset It is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_1_CTR_RST bit Writing a ‘1’ to this bit resets the CAN_RAM_SUB_1_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_1_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
25 M_CAN_1 _SUB_1_RST	M_CAN_1_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 M_CAN_2 _SUB_1_RST	M_CAN_2_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1701. RGM_PRST6 register field descriptions (continued)

Field	Description
27 M_CAN_3 _SUB_1_RST	M_CAN_3_SUB_1 reset Writing a '1' to this bit resets the M_CAN_3_SUB_1 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_3_SUB_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 M_CAN_4 _SUB_1_RST	M_CAN_4_SUB_1 reset Writing a '1' to this bit resets the M_CAN_4_SUB_1 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_4_SUB_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

60.3.1.20 Peripheral Reset Register 7 (RGM_PRST7)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See *Table 1702* for details.

Address: 0x62C Access: User read, Supervisor read/write, Test read/write

Table 1702. RGM_PRST7 register field descriptions

Field	Description
0 SAR_ADC_12BIT_1_RST	SAR_ADC_12BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_12BIT_1_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 SAR_ADC_12BIT_3_RST	SAR_ADC_12BIT_3 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_3 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_12BIT_3_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 SAR_ADC_10BIT_1_RST	SAR_ADC_10BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. **Note:** This peripheral is coupled with RGM_PRST4.SAR_ADC_10BIT_1_SEQ_RST therefore they have to be identically set. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 PSI5_1_RST	PSI5_1 reset Writing a ‘1’ to this bit resets the PSI5_1 peripheral. Writing a ‘0’ to this bit releases the reset to the PSI5_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 ETHERNET_0_RST	ETHERNET_0 reset Writing a ‘1’ to this bit resets the ETHERNET_0 peripheral. Writing a ‘0’ to this bit releases the reset to the ETHERNET_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
23 SENT_1_RST	SENT_1 reset Writing a ‘1’ to this bit resets the SENT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SENT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1702. RGM_PRST7 register field descriptions (continued)

Field	Description
28 DSPI_1_RST	DSPI_1 reset Writing a ‘1’ to this bit resets the DSPI_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_3_RST	DSPI_3 reset Writing a ‘1’ to this bit resets the DSPI_3 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 DSPI_5_RST	DSPI_5 reset Writing a ‘1’ to this bit resets the DSPI_5 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Caution: Use the RGM_PRST*n* registers with care. See *Section 60.4.8: Individual peripheral resets* for the proper sequence to prevent unexpected chip behavior.

60.3.1.21 Peripheral Reset Status Register 0 (RGM_PSTAT0)

This register provides the current reset status for various peripherals. It can be accessed in read only in all modes. See *Table 1703* for details.

Address: 0x630 Access: User read/write, Supervisor read, Test read

60.4 Functional description

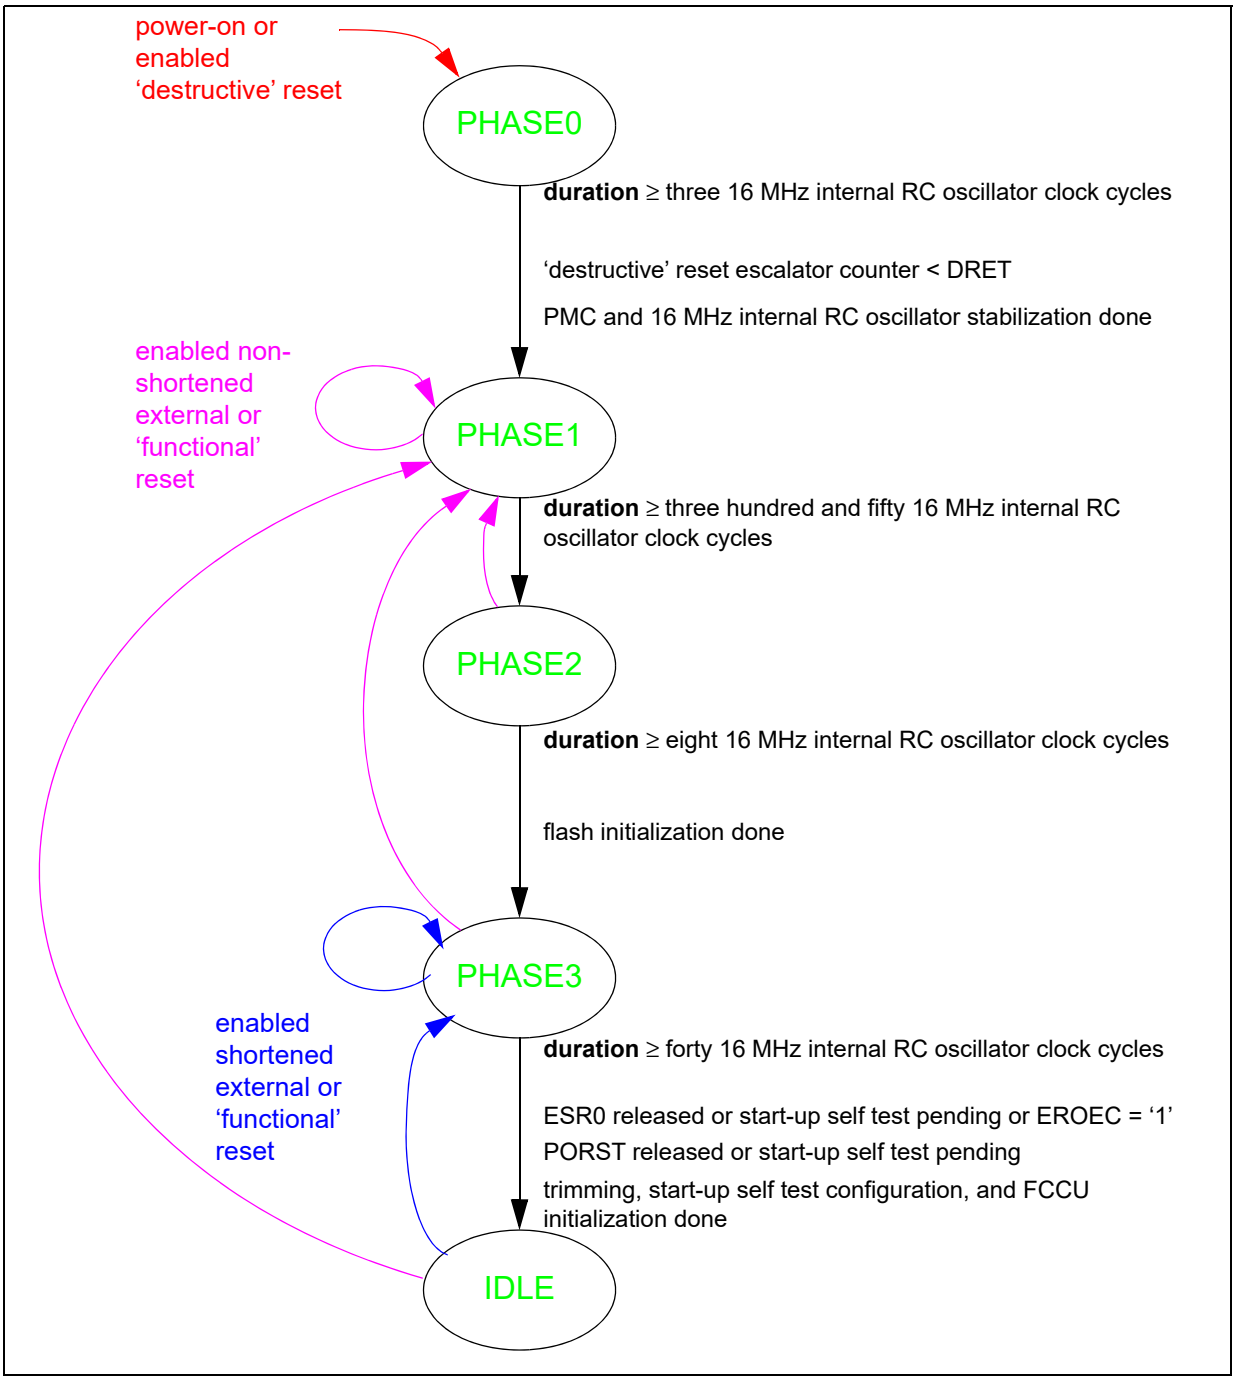
60.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in *Table 1711*.

Table 1711. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion(1)
power-on reset	all executes a start-up self test if enabled	yes
'destructive' resets	all except some clock/reset management executes a start-up self test if enabled	yes
long external (ESR0) reset	all except some clock/reset management and debug executes a start-up self test if enabled	programmable(2)
long external (ESR0) and long 'functional' resets	all except some clock/reset management, STCU, FCCU, and debug	programmable(2)
shortened 'functional' resets(3)	flip-flops except some clock/reset management, STCU, FCCU, and debug	programmable(2)

1. 'external reset assertion' means that the ESR0_B pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3
2. the assertion of the external reset is controlled via the RGM_FBRE register
3. the short sequence is enabled via the RGM_FESS register



Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and

until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in *Figure 1763*.

Figure 1763. MC_RGM state machine

60.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled ‘destructive’ reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled ‘destructive’ resets have been processed
- all processes that need to be done in PHASE0 are completed
  - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of three 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled ‘destructive’ reset event.
- the ‘destructive’ reset escalator counter has not reached the value in the RGM_DRET[DRET] field.

60.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or ‘functional’ reset event if it has not been configured to trigger a ‘short’ sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened ‘functional’ resets have been processed
- a minimum of three hundred and fifty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened ‘functional’ reset event

60.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
  - flash initialization
- a minimum of eight 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

60.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened ‘functional’ reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization
- a minimum of forty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened ‘functional’ reset event.
- ESR0 is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence or RGM_EROEC[EROEC] = 1.
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence.

60.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

60.4.2 ‘Destructive’ resets

A ‘destructive’ reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exceptions to the latter are the software ‘destructive’ reset and the external power-on reset which do allow the memory content to be preserved if the chip is configured to not execute a self-test on power-on, ‘destructive’, and external resets.

The status flag associated with a given ‘destructive’ reset event (RGM_DES.F_<destructive reset> bit) is set when the ‘destructive’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘destructive’ reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note: The RGM_DERD register can be written only once between two ‘destructive’ reset events.

The chip’s low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD or HVD, or both) is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled ‘destructive’ reset will trigger a reset sequence starting from the beginning of PHASE0.

60.4.2.1 External power-on reset – PORST

The bidirectional external power-on reset pin PORST is a special case ‘destructive’ reset.

The detection of a falling edge on PORST will start the reset sequence.

The chip asserts PORST if the reset sequence was triggered by one of the following:

- a power-on reset
- a ‘destructive’ reset event

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 us after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets, this is the exit of PHASE3 after self test execution has completed.

60.4.3 External reset

The MC_RGM manages the external reset coming from ESR0. The detection of a falling edge on ESR0 will start the reset sequence.

The status flag associated with the external reset falling edge event (RGM_FES.F_ESR0 bit) is set when the external reset is asserted and the power-on reset is not asserted.

Note: The RGM_FERD register can be written only once between two 'destructive' reset events.

An enabled external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_ESR0 is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the flash memory.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an external reset event if configured via the RGM_FBRE register to assert the external reset
- a 'functional' reset event configured via the RGM_FBRE register to assert the external reset

In this case, ESR0_B is asserted until all conditions for exiting PHASE3 have been met with the exception of the ESR0 assertion check.

If the OPT_RGM_ESR0_HW bit of the "UTEST Miscellaneous" DCF client is set to '0', the MC_RGM continues to assert ESR0 until the RGM_EROEC[EROEC] bit has been cleared by software.

In addition, the MC_RGM asserts ESR0 while the start-up self test is being executed.

The ESR0 input is disabled immediately as of the ESR0 output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the ESR0 output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

If ESR0_B is stopped being asserted by the MC_RGM and the 4 µs input mask period expires during the reset IDLE phase (for example due to the EROEC bit being cleared by software), and now a low value is detected on ESR0, an external reset falling edge event will not occur, and no new reset sequence will be triggered. For a new reset sequence to trigger, ESR0 must first be deasserted.

60.4.4 'Functional' resets

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (RGM_FES.F_<functional reset> bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given ‘functional’ reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note: The RGM_FERD register can be written only once between two power-on reset events.

An enabled ‘functional’ reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a ‘functional’ reset. When RGM_FESS.SS_<functional reset> is set, the associated ‘functional’ reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a ‘functional’ reset should not reset the flash memory module.

See *Chapter 65: Mode Entry Module (MC_ME)* for details on the DRUN mode.

60.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_DERD/FERD and RGM_DEAR/FEAR registers as shown in *Table 1712*.

Table 1712. MC_RGM alternate event selection

RGM_DERD/FERD bit value	RGM_DEAR/FEAR bit value	Generated event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (that is at the reset source that caused the alternate request) and also clearing the appropriate RGM_DES/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

If a masked ‘destructive’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any SAFE mode/interrupt request to the MC_ME.

If a masked ‘functional’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any SAFE mode/interrupt request to the MC_ME.

60.4.6 ‘Functional’ reset escalation

‘Functional’ reset escalation can be used to generate a ‘destructive’ reset if a number of ‘functional’ or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once ‘functional’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘functional’ or external reset which causes a reset sequence to be initiated (entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or ‘destructive’ reset. If the counter reaches the value in the RGM_FRET register’s FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

60.4.7 ‘Destructive’ reset escalation

‘Destructive’ reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of ‘destructive’ resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once ‘destructive’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘destructive’ reset[v] which causes a reset sequence to be initiated (entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register’s DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

60.4.8 Individual peripheral resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRST*n* registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRST*n* registers.
4. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is set.
5. Clear the bit corresponding to the peripheral in the RGM_PRST*n* registers.
6. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is cleared.

The peripheral can be kept in reset indefinitely by not executing steps *5.* and *6.*. After the completion of step *6.*, the peripheral can be enabled again via the MC_ME.

v. Only exception is the external power-on reset pin PORST that does not affect the increase of counter.

61 Boot Assist Flash (BAF)

61.1 Introduction

The BAF code is programmed by ST. The two main tasks of BAF are to provide a serial bootloader feature and to search for the application entry point.
For details regarding how the BAF code is executed, refer to *Chapter 8: Reset and Boot*.

The BAF is executed via the IRCOSC as clock source.

The MCU is booted through a collaboration of several blocks, hardware and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the HW boot core of the device pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. When the Life Cycle is set to FAIL_ANALYSIS, the BAF code shall check the UOPS[BAF_FA] bit inside SSCM as described in *Chapter 62: System Status and Configuration Module (SSCM)*. This bit mirrors the bit 31 of the UTEST_Miscellaneous_2 DCF. It tells whether the BAF shall stay in an endless loop or not when the Life Cycle is set to FAIL_ANALYSIS. In case the DCF is not programmed, the bit shall be 0 (refer to *Figure 1764*). Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module or the M_CAN module. The package pins used by LINFlexDs are the same pins used by the M_CAN modules. Hence, the external PHY can be either LIN or CAN (refer to *Section 61.3.9* for configuration details).

61.2 Memory map

For the BAF location in flash, refer to the Embedded memories chapter. The BAF block base address is 0x0040_4000. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in *Table 1713*.

Note: The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic '0' the BAF Flash block can not be programmed.

Table 1713. BAF memory organization

BAF Component	Address
BAF image header	0x0040_4000
BAF code entry point	0x0040_4100
BAF data area and stack	0x5280_0000–0x5280_0603

61.2.1 BAF image header

BAF image contains a 256-byte header starting from address 0x0040_4000. The BAF header is explained in *Table 1714*.

Table 1714. BAF image header

Address offset	Size (bits)	Field description
0x0000	32	SSCM boot record tag
0x0004	32	BAF start address
0x0008	32	BAF version number
0x000C–0x000F	Reserved	
0x0010	32	Part Clock Jitter Activation Constant
0x0014	32	Clock Jitter Activation Constant
0x0018–0x00FF	Reserved	

61.2.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0x0040_4000. The 32-bit field is explained in *Table 1715*.

Table 1715. BAF image version

Field	Description
0:7	Major Number: This field contains the major version number for the BAF image
8:15	Minor Number: This field contains the minor version number for the BAF image
16:31	Reserved

61.2.1.2 Clock Jitter Activation constant

The Clock Jitter Activation constant is a 32-bit flag, but the smallest element in flash that can be programmed is 64 bits, so the first 32 bits are reserved to allow programming of this constant. This 32-bit flag can be programmed by the customer and is used to activate the Clock Jitter feature that adds clock edge jitter to the baud rate clocks of several communications modules.As part of the BAF startup procedure, BAF copies this constant from flash to the PASS Clock Jitter Enable Register.

Table 1716. BAF Clock Jitter Activation Constant

Field	Description
0:31	Clock Jitter Activation Constant. The initial state of production disable flag is erased - 0xFFFF_FFFF. This equates to NO clock jitter.

61.3 Functional description

A functional description of the BAF modes is contained in the following sections.

61.3.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of these different boot modes.

- Application code execution

  If the internal flash contains application code with a valid boot header, the application is executed.

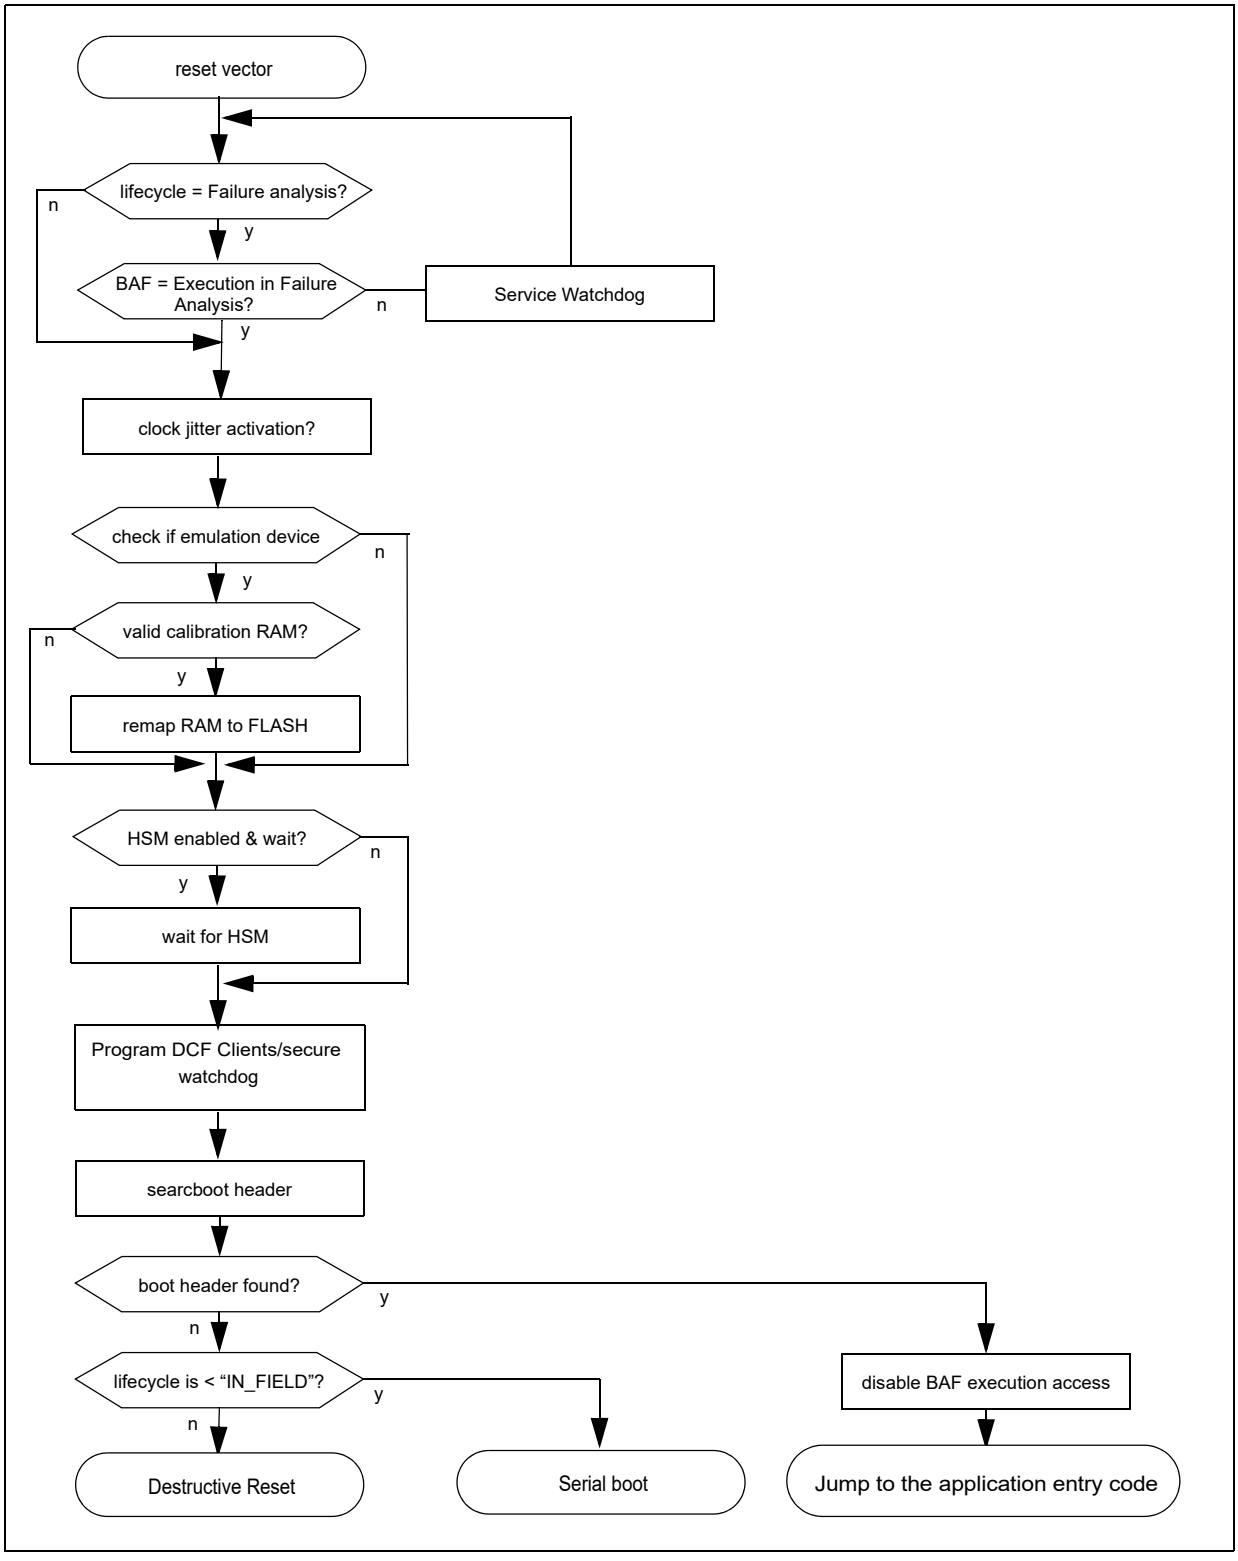
- Serial boot

  If no valid boot header is found and the current life cycle phase of the device is less than Infield, an attempt is made to download the application by a serial protocol using the LINFlexD modules or M_CAN modules. The downloaded code is then executed by the boot CPU.

- Static mode

  The device enters power safe mode and waits for an external reset.

61.3.2 Device initialization



The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the Hardware Security Module (HSM) in the following way:

- HSM: If the HSM is enabled and the “wait for HSM” flag is present, then the boot core waits for the HSM to become ready.
- BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module’s MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
- BAF uses DMEM memory area of the boot CPU as in *Table 1713: BAF memory organization* for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.
- The memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration. At this point the BAF has finished its operation.

61.3.3 Flow of control

Figure 1764 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

Figure 1764. Flow of control

61.3.4 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (SSCM_UOPS[HSB = 1]). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

61.3.5 Initialization of BAF DCF clients

61.3.5.1 'Soft' DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32 bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is 0xFFFF_FFFF). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in *Table 1717*.

The DCF clients which are used for initialization of security watchdog are explained in *Section 61.3.5.2: Security watchdog configuration*.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information.

The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in *Table 1717* provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside within the BAF or UTEST blocks only. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in *Section 61.3.5.6: SER_BOOT_CBACK – BAF serial boot DCF client*.

Table 1717. BAF DCF client list

Address (hex)	Name	Label	Description
0x0000	Security Watchdog Control Register	SEC_SWT_CR	Data to write to SWT Control Register
0x0001	Security watchdog Time out register	SEC_SWT_TO	Security watchdog counter value
0x0002	Security watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0x0003	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog
0x0004–0x01FF	Reserved		
0x0200	Address	ADDR	The address to which DATAX is written
0x0201	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0x0202	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0x0203	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0x0204–0x020F	Reserved		
0x0210	Callback Address	CALLBACK	The address of a callback function
0x0211	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0x0212–0x0213	Reserved		Reserved for future use.
0x0214	Reserved		Reserved for future use.
0x0215–0x7FFF	Reserved		Reserved for future use.

Note: BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

61.3.5.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then program the security watchdog registers. BAF configures only SWT2 as security watchdog for the CPU2 core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

61.3.5.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0000 while parsing, BAF programs the DCF client "Security watchdog control register" with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

61.3.5.2.2 Security Watchdog TImeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

61.3.5.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in 'fixed address execution service mode'. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0x0002 while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

Note: To program the core IAC8 special purpose register, the ownership of this register should be with software. If hardware has its ownership software will not be able to write to it using mtspr instruction.

61.3.5.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to BAF which CPU will use the security watchdog. BAF parses the DCF record and if it finds a record with CS14 set and address field set as 0003h, BAF programs this DCF client. This means that BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. *Figure 1765* and *Table 1718* indicate the data layout for this client in the DCF record. This client is written once during reset. Subsequent writes are ignored.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients are not written, data is configured erroneously.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). If the security watchdog is assigned to CPU2 (IOP), first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

DCF Client Address 0x0003

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				0				0			

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				0	0	SC	

Figure 1765. SEC_SWT_CPU bit configuration

Table 1718. SEC_SWT_CPU field description

Field	Description
30:31 SC	These two bits select the CPU which will use the security watchdog. 00 Reserved 01 Reserved 10 CPU2 (IOP) 11 Reserved

Note: BAF programs FCCU for enabling SWT2 and SWT3 as fault source and makes them hardware recoverable. This is done to ensure that fault latched in FCCU get cleared on reset and on next SWT timeout FCCU can again trigger reset. BAF does not clear the faults latched in FCCU as they can be of interest for application.

61.3.5.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0x0200 while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

DCF Client Address 0x0200

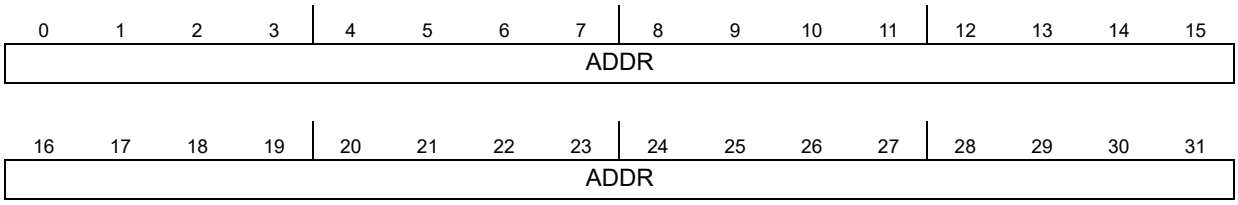


Figure 1766. BAF DCF ADDR client configuration

Table 1719. BAF DCF ADDR client description

Field	Description
0:31 ADDR	32-Bit Address DCF client This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU.

61.3.5.4 BAF DCF client - DATAX

Caution: While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

61.3.5.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0201 while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

DCF Client Address 0x0201

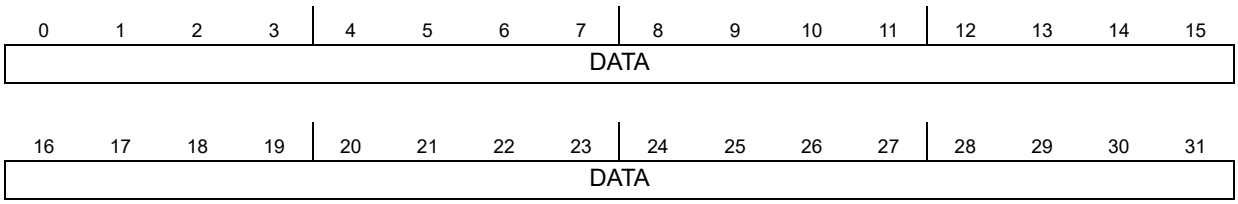

Figure 1767. DATA32 DCF client configuration

Table 1720. DATA32 DCF client configuration

Field	Description
0:31 DATA	32-Bit DCF data

61.3.5.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0202 while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to ‘0’ (Only 16-bit aligned

writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

DCF Client Address 0x0202

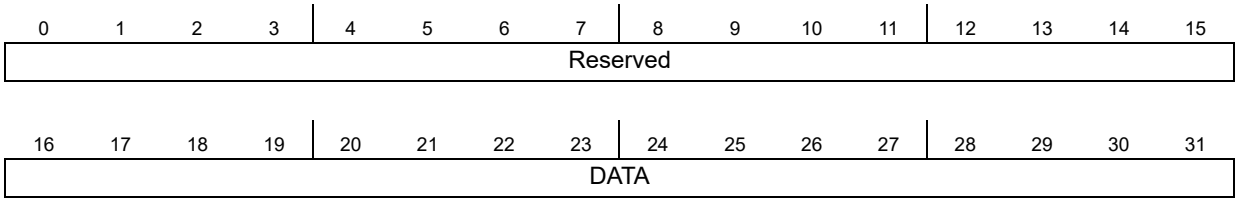

Figure 1768. DATA16 DCF Client Configuration

Table 1721. DATA16 DCF client configuration

Field	Description
16:31 DATA	16-Bit DCF data

61.3.5.4.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0203 while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

DCF Client Address 0x0203

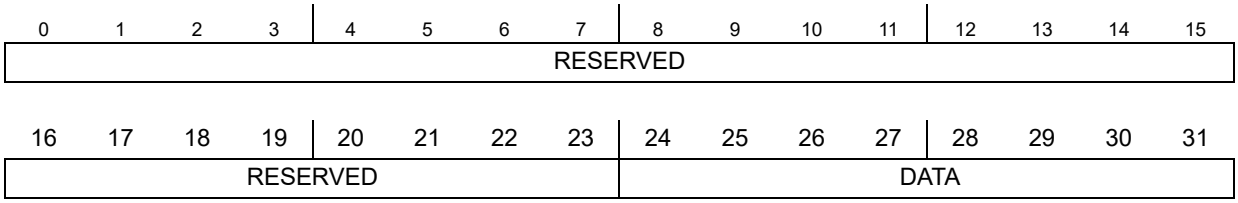

Figure 1769. DATA8 DCF Client Configuration

Table 1722. DATA8 DCF client configuration

Field	Description
24:31 DATA	8-Bit DCF data

61.3.5.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0210 while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in Power Architecture web site and

to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Caution: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore, several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

61.3.5.6 SER_BOOT_CBACK – BAF serial boot DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0211 while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32 bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in over Architecture web site and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: No parameters are passed to the function invoked by the BAF.Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed (refer to *Table 1723* for details regarding return value).

Table 1723. Serial boot callback function return value definition

Return values	Description
0x00	Boot from internal flash using standard search for boot record (refer to ‘Search boot header and boot options’ in *Chapter 7: Device configuration*).
0x01	Serial boot using both M_CAN and LINFlexD (in UART mode) (refer to ‘Search boot header and boot options’ in *Chapter 7: Device configuration*). **Note:** Serial boot is conditioned by life cycle as described in *Figure 1764*

61.3.6 Production disable activation protocol and implementation

Module failure analysis is a standard requirement. But some OEMs have an additional requirement that upon entering failure analysis mode, the MCU operation is modified in such a way that the MCU can never be used in production ECU. The chosen operational modification for production disable is to apply clock jitters to can modules so that it prevents active communications with another can device on a can network. For detail regarding production disable refer to the PASS chapter.

The BAF maintains a 64-bit flag in BAF code flash region as explained in *Section 61.2.1.2: Clock Jitter Activation constant*. On every POR BAF copies the clock jitter activation constant from this flag to clock jitter enable register in PASS module to enable jitters on can baud clock. Default value of this flag is shown in *Section 61.2.1.2: Clock Jitter Activation constant*. Hence, jitter on the MCAN baud clock is disabled if the default value is used. To enable jitter on can clock the value of this flag should be modified to 0xFFFF_FFFE.

The BAF flash memory is write protected and locked. To enable modification of this flag and activate production disable feature, BAF implements production disable activation protocol as explained in *Table 1725*. BAF implements this protocol in a power.ORG EABI compliant callback routine. This callback routine can be invoked by programming a callback based soft DCF client as explained in *Section 61.3.5.5: CALLBACK – BAF callback DCF client*. The callback function address is shown in *Table 1724*.

Table 1724. Production Disable Callback routine entry point

Description	Address
Production disable protocol callback function address	0x0040_40E0

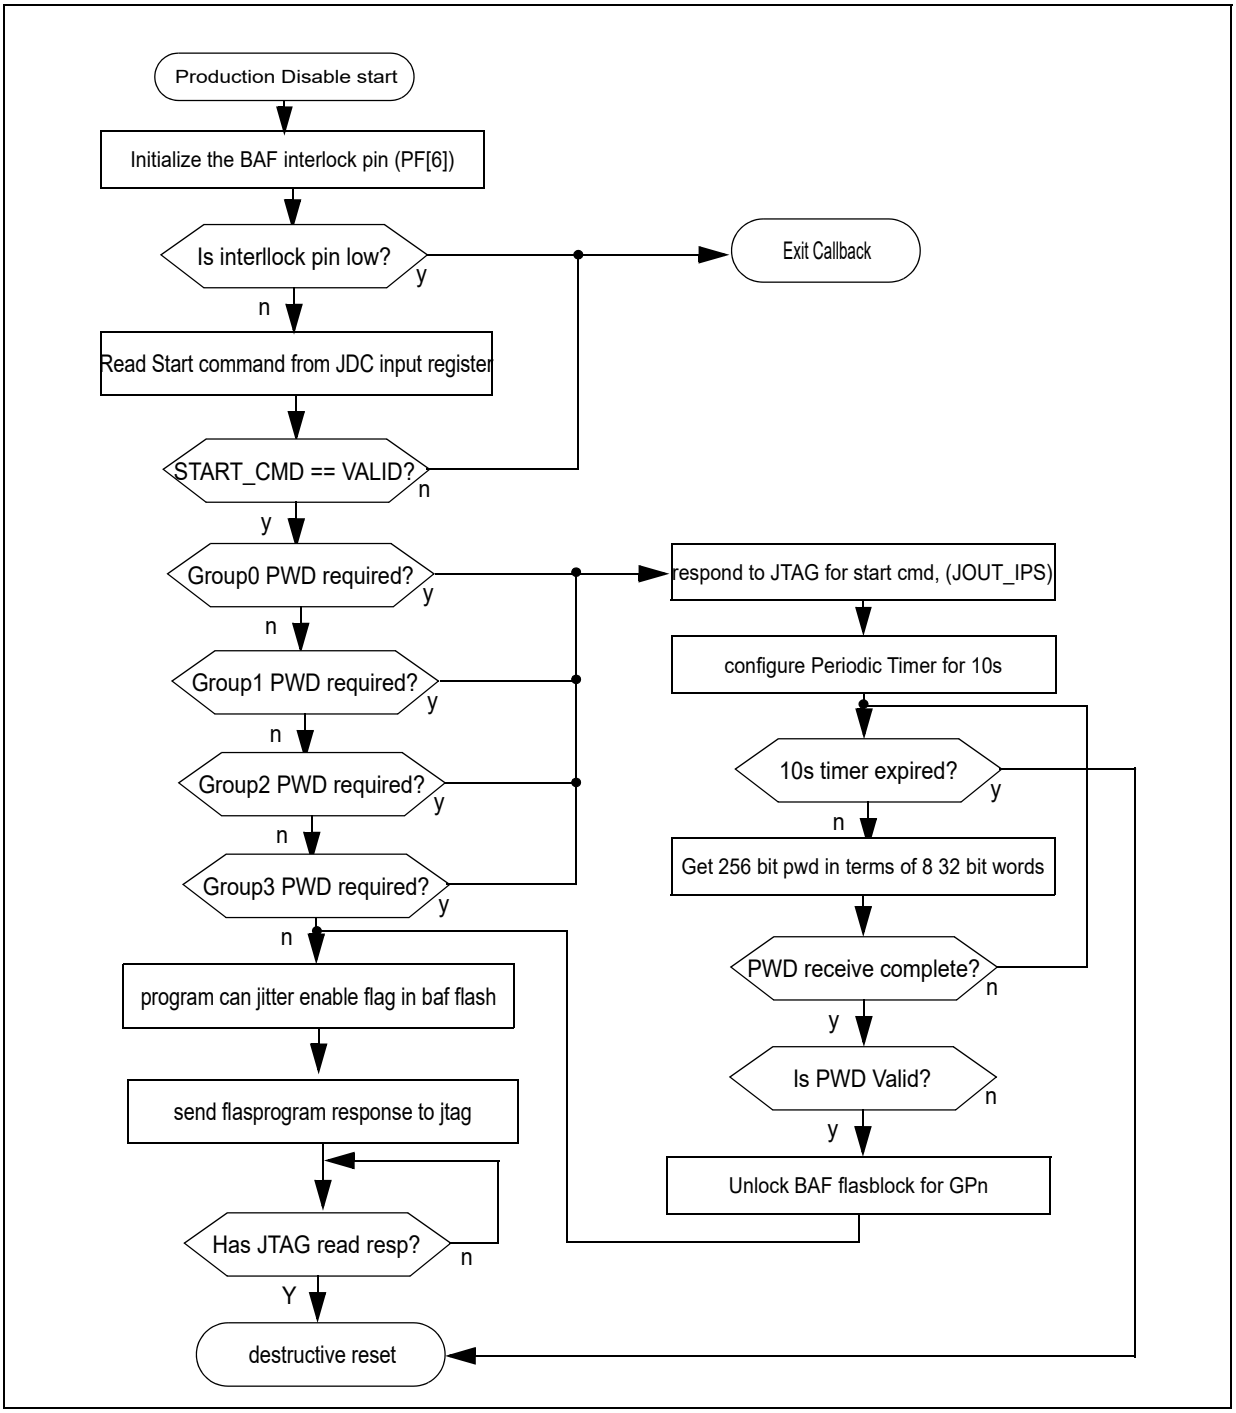

Table 1725. Production Disable protocol description

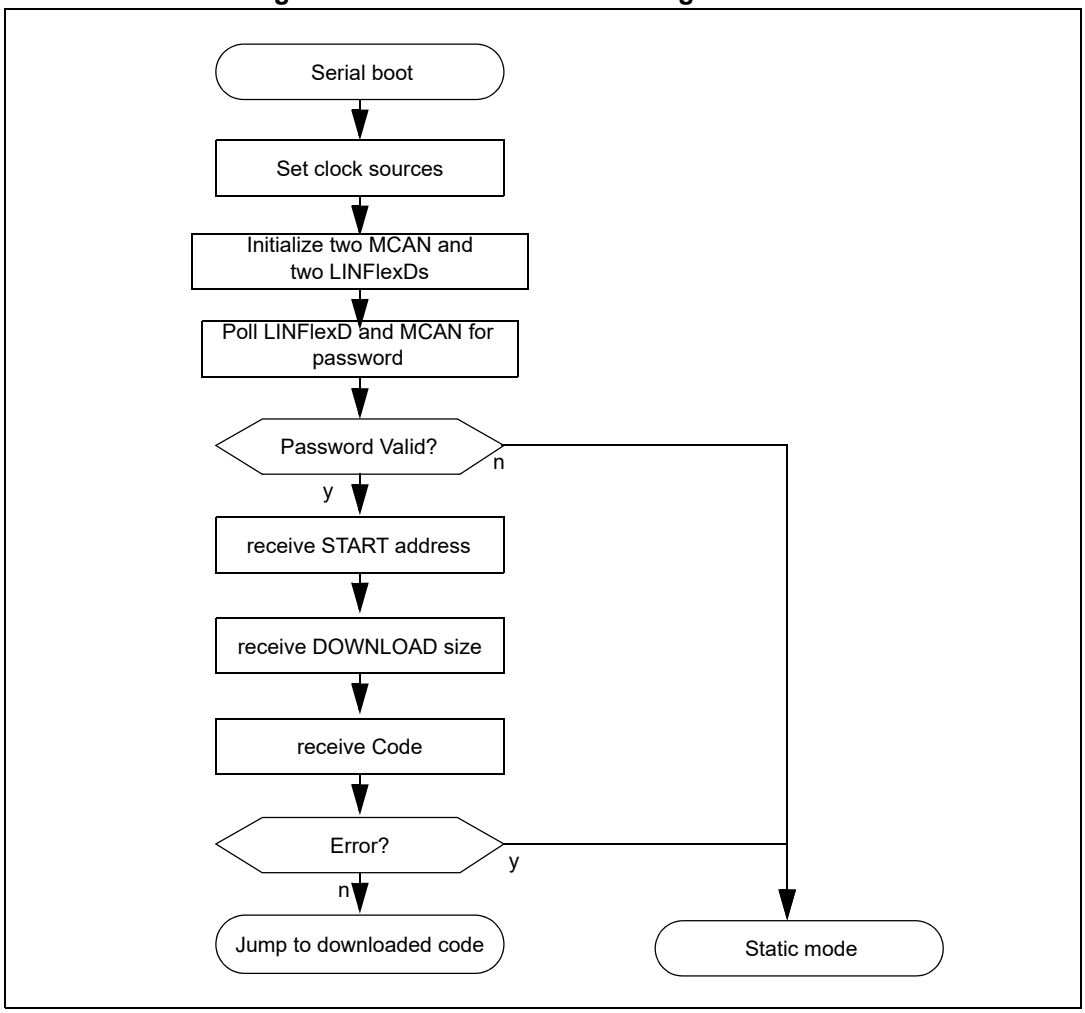
Step	Description	Tool Action/Response	MCU Action/Response
1	After power-on tool holds the MCU in reset and writes the activation code to JDC via JTAG interface. The tool pulls hardware interlock pin high, then releases reset.	Assert hardware interlock pin Write 0xF5A0_AA55 to JDC	Starts production disable activation
2	The MCU responds by writing to the JDC an acknowledgment code and which of the 4 PASS passwords are required to unlock the BAF flash block		Write 0xFA50_000*n* to JDC if password for pass group n is required to unlock the BAF flash block. (n is either 0,1,2 or 3)
3	The tool reads the acknowledge from JDC module and writes the relevant password to the JDC module. MCU performs password comparison and writes error code to JDC module password provided by tool was incorrect.	Read JDC Write 256 bit password for pass group n to JDC in eight 32 bit words. (n is 0,1,2 or 3)	Write 0xFA50_F00*n* if password does NOT match. Once the status has been read by the tool then cause reset. (n is either 0,1,2 or 3)

Table 1725. Production Disable protocol description (continued)

Step	Description	Tool Action/Response	MCU Action/Response
4	If more than one password is required to unlock the BAF flash block step 2 and step 3 are repeated until all relevant password has been supplied.		If password matches step 2 and step 3 are repeated for the next pass group until all pass group that lock BAF flash has been processed.
5	The MCU then attempts to program the can jitter activation constant within the BAF flash block. The can jitter activation constant flag is a write once flag. Once written it cannot be re-programed as BAF flash block is OTP. MCU write a code to JDC to signal success or failure of flash programming operation and issue reset.		Program can jitter activation constant in BAF flash block. If successful write 0xFA51_0000 to JDC. If unsuccessful write 0xFA51_F000 to JDC Issue reset.

Figure 1770. Production Disable callback function flow chart

61.3.7 TDM Diary Operation



On every reset, BAF copies the first four bytes of last record of every Tamper Detect Region to corresponding Software Tamper Override Key Region Registers in TDM. BAF reads the base address of TDM Diary from DBA register in TDM. For more details on TDM refer to the corresponding section. This is done as a part of TDM Diary Override enhancement.

61.3.8 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than In Field, it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

If the customer selects serial boot using serial boot using serial boot DCF client, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than Failure Analysis, it attempts a serial boot.

Figure 1771. Flow of control during serial boot

The clock source in the MC_CGM is configured (with IRCOSC for LINFlexD and with XOSC for CAN) and the PADs are set up for two LINFlexDs and two M_CANs signals, then the code is downloaded using LINFlexD or M_CAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via LINFlexD or M_CAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At start of serial boot sequence the Rx-channels of all two serial interfaces shall be enabled and the BAF code shall take care for polling all two Rx-channels for detecting the valid serial boot message. After a successful detection of the active Rx-channel the corresponding Tx-channel shall be enabled and the inactive Rx-channel shall be disabled.

At the start of the process both LINFlexDs and M_CANs are configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and does not participate further in serial boot.

If a CAN message of 8 bytes with ID 0x11 is received on the M_CAN controller first, the BAF program

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message not containing 8 bytes or NOT with ID 0x11 is received by M_CAN controller or a M_CAN controller generates a CAN error, it is probable that the tool is sending a LINFlexD frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is 0xFE of the password. If not continue polling. The data may be a valid CAN message.
- If it is first byte of the password (0xFE) then disable the M_CAN controller and restore to its reset state.
- Configures the M_CAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

61.3.8.1 Serial boot mode protocol

From a high-level perspective, the download protocol over M_CAN and LIN interfaces follows the steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.

   NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Note: Since this device supports only VLE code and no Book E code, the VLE bit is used only for backward compatibility.

3. Host transmits a sequence of data bytes that are to be executed.
4. The boot CPU executes code from start address provided in step 2.

Each step must be completed before the next step starts.

The exact protocol between LINFlexD and M_CAN are slightly different.

61.3.8.2 LINFlexD download protocol

The communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   – If the data is correct, the host can send the next byte of data.
   – If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. *x* bytes of code that is downloaded to SRAM and executed (*x* must match the value specified in step *3.*).

61.3.8.3 M_CAN download protocol

The M_CAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by M_CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 0x11 as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 0x1.
2. A message with 0x12 as the ID and 8-byte length to send the start address, size of the code and VLE mode bit.The MCU transmits back the same data but with an ID of 0x2.
3. A message with 0x13 as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 0x3.

61.3.8.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password 0xFEED_FACE_CAFE_BEEF.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

61.3.8.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in *Figure 1772* and *Figure 1773*.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

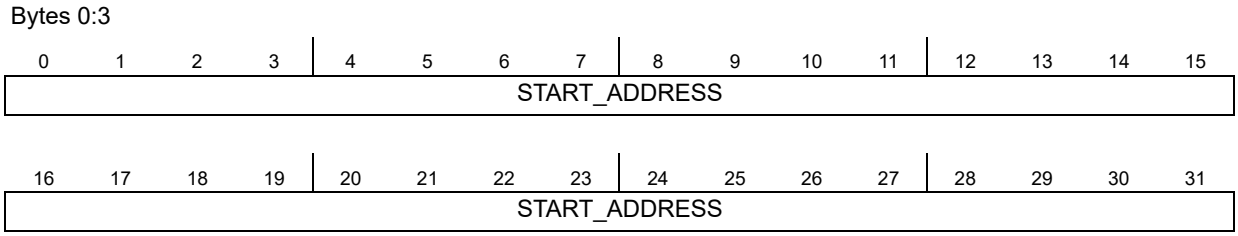


Figure 1772. Start address

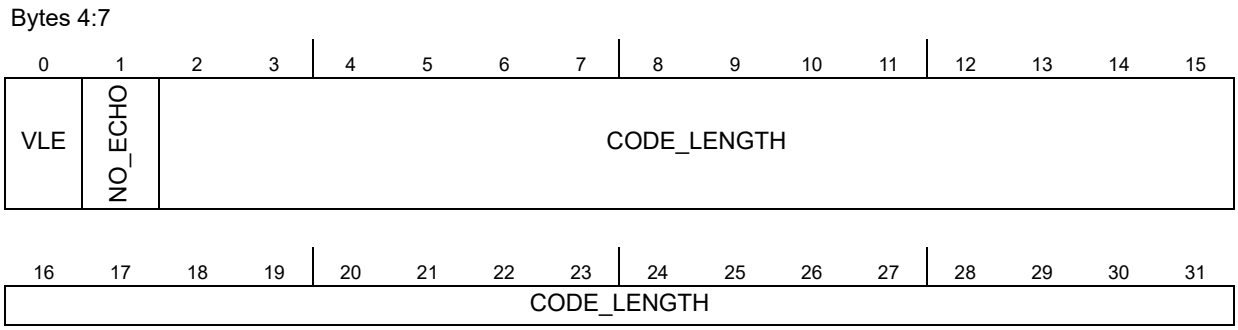

Figure 1773. VLE bit, NO_ECHO bit and code size

61.3.8.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero's and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0x0000_0000_0000_0000) to the next address location. This is written to avoid possible ECC error during core prefetch.

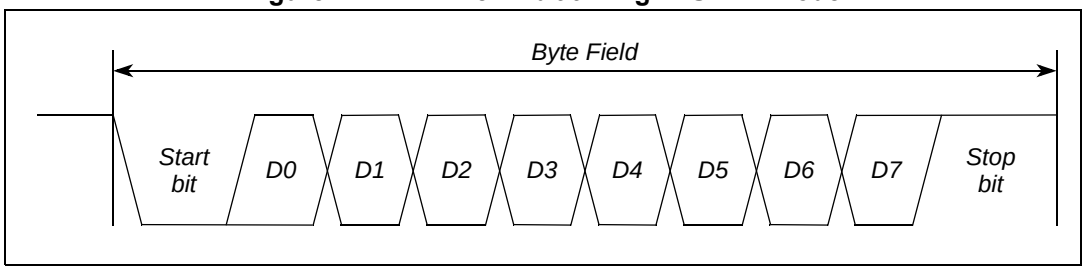
61.3.8.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

61.3.9 Serial boot configuration

61.3.9.1 LINFlexD configuration

Boot using UART protocol is implemented by LINFlexD module.



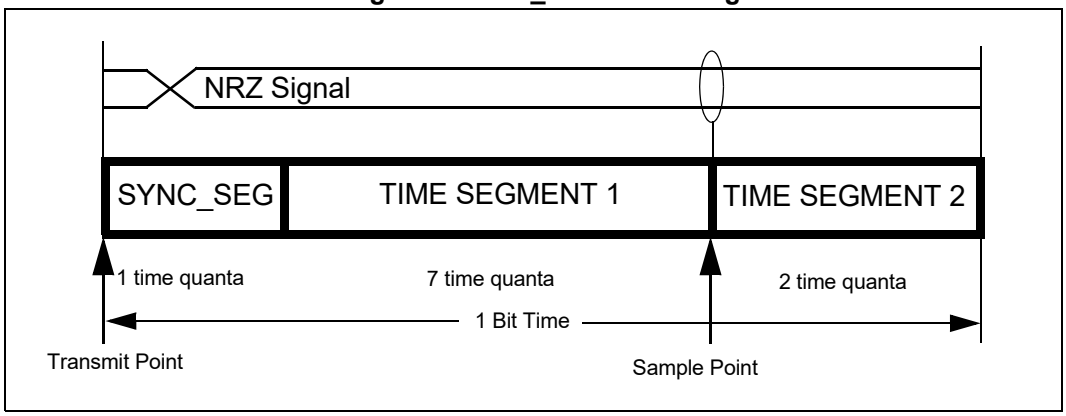
Note: Refer to the pin configuration table in Chapter 7: Device configuration for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx is configured as an input and multiplexed to the LINFlexD module. The LINFlexD_Tx remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data . The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx pin transmission.

The LINFlexD controller is configured to operate with an 8-bit data frame without parity bit and 1 stop bit.

Figure 1774. LINFlexD bit timing in UART mode



61.3.9.2 M_CAN configuration

The M_CAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0A specification (refer to *Table 1726* for baud rates).

The Bit timing is configured as shown in *Figure 1775*

Figure 1775. M_CAN Bit Timing

61.3.9.3 Baud rates

The LINFlexD baud rate is set at 250kbaud. *Table 1726* below shows some possible baud rates.

The M_CAN baud rate is set by the frequency of the external crystal/40.

Table 1726. M_CAN baud rates

Frequency	M_CAN baud rate
8 MHz	200 Kbaud
12 MHz	300 Kbaud
16 MHz	400 Kbaud
20 MHz	500 Kbaud
40 MHz	1000 Kbaud

61.3.9.4 LINFlexD and M_CAN pin configuration

Refer to *Chapter 7: Device configuration* for pin details.

61.3.9.5 Protocol summary

Table 1727 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 1727. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is not echoed, otherwise data is echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	None	None	Branch to downloaded code

Table 1728 shows the M_CAN serial boot protocol.

Table 1728. M_CAN serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	CAN ID 0x011 + 64-bit password	CAN ID 0x001 + 64-bit password	Password checked against fixed password (0xFEED_FACE_CAFE_BEEF). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 0x012 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	CAN ID 0x002 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 0x013 + 8 to 64-bits of raw binary data	VLE bit + 31 bit number of bytes (MSB first)	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	None	None	Branch to downloaded code

61.4 Resources accessed by BAF code execution

The BAF code execution uses several IPs to achieve the main functions.

- Magic carpet (clocks)

Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD and M_CAN

The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.

- PFLASH

PFLASH module is used to disable BAF execution. Remapping of the external overlay memory is configured automatically under certain conditions. The two PFLASH are used.

- Interrupts

No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.

- Security watchdog

When SWT2 is chosen as security watchdog, SWT3 is used for task monitoring purpose.

- FCCU

FCCU is used to configure Fault Reaction of SWT2 and SWT3.

- TDM

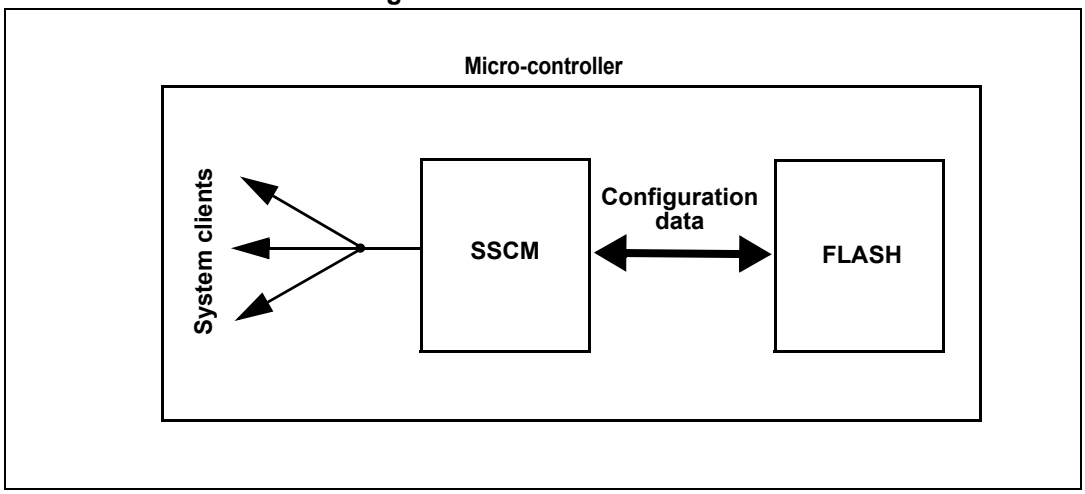
TDM for implementing TDM Diary enhancements.

- SSCM

Used to read some register bits (mirrors of DCF)

- PASS

Used for clock jitter enabling



62 System Status and Configuration Module (SSCM)

62.1 Introduction

62.1.1 Overview

The System Status and Configuration Module (SSCM) is aimed at reading the system configuration from the Flash and distributing to various clients inside the micro-controller, pictured in *Figure 1776*.

Figure 1776. SSCM overview

62.1.2 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Determine HSM boot vector
  - Decodes the Device Life Cycle

62.1.3 Modes of operation

The SSCM operates identically in all system modes.

62.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

Table 1729 shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Note: All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit

boundaries. As an example, the STATUS register is accessible by a 16-bit READ/WRITE to address Base + 0x0002, but performing a 16-bit access to Base + 0x0003 is illegal.

Table 1729. SSCM memory map

Address offset	Register	Access	Reset value	Section
0x0000	SSCM System Status (STATUS)	R/W	0xyyy0(1)	*Section 62.2.1.1*
0x0002	SSCM System Memory and ID Register (MEMCONFIG)	R	0xyyyy(1)	*Section 62.2.1.2*
0x0004–0x0005	Reserved			
0x0006	SSCM Error Configuration Register (ERROR)	R/W	0x0000	*Section 62.2.1.3*
0x0008–0x0009	Reserved(2)			
0x000A–0x001C	Reserved			
0x0020	SSCM HSM and User Option Status Register (UOPS)	R	0xyyyy_yyyy(1)	*Section 62.2.1.4*
0x0024–0x0027	Reserved			
0x0028	Processor Start Address Register (PSA)	R	0xyyyy_yyyy(1)	*Section 62.2.1.5*
0x002C–0x002F	Reserved			
0x0030	SSCM HSM Start Address Register (HSA)	R	0xyyyy_yyyy(1)	*Section 62.2.1.6*
0x0034	Life Cycle Status Register (LCSTAT)	R	0x0000_0y0y(1)	*Section 62.2.1.7*
0x0038–0x004F	Reserved			

1. Refer to register description for reset value details.
2. No register abort on this location.

62.2.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

62.2.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CER	0	NXEN1	NXEN	1	0	0	BMODE			VLE	0	0	0	0
W		w1c														
Reset	0	0	0	-(2)	-(2)	1	0	0	-(2)			-(1)	0	0	0	0

1. Reset value depends on the associated option bits in flash memory.
2. Reset value depends on the device status after leaving reset.

Figure 1777. System Status Register (STATUS)

Table 1730. STATUS field descriptions

Field	Description
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error while loading DCF clients (with PARITY Enabled). This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
8:10 BMODE	Device Boot Mode 000 Reserved 001 Reserved 010 Reserved 011 User Code Boot (BAF not executed) 100 Reserved 101 BAF Code Boot (BAF executed) 110 Reserved 111 Reserved This field is only updated during reset.
11 VLE	Variable Length Instruction Mode When booting in User Code Boot mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0 User Code Boot Location contains standard PPC code 1 User Code Boot Location contains VLE code

62.2.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Offset: 0x0002 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	1	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0

1. Reset value reflects the JTAG ID of the device.

Figure 1778. System memory and ID register (MEMCONFIG)

Table 1731. MEMCONFIG field descriptions

Field	Description
0:9 JPIN	JTAG Part ID Number
11:14 MREV	Minor Mask Revision

62.2.1.3 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Offset: 0x0006 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1779. Error Configuration Register (ERROR)

Table 1732. ERROR field descriptions

Field	Description
14 PAE	Peripheral Bus Abort Enable This bit enables bus aborts on: – any access to a peripheral slot that is not used on the device. – illegal accesses to off-platform peripherals. On platform peripherals cannot be controlled by SSCM peripheral abort. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
15 RAE	Register Bus Abort Enable This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception **Note:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the PBRIDGE level). In this case, the PAE and RAE register bits have no effect on the abort.

62.2.1.4 HSM and User Option Status Register (UOPS)

Offset: 0x0020 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	BAF_FA	0	FL_RUN	0	0	0	0	0	0	0	0	0	HSB			HSE
W																
Reset	0/1(1)	0	0	0	0	0	0	0	0	0	0	0	0/1(1)	0/1(1)	0/1(1)	0/1(1)

1. Values are determined by DCF record and life cycle - default is 0.

Figure 1780. HSM and User Option Status Register (UOPS)

Table 1733. UOPS field descriptions

Field	Description
16 BAF_FA	BAF execution mode when bypass mode DCF is zero and lifecycle is FA 0 BAF enters an infinite loop 1 BAF executes as normal **Note:** This bit is mirrored from bit 31 of the UTEST_Miscellaneous_2 DCF client.
18 FL_RUN	Code flash on during RUNx mode, despite MC_ME programming 0 Code Flash can be switched off in RUNx mode, if programmed in MC_ME.MC_DRUx.CFLAON 1 Code Flash can be switched off in RUNx mode, even if programmed in MC_ME.MC_RUNx.CFLAON **Note:** This bit is mirrored from bit 29 of UTEST_Miscellaneous_2 DCF client. When this bit is set, writing on MC_ME.MC_RUNx.CFLAON has no effect.
28:30 HSB	HSM Boot Configuration 001 When the device is in BAF Code Boot mode, BAF waits for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM waits for HSM ready flag before allowing application code to start. Others: When the device is in BAF Code Boot mode, BAF will not wait for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM will not wait for HSM ready flag before allowing application code to start. This field can be set via DCF record (refer to the SPC58xNx Microcontroller Security Reference Manual for the HSM details).
31 HSE	HSM Enabled This bit is set to 1 if HSM is enabled via DCF record.

62.2.1.5 Processor Start Address Register (PSA)

Table 1735. HSA field descriptions

Field	Description
0:31 HADR	HSM Start Address HSM will start executing application code from this address. The value of this register is determined by the HSM boot header search.

62.2.1.7 Life Cycle Status Register (LCSTAT)

Offset 0x0034 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	LC		
W																
Reset	0	0	0	0	0	0	0/1(1)	0/1(1)	0	0	0	0	0	0/1(2)	0/1(2)	0/1(2)

1. Reset value reflects the Test Life Cycle of the device.
2. Reset value is the Life Cycle of the device.

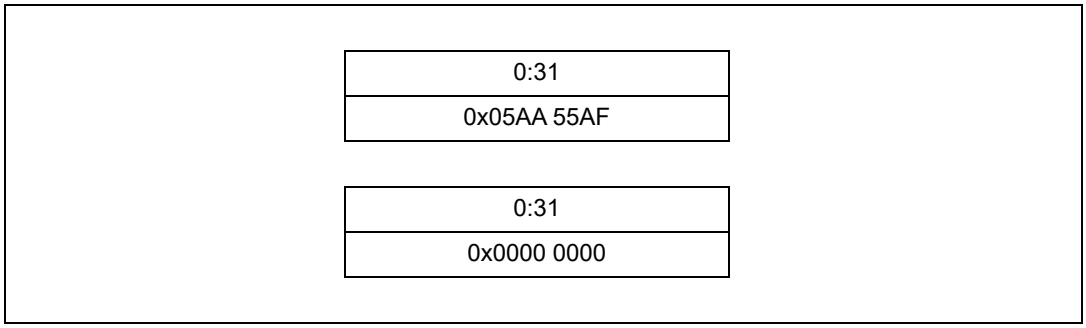
Figure 1783. Life Cycle Status Register (LCSTAT)

Table 1736. LCSTAT field descriptions

Field	Description
29:31 LC	Life Cycle As determined by the SSCM by reading the LC slots. The encoding is: 000 FAIL_ANALYSIS 001 Reserved 010 PROD_OEM 011 CUST_DELIV 100 Reserved 101 Reserved 110 ST_PROD 111 IN_FIELD

62.3 Functional description

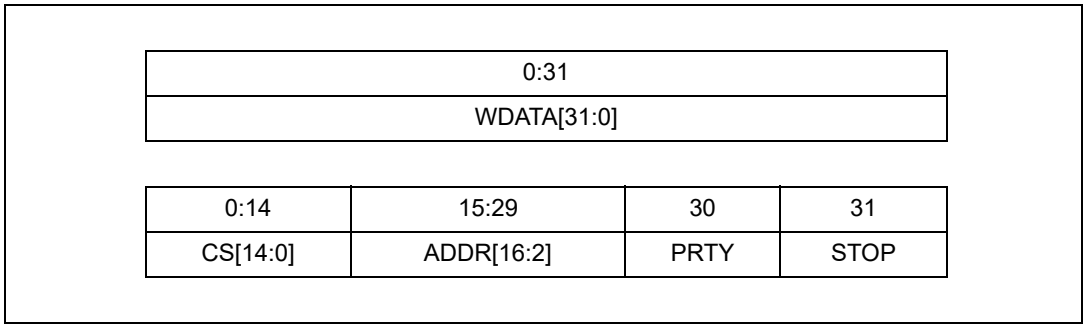
The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.



62.3.1 DCF mechanism

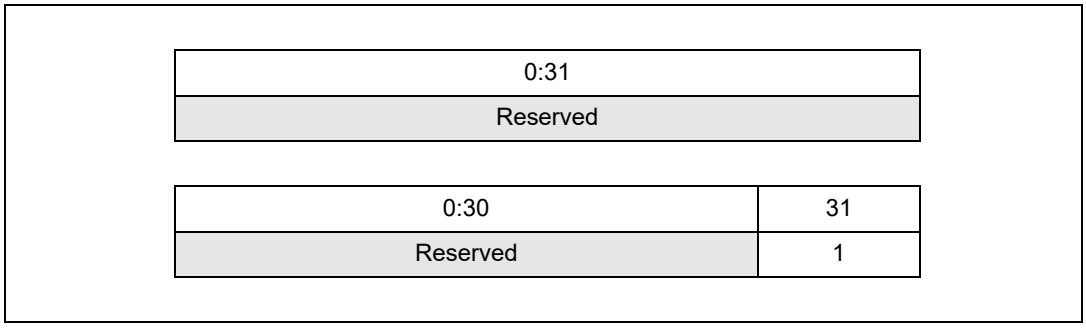
The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.



Each record is 64 bits in length. *Figure 1784* shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Figure 1784. DCF start record

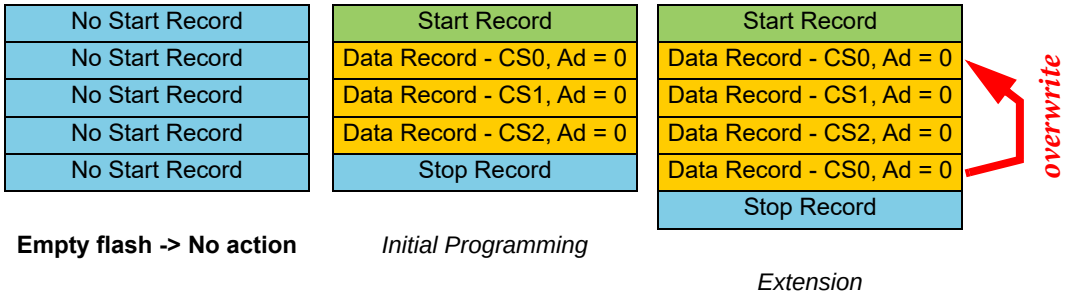


The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - refer to *Figure 1785*. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Figure 1785. Format of a DCF data record

The stop record indicates that processing should stop. The general format of the stop record is shown in *Figure 1786*. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Figure 1786. DCF stop record



If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 1737*.

Table 1737. Series of DCF records in UTEST

ADDR offset	DATA			
0x00	0x05AA_55AF			
0x04	0x0000_0000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8n - 1 + 0x0	Reserved			
8n - 1 + 0x4	Reserved			1
8n + 0x0				
8n + 0x4				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 1787*.

Figure 1787. Appending DCF records

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0x0000_0001 then the PRTY field needs to be set to '1', so that the total number of 1s is even).

62.3.2 ECC error monitoring

During flash memory scanning (such as Life Cycle or DCF records), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs the SSCM will request a destructive reset.

62.3.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

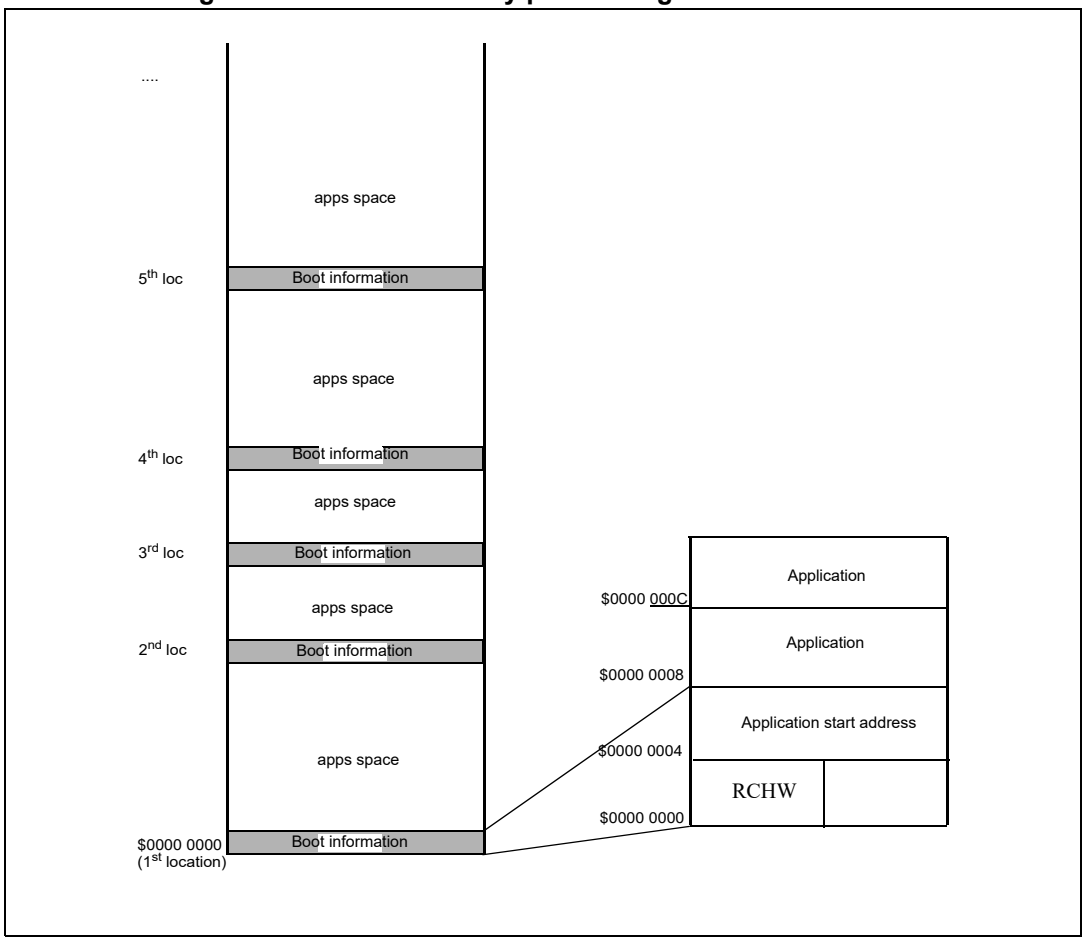
- User Code Boot mode (SSCM): the device will boot from the first bootable section of the flash memory main array (BOOT_ID = 0x5A).
- BAF Code Boot: the device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup (BOOT_ID = 0xA5).

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location for SSCM and BAF, that is 0x5A and 0xA5 respectively) then the device will enter serial boot mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. Refer to *Section 62.3.6: HSM boot header search* for details.

62.3.4 BAF configuration

In BAF Code Boot mode the boot core will start to execute the BAF code at the location provided in the “Embedded Flash Memory” chapter (TestFlash block memory map). The BMODE field in the SSCM status register will be set to the value 0b101. Details of the BAF operation are described in the BAF chapter.



62.3.5 User code boot sector search

62.3.5.1 Potential boot sectors

As shown in *Figure 1788* in User Code Boot mode, several locations are searched for a valid boot ID. The lowest sector which starts with a valid boot ID will be used to boot the device.

The flash memory locations that are searched for boot information are shown in the “Reset and Boot” chapter (section “HW boot record search (SSCM search)”).

Figure 1788. Flash memory partitioning and RCHW search

62.3.5.2 Reset Configuration Half-Word

For each boot sector in the flash memory, SSCM checks the content of the Reset Configuration Half-Word (RCHW) at offset 0x00. If the RCHW field BOOT_ID holds the value 0x5A then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. (If a device only supports VLE code for future compatibility the flag must always be set to '1'.) All other bits are reserved.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	VLE	BOOT_ID							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Reserved

Figure 1789. Reset Configuration Half-Word

Once the device detects that it needs to boot from flash memory, and finds a valid BOOT_ID, it will boot from the application start address at offset 0x04 within the boot sector.

62.3.6 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (refer to the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.
The HSM Boot Header has the format as described in *Figure 1790*.

Figure 1790. Boot header structure

0x00	Boot Header ID	
0x08	Reserved	Start Address
10x0	Reserved for Configuration Bits	

A valid Boot Header ID has the value 0xFFFF_0000_FFFF_0000.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0x0000_0000_0000_0000. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

62.3.7 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from UTEST flash memory area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- ST Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 256 bits each, at fixed locations in UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- The valid field
- The invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 status:

Table 1738. Life Cycle slots

Use case	Offset	LC slot	Valid field (128 bits)		Invalid field (128 bits)		LC slot status
1	0x00-0x10	1	Erased	Erased	Erased	Erased	Erased
2	0x00-0x10	1	Marked	Erased	Marked	Erased	Inactive
3	0x00-0x10	1	Marked	Erased	Erased	Erased	Active
4	0x00-0x10	1	Any other value				Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 0x55AA_50AF_55AA_50AF, “Erased” is detected by the bit pattern 0xFFFF_FFFF_FFFF_FFFF.

Table 1739 shows how the slots are arranged in memory.

Table 1739. Life Cycle Slots in Memory

Offset	LC Slot word
0x00 - 0x07	Valid[63:0]
0x08 - 0x0F	Don't care

The Life Cycle is determined as shown in *Table 1740*. The priority of the entries is from top to bottom, so the first row which applies determines the resulting Life Cycle.

Table 1740. Resulting Life Cycle

LC Slot 0 ST_PROD(1)	LC Slot 1 CUST_DEL(1)	LC Slot 2 OEM_PROD(1)	LC Slot 3 IN_FIELD(1)	LC Slot 4 FA(1)	Resulting LifeCycle
Active	Erased	Erased	Erased	Erased	ST Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	*Inactive*	**Active**	Erased	Erased	OEM Production
Inactive	*Inactive*	*Inactive*	**Active**	Erased	In Field
Inactive	*Inactive*	*Inactive*	*Inactive*	**Active**	FA
Any other combination				Erased	In Field
Any other combination					System Reset

1. Erased = all slot bits at ‘1’

62.4 Initialization and application information

62.4.1 Reset

The reset state of each individual bit is shown within the Register Description section (refer to *Section 62.2.1: Register descriptions*).

62.5 Additional safety measures

62.5.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the MC_RGM. In case of a spurious reset the SSCM will not interfere with the flash memory bus or overwrite configuration registers. Status internal to the SSCM will be lost, however.

63 Power management controller digital interface (PMC_Dig)

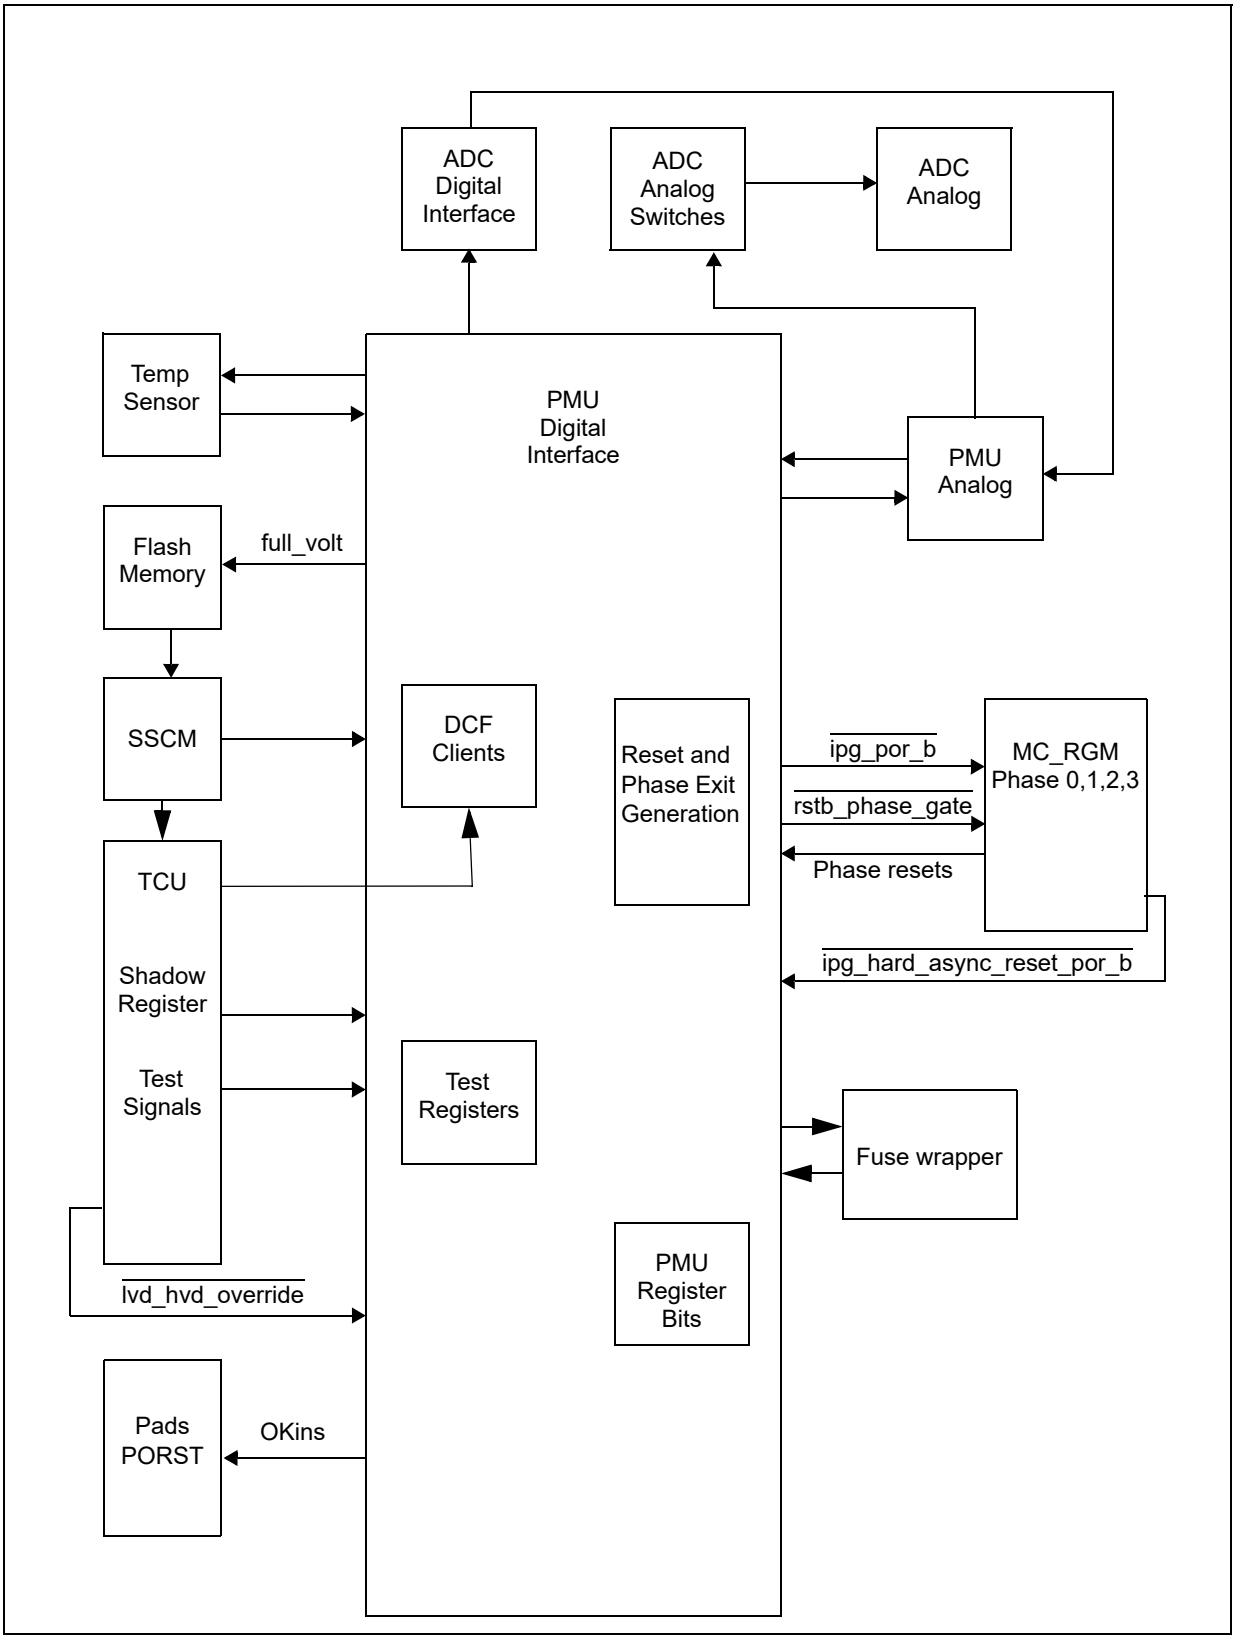
63.1 Introduction

The Control PMU manages the PMU at reset and during run. It checks the LVD or HVD accuracy.

The PMC analog block interfaces the digital part of the device by the PMC_Dig block.

This chapter describes the digital block of the PMU.

The PMC_Dig contains all of the registers and digital logic to generate all of the enable signals, two stage trim control bits, power on reset (POR) generation and test mode logic for the analog block. The PMU digital logic also contains the controls for PMU analog outputs to be sensed with the ADC module.



In addition, the PMU digital logic contains the enable signals, trim bits and other registers for the temperature sensor for SOC and a dedicated temperature sensor for RC regulator.

There are also several custom interfaces to various other blocks: the Reset Generation Module (MC_RGM) block receives the LVD values during POR to use for phase transition conditions and reset generation of fuse_wrapper.

There are two custom interfaces, one to Flash memory via the SSCM (and DCF client blocks) that is used to load the trim values during initial POR. The other to the fuse block via fuse_wrapper that is responsible for first stage trimming, that is to say, bandgap trimming of both regulator and monitor.

The PMU digital block generates a transfer error event to the system if the selected address is out of range of PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed. *Figure 1791* shows the top level block diagram of the digital PMU and its interfaces to the device modules.

Figure 1791. Digital PMU block diagram

63.2 Main features

- PMU management at a main reset
- Resets signal generation

63.2.1 Standard features

- IPS bus interface

63.3 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers
- any other operation (free byte enables or other operations) must be avoided

The PMC_Dig block generates a transfer error in the following cases:

- The PMU digital block generates a transfer error event to the system if the selected address is out of range of PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register

The registers of the PMC_Dig block are accessible (read/write) in each access mode: user, supervisor or test.

About the Reset used among the registers:

- The POR reset is used on EPR_LVx, EPR_HVx, REE_LVx, REE_HVx, RES_LVx and RES_HVx registers
- The destructive reset is used on REE_TD, RES_TD, FEE_LVx, FEE_HVx and FEE_TD registers
- The functional reset is used on IE_HVx, IE_LVx, IE_G, CTL_TD registers

63.4 Memory map/register definition

Table 1741 shows the PMU memory map. The PMU includes many registers for configuring and monitoring LVD monitors and some other control registers.

VD14	LVD400_IF	HV detector asserts when IO FLEXRAY supply < 4.00 V
VD14	LVD400_IJ	HV detector asserts when IO JTAG supply < 4.00 V
VD14	LVD400_IM	HV detector asserts when IO MAINS supply < 4.00 V
VD15	UVD600_C	HV detector asserts when PMU supply > 6.00 V
VD15	UVD600_FL	HV detector asserts when Flash supply > 6.00 V
VD15	UVD600_IF	HV detector asserts when IO FLEXRAY supply > 6.00 V
VD15	UVD600_IJ	HV detector asserts when IO JTAG supply > 6.00 V

63.5 Registers description

63.5.1 Event Pending Register (EPR_LV0)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 0 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Offset: 0x0000 Access: User read/write, Supervisor read/write, Test read/write

Figure 1792. Event Pending Register (EPR_LV0)

Table 1744. EPR_LV0 field descriptions

Field	Description
5 LVD3_FL	LVD3_FL flag. This bit is the low-voltage status flag associated with LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 1.00 V point supply
7 LVD3_C	LVD3_C flag This bit is the low-voltage status flag associated with LVD100_C VD, the voltage level detect for the low voltage CORE 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 1.00 V point supply
23 MVD1_B	MVD1_B flag This bit is the low-voltage status flag associated with MVD082B VD, the voltage level detect for the low voltage 0.82 V of buddy device supply. It is asserted when the supply falls below its corresponding Voltage Detector 1 threshold, and clears when the supply rises above its corresponding MVD threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 0.82 V point supply

63.5.2 Reset Event Enable Register (REE_LV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Figure 1793. Reset Event Enable Register (REE_LV0)

Table 1745. REE_LV0 field descriptions

Field	Description
3 REE3_SB	REE3_SB reset enable This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates a system reset. The RES3_SB bit determines whether the reset is functional or destructive. **Note:** Do not use this bit. It is for Standby feature. SPC58xNx does not support Standby. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
5 REE3_FL	REE3_FL reset enable This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage of 1.00 V on Flash supply, generates a system reset. The RES3_FL bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE3_C	REE3_C reset enable This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates a system reset. The RES3_C bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

63.5.3 Reset Event Select Register (RES_LV0)

This Reset Event Select Register controls, in LOW VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Table 1746. RES_LV0 field descriptions

Field	Description
3 RES3_SB	RES3_SB reset event select This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply of the cold point, generates a destructive reset or a functional reset. The REE3_SB bit determines whether the reset event is enabled. **Note:** Do not use this bit. It is for Standby feature. SPC58xNx does not support Standby. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset. For LVD100_SB it is not allowed to enable destructive reset, only functional reset is supported.

Table 1746. RES_LV0 field descriptions (continued)

Field	Description
5 RES3_FL	RES3_FL reset event select This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES3_C	RES3_C reset event select This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

63.5.4 Interrupt Enable (IE_LV0)

This configuration register contains a set of LV0 interrupt Enable bits that correspond to each of the LV0 Event Pending Registers (EPR_LV0). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0x0088. The IE_LV0 bits can be read or written at any time.

Offset: 0x000C Access: User read/write, Supervisor read/write, Test read/write

Field	Description
3 VD3IE_SB	VD3IE_SB Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply event. **Note:** Do not use this bit. It is for Standby feature. SPC58xNx does not support Standby. 0 Interrupt disabled 1 Interrupt enabled Interrupt occurrence in case of LVD happens only in normal mode (interrupt being not powered in standby mode).
5 VD3IE_FL	VD3IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply event. 0 Interrupt disabled 1 Interrupt enabled
7 VD3IE_C	VD3IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply event. 0 Interrupt disabled 1 Interrupt enabled

63.5.5 FCCU Event Enable Register (FEE_LV0)

This FCCU Event Enable Register LV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Offset: 0x0010 Access: User read/write, Supervisor read/write, Test read/write

Figure 1796. FCCU Event Enable Register (FEE_LV0)

Table 1748. FEE_LV0 field descriptions

Field	Description
3 FEE3_SB	FEE3_SB FCCU event enable This bit defines whether a VD assertion of LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates an FCCU event. **Note:** Do not use this bit. It is for Standby feature. SPC58xNx does not support Standby. 0 Disabled. A VD assertion of LV0 on the supply of the always on IO ring does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the always on IO ring causes an FCCU event. FCCU event in case of LVD happens only in normal mode (FCCU being not powered in standby mode).
5 FEE3_FL	FEE3_FL FCCU event enable This bit defines whether a VD assertion of LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Flash causes an FCCU event.
7 FEE3_C	FEE3_C FCCU event enable This bit defines whether a VD assertion of LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Core causes an FCCU event.

63.5.6 Event Pending Register (EPR_LV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0020 Access: User read/write, Supervisor read/write, Test read/write

Figure 1803. Reset Event Enable Register (REE_HV0)

Table 1755. REE_HV0 field descriptions

Field	Description
1 REE11_AD	LVD11_AD reset enable This bit defines whether LVD290_AD VD, the voltage level detect for the high voltage assertion on the Sigma Delta ADC 2.90 V supply generates a system reset. The RES11_AD bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
2 REE11_AS	LVD11_AS reset enable This bit defines whether LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply generates a system reset. The RES11_AS bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
3 REE11_IF	LVD11_IF reset enable This bit defines whether LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO Flexray 2.90 V supply generates a system reset. The RES11_IF bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
4 REE11_IJ	LVD11_IJ reset enable This bit defines whether LVD290_IJ VD, the voltage level detect for the high voltage assertion on the IO JTAG 2.90 V supply generates a system reset. The RES11_IJ bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
6 REE11_FL	LVD11_FL reset enable This bit defines whether LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply of the cold point generates a system reset. The RES11_FL bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE11_C	LVD11_C reset enable This bit defines whether LVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply, of the cold point generates a system reset. The RES11_C bit determines whether a system reset is enabled or not. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

63.5.13 Reset Event Select Register (RES_HV0)

This Reset Event Select Register controls, in HIGH VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled,

the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Figure 1804. Reset Event Select Register (RES_HV0)

Table 1756. RES_HV0 field descriptions

Field	Description
1 RES11_AD	RES11_AD reset event select This bit defines whether an LVD assertion on the Sigma Delta ADC 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_ad bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
2 RES11_AS	RES11_AS reset event select This bit defines whether an LVD assertion on the SAR ADC 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_AS bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
3 RES11_IF	RES11_IF reset event select This bit defines whether an LVD assertion on the IO Flexray 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_IF bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

Table 1756. RES_HV0 field descriptions (continued)

Field	Description
4 RES11_IJ	RES11_IJ reset event select This bit defines whether an LVD assertion on the IO JTAG 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_IJ bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
6 RES11_FL	RES11_FL reset event select This bit defines whether an LVD assertion on the Flash 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES11_C	RES11_C reset event select This bit defines whether an LVD assertion on the Core 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

63.5.14 Interrupt Enable (IE_HV0)

This configuration register contains a set of HV0 interrupt Enable bits that correspond to each of the HV0 Event Pending Registers (EPR_HV0). These bits indicate whether an interrupt enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0x0088. The IE_HV0 bits can be read or written at any time.

Field	Description
1 LVD11IE_AD	LVD11IE_AD Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_AD VD, the voltage level detect for the high voltage assertion on the Sigma Delta ADC 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
2 LVD11IE_AS	LVD11IE_AS Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply event occurs. 0Interrupt disabled 1 Interrupt enabled
3 LVD11IE_IF	LVD11IE_IF Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO Flexray 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
4 LVD11IE_IJ	LVD11IE_IJ Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_IJ VD, the voltage level detect for the high voltage assertion on the IO JTAG 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled

Table 1757. IE_HV0 field descriptions (continued)

Field	Description
6 LVD11IE_FL	LVD11IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
7 LVD11IE_C	LVD11IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the IVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled

63.5.15 FCCU Event Enable Register (FEE_HV0)

This FCCU Event Enable Register HV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Field	Description
1 FEE11_AD	FEE11_AD FCCU event enable This bit defines whether a LVD290_AD VD, the voltage level detect for the high voltage assertion on the Sigma Delta ADC 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the ADC does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the ADC causes an FCCU event.

Table 1758. FEE_HV0 field descriptions (continued)

Field	Description
2 FEE11_AS	FEE11_AS FCCU event enable This bit defines whether a LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the ADC does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the ADC causes an FCCU event.
3 FEE11_IF	FEE11_IF FCCU event enable This bit defines whether a LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO Flexray 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the IO Flexray does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the IO Flexray causes an FCCU event.
4 FEE11_IJ	FEE11_IJ FCCU event enable This bit defines whether a LVD290_IJ VD, the voltage level detect for the high voltage assertion on the IO JTAG 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the IO JTAG does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the IO JTAG causes an FCCU event.
6 FEE11_FL	FEE11_FL FCCU event enable This bit defines whether a LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Flash causes an FCCU event.
7 FEE11_C	FEE11_C FCCU event enable This bit defines whether a LVD290_C VD, the voltage level detect for the high voltage assertion on the Core 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Core causes an FCCU event.

63.5.16 Event Pending Register (EPR_HV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in HIGH VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Figure 1807. Event Pending Register (EPR_HV1)

Table 1759. EPR_HV1 field descriptions

Field	Description
9 LVD14_AD	LVD14_AD flag This bit is the High voltage status flag associated with LVD400_AD VD, the VD for the high voltage Sigma Delta ADC 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_AD threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
10 LVD14_AS	LVD14_AS flag This bit is the High voltage status flag associated with LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_AS threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
12 LVD14_IF	LVD14_IF flag This bit is the High voltage status flag associated with LVD400_IF VD, the VD for the high voltage IO Flexray 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IF threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

Table 1759. EPR_HV1 field descriptions (continued)

Field	Description
13 LVD14_IJ	LVD14_IJ flag This bit is the High voltage status flag associated with LVD400_IJ VD, the VD for the high voltage IO JTAG 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IJ threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
14 LVD14_IM	LVD14_IM flag This bit is the High voltage status flag associated with LVD400_IM VD, the VD for the high voltage IO main 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IM threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
21 HVD13_IF	HVD13_IF flag This bit is the High Voltage status flag associated with HVD400_IF VD, the VD for the high voltage IO Flexray 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply falls below its corresponding HVD13_IF threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
22 HVD13_IJ	HVD13_IJ flag This bit is the High Voltage status flag associated with HVD400_IJ VD, the VD for the high voltage IO JTAG 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply falls below its corresponding HVD13_IJ threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
23 HVD13_C	HVD13_C flag This bit is the High Voltage status flag associated with HVD400_C VD, the VD for the high voltage Core 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply below its corresponding HVD13_C threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

63.5.17 Reset Event Enable Register (REE_HV1)

This Reset Event Enable Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Field	Description
9 LVDIE14_AD	LVDIE14_AD Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_AD VD, the VD for the high voltage Sigma Delta ADC 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
10 LVDIE14_AS	LVDIE14_AS Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
12 LVDIE14_IF	LVDIE14_IF Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_IF VD, the VD for the high voltage IO Flexray 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
13 LVDIE14_IJ	LVDIE14_IJ Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_IJ VD, the VD for the high voltage IO JTAG 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
14 LVDIE14_IM	LVDIE14_IM Interrupt Enable. This bit determines whether an interrupt is enabled or disabled for the LVD400_IM VD, the VD for the high voltage IO main 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

Table 1762. IE_HV1 field descriptions (continued)

Field	Description
21 HVDIE13_IF	HVDIE13_IF Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_IF VD, the VD for the high voltage IO Flexray 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
22 HVDIE13_IJ	HVDIE13_IJ Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_IJ VD, the VD for the high voltage IO JTAG 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
23 HVDIE13_C	HVDIE13_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_C VD, the VD for the high voltage Core 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

63.5.20 FCCU Event Enable Register (FEE_HV1)

This FCCU Event Enable Register HV1 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Figure 1811. FCCU Event Enable Register (FEE_HV1)

Table 1763. FEE_HV1 field descriptions

Field	Description
9 FEE14_AD	FEE14_AD FCCU event enable This bit defines whether a VD assertion of LV14 on LVD400_AD for the supply of the Sigma Delta ADC generates an FCCU event. 0 Disabled. A VD assertion of LV14 does not cause an FCCU event. 1 Enabled. A VD assertion of LV14 causes an FCCU event.
10 FEE14_AS	FEE14_AS FCCU event enable This bit defines whether a VD assertion of LV14 on LVD400_AS for the supply of the SAR ADC generates an FCCU event. 0 Disabled. A VD assertion of LV14 does not cause an FCCU event. 1 Enabled. A VD assertion of LV14 causes an FCCU event.
12 FEE14_IF	FEE14_IF FCCU event enable This bit defines whether a VD assertion of LV14 on LVD400_IF for the supply of the IO Flexray generates an FCCU event. 0 Disabled. A VD assertion of LV14 does not cause an FCCU event. 1 Enabled. A VD assertion of LV14 causes an FCCU event.
13 FEE14_IJ	FEE14_IJ FCCU event enable This bit defines whether a VD assertion of LV14 on LVD400_IJ for the supply of the IO JTAG generates an FCCU event. 0 Disabled. A VD assertion of LV14 does not cause an FCCU event. 1 Enabled. A VD assertion of LV14 causes an FCCU event.
14 FEE14_IM	FEE14_IM FCCU event enable This bit defines whether a VD assertion of LV14 on LVD400_IM for the supply of the IO main generates an FCCU event. 0 Disabled. A VD assertion of LV14 does not cause an FCCU event. 1 Enabled. A VD assertion of LV14 causes an FCCU event.
21 FEE13_IF	FEE13_IF FCCU event enable This bit defines whether a VD assertion of HV14 on HVD400_IF for the supply of the IO Flexray generates an FCCU event. 0 Disabled. A VD assertion of HV14 does not cause an FCCU event. 1 Enabled. A VD assertion of HV14 causes an FCCU event.
22 FEE13_IJ	FEE13_IJ FCCU event enable This bit defines whether a VD assertion of HV14 on HVD400_IJ for the supply of the IO JTAG generates an FCCU event. 0 Disabled. A VD assertion of HV14 does not cause an FCCU event. 1 Enabled. A VD assertion of HV14 causes an FCCU event.
23 FEE13_C	FEE13_C FCCU event enable This bit defines whether a VD assertion of HV14 on HVD400_C for the supply of the Core generates an FCCU event. 0 Disabled. A VD assertion of HV14 does not cause an FCCU event. 1 Enabled. A VD assertion of HV14 causes an FCCU event.

63.5.21 Supply Gauge Status Register (GR_S)

This status register contains the gauge of the indicated supply. This indicates the present state of the voltage detect events for each of the supplies. Each of the voltage detect signals for a given voltage are combined to form a single bit, refer to *Table 1764*.

Figure 1812. Supply Gauge Status Register (GR_S)

Table 1764. GR_S field descriptions

Field	Description
1 TEMP_2	TEMP_2 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (165 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
2 TEMP_1	TEMP_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
3 TEMP_0	TEMP_0 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (-40 °C). It is asserted when the temperature falls below its corresponding threshold, and clears when the temperature is above its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
7 VD14_AD	VD14_AD low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_AD for the high voltage 4.00 V Sigma Delta ADC supply. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies

Table 1764. GR_S field descriptions (continued)

Field	Description
8 VD14_AS	VD14_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_AS for the high voltage 4.00 V SAR ADC supply. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
9 VD14_IF	VD14_IF low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_IF for the high voltage 4.00 V IO Flexray supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
10 VD14_IJ	VD14_IJ low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_IJ for the high voltage 4.00 V IO JTAG supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
11 VD14_IM	VD14_IM low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_IJ for the high voltage 4.00 V IO main supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies fall below the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
13 VD13_IF	VD13_IF high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_IF for the high voltage 4.00 V IO Flexray supply. It is asserted when the IO supply rises above its corresponding HVD threshold, and clears when the supply rises above its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply
14 VD13_IJ	VD13_IJ high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_IJ for the high voltage 4.00 V IO JTAG supply. It is asserted when the IO supply rises above its corresponding HVD threshold, and clears when the supply rises above its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply

Table 1764. GR_S field descriptions (continued)

Field	Description
15 VD13_C	VD13_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_C for the high voltage 4.00 V Core supply. It is asserted when the Core supply rises above its corresponding HVD threshold, and clears when the supply falls its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply
20 VD11_AD	VD11_AD low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_AD for the high voltage 2.90 V Sigma Delta ADC supplies. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
21 VD11_AS	VD11_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_AD for the high voltage 2.90 V SAR ADC supplies. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
22 VD11_IF	VD11_IF low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_IF for the high voltage 2.90 V IO Flexray supplies. It is asserted when any of the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
23 VD11_IJ	VD11_IJ low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_IJ for the high voltage 2.90 V IO JTAG supplies. It is asserted when any of the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
24 VD11_FL	VD11_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_FL for the high voltage 2.90 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies

Table 1764. GR_S field descriptions (continued)

Field	Description
25 VD11_C	VD11_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_C for the high voltage 2.90 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
27 VD6_C	VD6_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD134_C for the high voltage 1.34 V Core supplies. It is asserted when any of the Core supplies rises above the corresponding HVD threshold, and clears when all the Core supplies fall below the corresponding HVD threshold. All the 1.34 V HVDs are combined to form this bit. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 1.34 V supply
30 VD3_FL	VD3_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_FL for the high voltage 1.00 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.00 V supplies
31 VD3_C	VD3_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_C for the low voltage 1.00 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.00 V supplies

63.5.22 Pending Gauge Status Register (GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

63.5.23 Global Interrupt Enable Register (IE_G)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt is enabled. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are enabled via a write of ‘1’ to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

Offset: 0x0088 Access: User read/write, Supervisor read/write, Test read/write

63.5.27 Event Pending Register (EPR_TD)

This Event Pending Register indicates the present and past state of the temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0300 Access: User read/write, Supervisor read/write, Test read/write

Figure 1818. Event Pending Register (EPR_TD)

Table 1771. EPR_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (165 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_2 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_2] is also asserted, a system reset is generated, *which clears IETD_2 and negate the interrupt request*. If REE_TD[TEMP_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
30 TEMP_1	TEMP_1 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_1 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_1] is also asserted, a system reset is generated, *which clears IETD_1 and negate the interrupt request*. If REE_TD[TEMP_1] is asserted and a destructive reset is selected (via RES_TD[TEMP_1] being 0), then a destructive reset is generated. If RES_TD[TEMP_1] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
31 TEMP_0	TEMP_0 flag. This bit is the temperature status flag associated with the temperature for the *cold* temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_0 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_0] is also asserted, a system reset is generated, *which clears IETD_0 and negate the interrupt request*. If REE_TD[TEMP_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP_0] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected

63.5.28 Reset Event Enable Register (REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Offset: 0x0304 Access: User read/write, Supervisor read/write, Test read/write

Figure 1819. Reset Event Enable Register (REE_TD)

Table 1772. REE_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
30 TEMP_1	TEMP_1 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
31 TEMP_0	TEMP_0 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.

63.5.29 Reset Event Select Register (RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Figure 1820. Reset Event Select Register (RES_TD)

Table 1773. RES_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_2] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
30 TEMP_1	TEMP_1 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_1] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
31 TEMP_0	TEMP_0 reset event select. This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.

63.5.30 Temperature Sensor Configuration Register (CTL_TD)

The Temperature Sensor Configuration Registers (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to be operable. It also includes two 5-bit signed trim adjustment register fields that are used to modify both TS trim values (one bus for over temperature and one bus for under temperature).

Offset: 0x030C Access: User read/write, Supervisor read/write, Test read/write

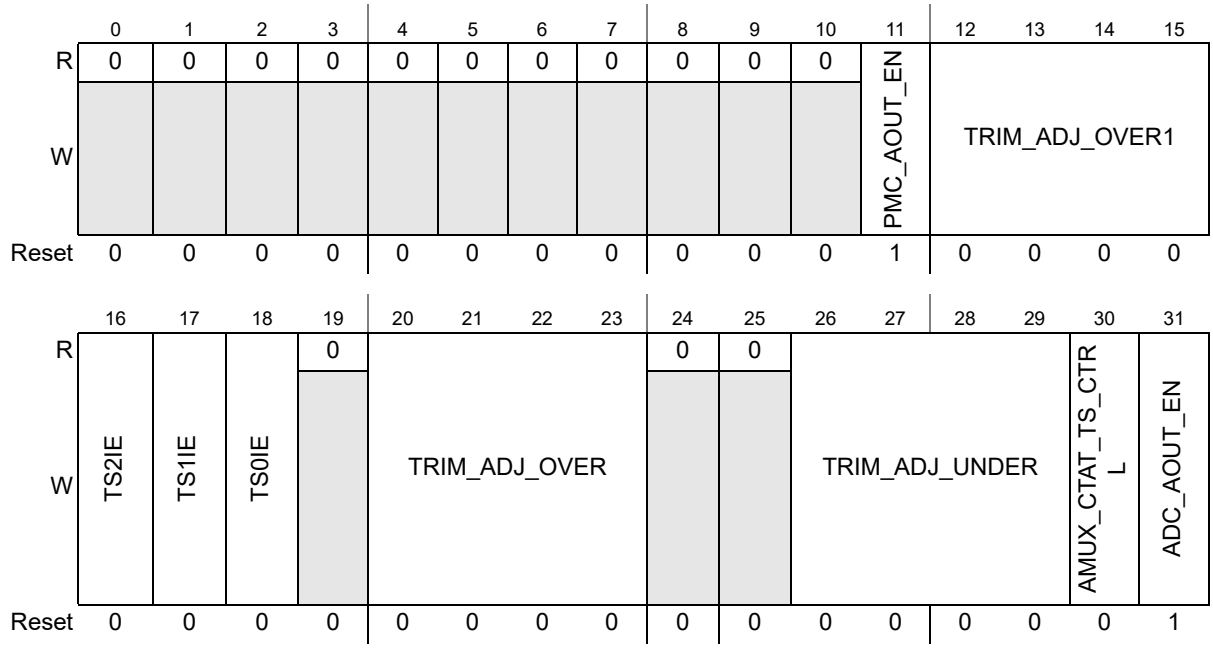

Figure 1821. Temperature Sensor Configuration Register (CTL_TD)

Table 1774. CTL_TD field descriptions

Field	Description
11 PMC_AOUT_EN	PMC_AOUT_EN. Temperature Sensor Enable for PMU. Refer to the Temperature Sensor chapter for details.
12:15 TRIM_ADJ_OVER1	TRIM_ADJ_OVER1[3:0]. Customer adjustable over trim register for PMU. These bits are a signed binary number that is added to the over temperature trim (NT_TD1) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
16 TS2IE	TS2IE Temperature Sensor input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
17 TS1IE	TS1IE Temperature Sensor input 1 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
18 TS0IE	TS0IE Temperature Sensor input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs

Table 1774. CTL_TD field descriptions (continued)

Field	Description
20:23 TRIM_ADJ_OVER	TRIM_ADJ_OVER[3:0]. Customer adjustable over trim register for ADC. These bits are a signed binary number that is added to the over temperature trim (NT_TD2) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
26:29 TRIM_ADJ_UNDER	TRIM_ADJ_UNDER[3:0]. Customer adjustable under trim register. These bits are a signed binary number that is added to the Under temperature trim value (NT_TD0). The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
30 AMUX_CTAT_TS_CTRL	AMUX_CTAT_TS_CTRL. Analog mux enable. Refer to the Temperature Sensor chapter for details.
31 ADC_AOUT_EN	ADC_AOUT_EN. Temperature Sensor Enable for ADC. Refer to the Temperature Sensor chapter for details.

63.5.31 Temperature Sensor FCCU Event Enable Register (FEE_TD)

This Temperature Sensor FCCU Event Enable Register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

Figure 1827. User BIST Control register (BIST_CTRL)

Table 1780. BIST_CTRL field descriptions

Field	Description
11 IRQST	IRQST is the interrupt request pending status bit to generate a User BIST Interrupt. It is a R/W0 register. That means Set by HW and Cleared by SW. The destructive reset resets this bit. 0 No interrupt occured 1 An interrupt occured
15 IRQEN	IRQEN is the interrupt request enable bit to permit a User BIST Interrupt. It is a R/W register. The destructive reset resets this bit. 0 Interrupt is disabled 1 Interrupt enabled
19 NCFST	NCFST is the Not Critical Fault bit. The assertion of this bit will generate FCCU event once user BIST fails. It is set by HW and Cleared by SW. The destructive reset resets this bit. 0 No User BIST NCF occured 1 A User BIST NCF occured
23 NCFEN	NCFEN is the Not Critical Fault enable bit to permit a User BIST Not Critical Fault and Fault indication is sent to FCCU. It is a R/W register. The destructive reset resets these bits. 0 No User BIST NCF enabled 1 A User BIST NCF enabled

Table 1780. BIST_CTRL field descriptions (continued)

Field	Description
25:27 STATUS	STATUS register consists of 3 read-only bits, that according to the value has its own meaning. 000 BIST_IDLE 001 BIST_RUN 010 BIST_PASSED 011 BIST_FAILED 100 BIST_ABORT 101 Reserved 110 Reserved 111 Reserved
31 START	START User BIST bit. If set by SW a 1 is present in the START bit for a System clock cycle only, then the START bit register is clear by HW. The destructive reset resets this bit. 0 No start pulse. 1 A start pulse occurs of a 1 System clock cycle duration

63.5.37 User BIST Time1 and Time0 register (BIST_TIME10)

The User BIST Time1 and Time0 Register (BIST_TIME10) contains two time numbers Time1 and Time0 giving the System clock cycles number required by the User BIST timer1 and timer0 (refer to *Section 63.10* for more information regarding the User BIST timer registers).

Offset: 0x03D8 Access: User read/write, Supervisor read/write, Test read/write

Table 1782. BIST_TIME32 field descriptions

Field	Description
4:15 TIME_3	TIME_3 is the system clock cycles number required by the TIMER 3 in the User BIST management. The destructive reset resets these bits.
20:31 TIME_2	TIME_2 is the system clock cycles number required by the TIMER 2 in the User BIST management. The destructive reset resets these bits.

63.5.39 User BIST Time6 and Time5 register (BIST_TIME65)

The User BIST Time6 and Time5 Register (BIST_TIME65) contains two time numbers Time6 and Time5 giving the system clock cycles number required by the User BIST timer6 and timer5 (refer to *Section 63.10* for more information regarding the User BIST timer registers).

20:31 TIME_5	TIME_5 is the system clock cycles number required by the TIMER 5 in the User BIST management. The destructive reset resets these bits.

63.5.40 User BIST VD Under Test Monitor register (BIST_DEBUG)

This VD Under Test Monitor register contains a monitor of the Voltage Detector Under Test of the USER BIST sub-block.

Note: The BIST_DEBUG register can only be read while BIST is running. Once BIST is finished the status can be obtained by checking the BIST_FLAGS_PHASE1 and BIST_FLAGS_PHASE2 registers.

Offset: 0x03E4 Access: User read-only

63.6 Standby entry/exit

Standby entry is an application initiated mode.The standby entry process starts once the application configures [MC_ME_MCTL] register for target mode as standby. For detailed description of entry/exit, refer to MC_PCU.

63.7 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of an analog enable, a set of mode registers, and an overtemp threshold select control.

For more information regarding the Temperature Sensor function, refer to the *Chapter 41: Temperature Sensor*.

63.8 Power On Reset (MC_RGM Phase Gates)

The PMU digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMU and Temperature Sensor Analog blocks.

There are two signals for both the PMU and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMU digital logic also indicates when the RGM allows transition to the next POR phase.

The digital PMU also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMU digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled LVDs and HVDs have become deasserted and the time from the LVD circuits to adjust to new trim values has elapsed, then the signal is sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

63.9 Flash interface (DCF client usage)

The PMU digital is updated during POR from the Flash block via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMU, Temperature Sensor, and ADC Bandgap).

These trim bits that are loaded from the Flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

A DCF client is used to interface to the Flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES bits. Refer to *Section 63.5.28: Reset Event Enable Register (REE_TD)* for more information regarding the REE/RES bits load from Flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (thus to allow the bits to be rewriteable) and same is the reset value of the REE register.

The monitors for which reactions are enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “1” (reset enabled) and in the Reset Event Select (RES_XX) register as “0” (destructive reset selected).

The monitors for which reactions are not enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “0” (reset disabled) and in the Reset Event Select (RES_XX) register as “1” (functional reset selected).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the POR reset signal.

For more information regarding the DCF records, refer to the DCF Records chapter.

The trim data is read out of the Flash's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the Flash indicates this to the PMU digital via the SSCM module.

Once the PMU trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the Flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD signals must indicate that a valid voltage has been reached before the voltage indication is sent to the Flash.

63.10 Voltage monitor BIST programming

The application has to program the BIST_TIMExx registers according to the following timings, respect to the configured PBRIDGE_CLK:

- BIST_TIME10[Time_0] = 40 µs.
- BIST_TIME10[Time_1] = 50 µs.
- BIST_TIME32[Time_2] = 50 µs.
- BIST_TIME32[Time_3] = 50 µs.
- BIST_TIME65[Time_5] = 200 ns.
- BIST_TIME65[Time_6] = 200 ns.

In case that aforementioned timings are not applied, some voltage monitor BIST could trigger fake faults.

The user can run a BIST mode by setting the BIST_CTRL[START] register bit. The following voltage detectors are then serially tested:

- MVD094_C
- MVD094_FA
- MVD094_FB
- LVD100_C
- LVD100_FL
- MVD270_C
- MVD270_FL
- LVD290_C
- LVD290_FL
- LVD290_AD
- LVD290_AS
- LVD290_IJ
- LVD290_IF
- LVD400_AD
- LVD400_AS
- LVD400_IM
- LVD400_IJ
- LVD400_IF
- MVD082_B
- HVD134_C
- UVD140_C
- UVD140_FL
- HVD400_C
- HVD400_IJ
- HVD400_IF
- UVD600_C
- UVD600_FL
- UVD600_IJ
- UVD600_IF

Interrupt can be enabled by programming BIST_CTRL[IRQEN] and interrupt status is checked with BIST_CTRL[IRQST] on completion of BIST sequence.

FCCU event can be enabled by programming BIST_CTRL[NCFEN]. The BIST_CTRL[NCFST] status indicates BIST Fail on completion of BIST sequence.

BIST_DEBUG[VD_MON] register bits allow to know which voltage detector is under test.

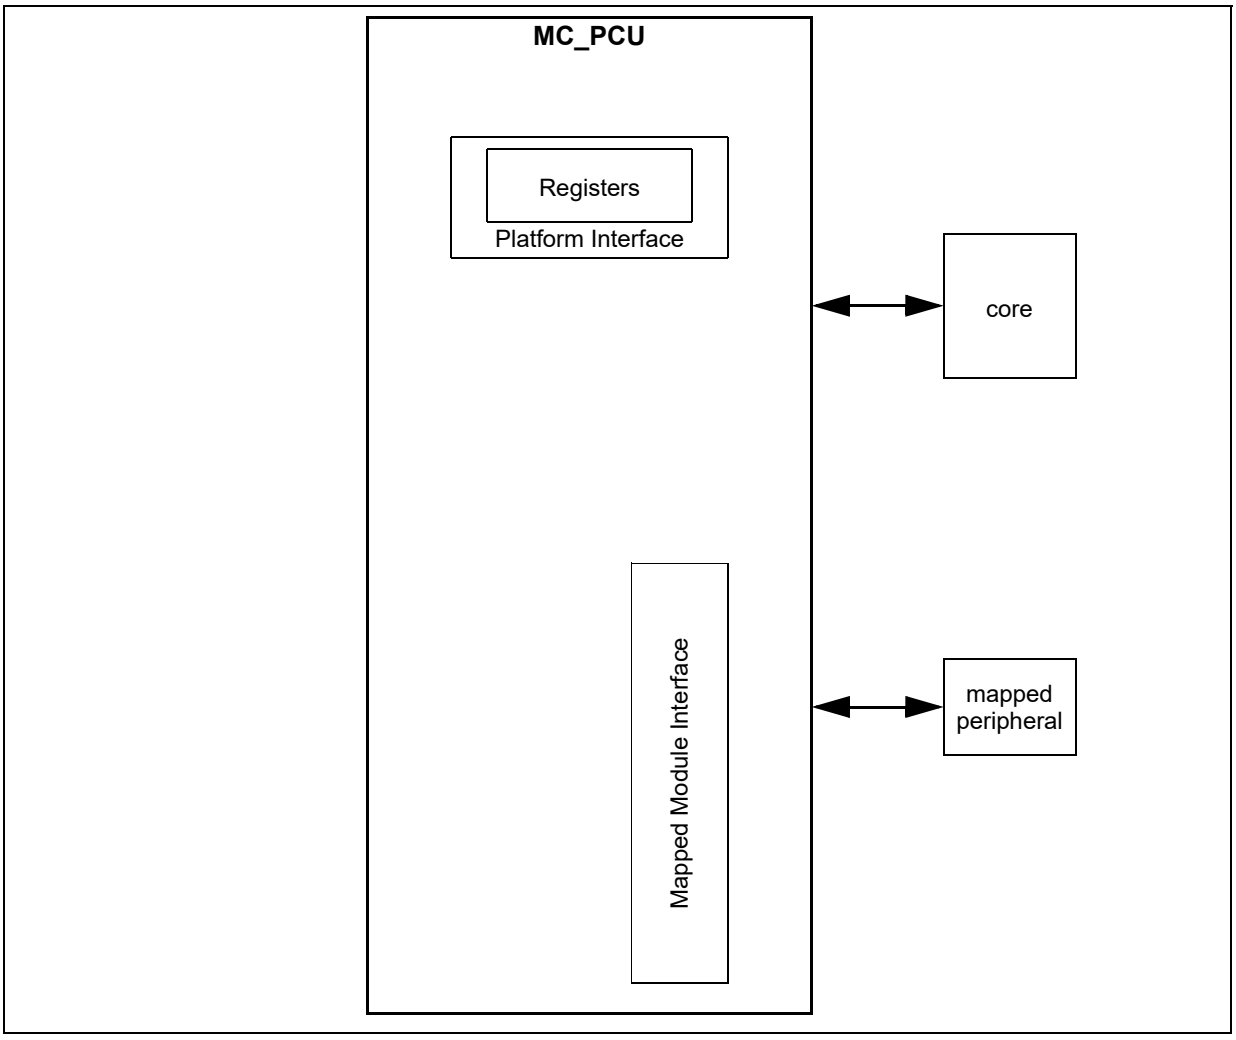
The overall status of BIST is provided by the BIST_CTRL[STATUS] register bits.

The status of individual monitors is checked in flag registers BIST_FLAGS_PHASE1 (pass is all zero) and BIST_FLAGS_PHASE2 (pass is all one).

Note: When the SOC supply is 3.3 V, the LVD400_xx monitors are not lifted but when we run BIST all the monitors are masked (during this time the event is seen in PMC_DIG_EPR_HV1

register). When the SOC supply is 5 V, the HVD400_xx monitors are not lifted but when we run BIST, the event is seen in PMC_DIG_EPR_HV1 register.

64 Power Control Unit (MC_PCU)



64.1 Introduction

64.1.1 Overview

The power control unit (MC_PCU) acts as a bridge for mapping the PMC peripheral to the MC_PCU address space.

Figure 1832 depicts the MC_PCU block diagram.

Figure 1832. MC_PCU block diagram

64.1.2 Features

The MC_PCU includes:

Maps the PMC registers to the MC_PCU address space.

64.2 External Signal Description

The MC_PCU has no connections to any external pins.

64.3 Memory Map and Register Definition

64.3.1 Memory Map

Table 1785. MC_PCU Register Description

Address offset	Register name	Location
0x0000–0x03F0	Reserved	
0x0040	Power Domain Status Register (PCU_PSTAT)	*Section 64.3.2.1*

Note: Any access to unused registers as well as write accesses to read-only registers will not change register content and will cause a transfer error

64.3.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at address offset 0x0040, as a half-word at address offset 0x0042, or as a byte at address offset 0x0043.

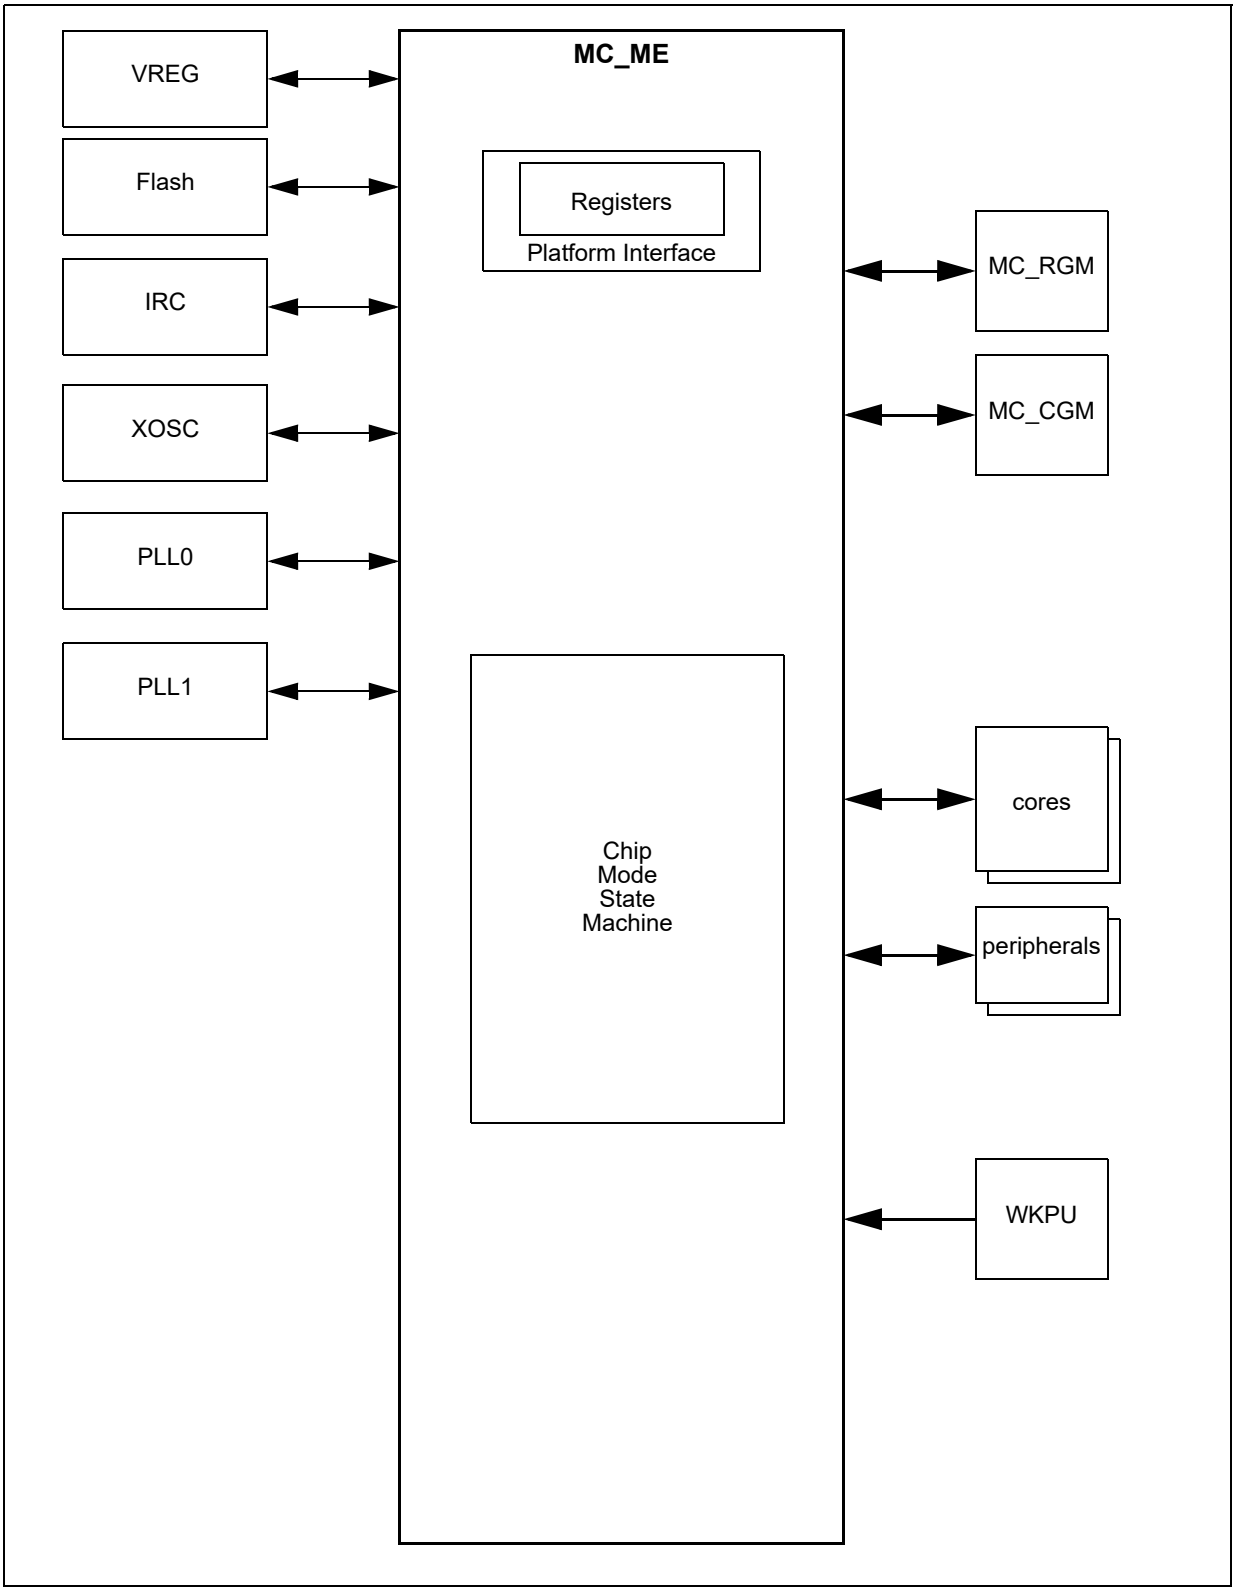
65 Mode Entry Module (MC_ME)



65.1 Introduction

65.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

Figure 1834 shows the MC_ME block diagram.

Figure 1834. MC_ME block diagram

65.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers
- additional core clock gating and boot address control based on the ME_CCTL*n* and ME_CADDR*n* registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

65.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as: RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as: RUN0–3, HALT0 and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0–3 are the chip software running modes.

Table 1787 describes the MC_ME modes.

Table 1787. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAF, when present, is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0–3	system reset assertion, RUN0–3, TEST via software, SAFE via software or hardware failure.

Table 1787. MC_ME mode descriptions (continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0–3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0–3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0–3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0–3 modes, HALT0, STOP0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals such as: clock sources, flash, main regulator, for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event or wakeup event

65.2 External signal description

The MC_ME has no connections to any external pins.

65.3 Memory map and register definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

65.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

65.3.2.1 Global Status Register (ME_GS)

This register contains global mode status.

Address: 0x000 Access: User read, Supervisor read, Test read

27 S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28:31 S_SYSCLK	System clock switch status These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

65.3.2.2 Mode Control Register (ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

Note: Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Address: 0x004 Access: User read, Supervisor read/write, Test read/write

Figure 1836. Mode Control Register (ME_MCTL)

Table 1790. ME_MCTL field descriptions

Field	Description
0:3 TARGET_MODE	Target chip mode These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0–3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
16:31 KEY	Control key These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101 1010 1111 0000 (0x5AF0) INVERTED KEY: 1010 0101 0000 1111 (0xA50F)

65.3.2.3 Mode Enable Register (ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET, SAFE, DRUN, and RUN0 modes are always enabled.

Address: 0x008 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1838. Interrupt Status Register (ME_IS)

Table 1792. ME_IS field descriptions

Field	Description
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) This bit is set if a write access to one of the ME_CCTL*n* registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDR*n* register was attempted during an ongoing mode transition 1 A write to an ME_CADDR*n* register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending
28 I_ICONF	Invalid mode configuration interrupt This bit is set whenever a write operation to ME_<*mode*>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending

Table 1792. ME_IS field descriptions (continued)

Field	Description
29 I_IMODE	Invalid mode interrupt This bit is set whenever an invalid mode transition is requested. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a ‘1’ to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a ‘1’ to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

65.3.2.5 Interrupt Mask Register (ME_IM)

This register controls whether an event generates an interrupt or not.

Address: 0x010 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1840. Invalid Mode Transition Status Register (ME_IMTS)

Table 1794. ME_IMTS field descriptions

Field	Description
26 S_MRIG	Mode Request Ignored status This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress, a transition to STOP0 mode is requested while a wakeup or interrupt request is active, or a transition to HALT0 mode is requested while an interrupt request is active. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not ignored 1 Mode transition requested is ignored
27 S_MTI	Mode Transition Illegal status This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is ‘1’). Please see *Section 65.4.5: Mode Transition Interrupts*, for the exceptions to this behavior. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a ‘1’ to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

65.3.2.7 Debug Mode Transition Status Register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Table 1795. ME_DMTS field descriptions

Field	Description
0:3 PREVIOUS_MODE	Previous chip mode These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has responded. 0 Handshake is not busy 1 Handshake is busy

Table 1795. ME_DMTS field descriptions (continued)

Field	Description
11 PMC_PROG	MC_PCU Mode Change in Progress indicator This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
16 CDP_PRPH_0_255	Clock Disable Process Pending status for Peripherals 0–255(1) This bit is set when any peripheral appearing has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table 1795. ME_DMTS field descriptions (continued)

Field	Description
19 IRC_SC	IRC State Change during mode transition indicator This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A secondary clock source is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status 0 No system clock source switching is pending 1 A system clock source switching is pending
23 FLASH_SC	FLASH State Change during mode transition indicator This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224–255(1) This bit is set when any peripheral appearing in ME_PS7 has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
25 CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192–223 This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_160_191	Clock Disable Process Pending status for Peripherals 160–191 This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1795. ME_DMTS field descriptions (continued)

Field	Description
27 CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128–159 This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96–127 This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64–95 This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32–63 This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0–31 This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTL*n* register. Please refer to *Table 1788* for the ME_PCTL*n* locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

65.3.2.8 RESET Mode Configuration Register (ME_RESET_MC)

This register configures system behavior during RESET mode. See *Table 1796* for details.

Note: The following configuration values are set according to the chip configuration:
XOSCON

Address: 0x020 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	PDO	0	0	MVRON	0	0	FLAON	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	PLL1ON	PLL0ON	XOSCON	IRCON	SYSCLK			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Figure 1842. RESET Mode Configuration Register (ME_RESET_MC)

65.3.2.9 TEST Mode Configuration Register (ME_TEST_MC)

This register configures system behavior during TEST mode. See *Table 1796* for details.

Note: Byte write accesses are not allowed to this register.

Address: 0x024 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	PWRLVL(1)			0	0	0	0	PDO	0	0	MVRON	0	0	FLAON

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Only bit [3] have an effect on progressive clock switching and bits [1:2] are ignored.

Figure 1843. TEST Mode Configuration Register (ME_TEST_MC)

65.3.2.10 SAFE Mode Configuration Register (ME_SAFE_MC)

This register configures system behavior during SAFE mode. See *Table 1796* for details.

Note: Byte write accesses are not allowed to this register.

Address: 0x028 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0	0	0	0	0	0	0	0	PLL1ON	PLL0ON	XOSCON	IRCON	SYSCLK			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Only bit [3] have an effect on progressive clock switching and bits [1:2] are ignored.

Figure 1844. SAFE Mode Configuration Register (ME_SAFE_MC)

65.3.2.11 DRUN Mode Configuration Register (ME_DRUN_MC)

This register configures system behavior during DRUN mode. See *Table 1796* for details.

Note: Byte write accesses are not allowed to this register.

The following configuration values are set according to the chip configuration:

XOSCON

Address: 0x02C Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	PWRLVL(1)			0	0	0	0	PDO	0	0	MVRON	0	0	FLAON

Figure 1848. STOP0 Mode Configuration Register (ME_STOP0_MC)

Table 1796. ME_<*mode*>_MC field descriptions

Field	Description
1:3 PWRLVL	Power level These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled. **Note:** For ME_RESET_MC, ME_HALT0_MC and ME_STOP0_MC registers this bit field is read-only and always 0.
8 PDO	I/O output power-down control This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
11 MVRON	Main voltage regulator control This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
14:15 FLAON	Flash power-down control This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
24 PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on

Table 1796. ME_<*mode*>_MC field descriptions (continued)

Field	Description
26 XOSCON	external crystal oscillator control 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28:31 SYSCLK	System clock switch control These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

65.3.2.15 Peripheral Status Register 0 (ME_PS0)

This register provides the status of the peripherals. See *Table 1797* for details.

Address: 0x060 Access: User read, Supervisor read, Test read

65.3.2.25 Peripheral Control Registers (ME_PCTL*n*)

These registers select the configurations during run and non-run modes for each peripheral. Please see *Table 1788* for information on which ME_PCTL*n* locations are actually occupied. The unoccupied locations contain a read-only byte value of 0x00.

Note: After modifying any of the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTLn registers, software must request a mode change and wait for the mode change to be completed before entering debug mode in order to have consistent behavior between the peripheral clock control process and the clock status reporting in the ME_PSn registers.

65.3.2.31 Core Address Register 0 (ME_CADDR0)

This register gives the boot address for peripheral core_2 and a bit for controlling whether peripheral core_2 is to be reset on the next mode change that has peripheral core_2 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (that is while

ME_GS[S_MTRANS] = 1). A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted.

Note: The reset value of the ME_CADDR0[ADDR] field is determined by the chip configuration and boot mode.

Address: 0x1E0 Access: User read, Supervisor read/write, Test read/write

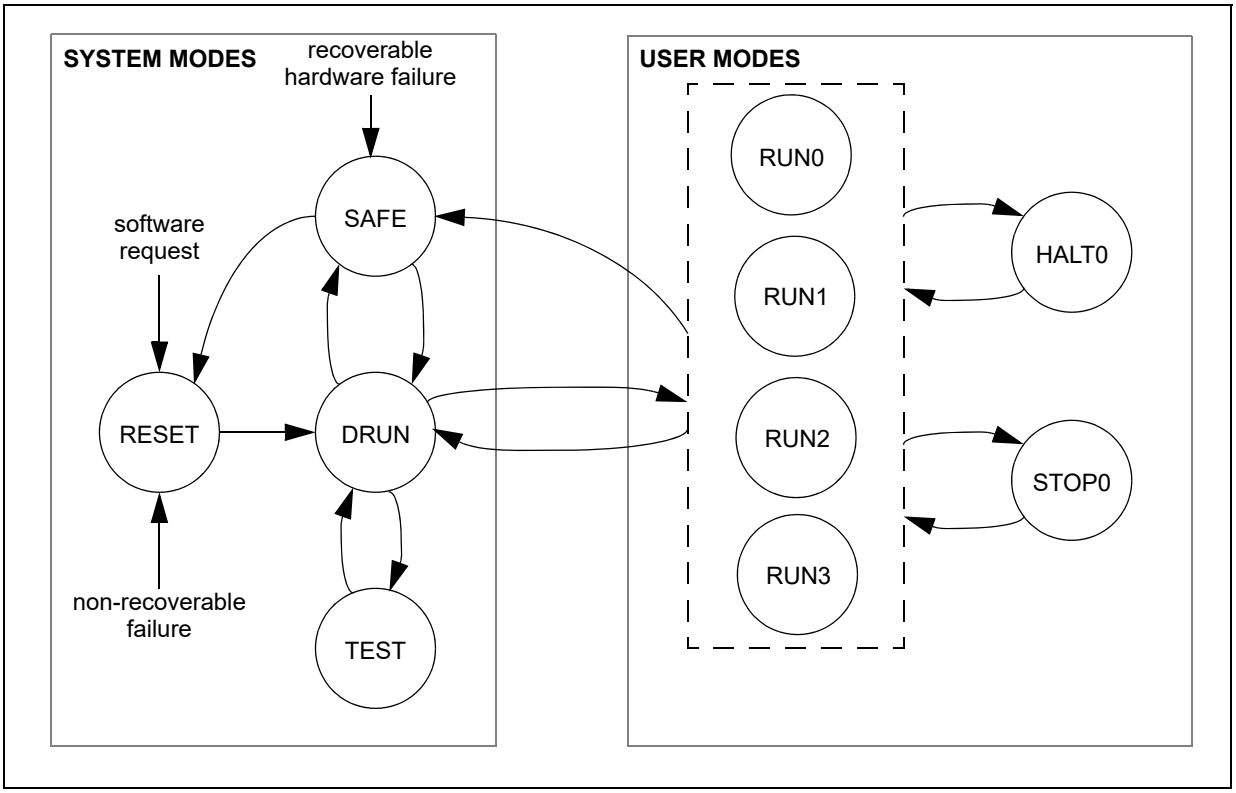
65.4 Functional description

65.4.1 Mode transition request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.



Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register.The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please see *Section 65.4.5: Mode Transition Interrupts*.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as: RUN0–3 → RUN0–3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0 or STOP0 modes.

If CMU reveals a loss of PLL/XOSC clock before a transition request, such transition is not completed. If failure removal and CMU flags are reset, then transition is executed correctly.

Figure 1869. MC_ME Mode Diagram

65.4.2 Modes details

65.4.2.1 RESET mode

The chip enters this mode on the following events:

- From SAFE, DRUN, RUN0–3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either “0000” for a ‘functional’ reset or “1111” for a ‘destructive’ reset
- From any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

65.4.2.2 DRUN mode

The chip enters this mode on the following events:

- Automatically from RESET mode after completion of the reset sequence
- From RUN0–3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0011”

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock

configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software:

To initialize all registers as per the system needs

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.3 SAFE mode

The chip enters this mode on the following events:

- From any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with “0010”
- From any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see *Chapter 60: Reset Generation Module (MC_RGM)*, for details)

Note: If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by hardware, a SAFE mode interrupt is generated. See *Section 65.4.5.3: SAFE Mode Transition Interrupt* for details.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note: If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip’s final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - Re-initialize the chip via the DRUN mode, or
  - Completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged. ,

65.4.2.4 TEST mode

The chip enters this mode on the following event:

From the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0001”

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to “1111”, and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software:

To execute software test routines.

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.5 RUN0–3 modes

The chip enters one of these modes on the following events:

- From the DRUN, SAFE, or another RUN0–3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0100–0111”
- From the HALT0 mode due to an interrupt event
- From the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0–3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0–3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software:

To execute application routines.

Note: Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.6 HALT0 mode

The chip enters this mode on the following event:

From one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1000”.

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.,

This mode is intended as a first-level low-power mode with:

- The core clocks frozen
- The additional core clocks frozen
- Only a few peripherals running

and to be used by software

- To wait until it is required to do something and then to react quickly (that is within a few system clock cycles of an interrupt event)

The normal exit of the HALT0 mode is from an interrupt event. Wakeup events will not cause HALT0 mode exit.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

65.4.2.7 STOP0 mode

The chip enters this mode on the following event:

From one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1010”.

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- The primary PLL
- The secondary PLL

The flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- The core clock frozen
- The additional core clocks frozen
- Almost all peripherals stopped

and to be used by software

To wait until it is required to do something with no need to react quickly (for example, allow for system clock source to be re-started).

The normal exit from the STOP0 mode is by an interrupt or a wakeup event.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

65.4.3 Mode transition process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the XOSC is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL's lock status bit.

65.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. See *Section 65.4.5: Mode Transition Interrupts*, for details.

In the case of mode transitions occurring because of hardware events such as: a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

65.4.3.2 Target mode configuration loading

On completion of the *Target mode request* step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (such as: voltage sources, clock sources, flash, pads) control process.

An overview of resource control possibilities for each mode is shown in *Table 1810*. A 'X' indicates that a given resource is configurable for a given mode.

Table 1810. MC_ME resource control overview

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0
IRC	on	X on	on	on	on	on	on
XOSC	off	X off	off	X off	X off	X off	X off
PLL0	off	X off	off	X off	X off	X off	off
PLL1	off	X off	off	X off	X off	X off	off
FLASH	normal	X normal	normal	X normal	X normal	X low-power	X power-down
MVREG	on	on	on	on	on	on	on
PDO	off	X off	X on	off	off	off	X off

65.4.3.3 Peripheral clocks disable

On completion of the *Target mode request* step and the system clock frequency ramp-down of the *System clock switching* step, the MC_ME requests each peripheral to enter its stop mode when:

the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0–7 and ME_LP_PC0–7, and the peripheral control registers ME_PCTL*n*

Note: The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please see *Section 65.4.6: Peripheral Clock Gating*, for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

65.4.3.4 Processor low-power mode entry

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the HALT0 mode, the MC_ME requests the processor to enter its halted state. The processor acknowledges its halt state request after completing all outstanding bus transactions.

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the STOP0 mode, the MC_ME requests the processor to enter its stopped state. The processor acknowledges its stop state request after completing all outstanding bus transactions.

65.4.3.5 Processor clocks disable

If, on completion of the *Processor low-power mode entry* step, and all processors which are configured in the ME_CCTL*n* registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

Caution: Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

65.4.3.6 System clock disable

If, on completion of the *Processor clocks disable* step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

65.4.3.7 Clock sources switch-on

On completion of the *Processor low-power mode entry* step, the MC_ME switches on all clock sources based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

65.4.3.8 Flash memory module switch-on

On completion of the step, if the flash memory needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the flash memory to exit from its low-power/power-down mode. When the flash memory is

available for access, the S_FLA bit field of the ME_GS register is updated to “11” by hardware.

Caution: It is illegal to switch the FLASH or the DFLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

65.4.3.9 Pad outputs-on

On completion of the step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- All pad outputs are enabled to return to their previous state
- Slew rate control mechanism is switched on

65.4.3.10 Peripheral clocks enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0–7, ME_LP_PC0–7, and the peripheral control registers ME_PCTL*n*, the MC_ME enables the clocks for selected modules as required. If the value of the PWRLVL field of the ME_<target mode>_MC register is less than that of the ME_<current mode>_MC register’s, this step is executed only after the *System clock switching* process is completed.

65.4.3.11 System and processor clocks enable

On completion of the *Flash memory module switch-on* step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTL*n* registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTL*n* registers to be running in the target mode and which have their RMC bits in the ME_CADDR*n* registers set to ‘1’. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the MW_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register’s, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the *System clock switching* process is completed.

65.4.3.12 Processor low-power mode exit

On completion of the *System and processor clocks enable* step, the MC_ME requests all processors which are configured in the ME_CCTL*n* registers to be disabled in the current mode and to be running in the target mode by deasserting the corresponding core_stop bits.

65.4.3.13 System clock switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the external crystal osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (that is the external crystal oscillator has stabilized).
- The target clock configuration for the secondary PLL takes effect only after the S_PLL0 bit of the ME_GS register is set by hardware (that is the primary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with “1111”. This is possible only in the TEST mode.

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the *Clock sources switch-on* process has completed if the target system clock source is one of the following:
  - The 16 MHz internal RC oscillator
  - The external crystal oscillator
  - The primary PLL
- The *Peripheral clocks disable* process has completed in order not to change the system clock frequency before peripherals close their internal activities
- The *Peripheral clocks enable* process has completed

An overview of system clock source selection possibilities for each mode is shown in *Table 1811*. A ‘X’ indicates that a given clock source is selectable for a given mode.

Table 1811. MC_ME System Clock Selection Overview

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0
16 MHz int. RC osc.		X (default)		X (default)	X (default)	X (default)	
external crystal osc.		X		X	X	X	
primary PLL (PHI)		X		X	X	X	

Table 1811. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0
secondary PLL		X		X	X	X	
system clock is disabled		X(1)					

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

65.4.3.14 Pad switch-off

If the PDO bit of the ME_<target mode>_MC register is '1' then

The outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the *Peripheral clocks disable* process has completed.

65.4.3.15 Clock sources switch-off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources switched off at this step:

- The 16 MHz internal RC oscillator
- The external crystal oscillator
- The primary PLL
- The secondary PLL

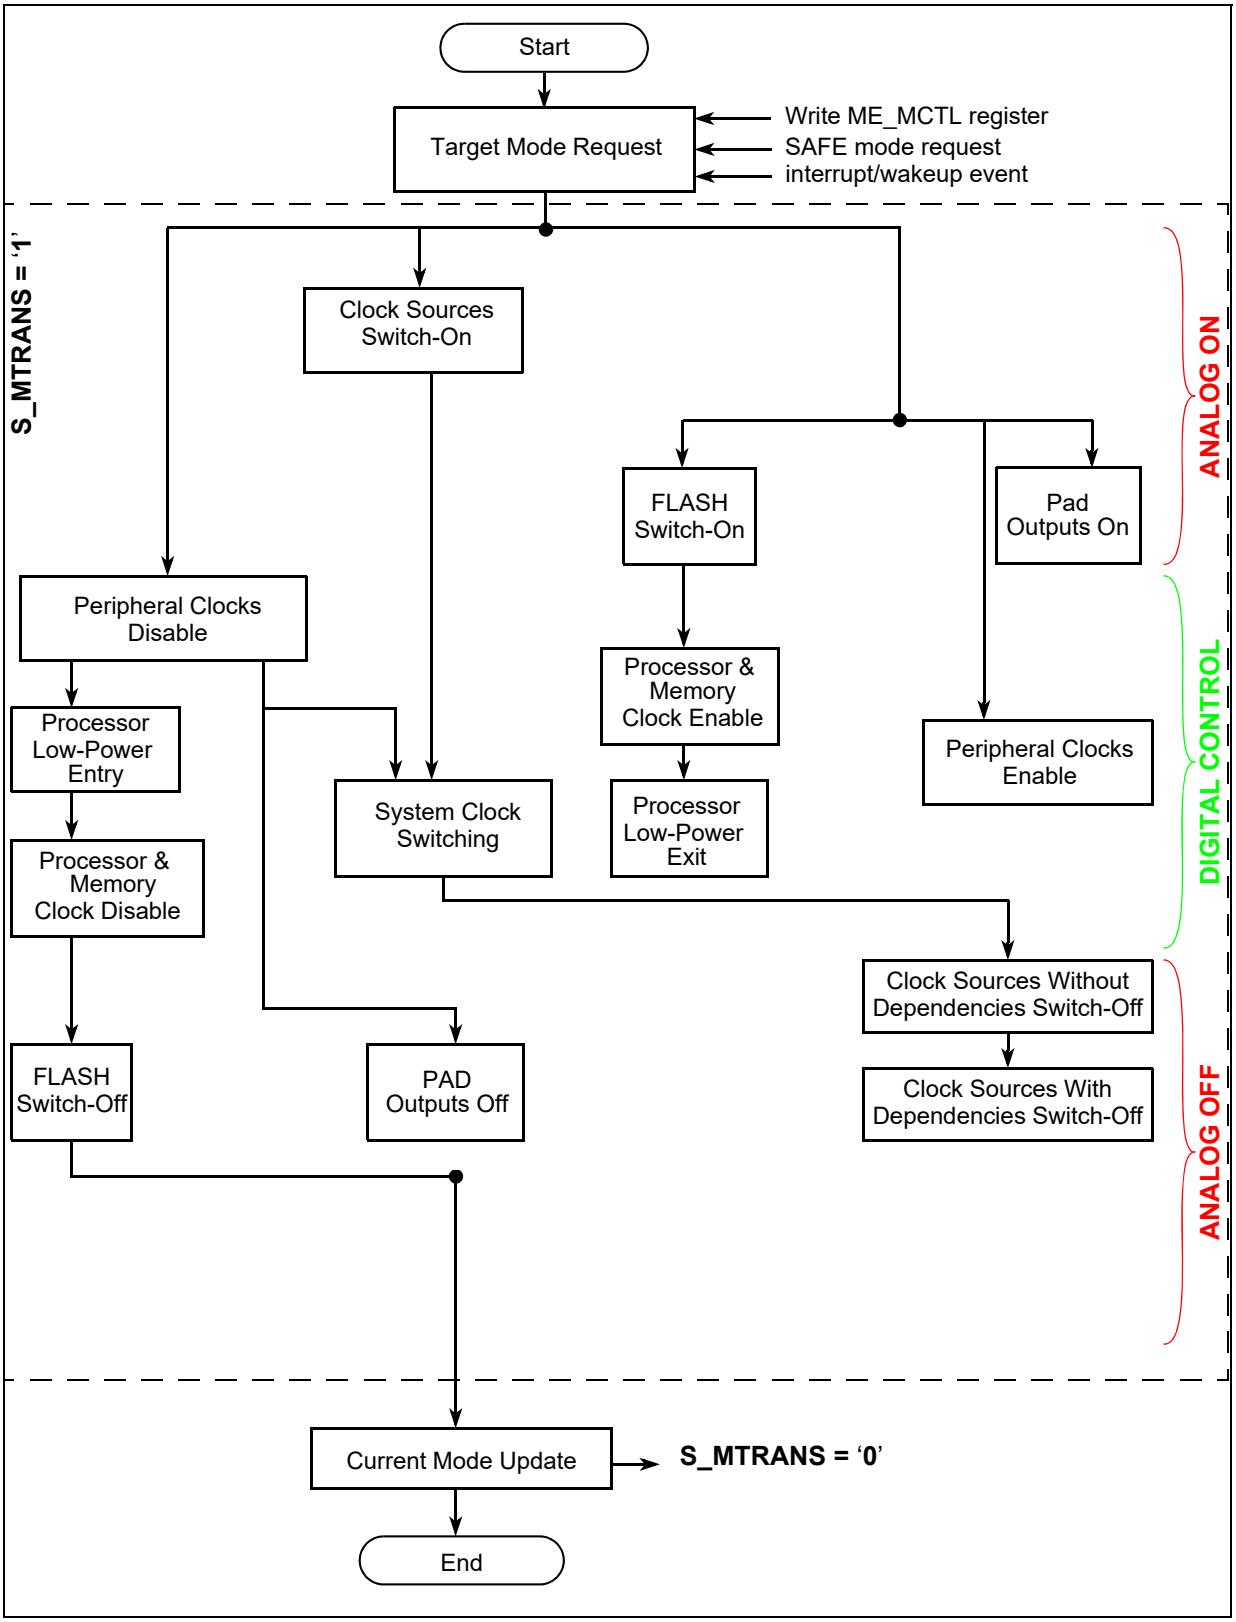
For the clock sources related to the system clock, this step is executed only after the *System clock switching* process has completed.

65.4.3.16 Flash memory switch-off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the flash is to be put in its low-power or power-down mode, the MC_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the *Processor clocks disable* and *System clock disable* processes have completed.

65.4.3.17 Current mode update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when:



- All the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register
- Power sequences are done
- Clock disable/enable process is finished
- Processor low-power mode (stop) entry and exit processes are finished

Note: SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

Figure 1870. MC_ME Transition Diagram

65.4.4 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz int. RC osc. is selected as the system clock, IRC must be on.
- If the external crystal osc. clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration “00” for the FLAON bit field is reserved.
- System clock configurations marked as ‘reserved’ may not be selected.
- Configuration “1111” for the SYSCLK bit field is allowed for the TEST mode, and only in this case may all system clock sources be turned off.

Caution: If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

65.4.5 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

65.4.5.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in the *Section 65.4.4: Protection of Mode Configuration Registers*, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is ‘1’.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0–7/ME_LP_PC0–7 and ME_PCTL*n* registers, the interrupt pending bit I_ICONF_CU of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CU of the ME_IM register is ‘1’.

If an attempt to write to one of the ME_CADDR*n* registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is ‘1’.

65.4.5.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new

mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.

- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (that is a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, t he write operation is ignored.
- If a HALT0 mode request occurs while an interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, t he write operation is ignored.
- If a STOP0 mode request occurs while a wakeup or interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, t he write operation is ignored.

Note: As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI. ,

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0–3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined ‘reasonable’ amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

Warning: Depending on the cause of the mode transition not completing, aborting via a request back to the parent mode may not be able to recover. In this case, software should request a change to either SAFE or RESET mode, since the cause of the hang-up is most likely due to a hardware fault.

- Self-transition requests (for example, RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (that is S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0–3 mode properly (that is all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again. ,

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'. ,

65.4.5.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1' .

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (by programming the ME_MCTL register).

65.4.5.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (that is the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

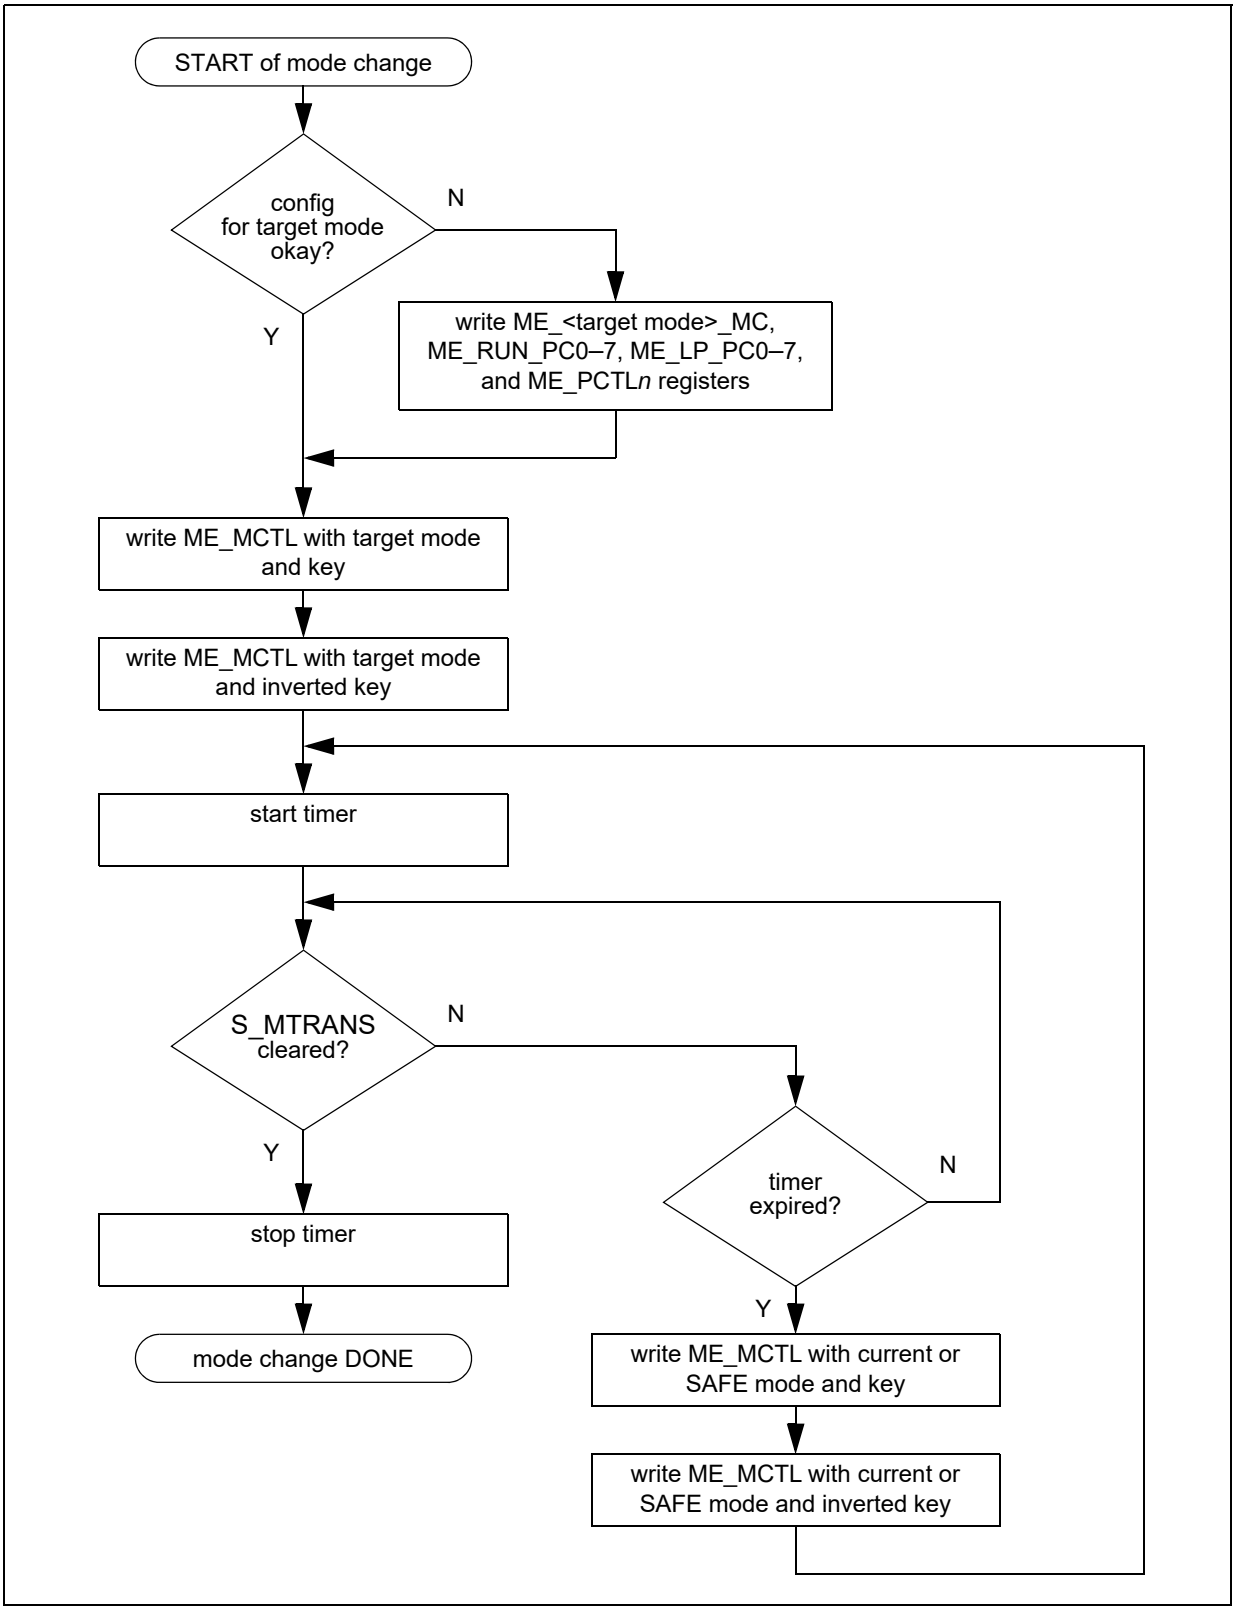
65.4.6 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0–7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0–3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTL*n* registers.

The low-power peripheral configuration registers ME_LP_PC0–7 are chosen only during the low-power modes HALT0 and STOP0 All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTL*n* registers.

Any modifications to the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers do not affect the clock gating behavior until a new mode transition request is generated.



Whenever the processor enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTL*n* register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits. Any further modifications of the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers during a debug session will take affect immediately without requiring any new mode request.

65.4.7 Application Example

Figure 1871 shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

Figure 1871. MC_ME Application Example Flow Diagram

66 e200z4256 Core Debug Support

This chapter describes the debug features of the e200z4256 core.

66.1 Overview

Internal debug support in the e200z4256 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z4256 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z4256 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

66.1.1 Software debug facilities

e200z4256 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

66.1.1.1 *PowerISA 2.06* compatibility

The e200z4256 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

66.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z4256 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger (Refer to *Section 66.1.4, Sharing debug resources by software/hardware*). A data trace port is also provided.

66.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z4256 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (that is the normal setting). Refer to the “Data Trace Control Register (DTC)” section in the Core (e200z420n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

66.1.3 Hardware debug facilities

The e200z4256 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z4256 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

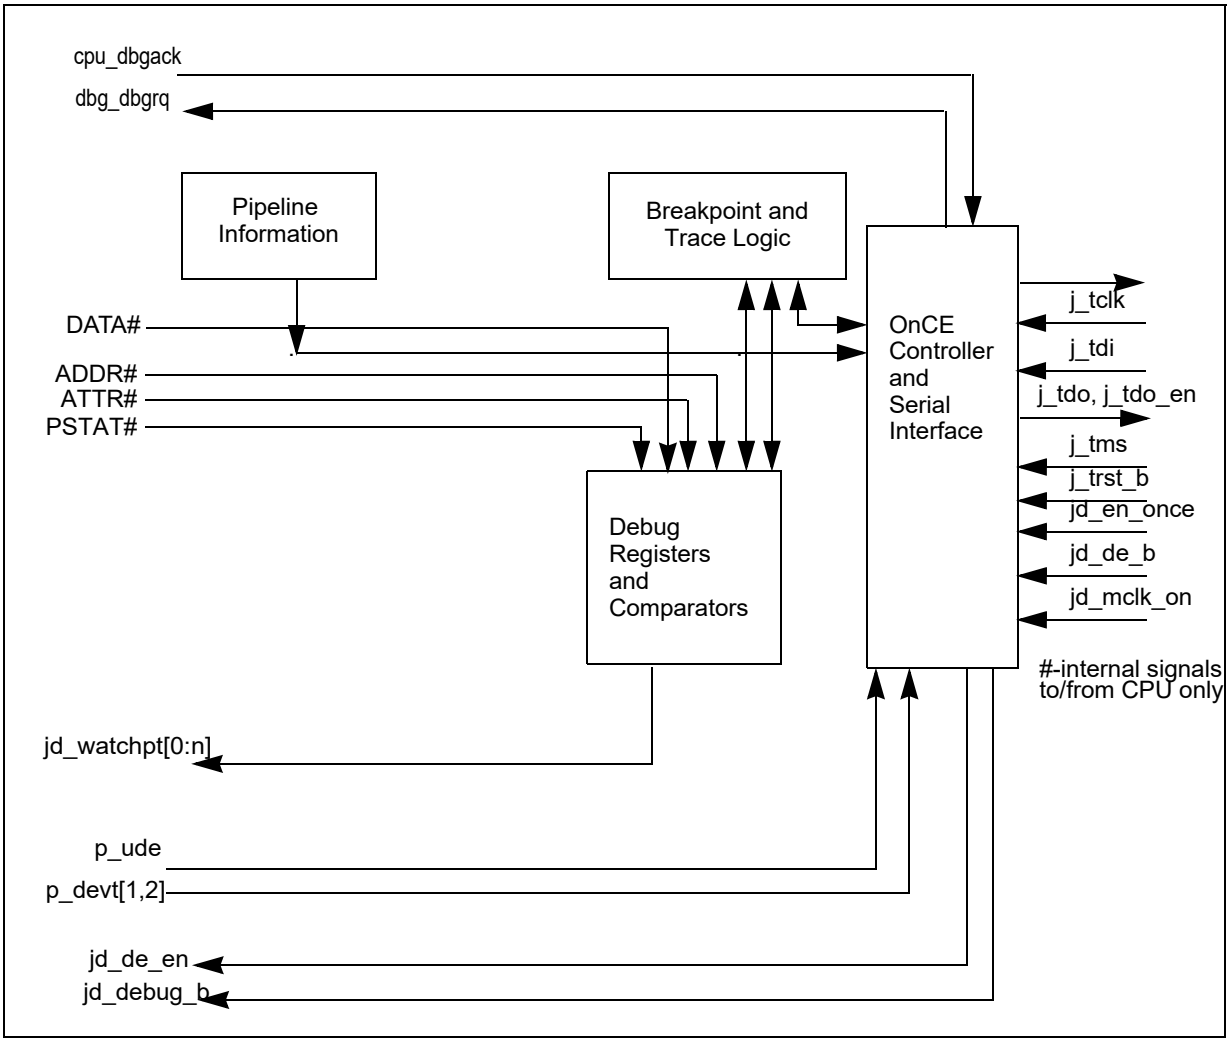
Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in *Section 66.3, Debug registers* are reserved for use by the external debugger. The same events described in *Section 66.2, Software debug events and exceptions* are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via

EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

66.1.4 Sharing debug resources by software/hardware



Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

66.1.4.1 Simultaneous hardware and software debug event handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1872 shows the e200z4256 debug resources.

Figure 1872. e200z4256 debug resources

66.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z4256 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in *Section 66.2.11, External debug event*.
- The Performance Monitor Interrupt event PMI, which is described in *Section 66.2.13, Performance Monitor Interrupt debug event*.

The e200z4256 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

Instruction Address Compare and Data Address Compare *Real address* mode is not supported.

A brief description of each of the event types follows.

66.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

66.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z4256 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, that is no data comparisons are performed since these instructions do not have associated data values.

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.*

66.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 1812 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in *Table 1812*, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 1812. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.

Table 1812. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1812. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1813 through *Table 1816* show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 1813. DAC events and resultant updates, dual-issue case 1

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)

Table 1813. DAC events and resultant updates, dual-issue case 1 (continued)

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1814. DAC events and resultant updates, dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	**Event(s)**	**Result**
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction (7). No ESR update. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1814. DAC events and resultant updates, dual-issue case 2 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instruction (4). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b101. No ESR update. DSRR0 points to instruction (7). No debug event updates for instruction (7). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1815. DAC events and resultant updates, dual-issue case 3

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 1815. DAC events and resultant updates, dual-issue case 3 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1816. DAC events and resultant updates, dual-issue case 4

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.

Table 1816. DAC events and resultant updates, dual-issue case 4 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

66.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be

recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

66.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

66.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ cannot be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

66.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when an EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

66.2.7 Interrupt Taken debug event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

66.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

66.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (that is before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

66.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (that is before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

66.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal

transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

66.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

66.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

66.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers are performed.

66.3.1 Debug Address and Value registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when

performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 1873*) corresponds to the byte data value transferred to/from memory byte offset such as 0, 8, and the least significant byte of the register (labeled B7 in *Figure 1873*) corresponds to byte offset such as 7, F. When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z420n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

Figure 1873. DVC1, DVC2 registers

66.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z4256 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

66.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z4256 adds some implementation specific bits to this register, as seen in *Figure 1874*.

EDM	IDM	RST	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC2	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0	CIRPT	CRET	0

SPR - 308; Read/Write; Reset(1) - 0x0

Figure 1874. Debug Control Register 0 (DBCR0) register

1. $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

Table 1817 provides bit definitions for Debug Control Register 0.

Table 1817. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0.
		Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.

IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.
26:31	—	Reserved

66.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in *Figure 1876*.

SPR - 310; Read/Write; Reset(1) - 0x0

Figure 1876. DBCR2 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1819 provides bit definitions for Debug Control Register 2.

Table 1819. DBCR2 field descriptions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table 1819. DBCR2 field descriptions (continued)

Bit	Name	Description
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.

Table 1819. DBCR2 field descriptions (continued)

Bit	Name	Description
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

66.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 1877*.

0	DVC1C	0	DVC2C	0	0	DAC1XMH	0	DAC2XMH	DAC1XM	DAC2XM	DAC1CFG	DAC2CFG
0	1	2	3	4:5	6:11	12	13	14	15	16:19	20:23	24:27	28:29	30:31

SPR - 563; Read/Write; Reset(1) - 0x0

Figure 1877. DBCR4 register

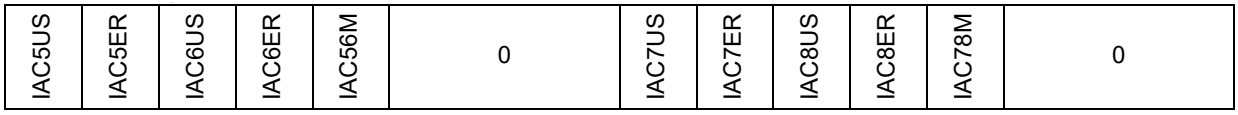
1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1820 provides bit definitions for Debug Control Register 4.

Table 1820. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits

Table 1820. DBCR4 field descriptions (continued)



Bit	Name	Description
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1820. DBCR4 field descriptions (continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01*xx* Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01*xx* Reserved 1*xxx* Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

66.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 1878*

SPR - 564; Read/Write; Reset(1) - 0x0

Figure 1878. DBCR5 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1821 provides bit definitions for Debug Control Register 5.

Table 1821. DBCR5 field descriptions

Bit	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)

66.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in *Figure 1880*.

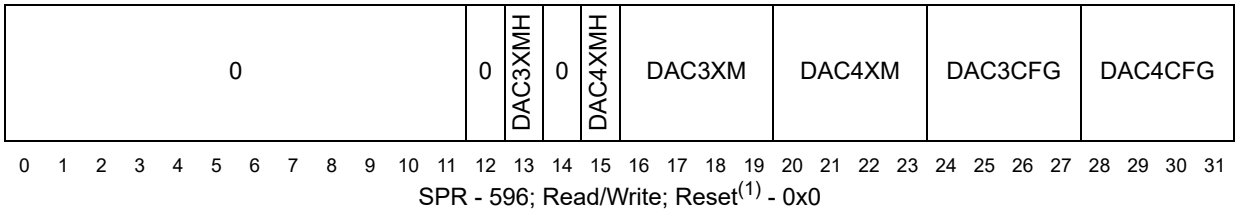

Figure 1880. DBCR7 register

1. DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1823 provides bit definitions for Debug Control Register 7.

Table 1823. DBCR7 field descriptions

Bit	Name	Description
0:12	—	Reserved
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High. DAC3XMH extends the range of the DAC3XM field. 0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits

Table 1823. DBCR7 field descriptions (continued)

Bit	Name	Description
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001–1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

66.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in *Figure 1881*.

SPR - 597; Read/Write; Reset(1) - 0x0

Figure 1881. DBCR8 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1824 provides bit definitions for Debug Control Register 8.

Table 1824. DBCR8 field descriptions

Bit	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 DAC3 debug events not affected by MSR_{PR} 01 Reserved 10 DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC3 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 DAC3 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 DAC4 debug events not affected by MSR_{PR} 01 Reserved 10 DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC4 debug events can only occur if MSR_{PR}=1 (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 DAC4 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1

Table 1824. DBCR8 field descriptions (continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

66.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 1882*.

IDE	UDE	MRR	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 1882. Debug Status Register (DBSR)

Table 1825 provides bit definitions for the Debug Status Register.

Table 1825. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred

Table 1825. DBSR field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

66.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is updated by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 1883*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 600; Read/Write; Reset - unaffected

Figure 1883. Debug Data Effective Address Register (DDEAR)

66.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in *Figure 1884*.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b**, reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 1884. External Debug Resource Allocation Control (EDBRAC0) register

Table 1826 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 1826. EDBRAC0 field descriptions

Bit	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored. 0 Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable.
2	RST	Reset Field Control 0 $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 Event owned by hardware debug. 1 Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 Event owned by software debug. $DBCR0_{TRAP}$ is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 Event owned by software debug. IAC1 control fields are software readable/writable.

Table 1826. EDBRAC0 field descriptions (continued)

Bit	Name	Description
9	IAC2	Instruction Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 Event owned by software debug. DAC1 control fields are software readable/writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1826. EDBRAC0 field descriptions (continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable. **Note:** This bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors that have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** This bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored. 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in *Table 1827* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

66.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. Refer to the "Data Acquisition ID Tag Field" section in the Core (e200z420n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 1885*.

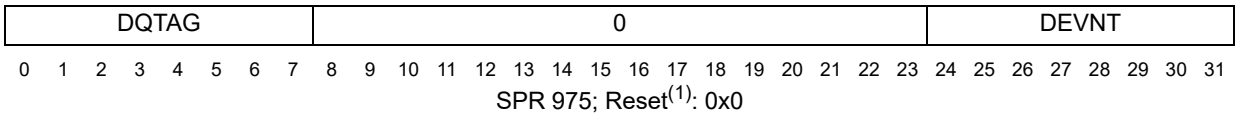

Figure 1885. Debug Event Select register (DEVENT) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.** Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

Table 1828 provides bit definitions for the Debug Event Register.

Table 1828. DEVENT field descriptions

66.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this

register. Refer to the “Data Acquisition Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 1886*.

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

66.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit

checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 1820*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack

limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 1820* and *Table 1823* in *Section 66.3.2, Debug Control and Status registers*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

66.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 66.2, Software debug events and exceptions* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

*It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

66.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

66.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 1887*.

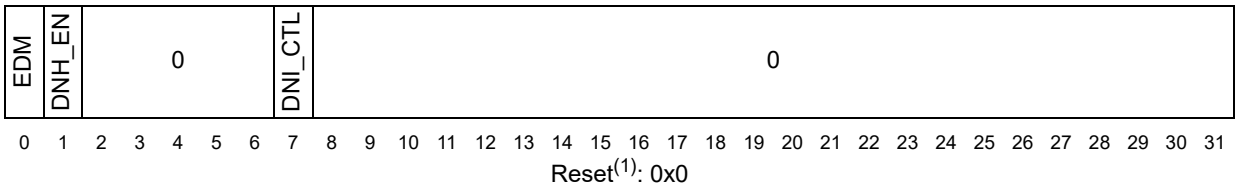

Figure 1887. External Debug Control Register 0 (EDBCR0)

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 1830 provides bit definitions for External Debug Control Register 0.

Table 1830. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	**dnh** Instruction Enable 0 Execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 Execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE}=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. **Note:** This control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1.
8:31	—	Reserved

66.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 1888*.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0

Figure 1888. External Debug Status Register 0 (EDBSR0)

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$=0.

Table 1831 provides bit definitions for External Debug Status Register 0.

Table 1831. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred

Table 1831. EDBSR0 field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

66.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A ‘1’ stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by

the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 1889*.

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0

66.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 1890*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

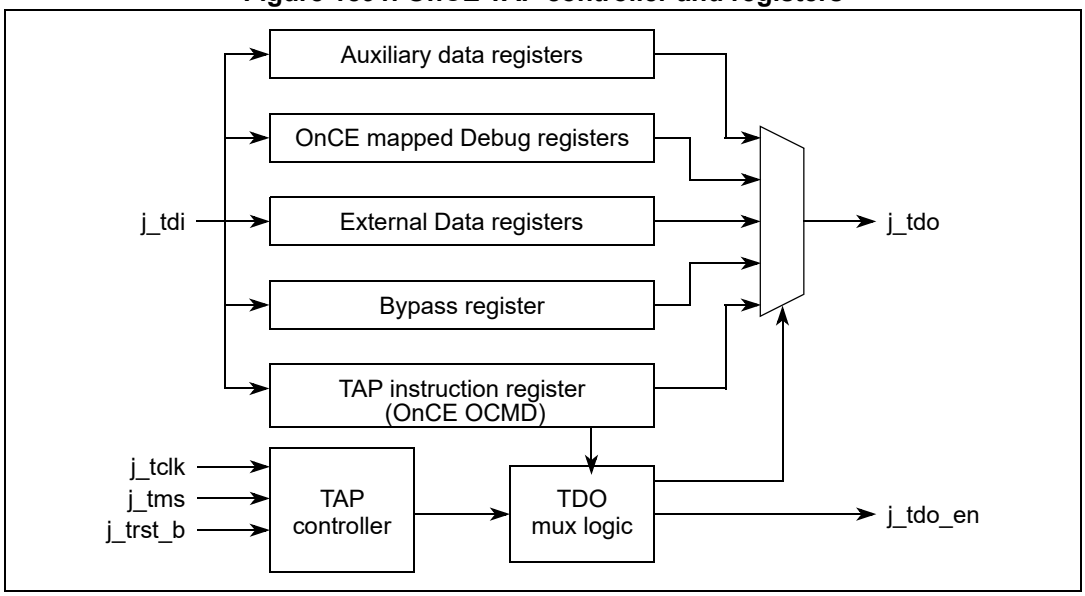
Figure 1890. External Debug Data Effective Address Register (EDDEAR)

66.5.2 OnCE introduction

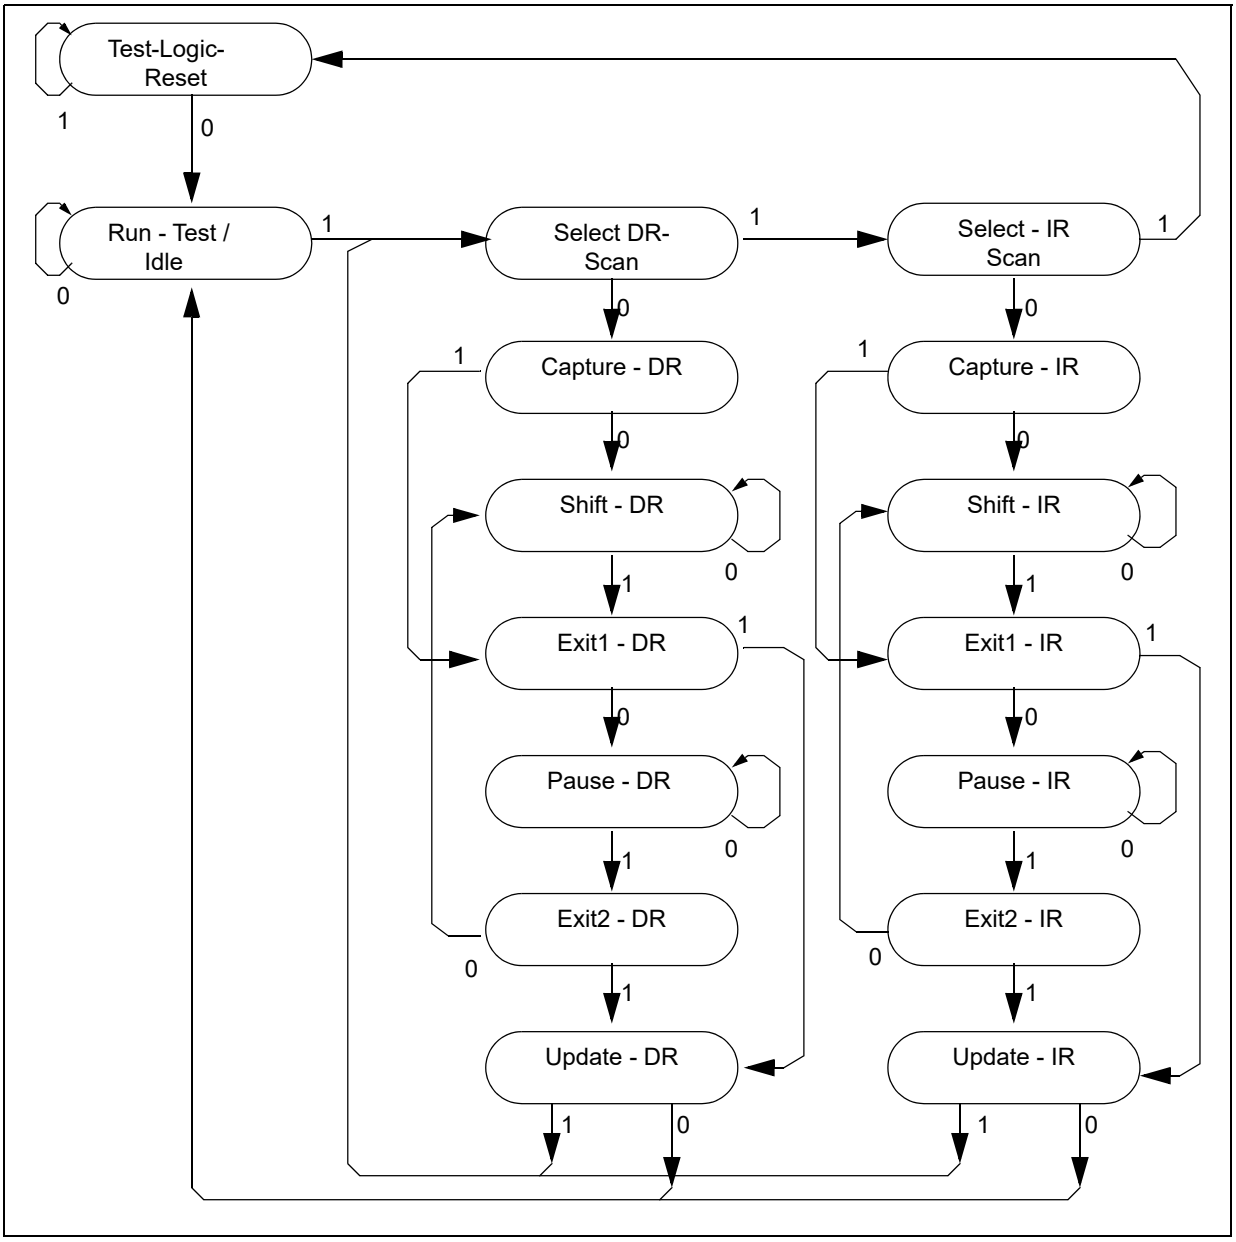
The e200z4256 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z4256 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction



functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.



The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1891. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1892. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 66.5.6.1, OnCE Status register*) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (refer to *Section 66.5.6.2, OnCE Command (OCMD) register*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

66.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

Table 1833 details the primary JTAG/OnCE interface signals.

Table 1833. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en(1)	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z420n3) Core Complex Overview.

66.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

66.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

66.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

66.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

66.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

66.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

66.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take effect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

66.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z4256 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

66.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. Refer to *Section 66.5.6.2, OnCE Command (OCMD) register* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

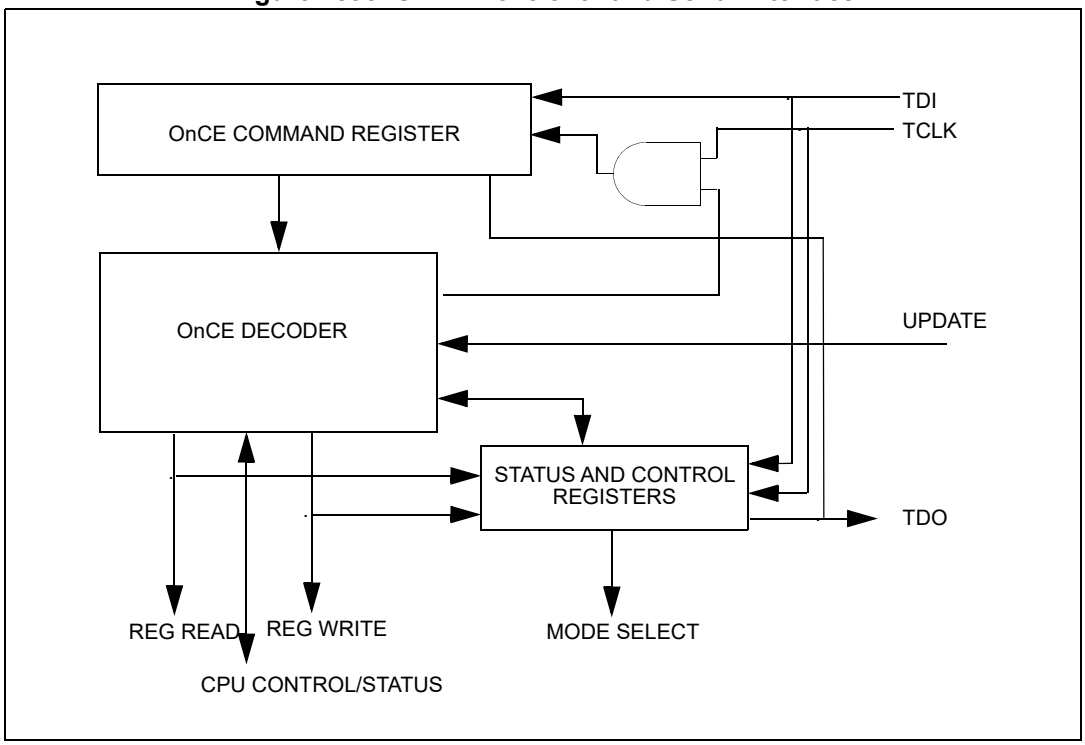
66.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z4256 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

66.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 1840* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

66.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)



This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

66.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 1893* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1893. OnCE Controller and Serial Interface

66.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 1894. OnCE Status register

Table 1834 provides bit definitions for the OnCE Status register.

Table 1834. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including such as External, Critical, machine check, Storage, Alignment, Program) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

66.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 1895*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as

such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step or exit functionality, or both, to be performed, even though the command appears to have no data resource requirement associated with it.

R/W	GO	EX	RS[0:6]
0	1	2	3 4 5 6 7 8 9

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test_Logic_Reset state

Figure 1895. OnCE Command (OCMD) register

Table 1835 provides bit definitions for the OCMD.

Table 1835. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 66.5.9.6, Exiting Debug mode and interrupt blocking*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1835. OCMD field descriptions (continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. **Note:** If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 66.5.9.6, Exiting Debug mode and interrupt blocking*.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 1836* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 1836 indicates the OnCE register addresses.

Table 1836. OnCE register addressing

RS[0:6]	Register Selected
000 0000	Reserved
000 0001	Reserved

1. Causes assertion of the j_en_once_regsel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (such as interrupts, machine checks, bus error conditions) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

66.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z4256 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (refer to *Section 66.7, MPU operation during debug*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 1896*.

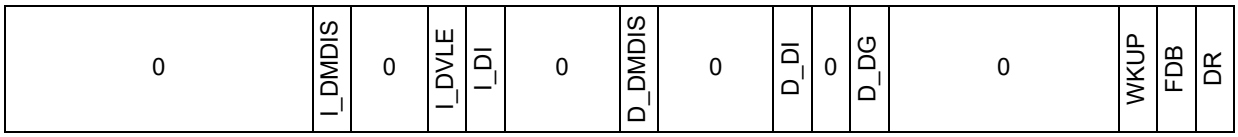

Figure 1896. OnCE Control Register (OCR)

Table 1837 provides bit definitions for the OnCE Control Register.

Table 1837. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug ‘G’ Attribute Bit This bit is used to provide the ‘G’ attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.

Table 1837. OCR field descriptions (continued)

Bit	Name	Description
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo-instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. **Note:** This bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

66.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z4256 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z4256 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z4256 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (such as DBSR) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 1838 provides a list of access requirements for OnCE registers.

Table 1838. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y

PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	

Table 1838. OnCE register access requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	—	—	—	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

66.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input. Refer to *Section 66.5.5.1, OnCE Enable (jd_en_once)* for details.

66.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z4256 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z4256 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

66.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

66.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

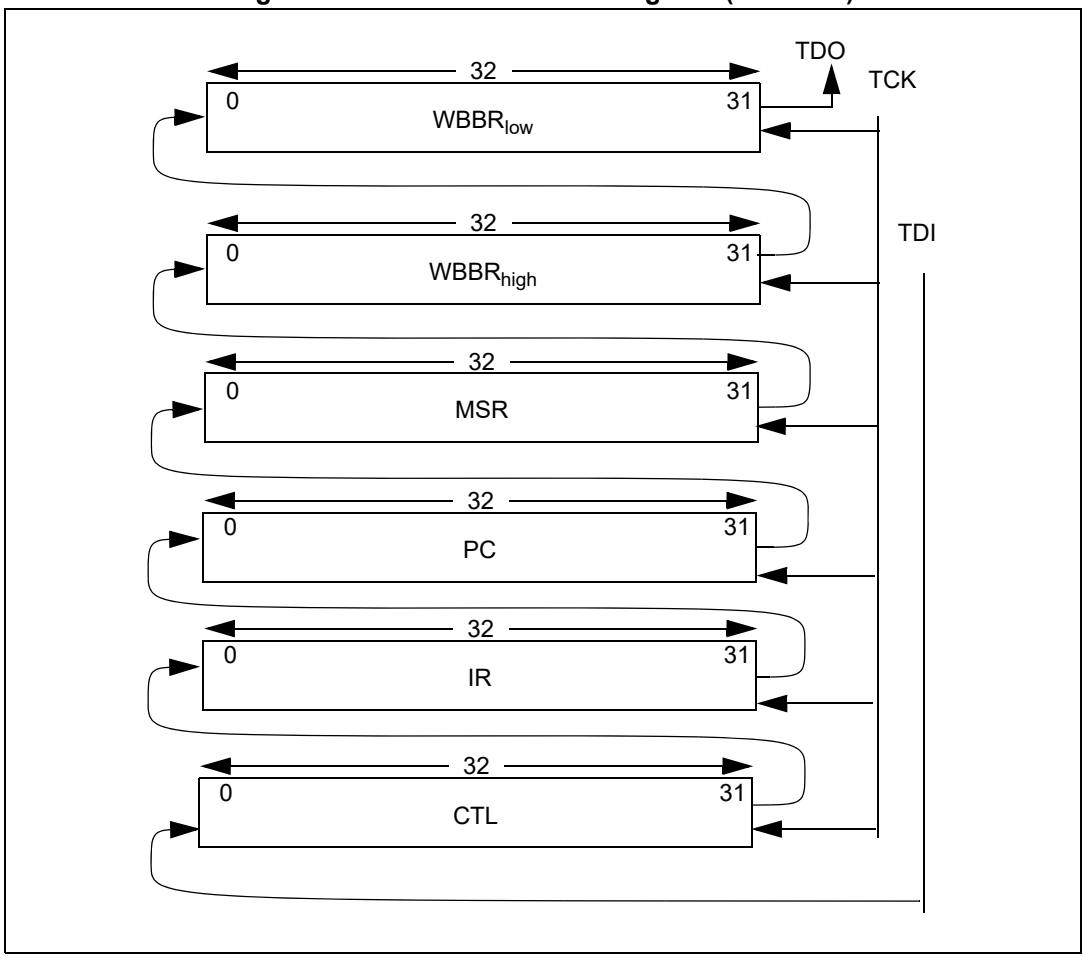
66.5.8.4 Debug request during Waiting, Halted, or Stopped state

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

66.5.8.5 Software request during normal activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z4256, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.



66.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z4256, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

66.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 1897* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1897. CPU Scan Chain Register (CPUSCR)

66.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

66.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the

external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

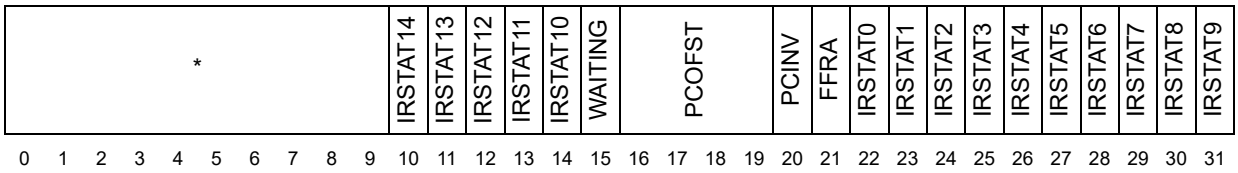


Figure 1898. Control State Register (CTL)

Table 1839. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. Refer to *Section 66.5.5.3, OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered

Table 1839. CTL field descriptions (continued)

Bit	Name	Description
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (Refer to PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of $WBBR_{lo}$ used as operand value.
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.

Table 1839. CTL field descriptions (continued)

Bit	Name	Description
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bits set to ‘0’, and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU,

the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

66.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

66.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 66.5.9.2, Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

66.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

66.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

66.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device or system damage, or both, these registers should not be accessed.

66.6 Watchpoint support

e200z4256 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes (refer to the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter).

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1840 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1840. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]

Table 1840. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.

Table 1840. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

66.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR *Section 66.5.6.3, OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 66.5.6.3, OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

66.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

66.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 66.5.9.2, Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 66.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 66.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

67 Debug and Calibration Interface (DCI)

67.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

67.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

67.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

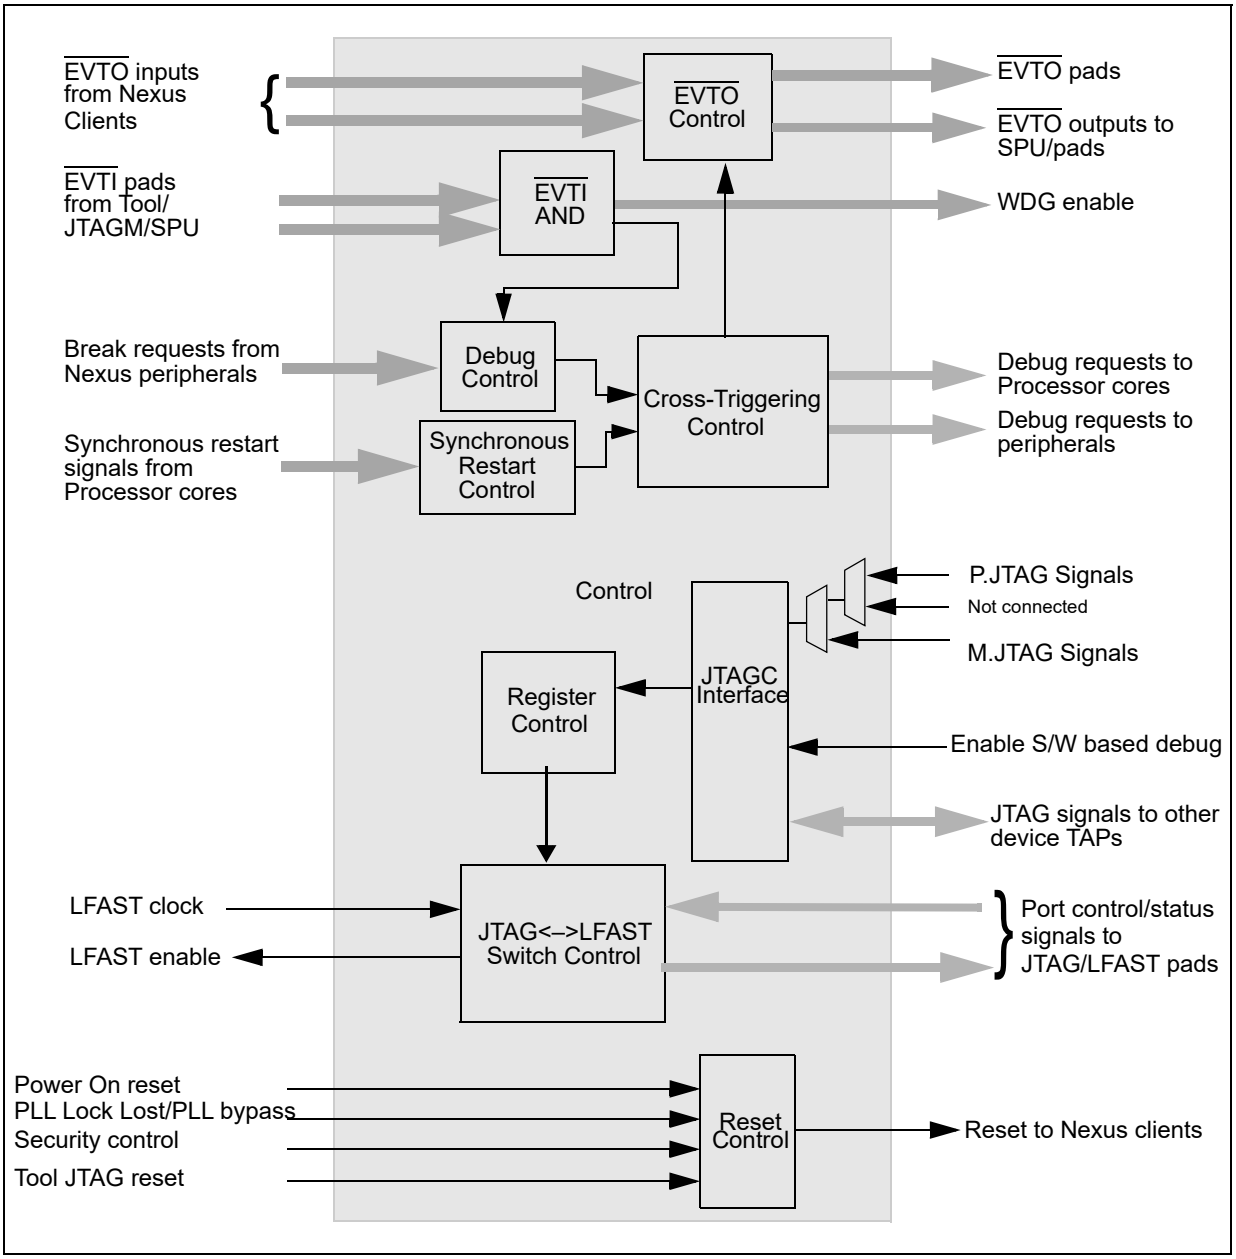
When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

Figure 1899 shows the DCI block diagram.

Figure 1899. DCI block diagram



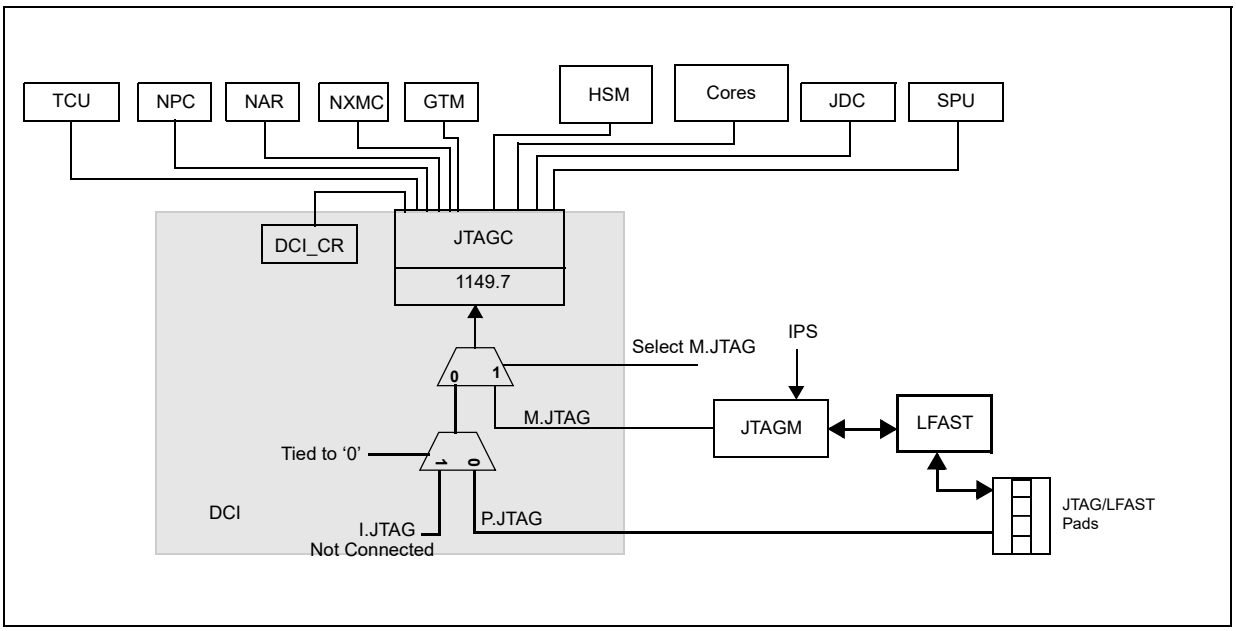


Figure 1900 shows the DCI configuration for the standard production package.

Figure 1900. DCI in a standard configuration

67.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 1841 shows a summary of the configuration options.

Table 1841. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

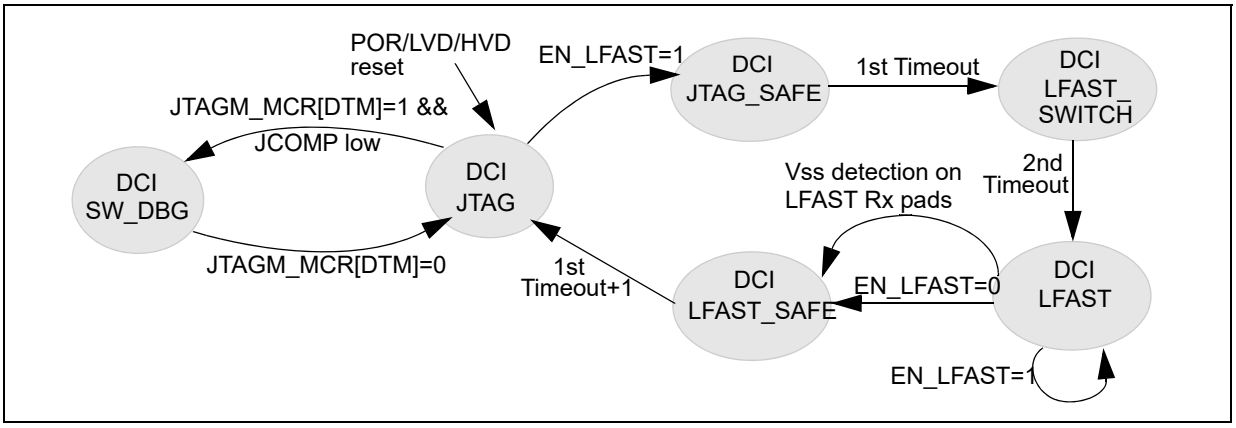
The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the

JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 67.1.3.1: Port sharing between JTAG and LFAST modes on page 3202*. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 1842* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1842. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

Figure 1901 shows the DCI mode switching operation.

Figure 1901. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

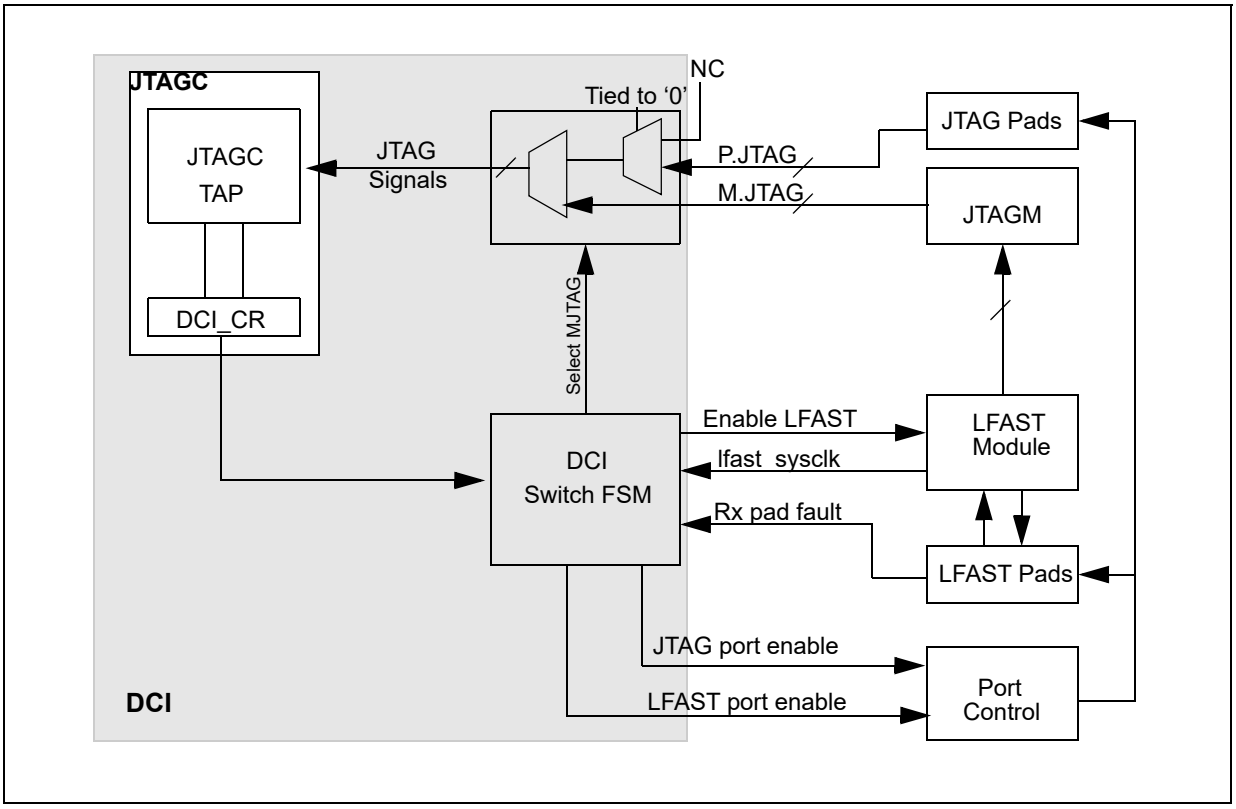


Table 1843 contains the operating mode descriptions.

Table 1843. DCI operating modes

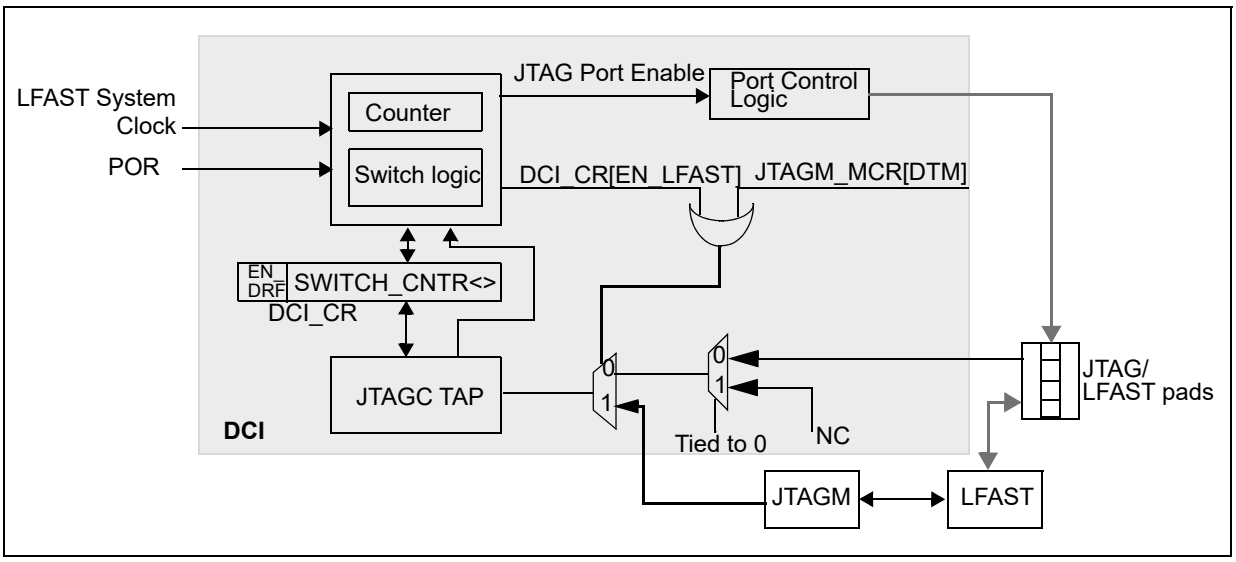
Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

Figure 1902 shows a block diagram of the JTAG/LFAST connections.

Figure 1902. DCI JTAG/LFAST switch integration

67.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):



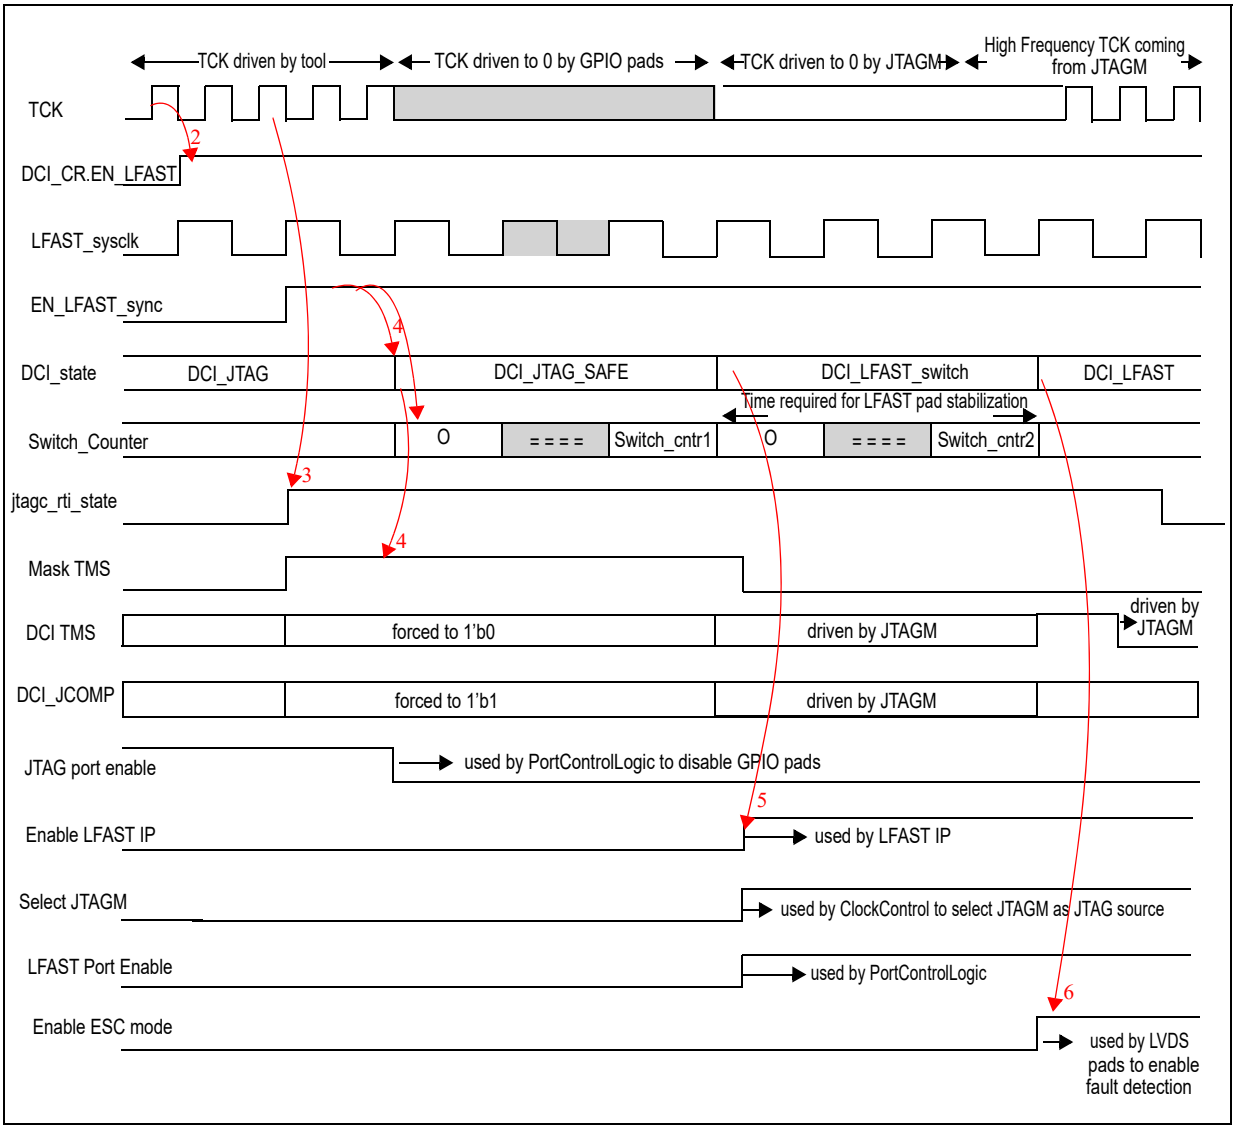
- EN_LFAST – Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2 – Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 1903*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 1903. DCI switching between JTAG and LFAST modes



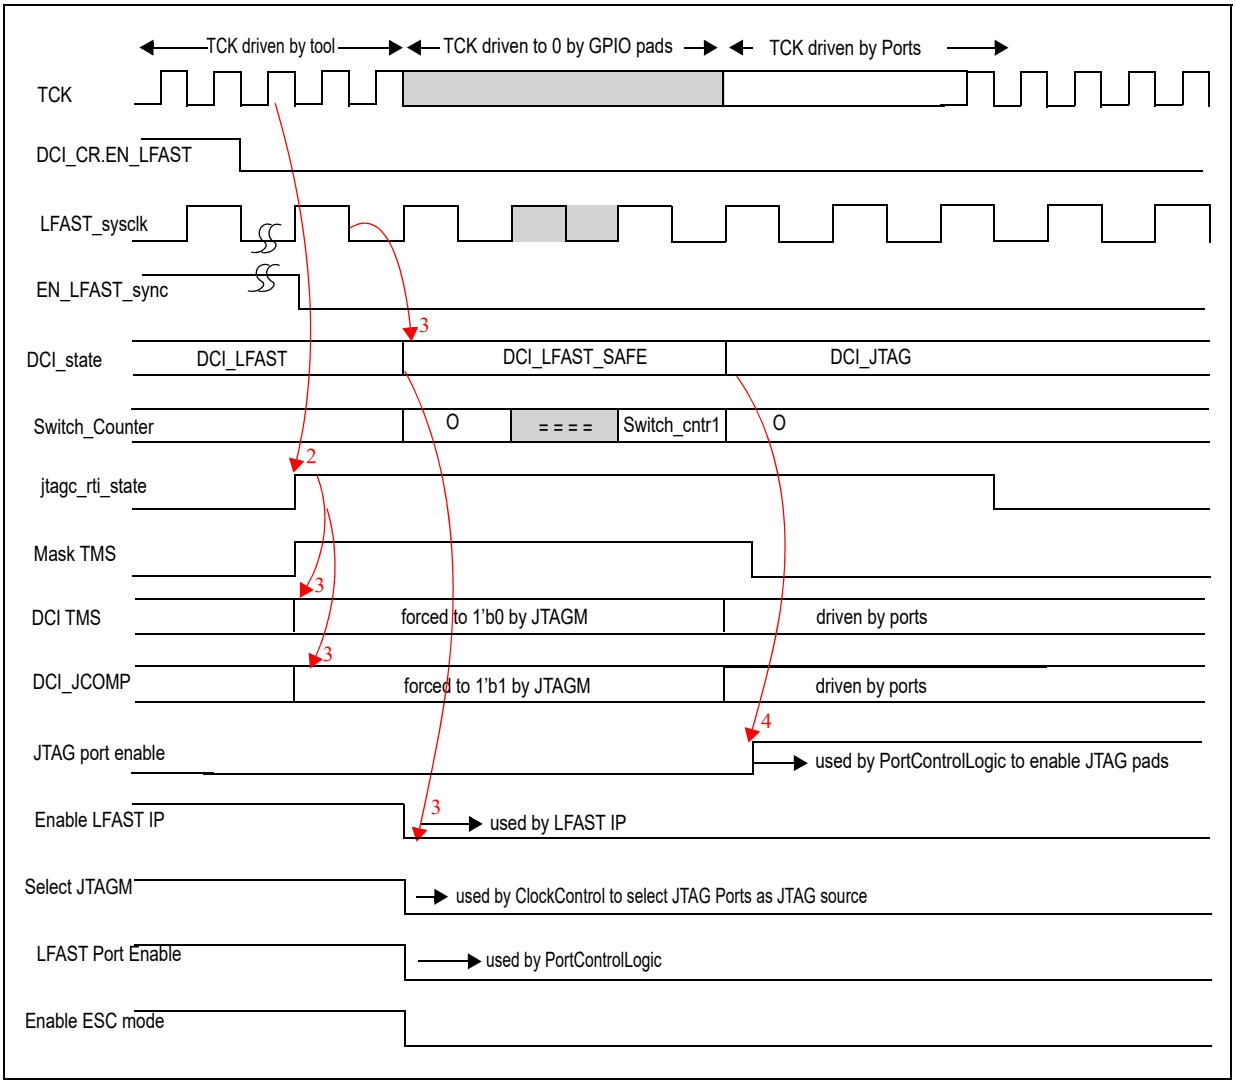
67.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 1904 shows the timing sequence.

Figure 1904. DCI JTAG to LFAST switching diagram



67.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 1847 and *Table 1849* summarize the MCU and tool behaviors. *Figure 1905* shows the timing sequence.

Figure 1905. DCI LFAST to JTAG switching diagram

67.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

67.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

67.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1844. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

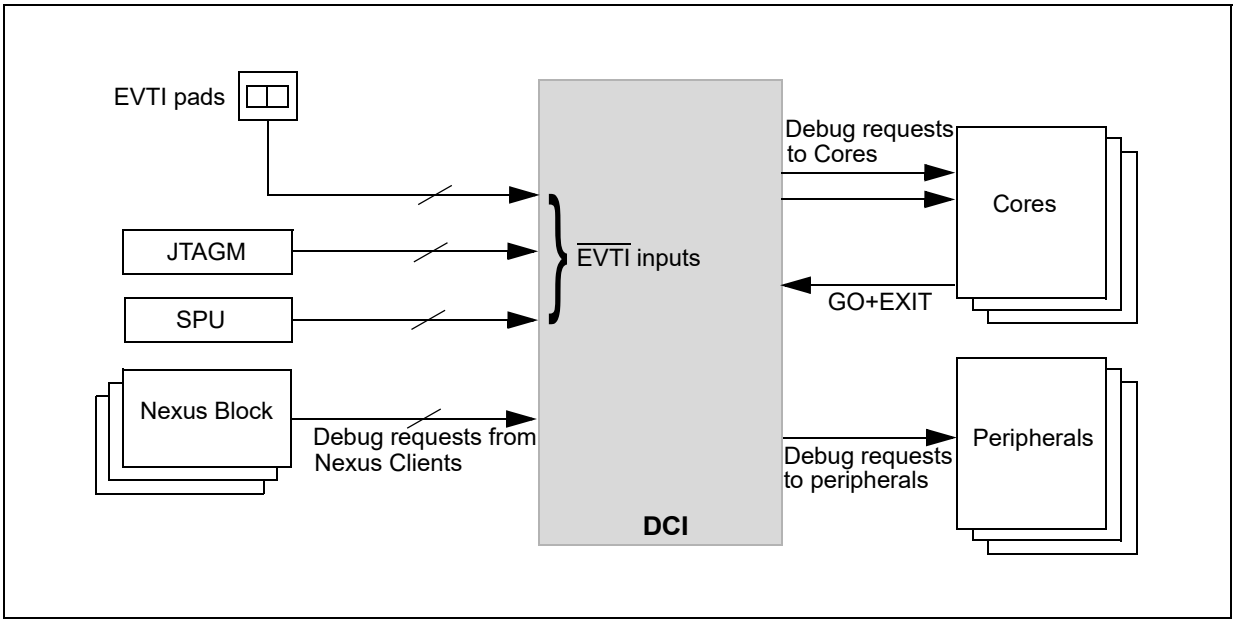
67.1.3.5 SWT control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the EVTI[0] pin is used. If the EVTI[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the EVTI[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the EVTI[0] pin.

Note: Debugger should check the SWT counter to confirm if SWT has actually stopped or not, otherwise repeat the sequence mentioned above to disable the SWT.

67.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.



There are various different input sources that provide debug requests:

- EVTI[1:0] signals from EVTI pads
- EVTI[1:0] signals from JTAGM
- EVTI[1:0] signals from the Sequence Processing Unit (SPU)

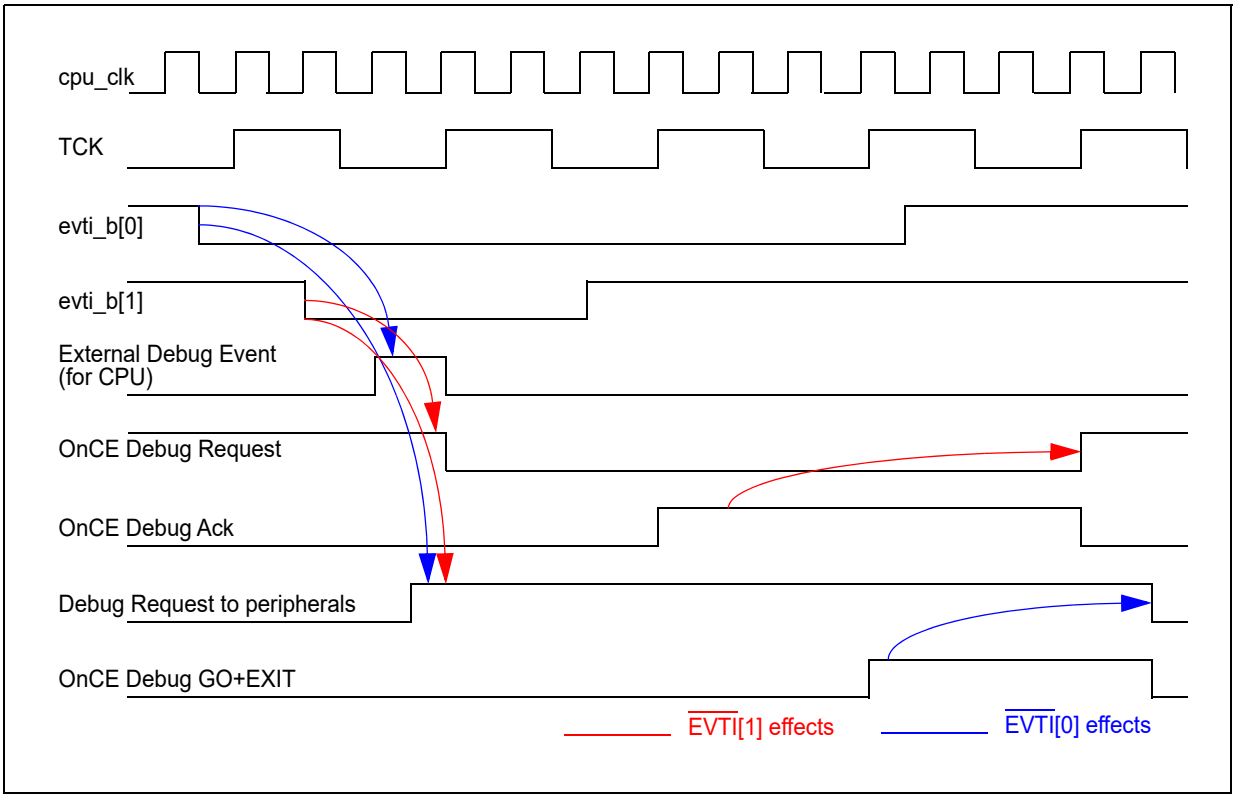
The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1906. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$ inputs are synchronized and logically ANDed in the DCI to generate the following:

- debug requests for each processor core
- external debug requests for each processor core
- debug request for all non-CPU peripherals



The $\overline{\text{EVTI}}$[0] from the EVTI pads, SPU and JTAGM are used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The $\overline{\text{EVTI}}$[1] from the SPU and JTAGM, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 1907 shows the timing sequence.

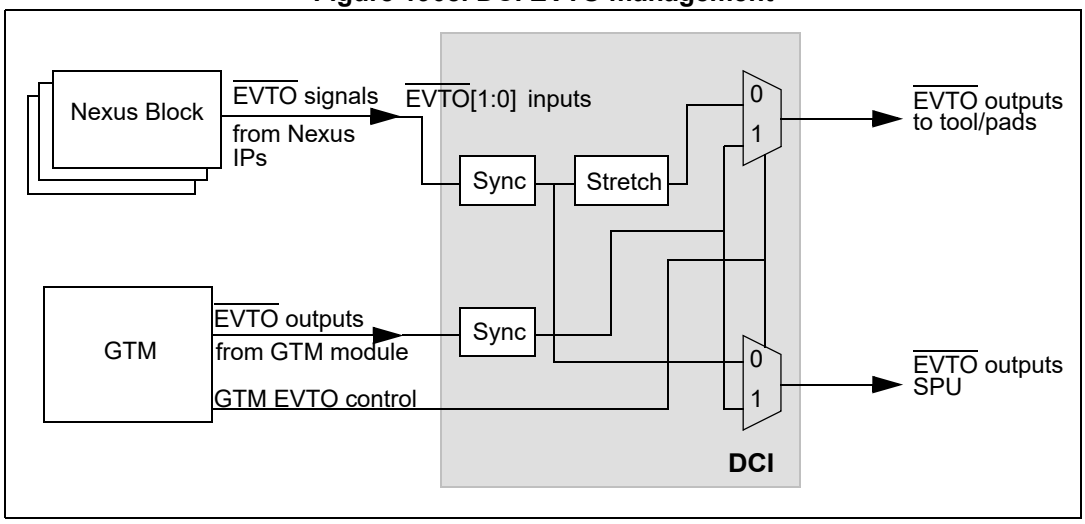
Figure 1907. DCI debug signal generation

67.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

67.1.3.8 Synchronous restart control



The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (that is set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

67.1.3.9 EVTO management

The EVTO management block diagram is presented in *Figure 1908*.

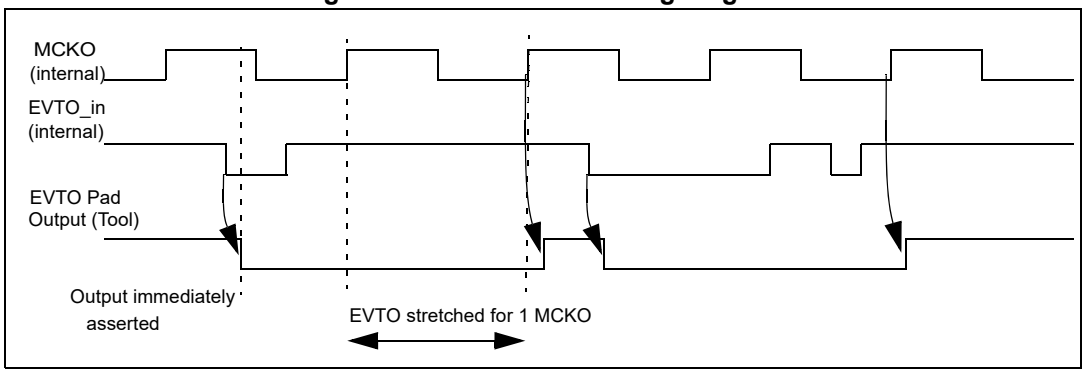


Figure 1908. DCI EVTO management

The DCI module controls distribution of the EVTO outputs from all Nexus Clients including the cores that produce EVTO[1:0] signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[1:0] signals from any Nexus client, the DCI immediately asserts EVTO[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool(*Figure 1909*). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 1909. DCI EVTO timing diagram

67.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

67.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

67.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

67.3 Register description

The DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

67.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 1910* shows the format of the DCI_CR.

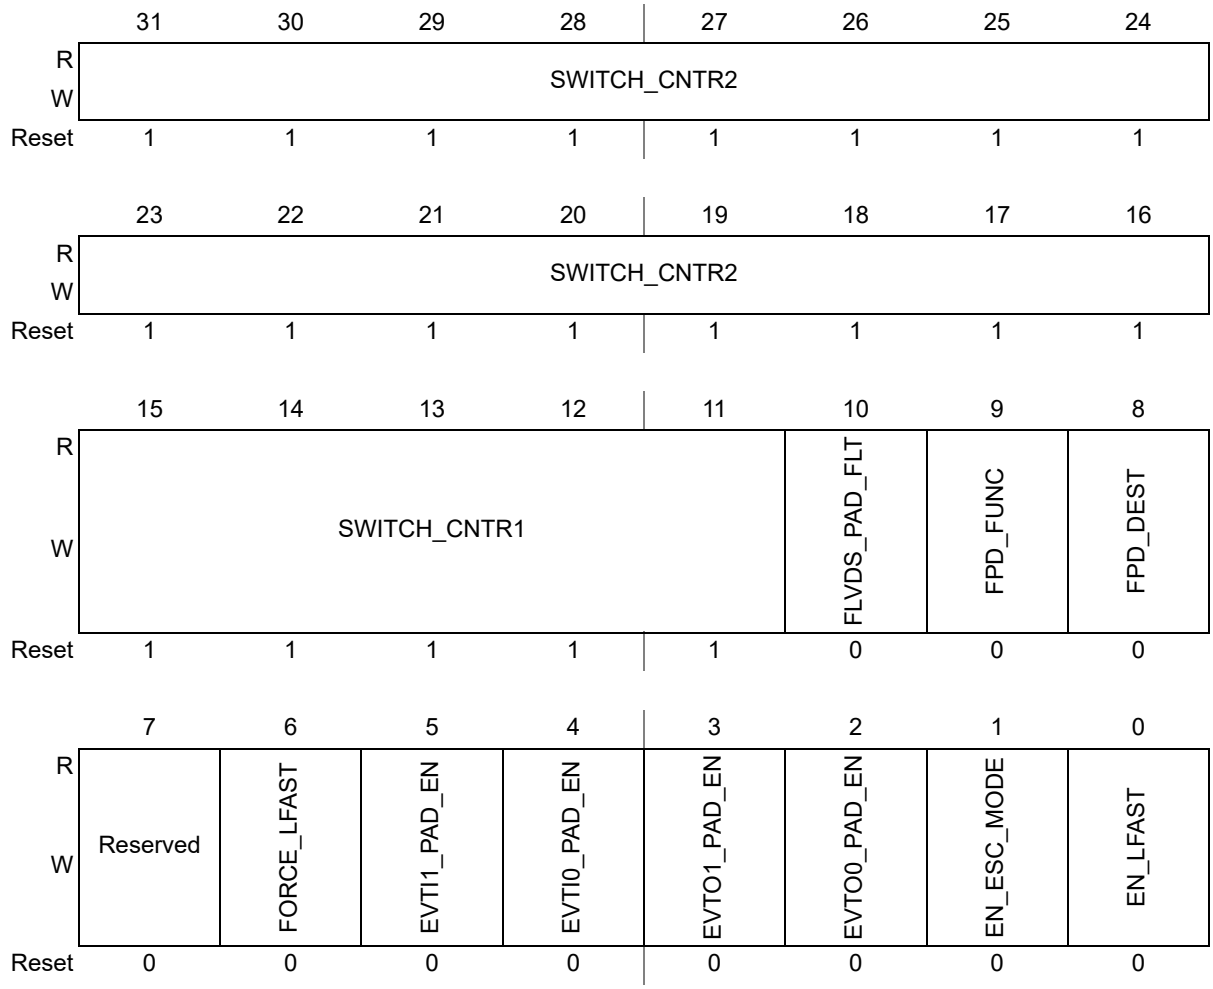

Figure 1910. DCI control register (DCI_CR)

The DCI_CR is described in *Table 1845*.

Table 1845. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2 Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1 Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}

Table 1845. DCI_CR field descriptions (continued)

Field	Description
10 FLVDS_PAD_FLT	Force LVDS Pad Fault Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN(1)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}$[1] pad 0 $\overline{\text{EVTO}}$[1] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[1] pad output enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled
1 EN_ESC_MODE	Enable Escape Mode Fault detect feature enable for LFAST Rx pads. 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(1)	Enable for LFAST-based tool selection This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

67.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter, ENABLE_DATA2. For

a description of the DCI_PINCR functionality, refer to Calibration and Debug configuration chapter (or the Debug and Trace chapter) which describes how the modules are configured.

67.4 Functional description

67.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 1846* and *Table 1847* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 1848* and *Table 1849* contain the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1846. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN

TCK	Logic Input	Logic Input	Logic Input	Hi-Z	Logic Output	Logic Output	Logic Output
Mode Escape	Inhibit	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable
LFAST_ SYSCL K _EN	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable	Enable

Table 1847. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don’t Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 1848. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 1849. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

67.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 1850* and *Table 1851* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 1850. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit

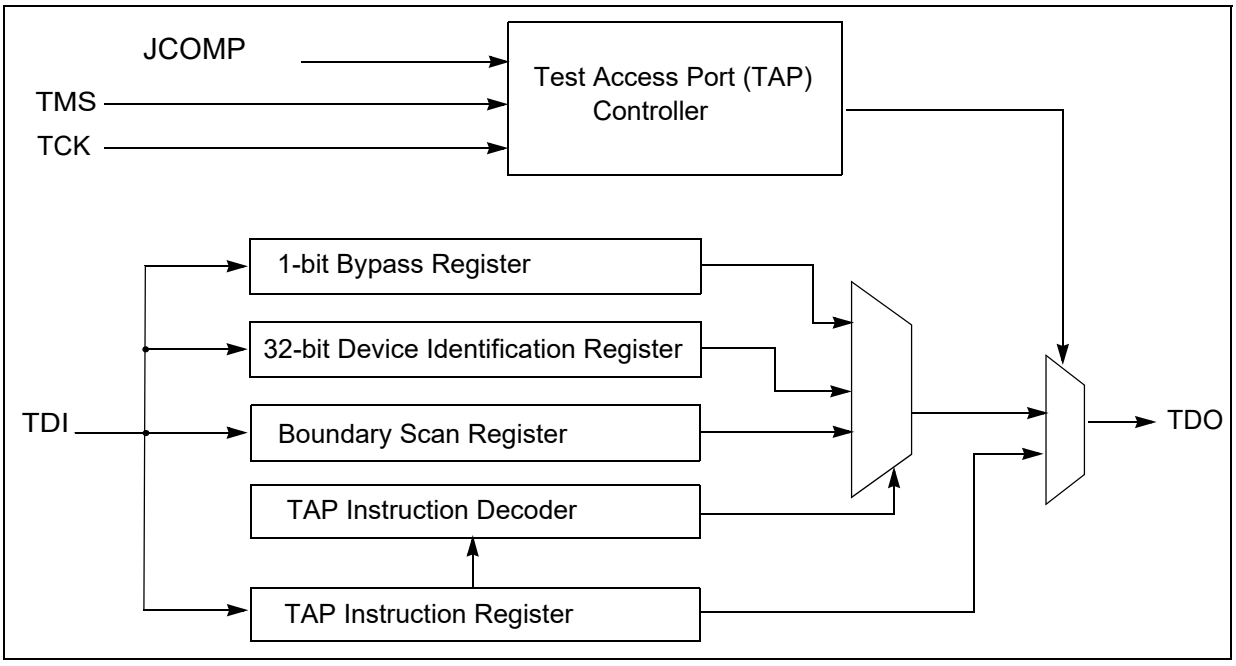
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don’t Care

68 JTAG Controller (JTAGC)



68.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input and output from the JTAGC block is communicated in serial format.

68.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1911. JTAG (IEEE 1149.1) block diagram

68.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1855* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

68.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

68.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

68.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 68.4.4*.

68.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

68.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1852. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

68.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

68.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

68.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 68.4.3*.

68.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

68.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

68.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

68.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

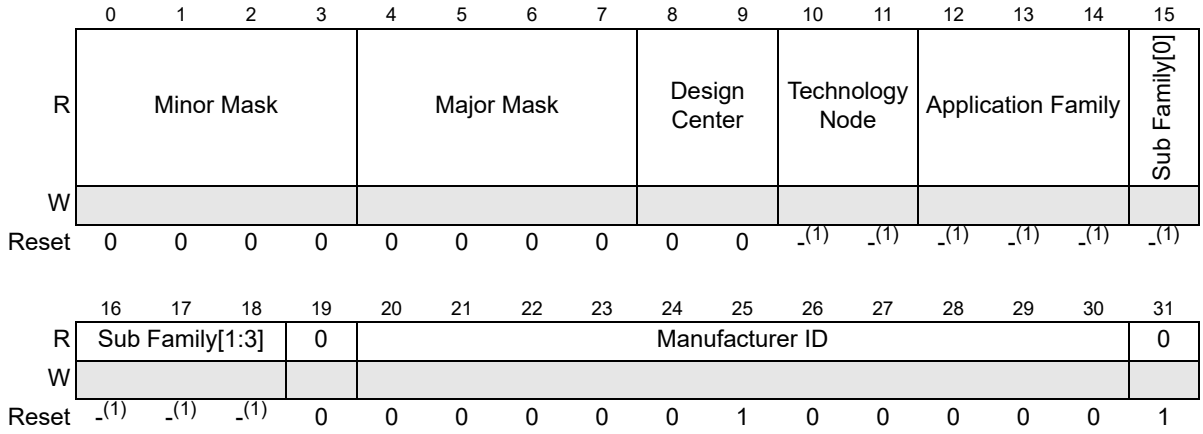


Figure 1912. 6-bit instruction register

68.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

68.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 1853*

Figure 1913. Device identification register

The following table describes the device identification register functions.

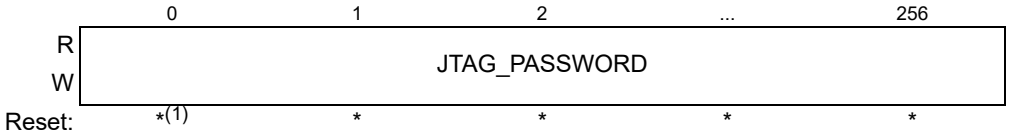

Table 1853. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 01 40nm
12:14 Application Family	Application Family These bits indicate the device application family 000 SPC58N - Powertrain 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 1000 SPC58NE84C3 , SPC58NE84E7
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

68.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine

is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1914. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1854. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

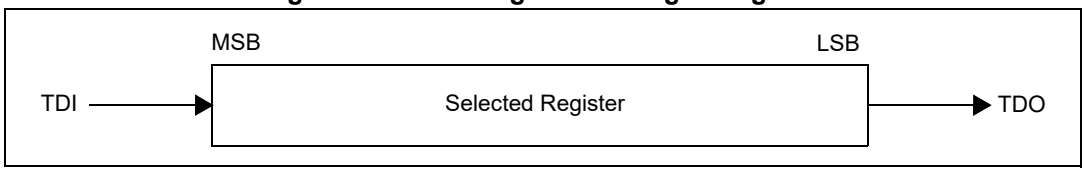
68.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 68.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

68.4 Functional description

This section explains the JTAGC functional description.

68.4.1 JTAGC reset configuration



While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

68.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 68.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

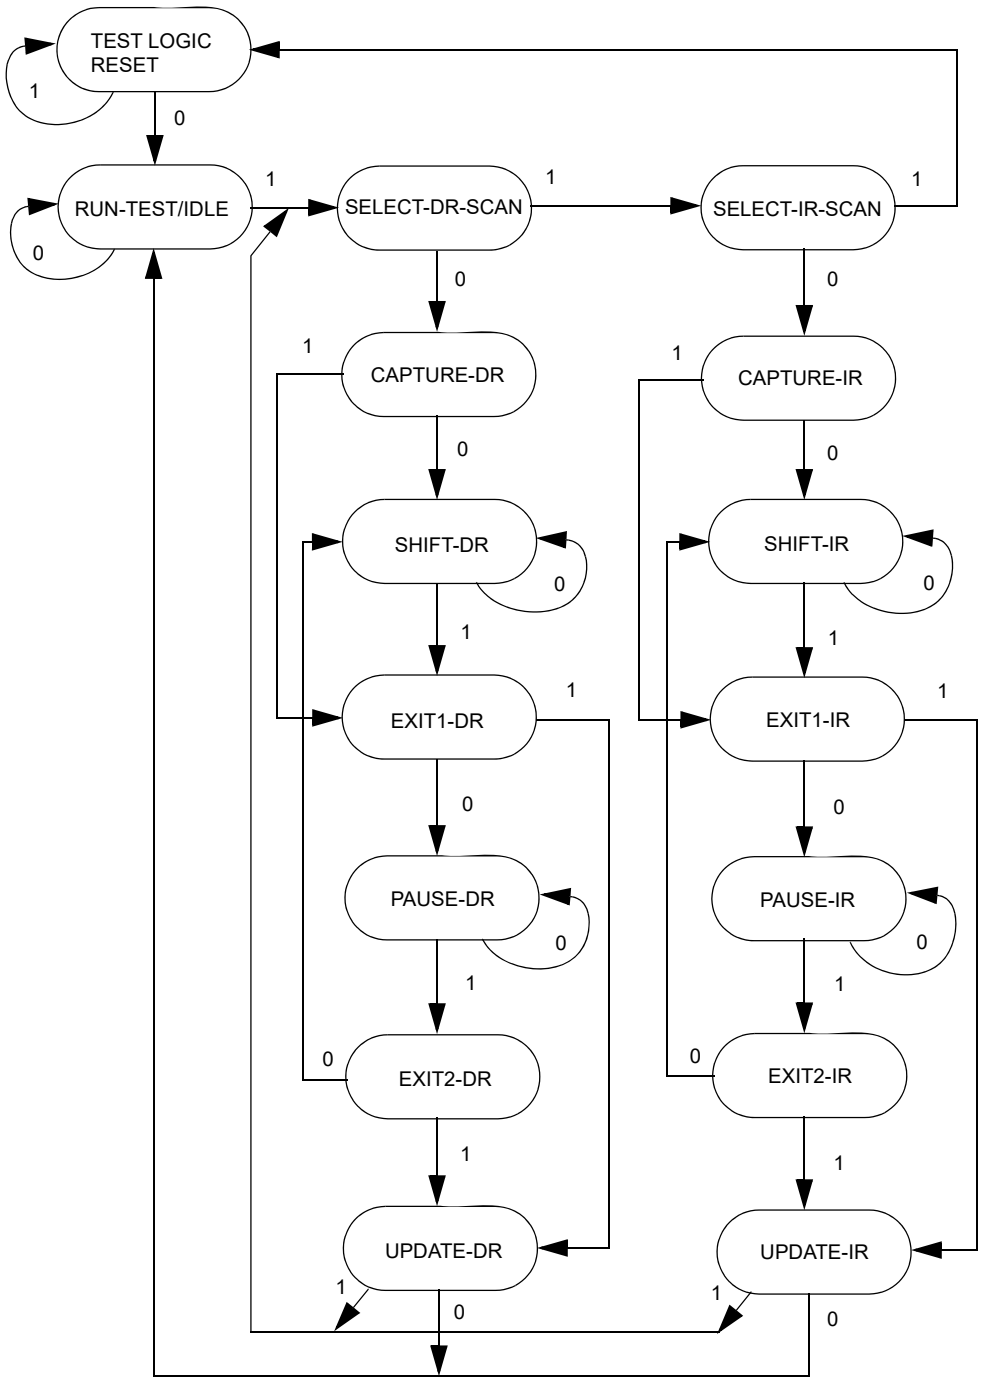


Figure 1915. Shifting data through a register

68.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 1916. IEEE 1149.1-2001 TAP controller finite state machine

Note: The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

68.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

68.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

68.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1855. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NR_PD	100001	Enables access to the NAR TAP controller on production device

Table 1855. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100010	Reserved
Reserved	100011	Reserved
Reserved	100100	Reserved
Reserved	100101	Reserved
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller, to access the HSM challenge and response registers
ACCESS_AUX_HSM	100111	Enables access to the HSM core TAP controller
ACCESS_AUX_CORE_0	101000	Enabled access to E200 Core 0
ACCESS_AUX_CORE_1	101001	Enables access to E200 Core 1
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
ACCESS_AUX_GTM	110011	Enables access to GTM TAP controller
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
Reserved	110110	Reserved
ACCESS_AUX_BUS_MON_3	110111	Enables access to NXMC Client 3 TAP controller
ACCESS_AUX_BUS_MON_4	111000	Enables access to NXMC Client 4 TAP controller
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

68.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

68.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

68.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

68.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

68.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

68.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (for example high impedance).

HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

68.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

68.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

68.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

68.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

68.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, must be loaded the appropriate instruction for the test or action to be performed.

69 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

69.1 References

- IEEE Std 1149.1-2001 (R2008), Standard Test Access Port and Boundary-Scan Architecture
- IEEE Std 1149.7, Standard for Reduced-Pin and Enhanced-Functionality Test Access Port and Boundary-Scan Architecture

69.2 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backward compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

69.2.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- Compliant
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- Extended
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- Advanced
  - Two-pin operation using the “Advanced Protocol” – signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

69.2.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

69.2.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in *Table 1856*. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

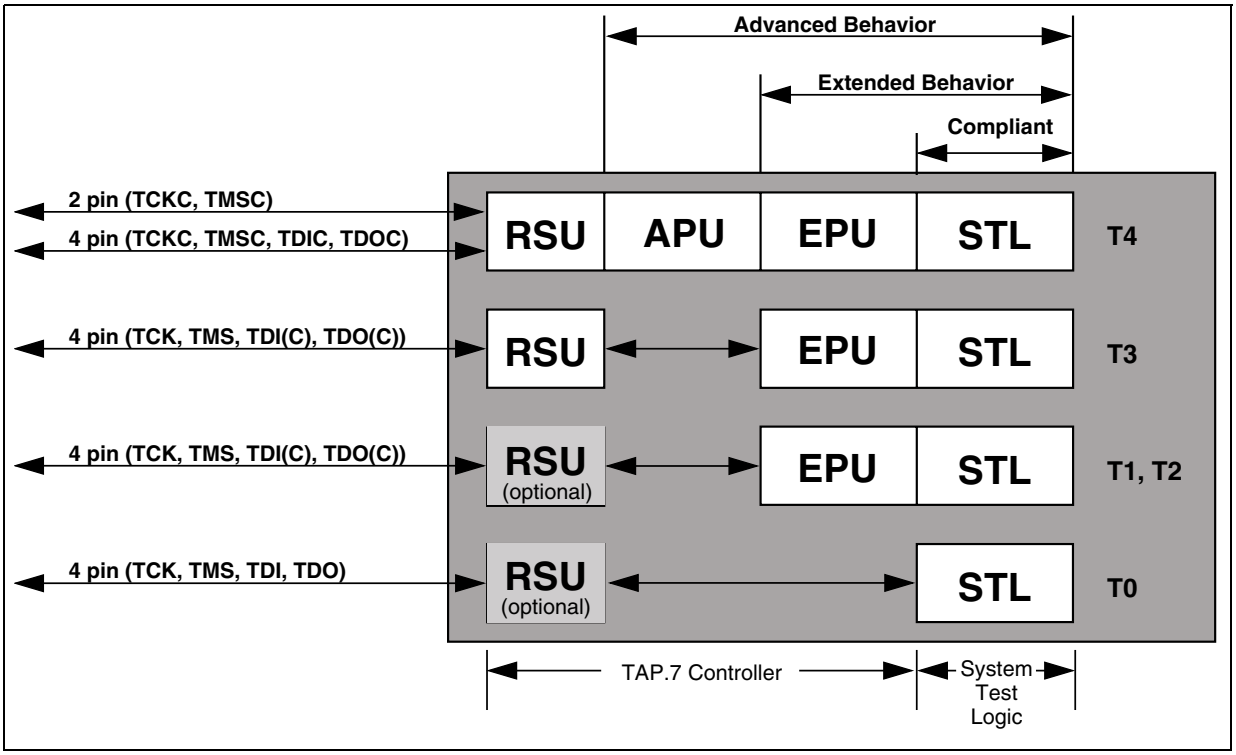
The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC, and nTRST pins.

Table 1856. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4



69.2.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in *Figure 1917*. It is described with the hardware layers listed below:

- **STL System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

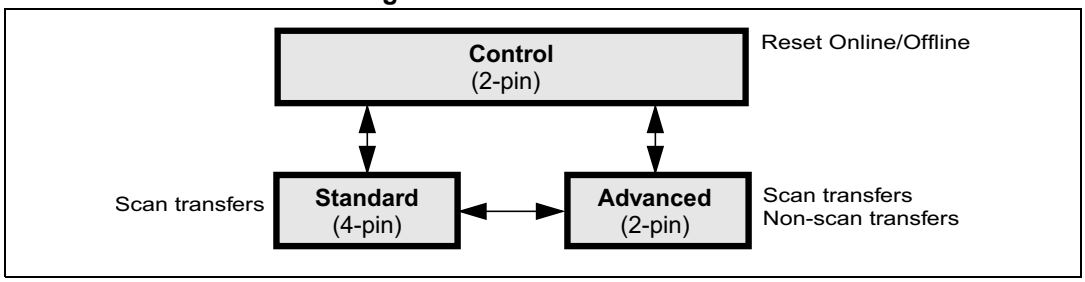


Figure 1917. TAP.7 Controller Architecture

69.2.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in *Figure 1918*.

Figure 1918. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in *Table 1857*.

Table 1857. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

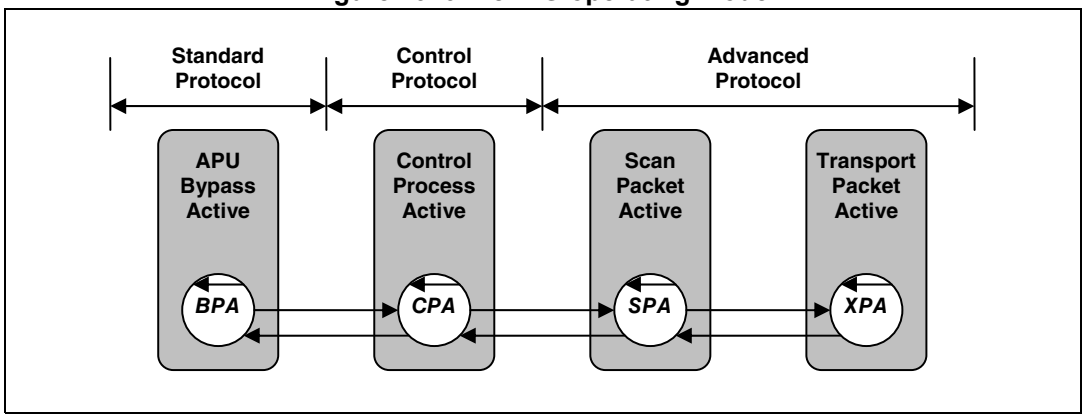
The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

69.2.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

69.2.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.



69.2.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

69.3 Operating models

Figure 1919 illustrates a simplified view of the CJTAG operating model.

Figure 1919. CJTAG operating model

69.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

69.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

69.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

69.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

69.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

69.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

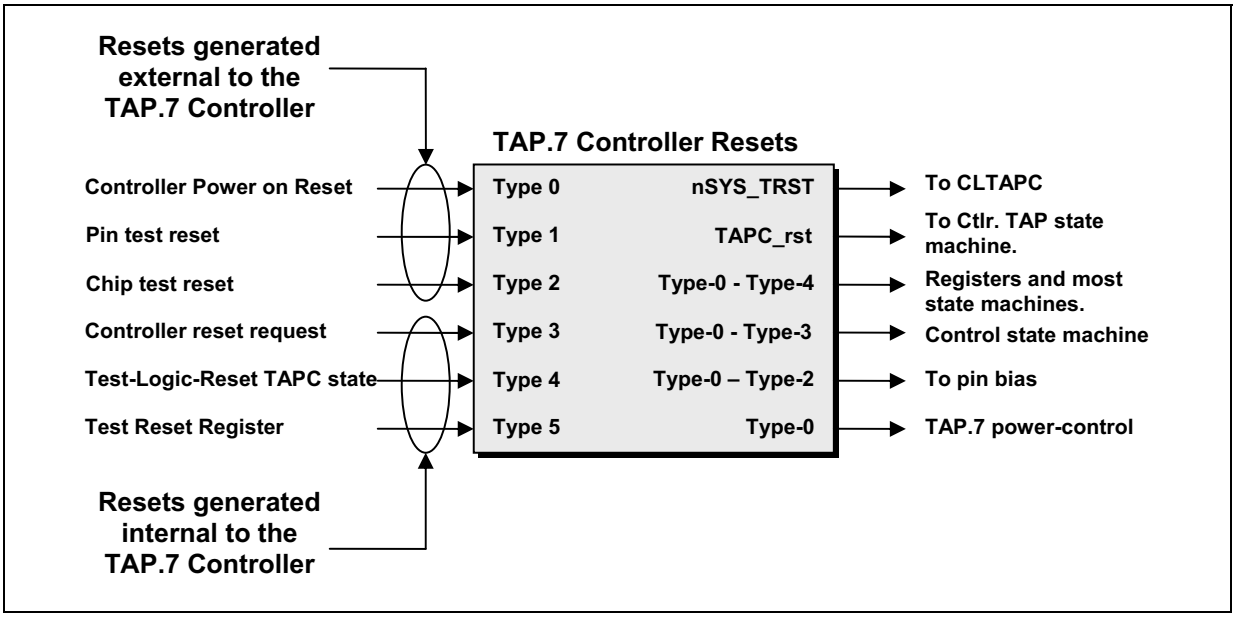
69.5 Ancillary services

69.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine



69.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 1920. Conceptual view of the EPU reset logic and state machines

69.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

69.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

69.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

69.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

69.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

69.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

69.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 1921. Reset state machine

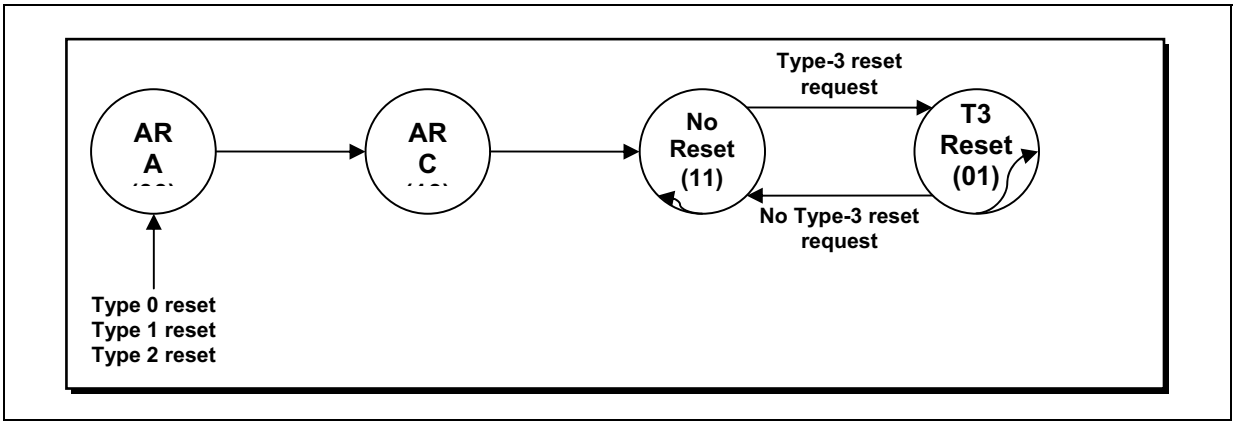


Table 1858. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in *Table 1859*.

Table 1859. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

69.5.3 Start-up Options

69.5.3.1 Overview

The TAP.7 start-up options are shown in *Table 1860*. The only startup option currently supported by the CJTAG module is 1149.1 compliant.

Table 1860. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

69.5.3.2 1149.1 Compliant start-up

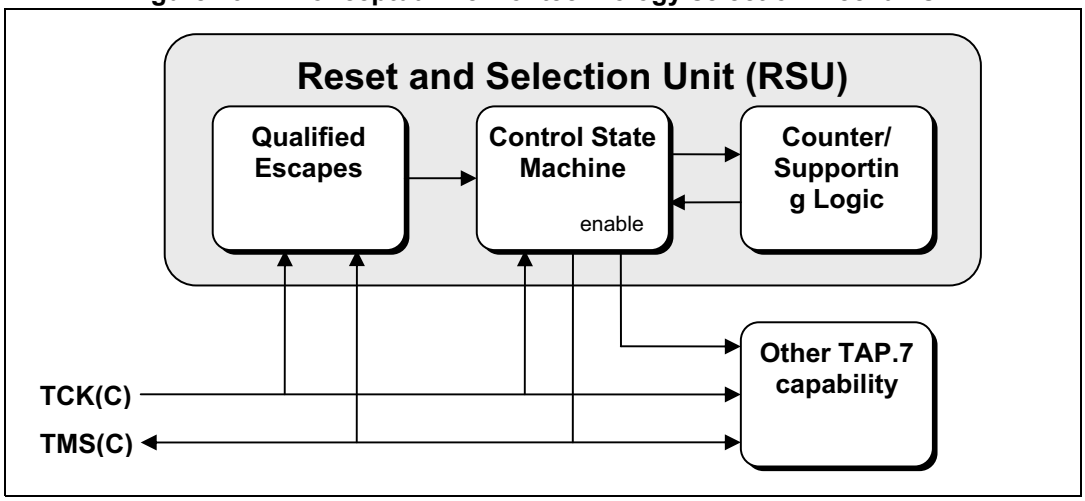
Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine
- The TDIC and TDOC pins are present and provide the TDI and TDO function
- The CLTAPC is coupled at start-up

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 1861. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU



69.5.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

69.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in *Figure 1922*.

Figure 1922. Conceptual view of technology selection mechanism

69.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

69.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset).

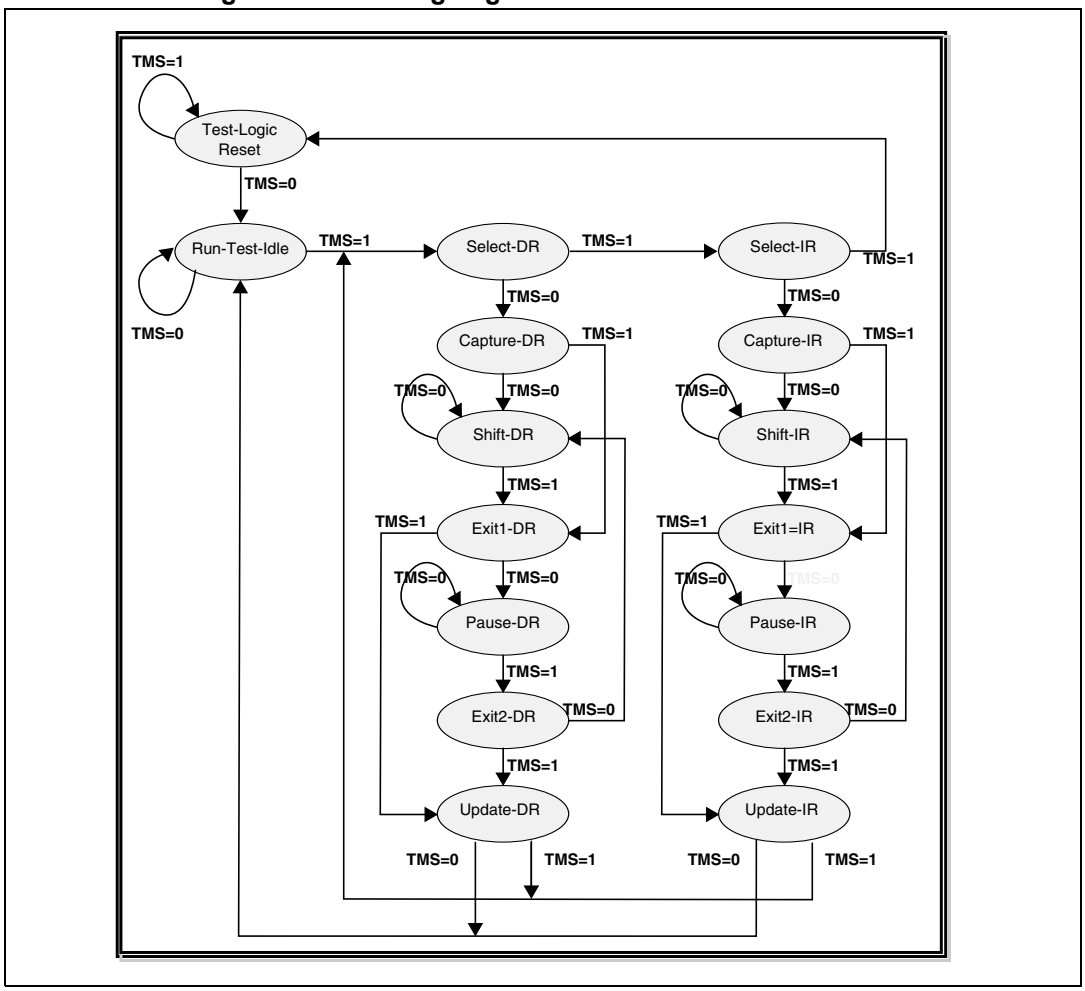
The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

69.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.



69.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occurs with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

69.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 1923. Falling edge TAP controller state machine

69.6 EPU (Extended Protocol Unit) Operation

69.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

69.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

69.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be

incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

69.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

69.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

69.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

69.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

69.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created.
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

69.6.2 EPU Registers

69.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose.

These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

69.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back.

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 1862. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
		1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Options Select	Local Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge

Table 1862. TAP.7 controller register list (managed with commands) (continued)

Register type	Global/ local	Width	Register mnemonic	Name
		32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
Read-only	Local	M = Mandatory register O = Optional register		

69.6.2.3 Registers

69.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

69.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the “System Path” (STL) is used.

- **1** – Suspend use of control levels. Enables “System Path.”
- **0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

69.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- **1** – Inhibit ZBS detection.
- **0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

69.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 1863. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state

Table 1863. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

69.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

69.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance

the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the “Global Register.”

69.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

69.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

69.6.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0x** – TDI and TDO have JTAG function.
- **1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

69.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

69.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

69.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0.

69.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 1864. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format
6:5	2	PWRMODE	Power-control Modes
7	1	FRESET	Functional Reset
8	1	TRESET	Test Reset

Table 1864. RDBACK register format (continued)

69.6.2.3.15 Register reset values

Table 1866. Reset values of TAP.7 controller registers managed with commands

Register type	Width	Register mnemonic	Name	Values for reset type			
				0	1 – 3	4	5
Control	1	ECL	Exit Control Level	0	0	0	NC
	1	SUSPEND	Suspend	0	0	0	
	1	ZBSINH	ZBS Detect Inhibit	0	0	0	
	5	SCNFMT	Scan Format	DF	DF	DF	
	1	SSDE	SSD Enable	0	0	0	
	2	DLYC	Delay control	00	00	00	
	2	RDYC	Ready Control	00	00	00	
Options	1	TRESET	Test Reset	0	0	0	NC
	2	APFC	Aux. Pin Functional Cntl.	DP	DP	NC	
Select	1	CGM	Conditional Group Member	0	0	0	NC
	1	SGC	Scan Group Candidate	DSGM	DSGM	DSGM	
	1	SREDGE	Sampling Rising Edge	0	0	0	
Read-only	32	RDBACK0	Read-back 0	N/A	N/A	N/A	N/A
	32	CNFG0	Configuration Register 0				

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

69.6.3 EPU Commands

There are two command types:

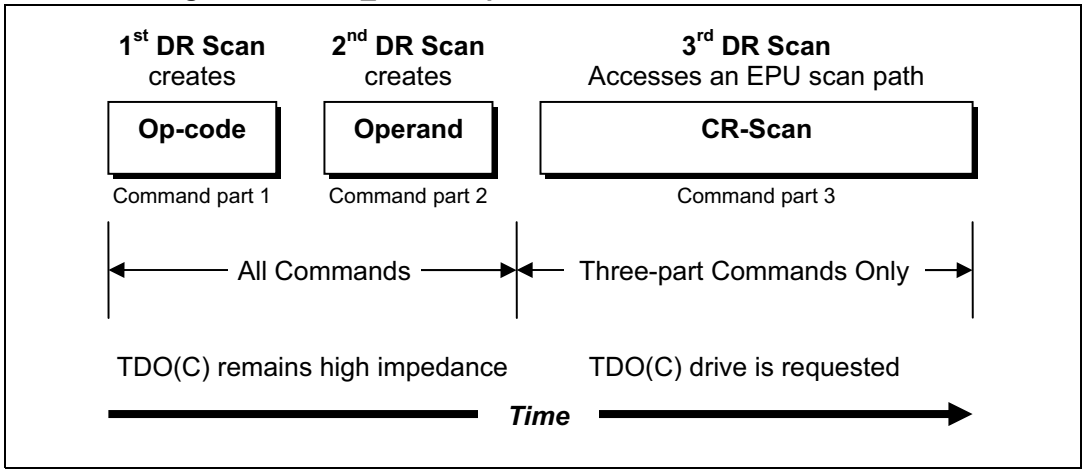
- Two-Part Commands
- Three-Part Commands

Any number of two-part and three-part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

69.6.3.1 Two-Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two).

The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.



69.6.3.2 Three-Part Commands

Some commands are used to send or receive, or both, data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

69.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in *Figure 1924*.

Figure 1924. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two-part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two-part commands, but only 3 three-part commands, each having a special purpose.

69.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in *Table 1867*.

Table 1867. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate(1)	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

69.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

69.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

69.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

69.6.3.5 Command Definitions

69.6.3.5.1 Store Commands

69.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 1868. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	Operand	bbb		x	y	Description
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	—	SGC = y
				1	—	CGM = y
		010	RdyCtl	-	—	RDYC = xy
		011	DlyCtl	-	—	DLYC = xy
		100	ScnFunc	0	—	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	—	—	Reserved
		110		—	—	
		111		—	—	

69.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 1869. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	—	SREDGE = v
			001	—	Reserved
			010	—	TRESET = v
			011 – 111	—	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

69.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 1870. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	Operand	c	bb	CAPE	Description
00010	c bb vv	0	00	—	Reserved
			01	—	STCKDC = vv
			10	—	APFC = vv
			11	—	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

69.6.3.5.1.4 Store Scan Format (STFMT)

Table 1871. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

69.6.3.5.2 Select Commands

69.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 1872. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

69.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 1873. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

69.6.3.5.3 Scan Commands

69.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 1874. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

69.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

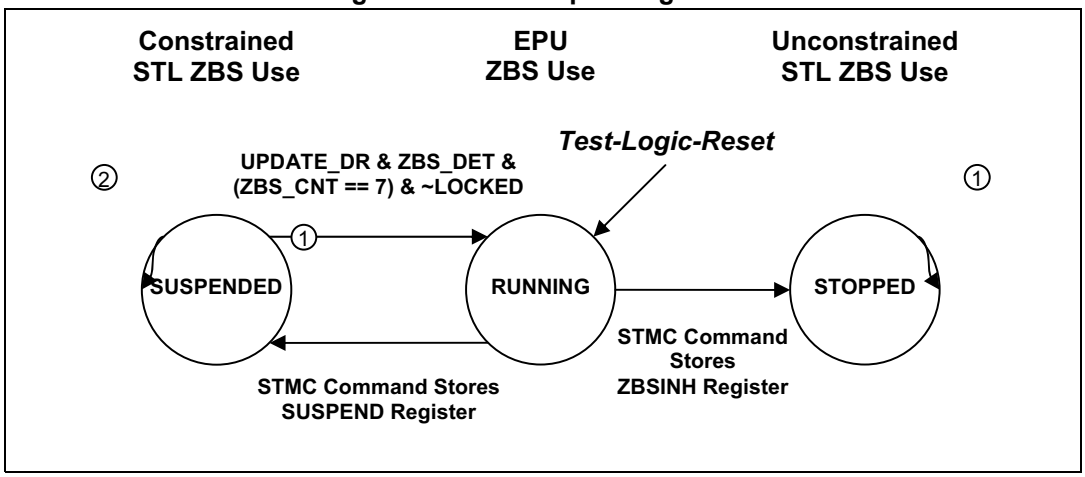


Table 1875. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

69.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in *Figure 1925*.

Figure 1925. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in *Table 1876*. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 1876. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

69.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path.
- **Bit** – Supports set and test bit operations (a 1-bit shift register).
- **String** – Support 32-bit reads or 32-bit writes.
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s.
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

69.7 APU (Advanced Protocol Unit) Operation

69.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

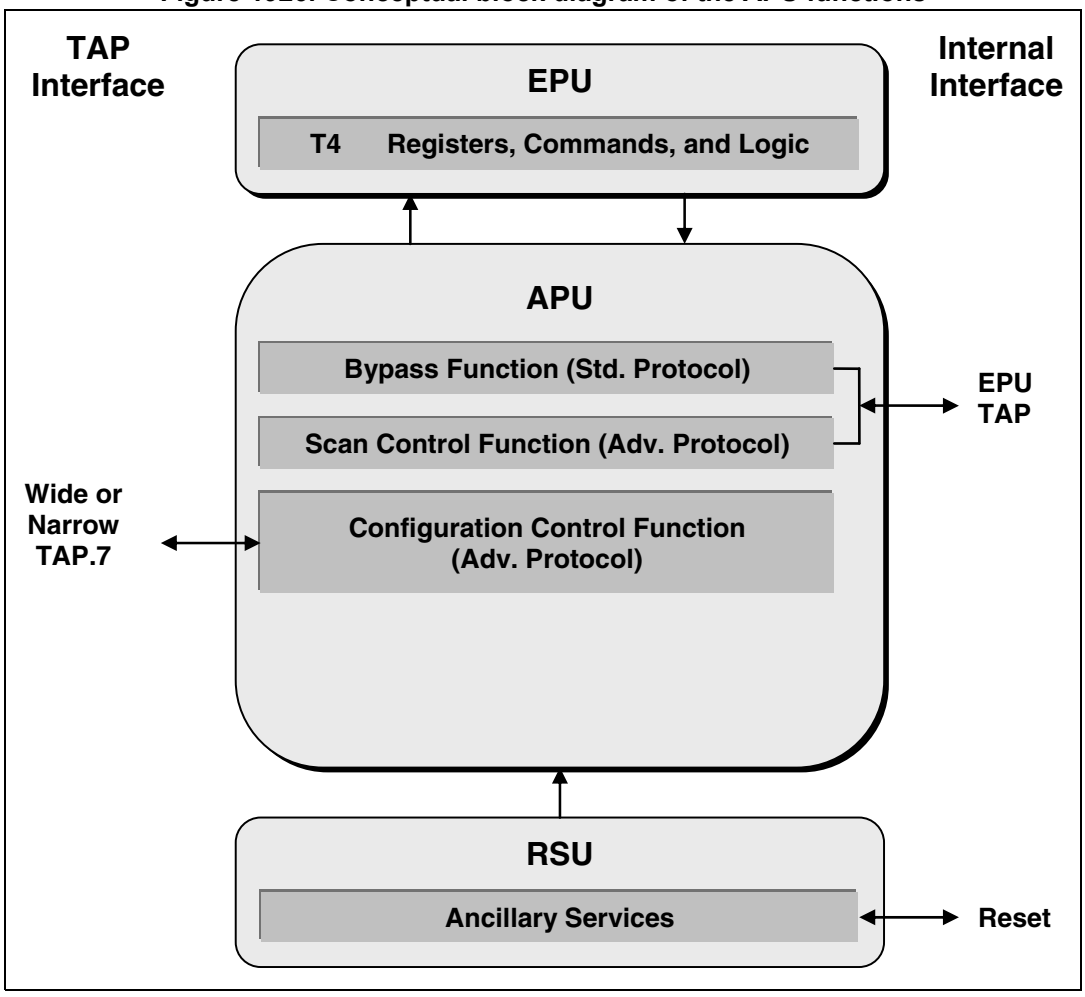
The entire EPU infrastructure (that is, ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.



The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

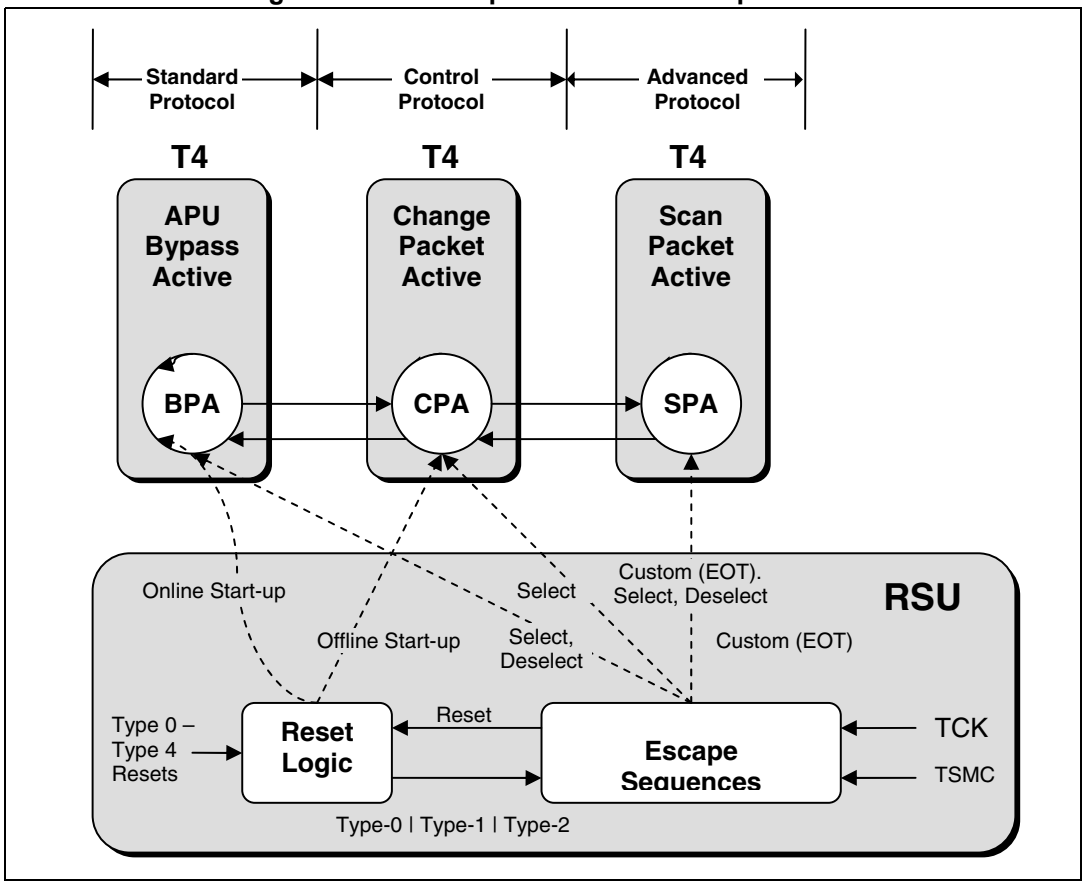
- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 1926. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function



When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

69.7.2 Operation

The conceptual view of the APU operation is shown in *Figure 1927*.

Figure 1927. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

69.7.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

69.7.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

69.7.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

69.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

69.7.4 Signal behaviors

The TCKC signal:

- The test clock

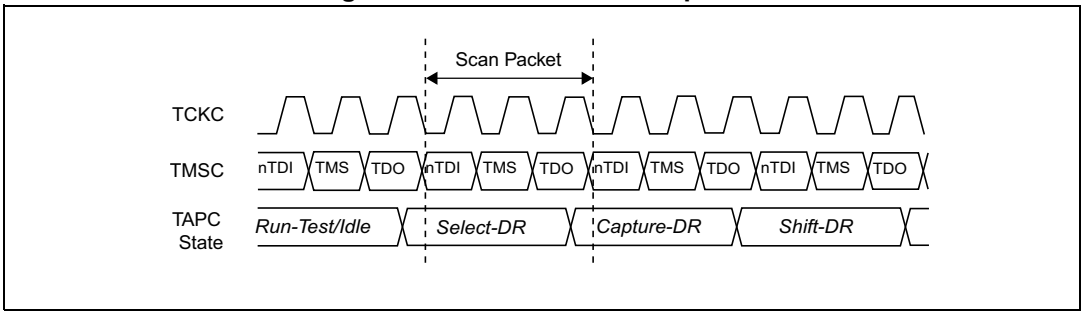
The TMSC signal:

- An input when the Standard Protocol is used
- Bidirectional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

69.7.5 APU Functions



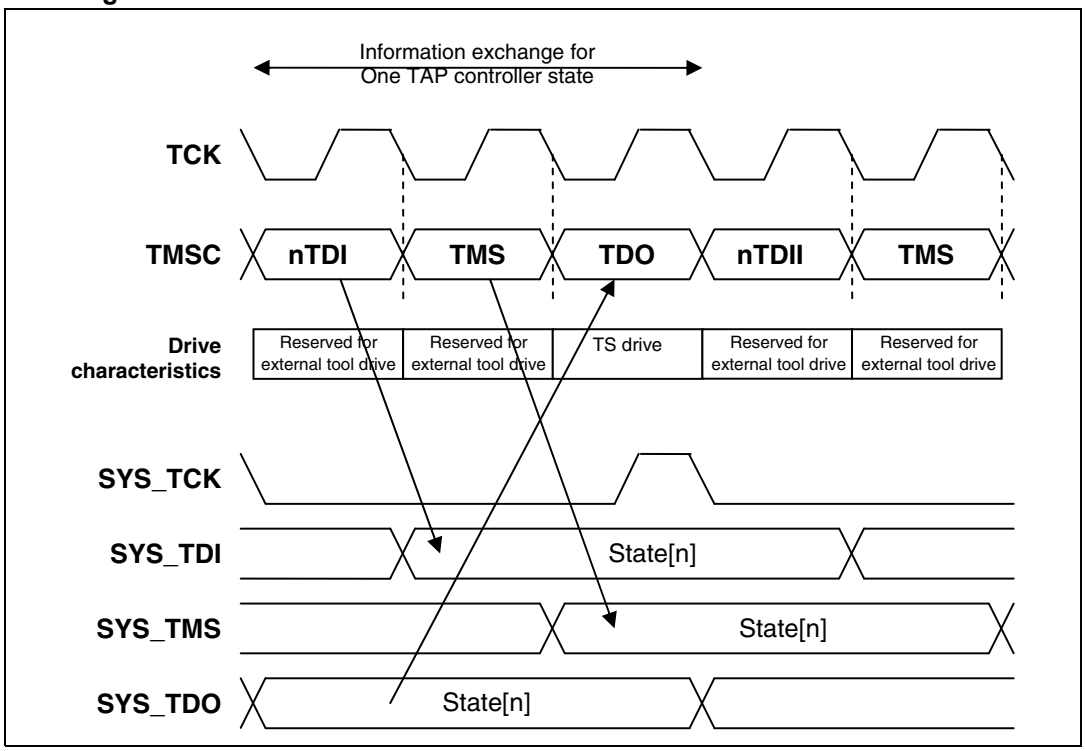
69.7.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (for example, a narrow TAP.7, or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

69.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in *Figure 1928*. There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 1928. Scan Packet sequence



A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in *Figure 1928*. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

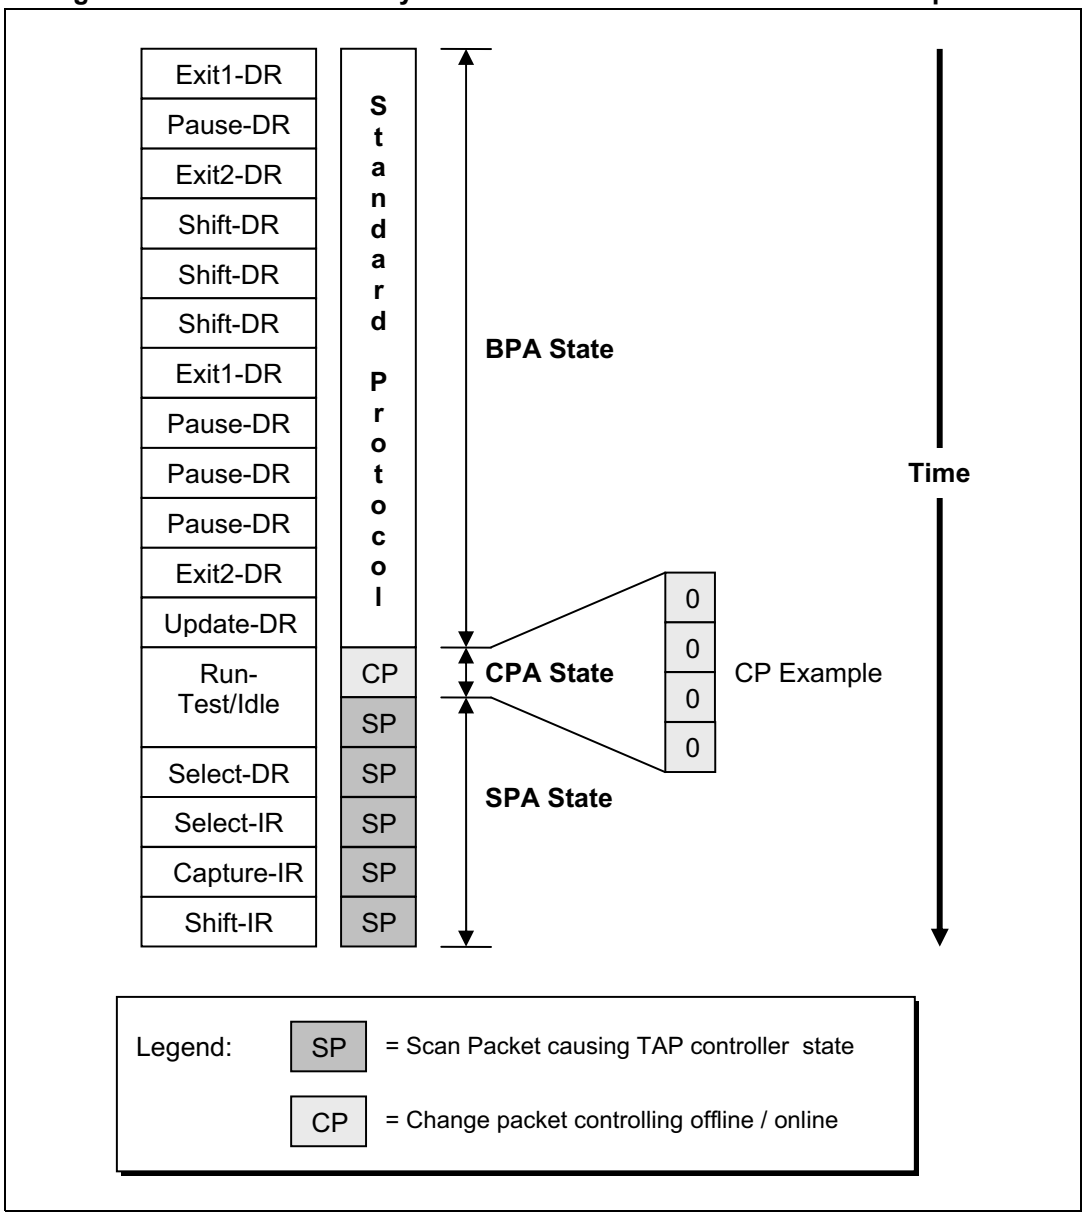
Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 1929. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats).

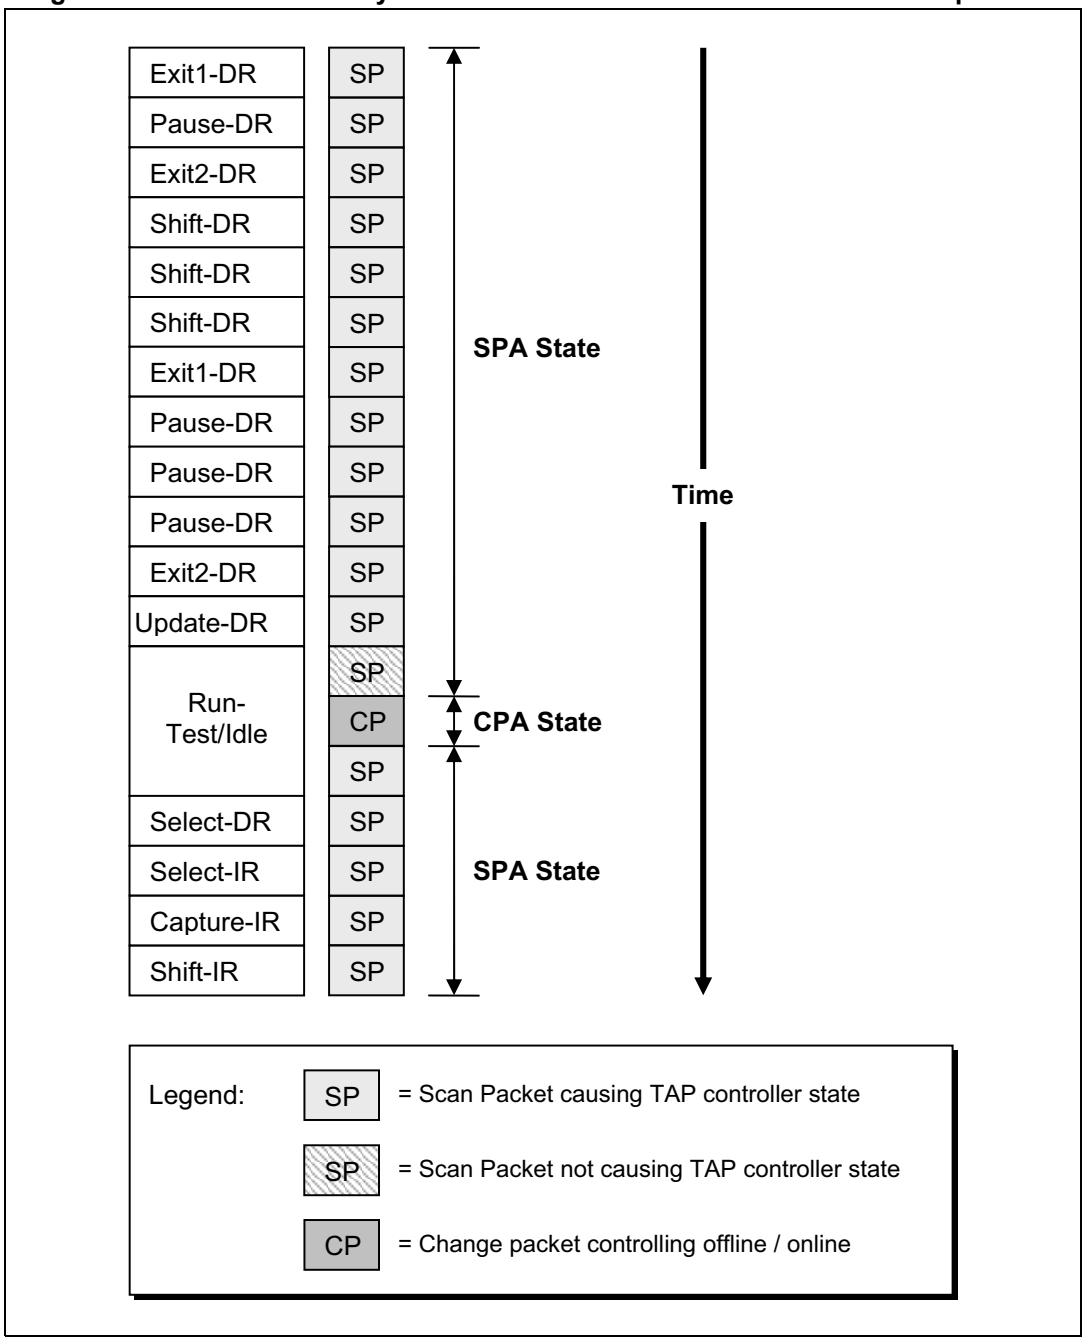
The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.



With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

69.7.5.3 Control Process Active (CPA) Function



While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

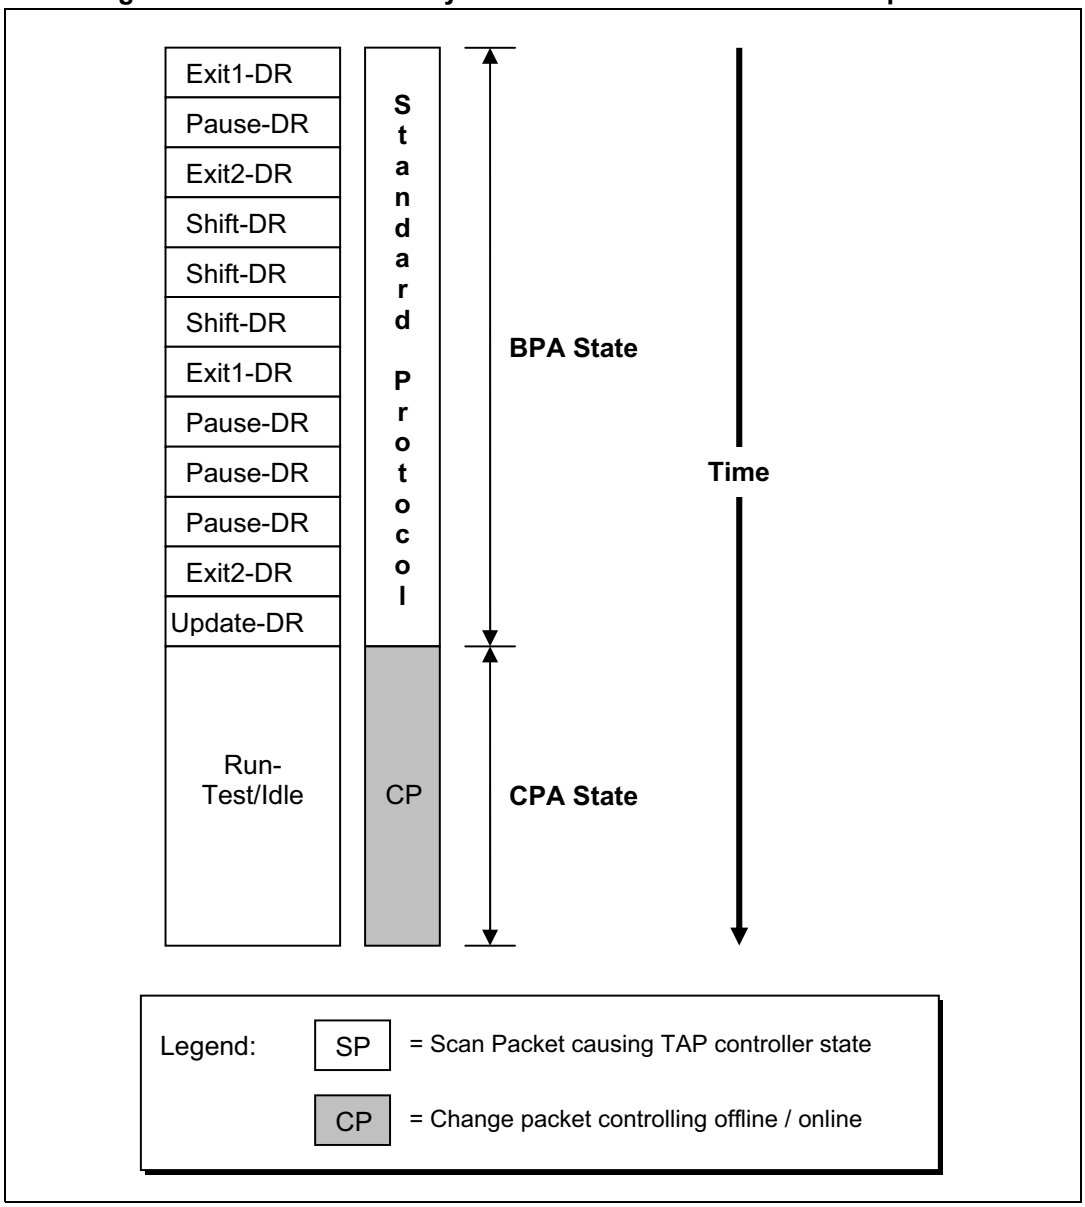
Figure 1930. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 1931. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 1932. CPA State Entry from the BPA State with Offline Operation



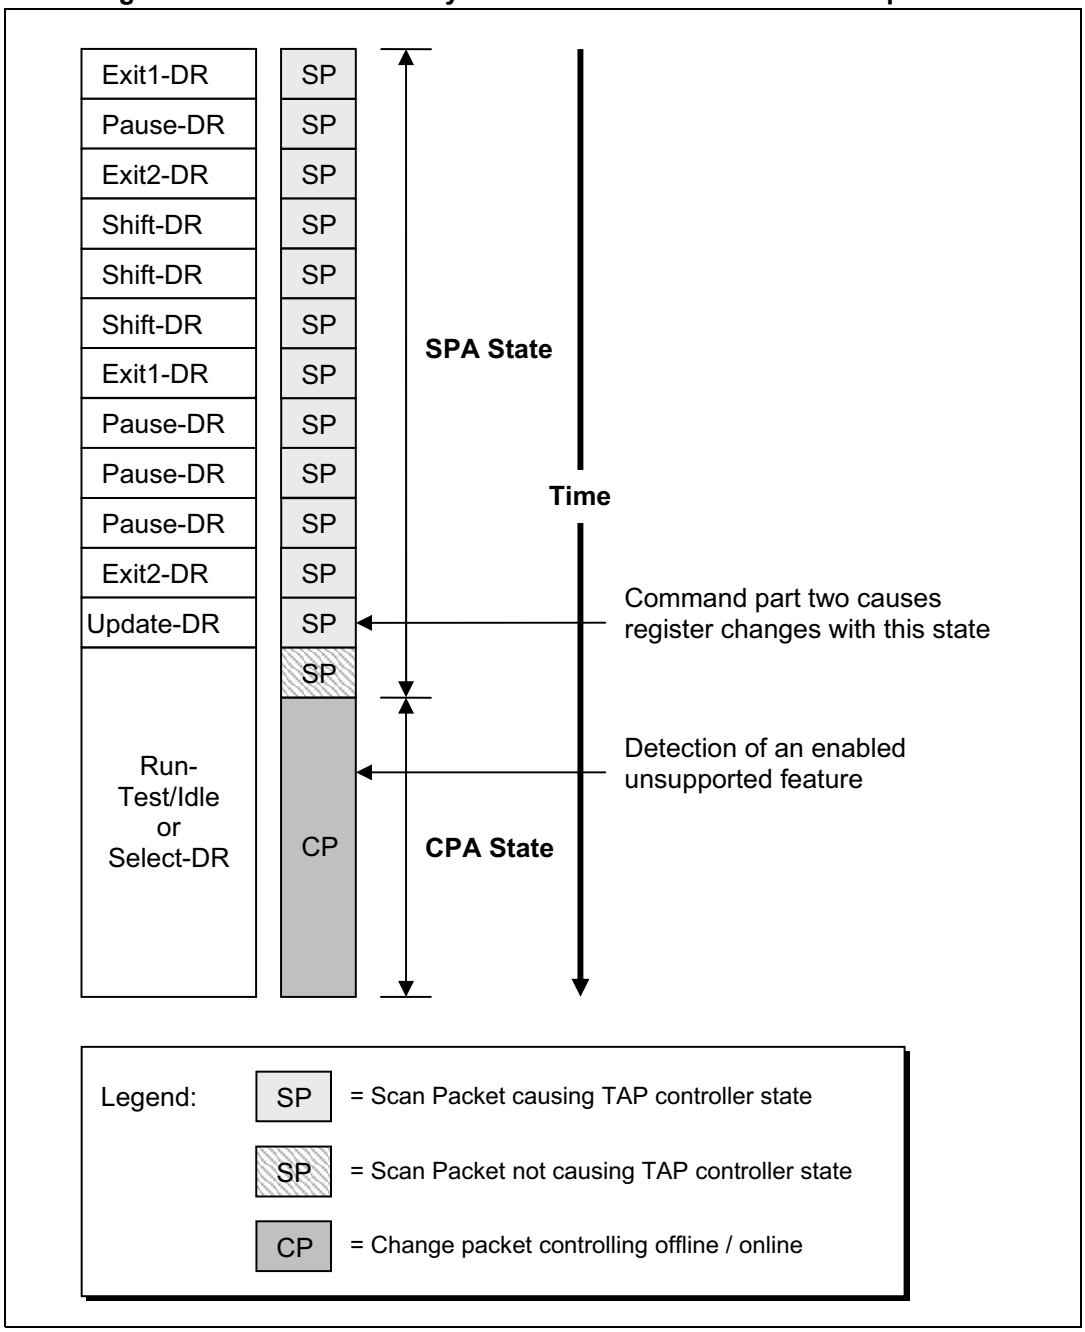


Figure 1933. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

69.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives:
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit)
- **Post amble** – A 1-bit value that is a don't care. This bi t facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

69.7.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof).
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

69.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

69.7.8.1 Payload Element Content

69.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

69.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in *Table 1877*.

Table 1877. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

69.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

69.7.8.3 Scan Formats

69.7.8.3.1 Overview
