The following table lists the delays between various trigger points (initiation request for conversion as registered at system clock) and the actual issue of start pulse (adc_start[(n)]) to the ADC hard-macrocell. Here, each possible trigger source is described with the number of clock cycles required for different operations until the trigger of adc_start. This table does not take into account any software delay involved in programming or polling of any bit in order to measure conversion timing.

Table 631. Start of conversion pulse delay table

Trigger source	Register control (PBRIDGE_CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Normal conversion triggered by software (setting of NSTART of MCR)	1	—	2	1-2[(3)]	Cumulative delay from wen (byte_en) assertion to actual issue of adc_start pulse = 3-4 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Normal conversion triggered by external trigger (hardware trigger through)	—	—	2	1–2[(3)]	Cumulative delay from the triggering edge (rising or falling) to the actual issue of adc_start pulse = 3–4 SARADC_CLK cycles.

n. adc_start is the start of conversion indication to ADC hard-macrocell to start the conversion.

Table 631. Start of conversion pulse delay table (continued)

Trigger source	Register control (PBRIDGE_ CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_ CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Normal conversion within a chain	—	—	0 (from EOC(1) of previous conversion)	—	Delay from the EOC(1) of last conversion, The start of next conversion is issued exactly on the same cycle when EOC(1) is expected for previous conversion.
Injected conversion triggered by software (setting of JSTART bit of MCR)	1	—	3	1–2(3)	Cumulative delay from wen (byte_en) assertion. Here delay for first start pulse of the injected chain execution when FSM was originally in IDLE state is considered = 4–5 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Injected conversion triggered by external Trigger (hardware trigger)	—	—	3	1–2(3)	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Injected conversion within a chain (delay between consecutive conversion of injected chain)	—	—	0 (from EOC(1) of previous conversion)	—	Delay from EOC(1) of last injected channel and adc_start pulse of next injected channel. The start of next conversion is issued exactly on the same cycle when EOC(1) is expected for previous conversion
Injected conversion over normal conversion (software injected conversion chain)	1	1–2(3)	3–5(2)	1–2(3)	Cumulative delay from wen (byte_en) assertion to actual trigger of first injected channel, when the FSM was in conversion cycle of previous normal conversion = 4–7 SARADC_CLK cycles + 2-3 PBRIDGE_CLK cycles.

Table 631. Start of conversion pulse delay table (continued)

Trigger source	Register control (PBRIDGE_CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Injection of conversion over normal conversion in JTRGSEQ mode	—	—	3	1–2(3)	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Abort of a Normal/Injected Channel conversion during Normal Chain/Injected Chain execution (setting of MCR[ABORT] bit)	1	1–2(3)	3–5(2)	1–2(3)	Delay from writing of ABORT bit (wen/byte_en assertion) to actual issue of adc_start pulse for the next channel conversion = 4–7 SARADC_CLK cycles + 2–3 PBRIDGE_CLK cycles.

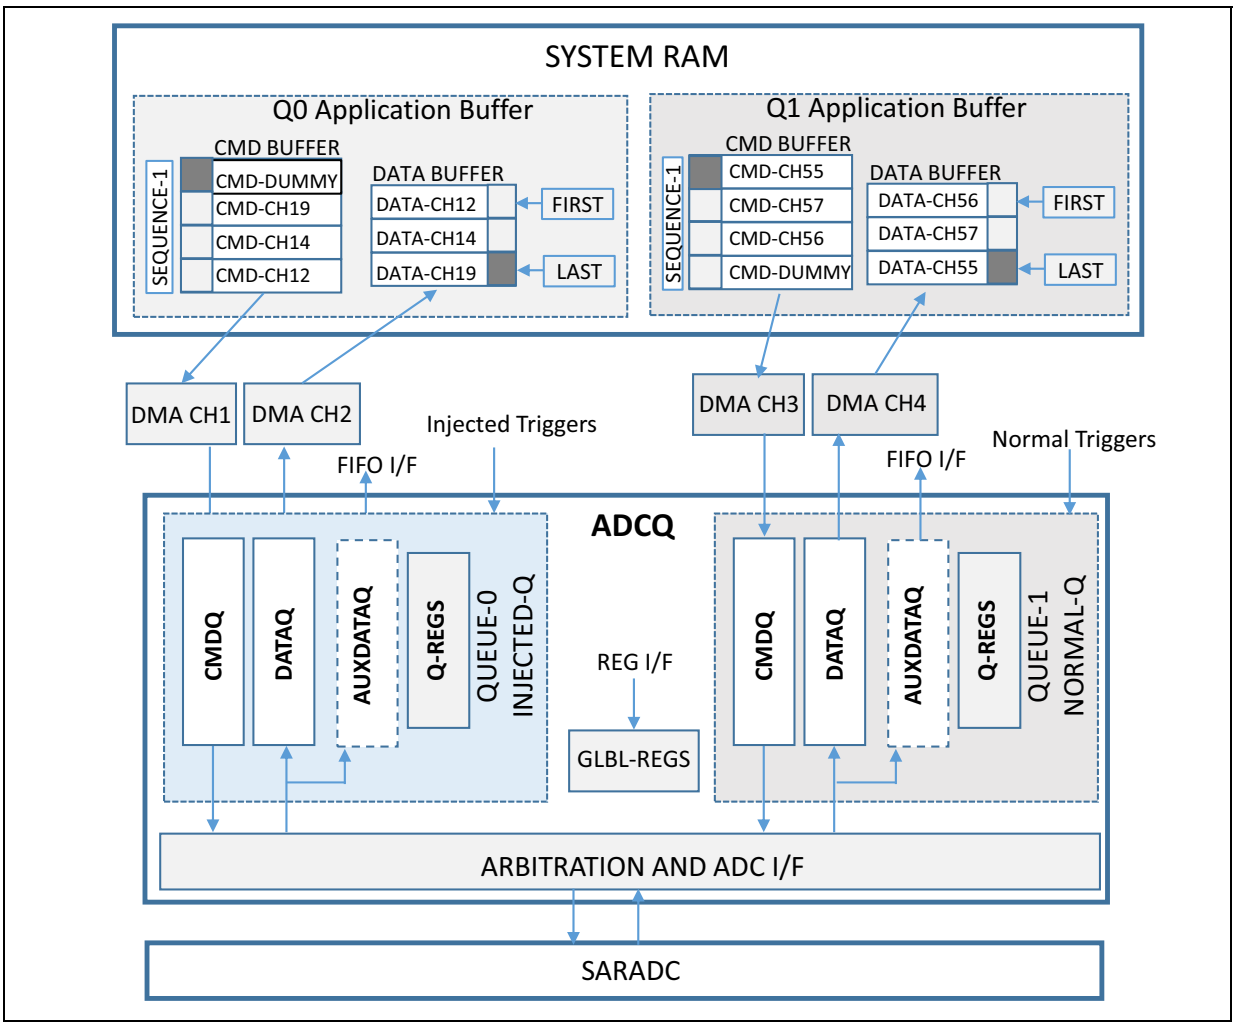
1. EOC is the end of conversion from ADC hard macrocell
2. The above delay values are calculated over a range of system and ADC clock frequencies. With PBRIDGE_CLK(max) = 50 MHz to PBRIDGE_CLK(min) = 40 MHz and SARADC_CLK(max) = 16 MHz to SARADC_CLK(min) = 14 MHz. L.H.S value corresponds to max frequencies and RHS corresponds to min frequencies.
3. The above variation is owing to inter domain synchronization.

38.7 Initialization information

To initialize the SARADC registers for data conversion, the following programming sequence is required:

1. Program the PDEDR register with appropriate power down exit delay valueand required CTU mode (MCR[CTU_MODE]) in case CTU mode has to be entered later on by setting CTUEN bit.
2. Exit the power down mode by clearing the MCR[PWDN] bit. After the power down mode is exited the SARADC enters the IDLE state, this can be checked by polling for MSR[ADCSTATUS] bits. Note that steps 3-7 can also be executed before step 2.
3. Program the required conversion mode and control options for example one-shot mode or scan mode, hardware trigger enable and selection for normal or injected conversions, hardware trigger edge select, overwrite enable, and so on, in MCR register.
4. Program the conversion mask registers ({I,T,E}C{N,J}CMR) for channels to be converted. If required, enable and select watchdog monitors ({I,T,E}CWENR, {I,T,E}CWSELR) as applicable for each channel, program the watchdog threshold values (WTHRHLR) for each watchdog monitor.
5. If required, Enable and select the External to Internal channel mapping by programming the ECMICR registers, Test to internal channel mapping by programming the TCCAPR registers.
6. Program the required Interrupt/DMA mask registers (DMAE, {I,T,E}CDSR, IMR, {I,T,E}C{N,J}MR, WTIMR) for each of the selected channels.

7. Program the Conversion timing registers(CTR0-3) for the required conversion durations. Enable the precharge phase, CTR selection per channel basis by programming the {I,T,E}CDR registers.
8. To initiate CTU mode conversion enter the selected CTU mode by setting the MCR[CTUEN] bit and program the CTU module accordingly to start the conversions. To initiate Normal/Injected mode conversions by software set the MCR[NSTART/JSTART] bit. To initiate hardware triggered Normal/Injected conversions program the external trigger module to provide the required triggers.
   a) Multiple bits in MCR register should be changed one at a time. For example, NSTART, JSTART and PWDN to be mutually exclusive.
   b) Stop mode and PWDN request to be mutually exclusive.
   c) Start of conversion to be asserted after PWDN exit (read ADC status). PWDN to be asserted when there is no conversion ongoing (read ADC status).
9. Read the conversion data and status in {I,T,E}CDR registers.



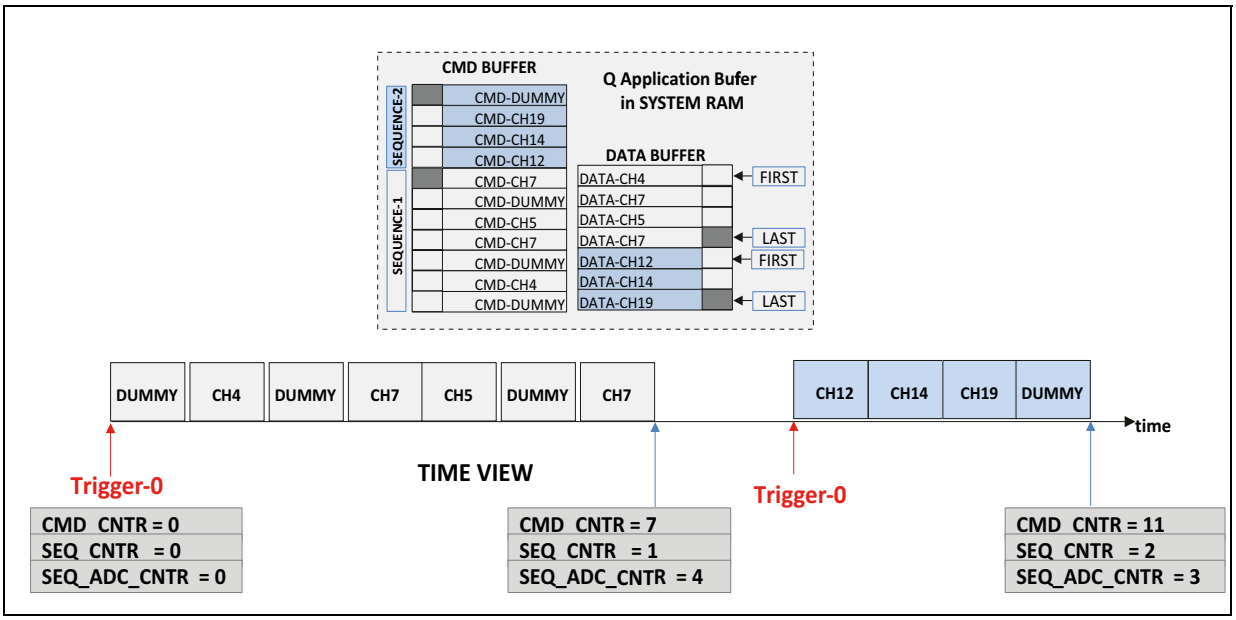
39 SARADC Queued digital interface (ADCQ)

39.1 Introduction

The key goal of the ADCQ design is to provide some SW defined measurement sequences. Multiple queues give the application SW independent paths to the ADC module with flexible ADC channel ordering within the command sequences. One command queue (CMDQ) together with one data queue (DATAQ) creates one logical unit from the application perspective. This is referred to as a queue. Both the CMDQ and the DATAQ are implemented using a FIFO architecture. Each ADC can be replaced by another ADC instance in the SW architecture without a need of SW functional changes; only the SW resource allocation is modified. Each ADCQ provides up to four queues, one of them having a higher priority over the others.

Figure 500 illustrates an ADCQ with dual queues.

Figure 500. ADCQ with dual queues



Once ADCQ module is setup, the SW application prepares the required measurement sequence in its own application buffer in the system RAM without need to access the ADCQ module. This ensures easier memory protection of allocated resources.

The user can define the channel measurement order based on ECU HW design and safety needs. Oversampling is achieved by repeating the channel in the measurement sequence. The length of the measurement sequence is defined by the user. The HW does not limit the length of the measurement sequence. This is achieved by marking the last command in the sequence. On encountering the last command the ADCQ module stops the measurement for the current trigger and waits for the next trigger event to commence with the next sequence in the command queue.

The command transfer from the application buffer to the command queue is through the DMA subsystem. The user application prepares data in advance in the application buffer, before queue trigger gets active. Once the buffer is ready, DMA channel is enabled. If command queue interface is ready to receive new commands then DMA will send prepared commands to the interface. The measurement sequence in a command queue can be triggered by either a single or multiple hardware input triggers or by a SW trigger. They can be triggered either on the rising or the falling or both edges of the hardware trigger. Once triggered the commands are sent to the ADC for conversion. Converted results are stored in the data queue. The stored results are then transferred to the application buffer again through DMA subsystem.

Figure 501 illustrates the key concepts of the measurement sequence and its triggering.

Figure 501. Measurement sequence

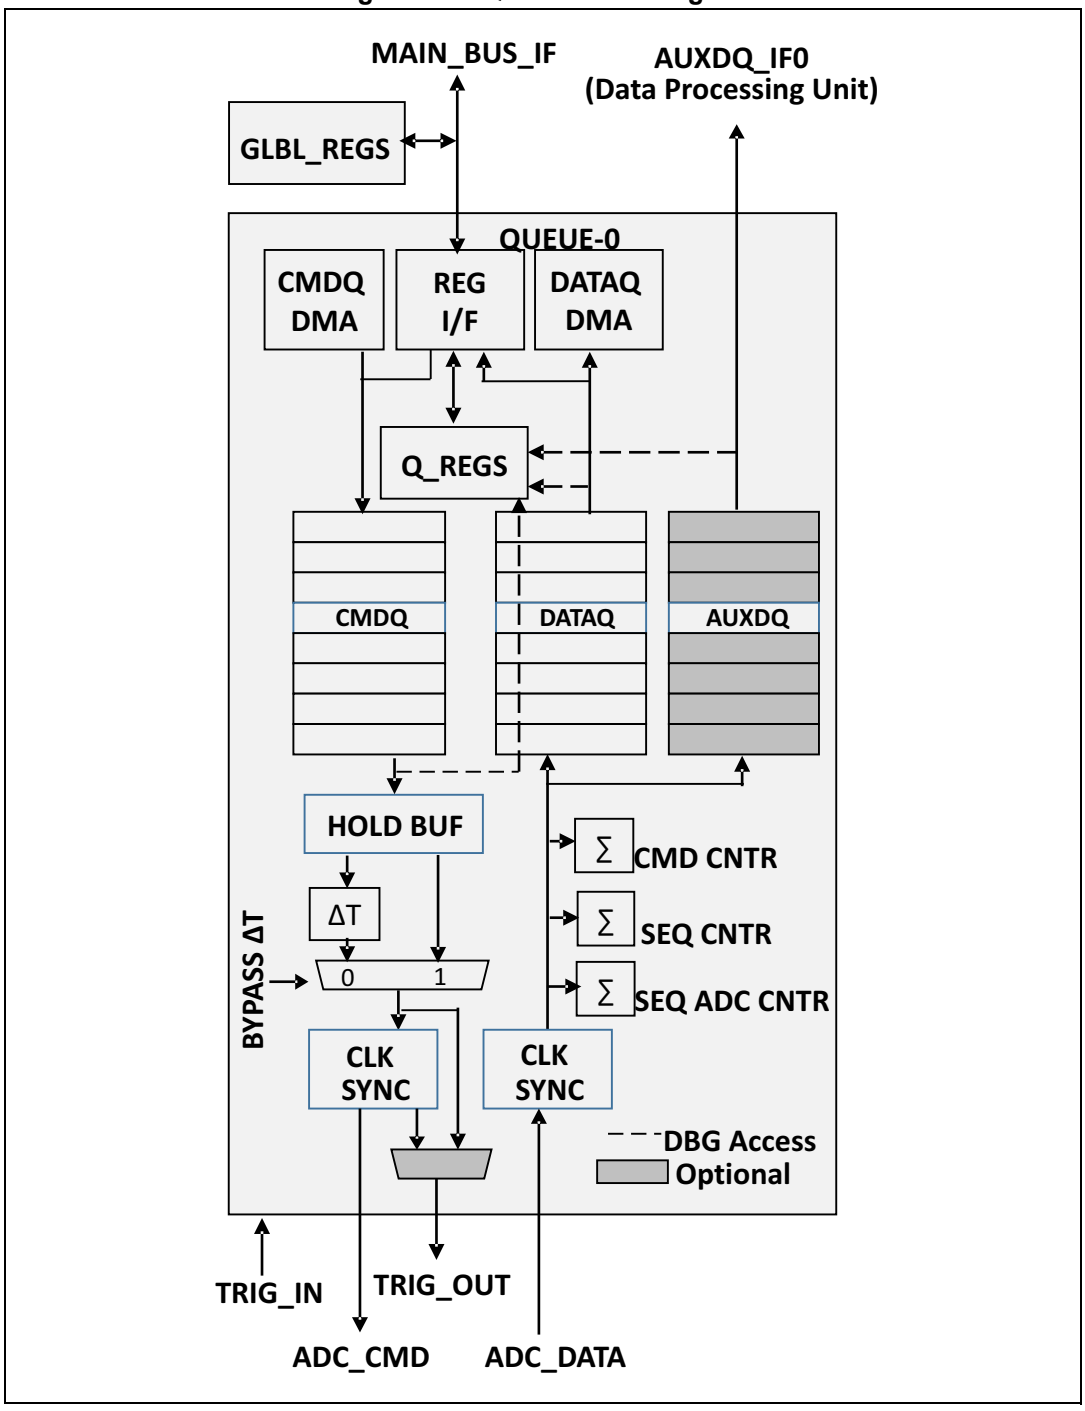
39.2 Feature description

- Supports up to 4 queues. The first queue is called injected queue while the others are called normal queues.
- Injected queue has higher priority and suspends an active measurement sequence of normal queue.
- SW can choose the injection mode. On injection the ongoing normal channel can either be aborted or allowed to finish.
- Flexible channel ordering within a measurement sequence.
- Oversampling by repeating a channel in the measurement sequence.
- Measurement sequence can be triggered by more than one trigger source.
- Measurement sequence can be triggered by rising, or falling or both edges of the trigger sources.
- Measurement within a sequence can be spaced in intervals of programmable ΔT.
- The ΔT is statically configured by the user during initialization phase of the queue.
- Can use dummy commands in a measurement sequence to space the commands in multiples of ΔT.
- Measurements within a sequence can be programmed to bypass ΔT.
- SW task can trigger measurement sequences.
- HW triggers and SW trigger can synchronously trigger measurements across multiple ADCQs.
- Cumulative measurement counters in each queue allow tracking of sequence synchronization across multiple ADCQs.
- Cumulative measurement counters keep track of number of commands executed and number of sequences executed.
- Reduce the SW overhead in accessing a slow peripheral by preparing the measurement sequences in System RAM and transfer them to the command queue through DMA. The result data is transferred from data queue to System RAM through DMA.
- Reduce the traffic on system bus and reduce the SW overhead in transferring data from ADC to other data processing units by optionally enabling the auxiliary data queue (AUXDQ) for each queue module.
- SW timestamping allows for optimal use of the data queues.
  - Optionally enable timestamping of input trigger events and ADC data
  - SW can define prepending of measurement data sequence with 24-bit trigger timestamp
  - SW can define 24-bit timestamp capture per command in a measurement sequence

39.3 Functional description

The basic queue structure is illustrated in *Figure 502*. For ADCQ module with two queues, this basic structure is repeated twice with the first instance having priority over the ADC resources and is called injected queue. All other instances of this module are called normal queues.

Figure 502. Queue block diagram



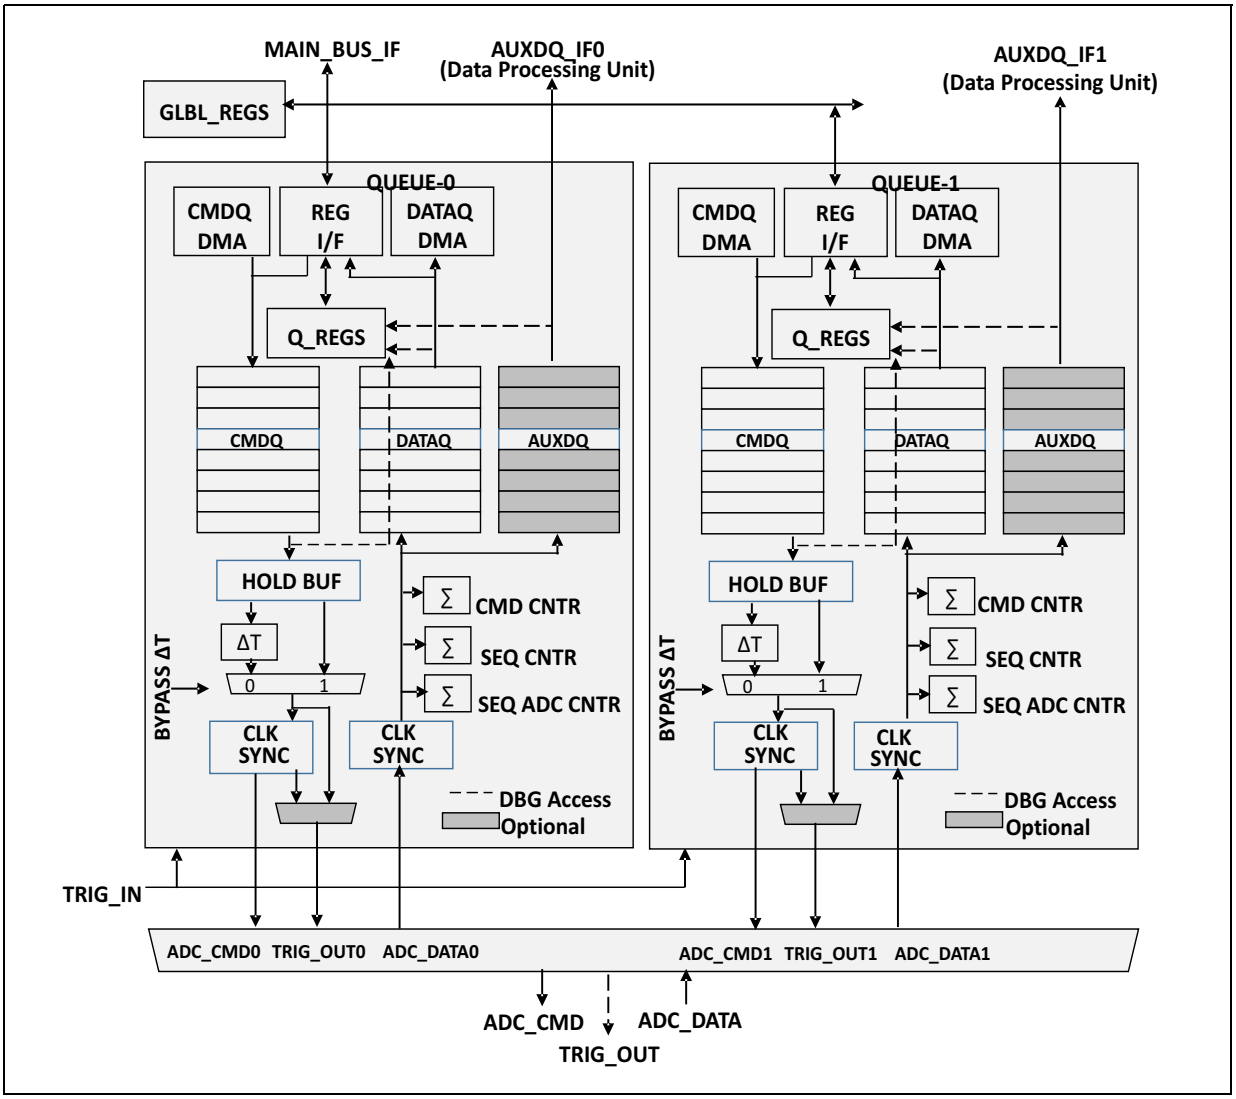


Figure 503 illustrates the ADCQ module with two instances of the basic queue structure. QUEUE-1 is the injected queue and QUEUE-2 is the normal queue.

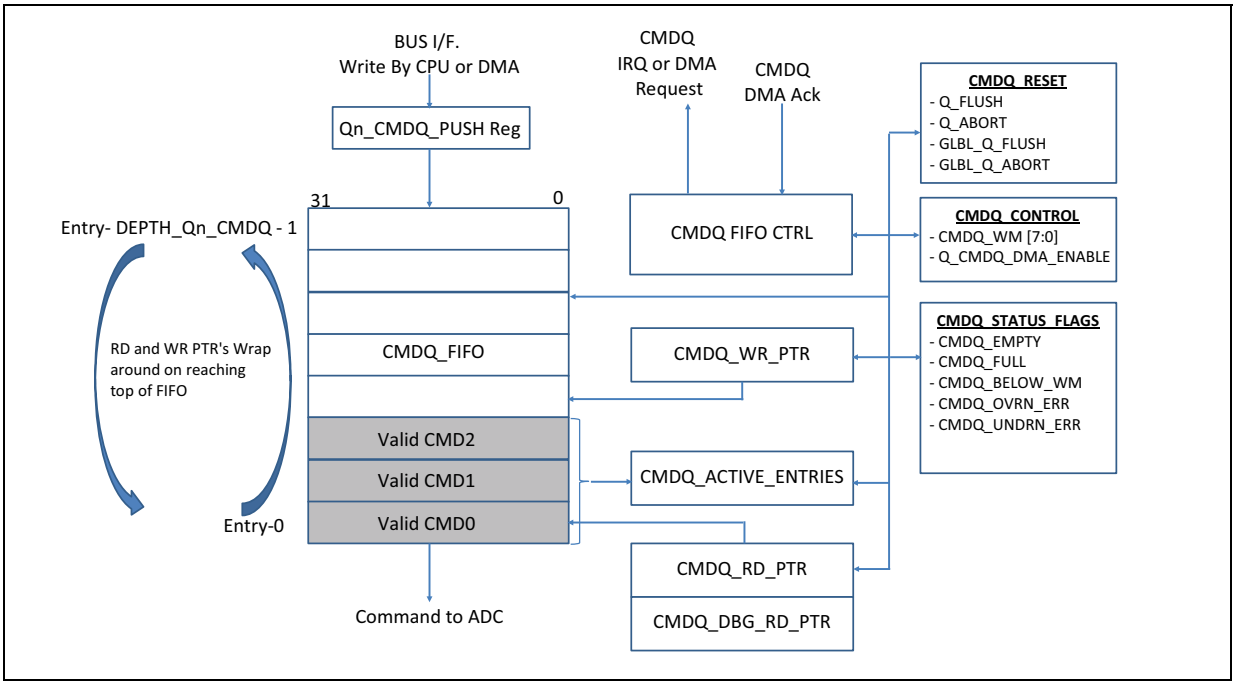
Figure 503. ADCQ with two queues

A queue is made up of the following sub-units:

1. Command FIFO (CMDQ) to accept measurement sequence commands from the system.
2. ADC result FIFO (DATAQ) to store and send measurement sequence data to the system.
3. An optional auxiliary data queue (AUXDQ) to interface directly with the other data processing units.
4. DMA interface for the CMDQ.
5. DMA interface for the DATAQ.
6. Per queue control and status registers (Q_REGS).
7. Per queue counters: command counter, sequence counter and sequence ADC command counter.
8. Per queue measurement interval timer (ΔT) to space measurement commands in a sequence.
9. Optional 8 trigger outputs per queue. The trigger characteristics are controlled by the SW.
10. Global control and status registers to manage all the queues in one ADCQ.

The following sections describe each entity of the queue in detail.

39.3.1 Command queue (CMDQ)



39.3.1.1 Overview

Every queue module is equipped with a command queue to accept the prepared measurement sequences from the system over the DMA interface. The order of execution of the commands is same as the order of reception.

The command queue is a 32-bit wide FIFO of fixed depth. The depth of each command queue is selected during design configuration. SW can check the depth of each command queue, CMDQ, by reading *39.4.11: Global Queue Configuration register (GLBL_Qn_CONFIG)*.

Figure 504 illustrates the CMDQ structure. The command queue watermark (CMDQ_WM) defines when the CMDQ DMA/Interrupt request is asserted. When the number of free entries in CMDQ is greater than or equal to the command queue watermark then CMDQ will assert its DMA/Interrupt request. If DMA mode is enabled (CMDQ_DMA_MODE_EN=1) then a DMA request is asserted. The system CPU or DMA controller will push the commands into the CMDQ through the Qn_CMDQ_PUSH register. After every push the CMDQ_WR_PTR points to the next free entry in the queue. On reaching the top of queue the write pointer wraps around. After every read the CMDQ_RD_PTR points to the next valid entry in the queue.

Figure 504. CMDQ block diagram

When CMDQ is full (CMDQ_FULL=1) and another entry is being pushed then the new entry does not overwrite any entry in the CMDQ and the CMDQ overflow flag (CMDQ_OVRN_ERR) is set.

39.3.1.2 Command queue errors and error handling

A command queue overrun occurs when the command queue is full and a new data is being written into the command queue. On overrun condition the new command does not overwrite any existing command. Only a command queue overrun flag is set and if error reporting is enabled then an error interrupt is raised.

A command sequence missing error occurs, when a trigger arrives and the command queue is empty. Command sequence missing error flag is set and if error reporting is enabled then an error interrupt is raised. In this scenario the pending trigger is also registered in the status register. If the sequence starts arriving then it is executed immediately for the pending trigger and the corresponding first data in the data sequence is marked with command missing flag.

39.3.1.3 Command Queue (CMDQ) descriptor

Each command entry of the command queue identifies the type of command, controls the behaviour of the command and has markers to delimit the commands.

The command queue supports three types of commands:

1. ADC conversion commands.
2. Optional trigger output commands.
3. Dummy commands to insert SW defined spacing between two ADC conversions or to generate SW defined trigger output pulse widths.

The following behaviours are controlled by the control bits in each command:

1. Whether to pass the command to ADC or not (dummy command).
2. Whether to bypass the measurement interval timer.
3. Whether to capture the ADC data timestamp for this command.
4. How to align the ADC result data in the data queues, right or left.
5. Which data queue should the result be routed to, DATAQ or AUXDQ or to both.
6. Which ADC CFG to use for the command (sampling times and other parameters).
7. Whether Pre-charge phase is enabled for the channel or not.
8. Whether to raise an interrupt on end of a measurement sequence.

The following data markers delimit the measurement sequence:

1. Last command marker identifies the end of measurement sequence.
2. Last ADC data marker identifies the last ADC conversion command in a measurement sequence.

Figure 505 and *Table 632* capture the bit positions and definitions of the CMDQ descriptor.

Figure 505. CMDQ descriptor bit fields

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16:23	24:31
LAST_CMD_OF_SEQ	LAST_ADC_CMD	TS_CAPTURE_EN	ALIGN_DATA_LEFT	Reserved	Reserved	BYPASS_TIMER	DUMMY_CMD	Reserved	Reserved	ADC_VREF_SEL	ADC_PRECHG_EN	ADC_CFG_SEL		DATA_TO_AUXDQ	DATA_TO_DATAQ	TRIG_OUT	ADC_CH_NUM

Table 632. CMDQ descriptor bit field descriptions

Field	Description
0 LAST_CMD_OF_SEQ	Denotes the last command in a sequence. Last command can also be a dummy command. The measurement sequence stops after this command and waits for a new trigger to start the next sequence in the CMDQ. For single conversion set the LAST_CMD and the LAST_ADC_CMD bits in the first command of the sequence.
1 LAST_ADC_CMD	Denotes that this command in the sequence is the last ADC command. Since a sequence can end with a dummy command and a dummy command is generally not stored in the data queues, there is no way to mark the last data in the data queues when the sequence ends with a dummy command. This bit allows marking the last ADC data in the DATAQ and the AUXDQ. This bit has no impact on the measurement sequence processing.
2 TS_CAPTURE_EN	Timestamp capture enable bit. When set timestamp is captured for this command. Usually not all CMD's need a TS capture. First command, last command and suspended commands in a sequence are the main targets for timestamp capture. User can set this bit for first, last or any intermediate commands to enable timestamp capture for that command. This bit enables capture of timestamp in both the DATAQ and the AUXDQ. The queue specific control bits enable/disable the capture of timestamps in the DATAQ and the AUXDQ.
3 ALIGN_DATA_LEFT	ADC result data stored in data queues is by default aligned right. If ALIGN_DATA_LEFT bit is set in the command then the ADC data is aligned left in the data queues. This is true only when the result data width is less than 16-bits
6 BYPASS_TIMER	When set then the command is executed immediately without waiting for ΔT to elapse. This bit affects all commands (ADC, dummy and trigger output commands).
7 DUMMY_CMD	When set, it denotes that the command is a dummy command which is not passed to the ADC.
8	Reserved
9	Reserved
10 ADC_VREF_SEL	To select one of the 2 ADC references for this CMD. Unused for dummy commands.

Table 632. CMDQ descriptor bit field descriptions (continued)

Field	Description
11 ADC_PRECHG_EN	When set then PRECHG phase is enabled for the channel. Unused for dummy commands.
12:13 ADC_CFG_SEL[30:31]	To select one of the 4 ADC parameters for this command. These bits should also be defined for dummy commands so that the correct ΔC can be applied to the dummy commands.
14 DATA_TO_AUXDQ	Is defined only when AUXDQ is present in the queue. When set the ADC result is routed to AUX DATAQ.
15 DATA_TO_DATAQ	ADC Data routing bit. Is defined only when AUXDQ is present in the queue. When AUXDQ is not present then by default ADC data is routed to DATAQ only. When set the ADC result is routed to DATAQ.
16:23 TRIG_OUT[24:31]	One hot digital trigger outputs. One hot encoding allows driving them simultaneously from a single command. SW has to manage the allocation of trigger outputs between queues using the TRIG_OUT_UNMASK [7:0] bits of the Q_TRGO_SETUP register. Trigger output pulse width is defined by SW in multiples of ΔT. When BYPASS_TIMER is set then ΔT is skipped.
24:31 ADC_CH_NUM[24:31]	Channel Number of ADC for the current command. All values from 0 to 255 are valid. Use a dummy command to stop forwarding the command to ADC, in which case this field is unused.

Figure 506 captures few valid combinations of a command queue descriptor with data routed to both data queues.

Figure 506. Examples of CMDQ descriptor

	0	1	2	3	4	5	6	7	8	9	10	11	12:13	14	15	16:23	24:31

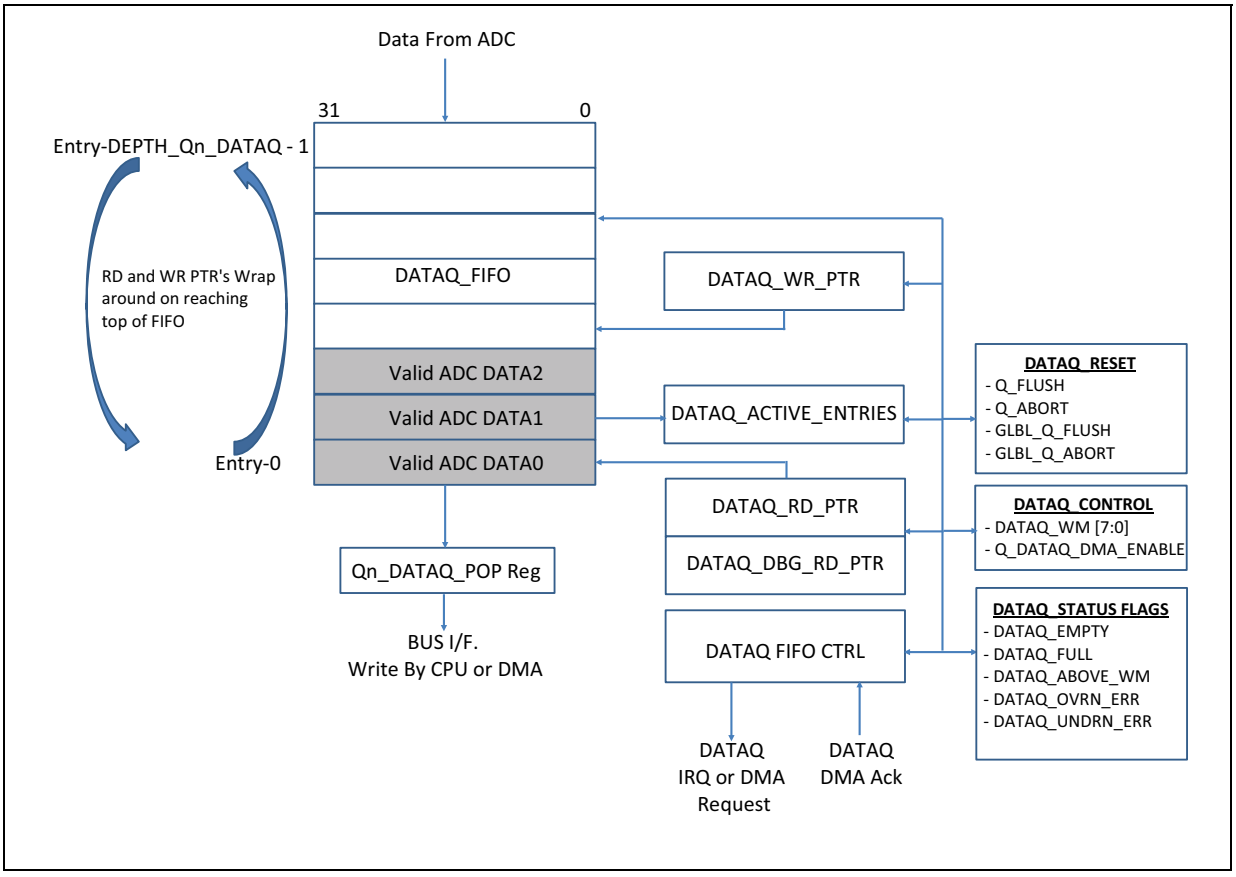
ADC command with timestamp capture enabled	0	0	1	0	0	0	0	0	0	0	0	0	0x0	1	1	0x0	CH
Last ADC command with timestamp capture enabled	0	1	1	0	0	0	0	0	0	0	0	0	0x0	1	1	0x0	CH
Last command is ADC command with timestamp capture enabled	1	1	1	0	0	0	0	0	0	0	0	0	0x0	1	1	0x0	CH

39.3.2 Data queues (DATAQ and AUXDQ)



39.3.2.1 Overview

There are two types of data queues in each queue module. One is the primary data queue, DATAQ, which is always present in the design. The second is auxiliary data queue, AUXDQ, which is present only when enabled during design configuration. The depth of both data queues is defined during design configuration.

The SW can check the presence of the AUXDQ and the depth of each data queue by reading *39.4.11: Global Queue Configuration register (GLBL_Qn_CONFIG)*.

The primary data queue interfaces to the system through the DMA interface. The auxiliary data queue provides a FIFO interface and can be used to pass the ADC data directly to other data processing units, like filters, thereby reducing the traffic on system bus and also reducing the SW overhead.

Figure 507. DATAQ block diagram

The SW can independently control the contents of each data queue. At the command level SW can route the results to either of the data queues or to both. At the queue level SW can enable the following actions independently for each data queue:

1. Whether to store dummy data corresponding to a dummy command.
2. Whether to store ADC data timestamps.
3. Whether to prepend the measurement sequence with trigger timestamp.

Each entry of data queue is 32-bit wide. The depth of each data queue is statically set during design configuration. Various data markers identify the type of the data present in the data queue. Most commonly the data queues hold the ADC conversion results for a sequence of ADC commands executed for a trigger event. The ordering of ADC data in the sequence follows the command execution order. The first and last ADC data of the sequence are marked with corresponding bits in the entry. Each ADC data entry is also tagged with the corresponding ADC channel number.

For debug purposes the current FIFO pointers and the number of active entries for both DATAQ and AUXDQ can be read from the registers.

39.3.2.2 Dummy data handling

By default dummy commands are not stored in the data queues. For test purposes the SW can enable the storage of dummy data corresponding to dummy commands. This can be done independently for each data queue. Dummy data entry is marked by a corresponding bit in the data entry. For dummy data the ADC channel number field has no meaning and the data field holds a dummy data.

39.3.2.3 Handling suspension of normal queue sequence

In multi-queue mode, an injected queue can suspend the active sequence of a normal queue. In such scenarios it is important to inform the application SW about the suspension. In order to do this, the ADC data which encountered suspension is marked with a corresponding status bit. If the suspension occurred during the execution of a dummy command in the normal queue and dummy command storage is disabled, then none of the ADC data entry of the normal sequence is marked as suspended. If a dummy cmd (which is not stored) met with suspension, then none of the dataq entry would reflect this suspension. If dummy command storage is enabled for the data queue then the dummy data is marked with suspension status.

39.3.2.4 Prepending trigger timestamp to measurement data sequence

For each data queue, DATAQ and AUXDQ, it is possible to independently enable the prepending of trigger timestamp to the measurement data sequence. When enabled the measurement data sequence is pre-pended with the timestamp when trigger occurred.

The trigger timestamp data is marked by a corresponding status bit in the data queue entry. The ADC channel number field along with ADC data field holds the 24-bit timestamp entry.

39.3.2.5 Behaviour of data queues during debug

During the SW debug one of the side effects in FIFO interfaces is the disruption of FIFO pointers. In order to avoid this when debug is activated the current FIFO pointers are stored and the debug FIFO pointers are used to access the FIFOs. Write into the data queues is also inhibited. On exit from debug mode the original FIFO pointers are restored and write is enabled.

During debug mode the AUXDQ, which is not on the system bus interface, can also be read using the system bus interface.

39.3.2.6 Data queue errors and their handling

A data queue overrun occurs when the data queue is full and a new data is being written into the data queue. Overrun can happen either due to wrong programming or due to high

DMA latency. On overrun condition the new data does not overwrite any existing data. On overrun condition a data queue overrun flag is set and if error reporting is enabled then an error interrupt is raised.

A data queue underflow occurs when the data queue is empty and the read interface is trying to read from the data queue. An underflow can happen due to a wrong DMA or SW programming. A data queue underflow flag is set and if error reporting is enabled then an error interrupt is raised.

This error reporting mechanism is the same for both the DATAQ and the AUXDQ but with their own error flags.

39.3.2.7 Data Queue (DATAQ) and Auxiliary Data Queue (AUXDQ) description

</table>

Table 633. DATAQ and AUXDQ bit field descriptions

Data Queue Descriptor Fields	
Field	**Description**
0:15 ADC_DATA/ DATA_TS_H/ TRIGGER_TS_H	For ADC data this field holds ADC conversion data for the channel specified in the ADC_CH_NUM field. If ADC data is less than 16-bits then the data alignment is defined by the corresponding bit in the command entry. For dummy data this field holds a 0xD0D0. For timestamps this field holds upper 16 bits of 24-bit timestamp. For sequence status this field holds the upper 16 bits of 24-bit timestamp for last ADC data.
16:23 ADC_CH_NUM/ DATA_TS_L/ TRIGGER_TS_L	8-bit ADC Channel Number corresponding to the data in the ADC Data field. For timestamps this field holds lower 8 bits of 24-bit timestamp. For sequence status this field holds the lower 8 bits of 24-bit timestamp for last ADC data.
24 TS_TRIGGER	When this field is set then bits [0:23] contain the timestamp for the trigger.
25 TS_DATA	When this bit is set then bits [0:23] contains the timestamp data for the channel.
26 DUMMY_DATA	Marker for denoting that this entry corresponds to a DUMMY CMD. This bit is significant only when DUMMY data dumping is enabled for a queue.
27 LAST_ADC_DATA	Marker for denoting the last ADC data of the Sequence.

Table 633. DATAQ and AUXDQ bit field descriptions (continued)

Data Queue Descriptor Fields	
Field	**Description**
28 FIRST_ADC_DATA	Marker for denoting the first ADC data of the sequence.
29:31 ERROR_CODE	Every erroneous ADC result is marked with error codes. *Table 634* captures different error codes.

Table 634. ADC error codes

Value	Error OP-CODE	Error description
0x0	NO_ERROR	No error occurred.
0x1	SUSPENDED	Marker for denoting that this entry encountered a SUSPEND due to Injection by a high priority queue. If multiple commands in a queue encounter suspension then all entries which encountered suspension are marked. This will allow the SW to do timing correction.
0x2	CMD_MISSING	This bit is set for ADC data in which a command missing error was encountered. If at any time a conversion is delayed because of an empty CMDQ FIFO then the delayed conversion's data entry will be marked with this error code.
0x3	ADC_CNV_TIMEOUT	After launch of a conversion if the ADC does not respond within a defined time then a conversion timeout is flagged. Any channel encountering an ADC conversion timeout has this error code. The data field of the result is set to 0xd0d0.
0x4	ADC_CH_INVALID	Conversion requested for the ADC channel is not present or it is disabled.
0x5	RESERVED	Reserved
0x6	RESERVED	Reserved
0x7	MULTIPLE_ERR	If the channel encounters multiple error conditions then this error code is attached to the result. The data field of the result is set to 0xd0d0.

Figure 509 captures all the valid combinations of a data queue descriptor. Any other combination should not occur in the data queues.

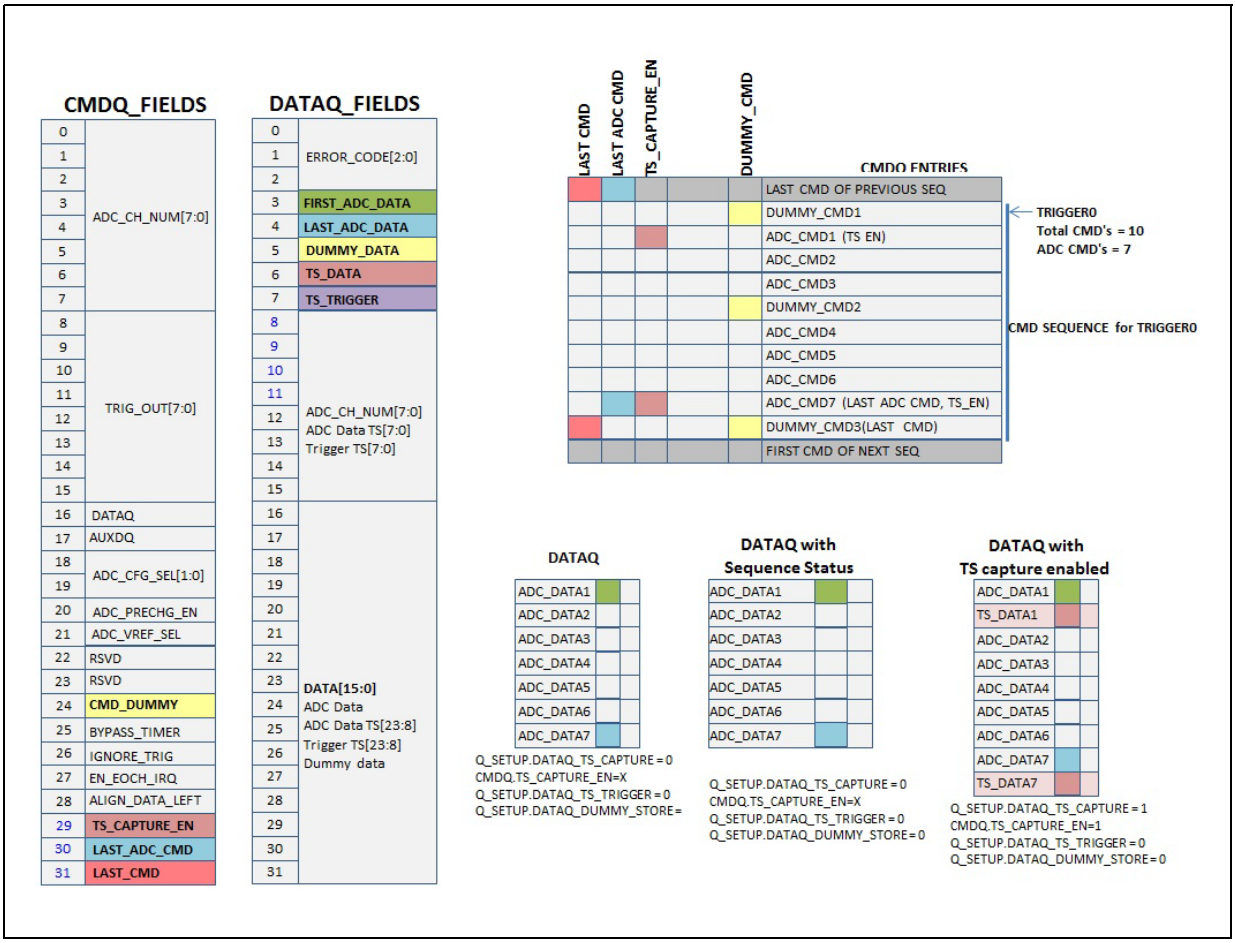
39.3.2.8 Various data queue scenarios

For the purpose of illustration the various scenarios for DATAQ are highlighted in *Figure 510* and *Figure 511*. The same scenarios are applicable for AUXDQ.

Figure 510. DATAQ scenarios–part 1



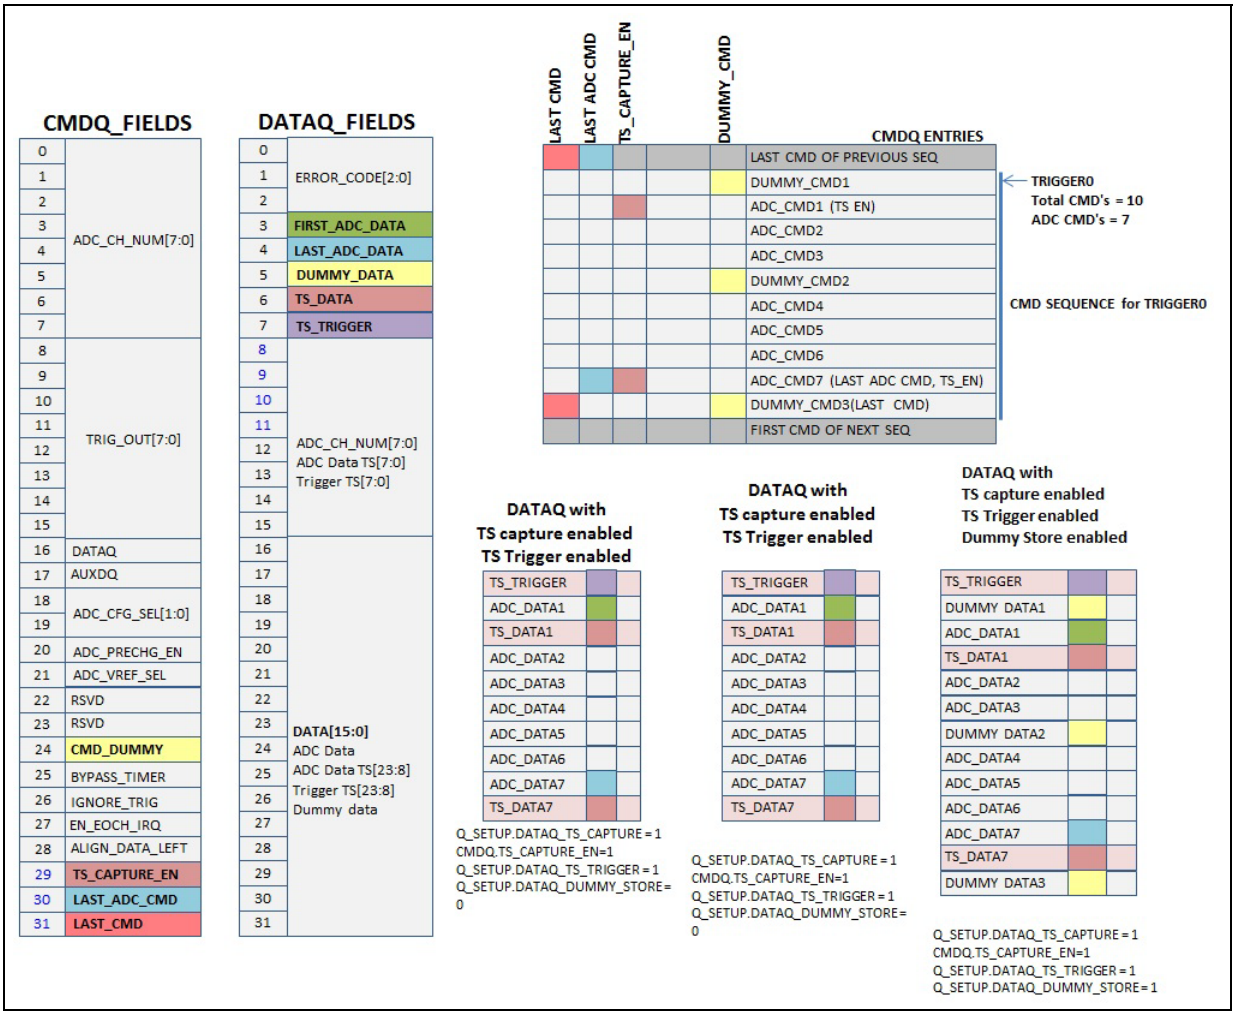


Figure 511. DATAQ scenarios–part 2

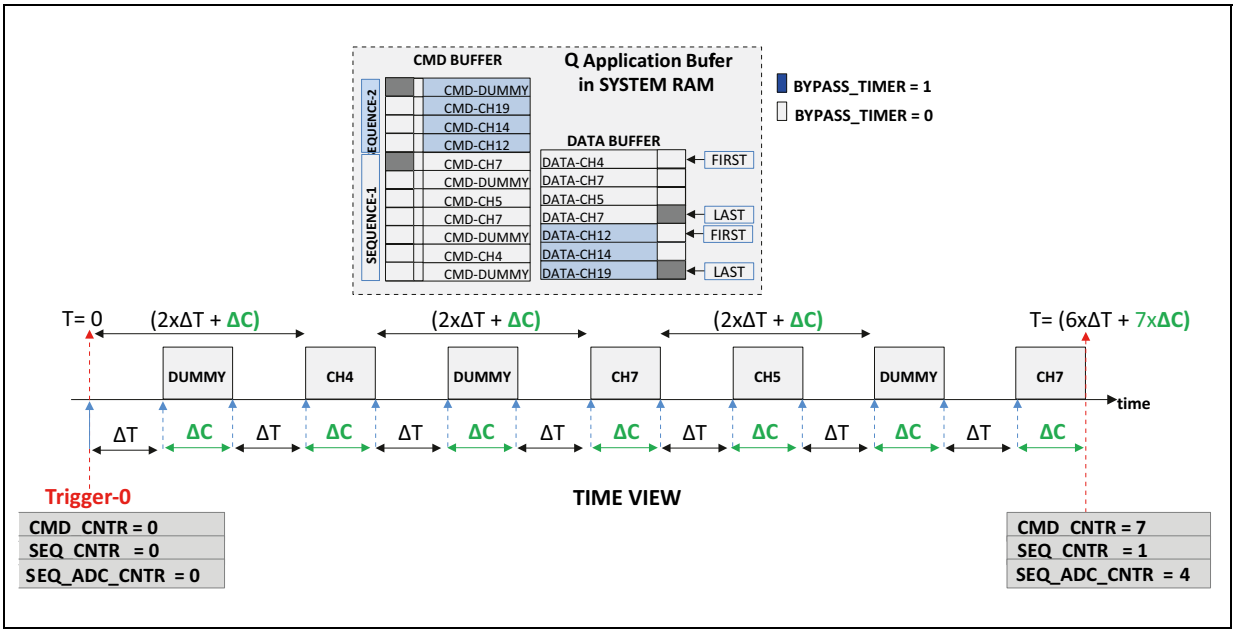
39.3.3 Measurement interval timer (ΔT)

Measurement Interval Timer (ΔT) along with dummy commands allows to space measurements in ΔT intervals. Each queue is equipped with a programmable measurement interval timer (ΔT). This is true for every command in the sequence including the first command. For every command in the command queue, the SW can specifically enable the BYPASS_TIMER bit to skip ΔT.

Figure 512 illustrates the case where the BYPASS_TIMER bit is not enabled for any of the commands.

Note the usage of dummy commands to space conversions. Dummy commands are not passed on to the ADC but undergo ΔC delay. So it is important to set the correct ADC_CFG_SEL bits even for dummy commands so that a predictable ΔC delay is achieved.

Figure 512. Measurement interval timers



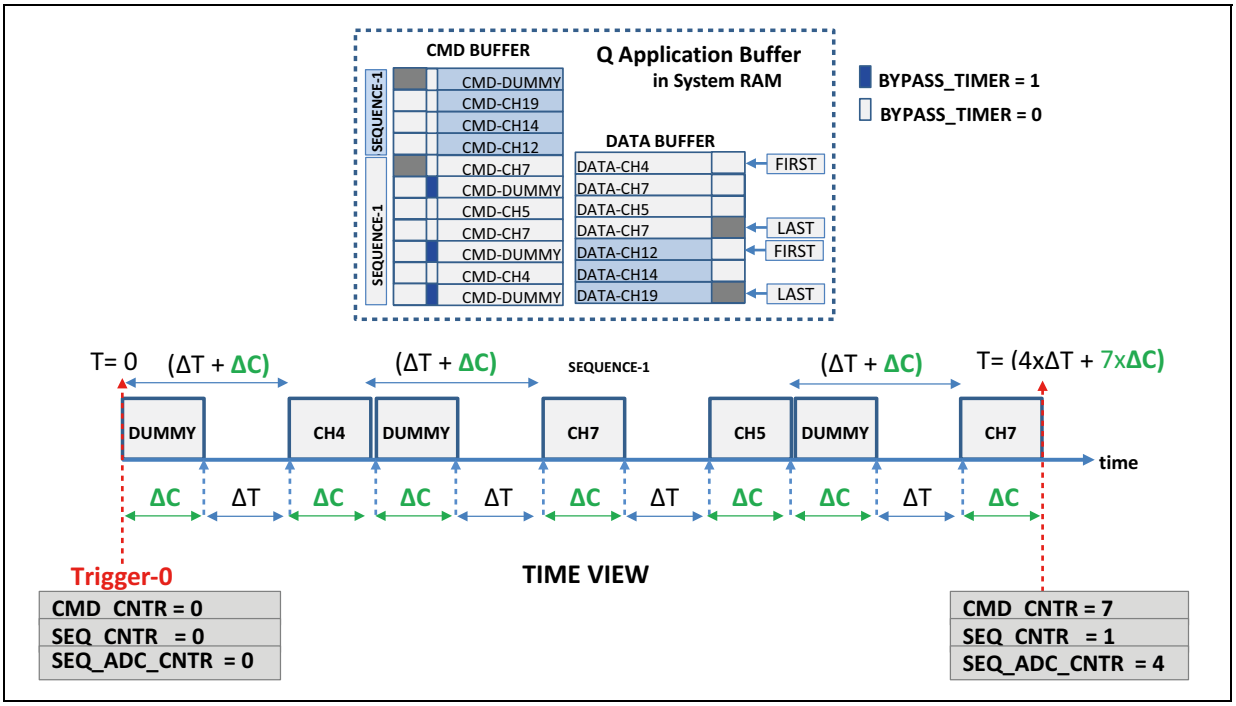


Figure 513 illustrates the case where the BYPASS_TIMER bit is enabled for the first command and some intermediate commands.

Note that the first command, after trigger, skips ΔT.

Figure 513. Measurement interval timer with BYPASS_TIMER enabled

When the data corresponding to previous command is available in the data queue either the new command processing or the new ΔT starts.

When an injected sequence suspends a command in a normal queue that is waiting for its ΔT to elapse then the ΔT is restarted from its reload value when the suspended sequence resumes.

39.3.4 Queue trigger input system

Each queue can support up to 32 hardware trigger inputs. The number of hardware triggers is defined during design configuration. The SW can check the number of HW trigger inputs that are present in the design by reading *39.4.10: Global module Configuration register (GLBL_CONFIG)*.

All hardware trigger inputs are routed to every queue. And each queue can choose which hardware trigger(s) to use to trigger its command sequence. So hardware trigger inputs are not classified as injected or normal triggers. Triggers enabled in queue-0 become injected triggers and triggers enabled in queues 1,2 and 3 become normal triggers.

39.3.4.1 Trigger enabling

Each queue has edge register which enables the selection of the rising (*Section 39.4.15: Queue Rise edge Enable register (Qn_RISEN)*) or falling (*Section 39.4.16: Queue Fall edge Enable register (Qn_FALLEN)*) edge (or both) for each hardware trigger input. When neither edge is enabled then the corresponding hardware trigger input is ignored.

The final trigger of each queue can be individually enabled or disabled using the queue control register (*Section 39.4.18: Queue Control register (Qn_CTRL)*).

A trigger can be synchronously enabled or disabled for multiple queues in one ADCQ using the global control register (*Section 39.4.2: Global Control Register (GLBL_Q_CTRL)*).

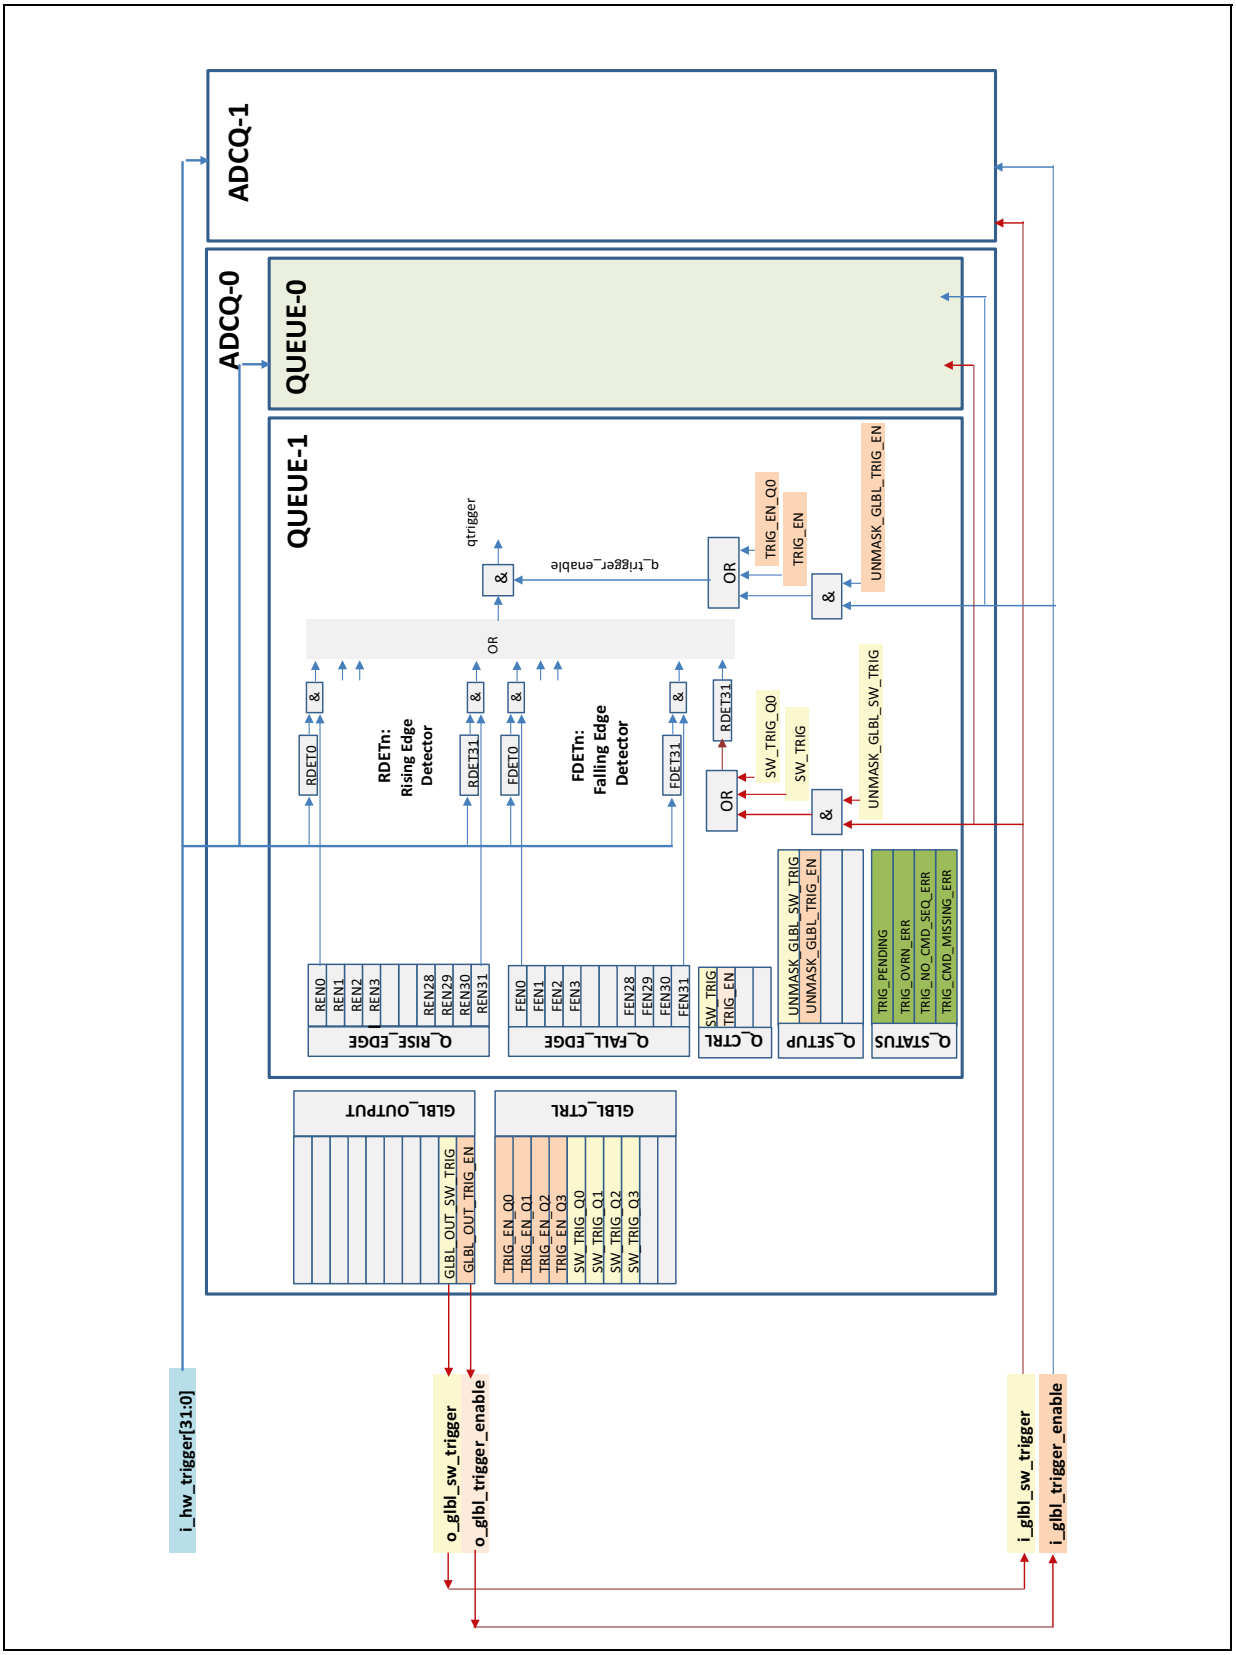
Each queue can participate in a synchronous global trigger enable operation across multiple ADCQs by unmasking its global trigger enable input.

39.3.4.2 SW triggering

The SW can trigger a queue measurement sequence using the queue control register.

The SW can synchronously trigger measurement sequence of multiple queues in one ADCQ using the global control register.

Each queue can participate in a synchronous global SW trigger operation across multiple ADCQ by unmasking its global SW trigger input.



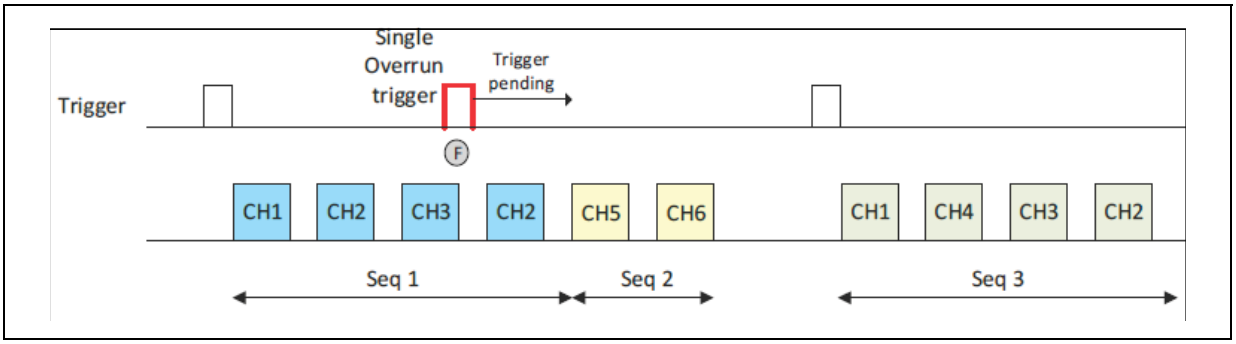
39.3.4.3 Multiple HW triggers

Enabling multiple rising or falling register bits will enable multiple hardware inputs to trigger a measurement sequence in a queue.

39.3.4.4 Trigger system illustration

Figure 514 illustrates the trigger input system.

Figure 514. Queue trigger input system



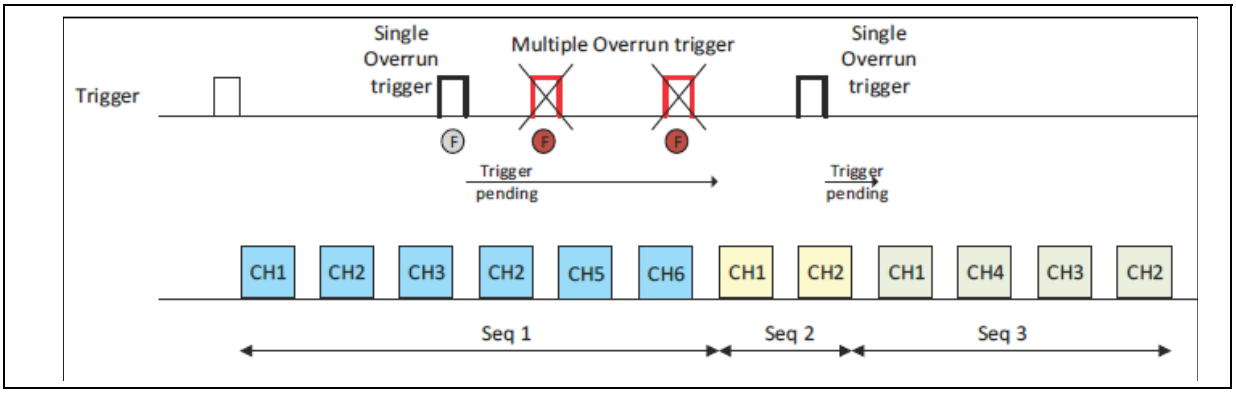
39.3.4.5 Pending triggers

If trigger is received while a sequence is ongoing then one trigger is buffered and is used to trigger next conversion sequence when current conversion sequence is finished. Only one trigger can be buffered at a time.

If a normal queue sequence is suspended and a new trigger is received then new trigger is buffered and is used to trigger the next conversion sequence after the suspended sequence.

Queue status register bit captures the pending trigger status.

Figure 515. Example of single pending trigger



39.3.4.6 Triggers overruns

If a trigger is already pending and a new trigger occurs then a trigger overrun error is flagged. The overrun trigger is not stored and is lost.

Queue status register captures the trigger overrun error condition. In case of overrun both pending and overrun flags of queue status can be set together.

Figure 516. Example of trigger overrun

39.3.5 Queue trigger output system

Trigger output feature is present only when enabled during design configuration. The SW can check the presence of this feature by reading the global IP configuration register.

Trigger outputs can be used in a measurement sequence to activate or deactivate something before or after an ADC conversion. Another use for TRIG_OUT is to accurately measure the time between the arrival of an input trigger and the exit of ADC command from ADCQ and the arrival of ADC result in ADCQ.

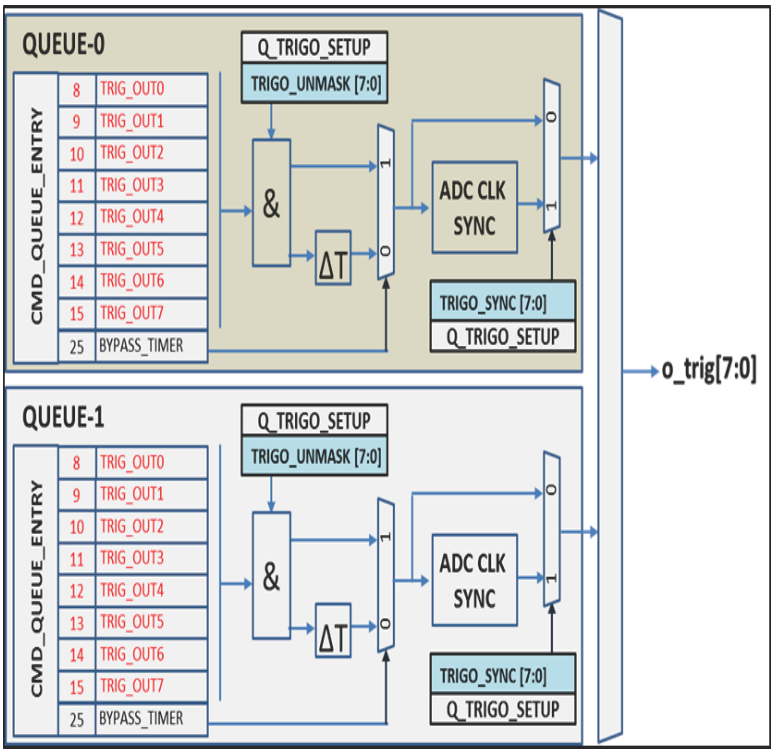
This feature enables 8 one-hot digital trigger outputs which are fully controlled and managed by the SW. One hot encoding allows for simultaneous controls of all trigger outputs. The SW can manage trigger output allocation between queues by unmasking the trigger outputs used by a particular queue. Then the unused trigger outputs of the queue are driven zero by the queue.

Trigger output pulse width is controlled by measurement interval timer (ΔT) and by having multiple trigger out commands in the queue. Setting "BYPASS_TIMER" bit in the command will over-ride Measurement Interval Timer (ΔT).

If an injected queue disrupts any normal queue then the trigger outputs are also overridden via injected queue command.

Figure 517 illustrates the trigger output system.

Figure 517. Queue trigger output system



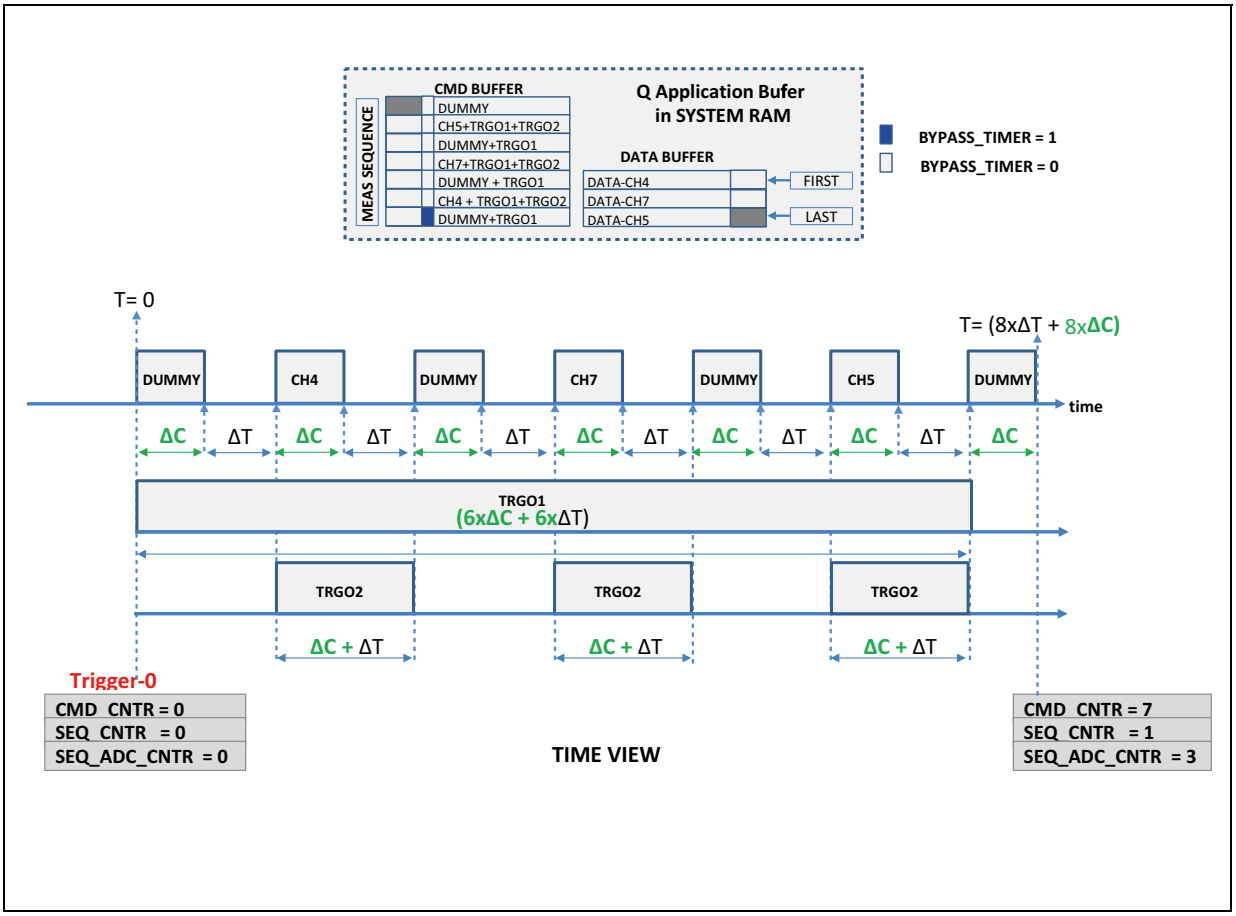


Figure 518. Trigger output timing

39.3.6 Queue counters

Queue counters keep track of the number of commands, the number of sequences and the number of ADC commands in a sequence. This can be used by the SW to synchronize conversions across queues in multiple ADCQs.

39.3.6.1 Command Counter (CMD_CNTR)

Each queue, normal and injected, provides a command counter (CMD_CNTR) to track the f total number of commands executed, including dummy commands. The main purpose is to use counters on different queue modules as an indicator of synchronous run. The counter increments every time an ADC result is stored in the DATAQ or on completion of a dummy command. This 16-bit counter wraps around once it reaches its maximum value. Counter wrap-around is registered in the queue status register and can signal it through an interrupt. The SW can read the current value at any time. This counter is cleared in any of the following cases:

1. When the SW issues a reset queue counters command through the queue control register.
2. When the SW issues a global reset queue counters command and the queue is participating in this global command.
3. When the SW issues a queue abort command.
4. When the SW issues a global abort command and the queue is participating in global abort operation.

39.3.6.2 Sequence Counter (SEQ_CNTR)

Each queue, normal and injected, provides a sequence counter (SEQ_CNTR) to track the number of sequences executed. The counter increments on completion of a command sequence. This 16-bit counter wraps around once it reaches its maximum value. Counter wrap-around is registered in the queue status register and can signal this through an interrupt. The SW can read the current value at any time. This counter is cleared in any of the following cases:

1. When the SW issues a reset queue counters command through the queue control register.
2. When the SW issues a global reset queue counters command and the queue is participating in this global command.
3. When the SW issues a queue abort command.
4. When the SW issues a global abort command and the queue is participating in a global abort operation.

39.3.6.3 Sequence ADC Command Counter (SEQ_ADC_CNTR)

Each queue, normal and injected, provides a sequence ADC counter (SEQ_ADC_CNTR) which keeps track of total number of ADC commands executed in a sequence. The counter increments on completion of each ADC command in a sequence. This 8-bit counter resets at start of next sequence.

If there are more than 256 ADC commands in a sequence this counter wraps around. The counter wrap-around is registered in the queue status register and can signal this through an interrupt.

For each queue it is possible to enable the attachment of this count in the sequence status word inside the DATAQ. The sequence status word is always at the end of the sequence in a DATAQ.

The SW can read the current value at any time. This counter is cleared in any of the following cases:

1. Automatically when a sequence ends.
2. When the SW issues a reset queue counters command through the queue control register.
3. When the SW issues a global reset queue counters command and the queue is participating in this global command.
4. When the SW issues a queue abort command.
5. When the SW issues a global abort command and the queue is participating in a global abort operation.

39.3.7 Queue DMA

In a queue module, command queue (CMDQ) and data queue (DATAQ) have independent DMA interfaces. When DMA mode is selected for the queue and DMA interface is enabled then DMA transfers are used to fill the CMDQ and empty the DATAQ.

39.3.7.1 CMDQ DMA

In CMDQ DMA the DMA controller transfers the commands to the CMDQ. When the number of free entries in the CMDQ is greater than or equal to the command queue watermark then the CMDQ will assert its DMA request.

The DMA transfer configuration (TCD) can be programmed to transfer the same number of 32-bit words in its minor loop as defined by the command queue watermark. If the number of commands in a measurement sequence is not a multiple of the command queue watermark then two transfer configuration structures are needed.

Example 1

Depth of CMDQ = 32

CMDQ is empty = true

CMDQ WM = 4

Number of commands in a measurement sequence = 8

Number of TCD = 1

Number of words transferred per minor loop = CMDQ WM = 4

Number of minor loops per major loop = 2

Since CMDQ is empty it has 32 free entries so it will keep its DMA request asserted. In the first minor loop 4 words are transferred. The DMA request is still kept asserted so the second minor loop executes and transfers the next 4 commands. The DMA request is still kept asserted since the number of free entries is greater than the watermark. The DMA controller can be programmed to disable its DREQ input on completion of a major loop.

Example 2

Depth of CMDQ = 32

CMDQ is empty = true

CMDQ WM = 4

Number of commands in a measurement sequence = 9

Number of TCDs required = 2

Number of words transferred per minor loop of the first TCD = CMDQ WM = 4

Number of minor loops in the first TCD major loop = 2

Number of words transferred the minor loop of the second TCD = 1

Number of minor loops in the major loop of the second TCD = 1

First TCD will transfer 8 words and the second TCD will transfer 1 word.

Since CMDQ is empty it has 32 free entries so it will keep its DMA request asserted. In the first minor loop of the first TCD 4 words are transferred. The DMA request is still kept asserted so the second minor loop of the first TCD executes and transfers the next 4 commands. The DMA request is still kept asserted since the number of free entries is greater than the watermark. In the first minor loop of the second TCD the last word is

transferred. The DMA controller can be programmed to disable its DREQ input on completion of the second major loop.

Example 3

Depth of CMDQ = 32

CMDQ is empty = No

CMDQ free entries = 4

CMDQ WM = 4

Number of commands in a measurement sequence = 8

Number of TCDs = 1

Number of words transferred per minor loop = CMDQ WM = 4

Number of minor loops in the major loop = 2

The CMDQ will assert its DMA request as soon as 4 entries are free. The first minor loop starts transferring 4 words. On receiving the first word the CMDQ DMA will de-assert its DMA request since number of free entries is less than the watermark (4). After completing the first minor loop the DMA controller stops and waits for the DMA request to be reasserted before transferring the remaining 4 commands. On the second DMA request the DMA controller will execute its second minor loop and transfer the remaining 4 commands.

39.3.7.2 DATAQ DMA

The DATAQ DMA interface behaves differently to the CMDQ DMA. In the DATAQ DMA the DATAQ transfers data to the DMA controller. The difference arises in the transfer of the last words of sequence data. When the number of entries in the DATAQ reaches the watermark level then the DATAQ will assert its DMA request. A DATAQ DMA request is always asserted if it receives the last data of a sequence.

The DMA TCD should be programmed to transfer the same number of 32-bit words in its minor loop as defined by the data queue watermark.

If the number of data words in a measurement sequence is not a multiple of the data queue watermark then two TCD structures are needed.

Example 1: One measurement sequence returning 8 ADC data words.

Depth of DATAQ = 32

DATAQ is empty = No

DATAQ free entries = 4

DATAQ WM = 4

Number of measurement sequences = 1

Number of expected data words for a measurement sequence = 8

Number of TCDs = 1

Number of words transferred per minor loop = DATAQ WM = 4

Number of minor loops per major loop = 2

Since the DATAQ WM is 4, the DATAQ DMA will assert its DMA request after receiving 4 ADC data words. The first minor loop of the DMA controller will read 4 words. After reading the first word, the DATAQ will de-assert its DMA request since the number of words left is less than the DATAQ WM. The DMA controller will complete the first minor loop after reading the remaining 3 words and then wait for the DMA request to be

reasserted to transfer the next 4 words. As soon as the DATAQ has 4 free entries, the DMA request is reasserted. The second minor loop will execute in the same way as the first loop.

Example 2: One measurement sequence returning 9 ADC data words.

Depth of DATAQ = 32

DATAQ is empty = No

DATAQ WM = 4

Number of measurement sequences = 1

Number of expected data words for a measurement sequence = 9

Number of TCDs = 2

Number of words transferred in a minor loop of first TCD = DATAQ WM = 4

Number of minor loops per major loop of the first TCD = 2

Number of words transferred in the minor loop of the second TCD = 1

Number of minor loops in the major loop of the second TCD = 1

The first TCD executes as described int the DATAQ example 1. Once 8 words are transferred then only one word is left to be transferred for the measurement sequence. The DATAQ DMA also keeps track of the ADC sequence length along with the watermark level. So for the 9th word, the WM level is not reached but since it is the last word of the sequence the DMA DATAQ will assert its DMA request and the first minor loop of second TCD will get activated and transfer only one word. When the last word is read the DMA controller will de-assert its DMA request.

If the DMA controller is programmed incorrectly and the first minor loop of the second TCD is programmed to transfer more than 1 data word, then the DATAQ DMA will report an underflow error.

Example 3: Two measurement sequences each having single conversions only.

Depth of DATAQ = 32

DATAQ is Empty = No

DATAQ WM = 4

Number of measurement sequence = 2

Number of expected data words for first measurement sequence = 1

Number of expected data words for second measurement sequence = 1

Number of TCDs required = 1

Number of words transferred in one minor loop of TCD = 1

Number of minor loops in one major loop = 2

This example illustrates the case of two back to back single conversions. The DATAQ will assert its DMA request as soon as the ADC data is available for the first sequence, even if the WM is not reached since it is the last data word of the first sequence. The first minor loop will read the data word. After the first read is completed and if the data for the next measurement sequence is not available, then the DATAQ will de-assert its DMA request. When the second data word arrives the above operation is repeated.

If the second data word becomes available before the first is read, then the DATAQ DMA will keep its DMA request asserted, the second data also being the last data word of a sequence. The DMA controller will execute both minor loops.

Example 4: One measurement sequence returning 9 ADC data and a sequence status word.

For a DATAQ with a WM of 4, the first TCD will read 8 words in two minor loops and the second TCD will read 2 words (the last data and the sequence status word) in its minor loop.

The DATAQ DMA will generate the first two DMA requests like it already did. The third DMA request will be asserted when both the last word and the sequence status word are written into the DATAQ.

Example 5: One measurement sequence returning 9 ADC data words and timestamp for the last data word and a sequence status word.

For a DATAQ with a WM of 4, the first TCD will read 8 words in two minor loops and the second TCD will read 3 words (the last data, TS of last data word and the sequence status word) in its minor loop.

The DATAQ DMA will generate the first two DMA requests like it already did. The third DMA request will be asserted after writing the last data word, TS of the last data word and the sequence status word into the DATAQ.

Example 6: One measurement sequence returning timestamp of trigger, 9 ADC data words, timestamp for the last data and a sequence status word.

For a DATAQ with a WM of 4, only one TCD with three minor loops is required. Each minor loop will read 4 words.

The DATAQ DMA will generate the first two DMA requests like it did earlier. In the first two requests it will transfer trigger timestamp and 7 ADC data words. The third DMA request will be asserted after writing the 8th and 9th words, TS of the last data and the sequence status word into the DATAQ.

39.3.8 Queue interrupts

Each queue module supports two types of interrupts: error interrupts and status interrupts. If enabled each error condition will assert an error interrupt. Similarly if enabled each status change will assert a status interrupt.

The error and status interrupt of all queues are registered at ADCQ level and if the global error interrupt for the queue is enabled then the ADCQ error interrupt is asserted. Similarly if the global status interrupt for the queue is enabled then the ADCQ status interrupt is asserted.

The SW can read the *39.4.5: Global IRQ Status register (GLBL_IRQ_STATUS)* to identify which queue has raised the interrupt and then read the *39.4.21: Queue IRQ Status register (Qn_IRQ_STATUS)* to identify the reason for the interrupt.

The figures below illustrate the interrupt hierarchy and structure. Please refer to *Table 657: Qn_IRQ_STATUS field descriptions* for complete description of each interrupt.

Figure 519. Queue status interrupts

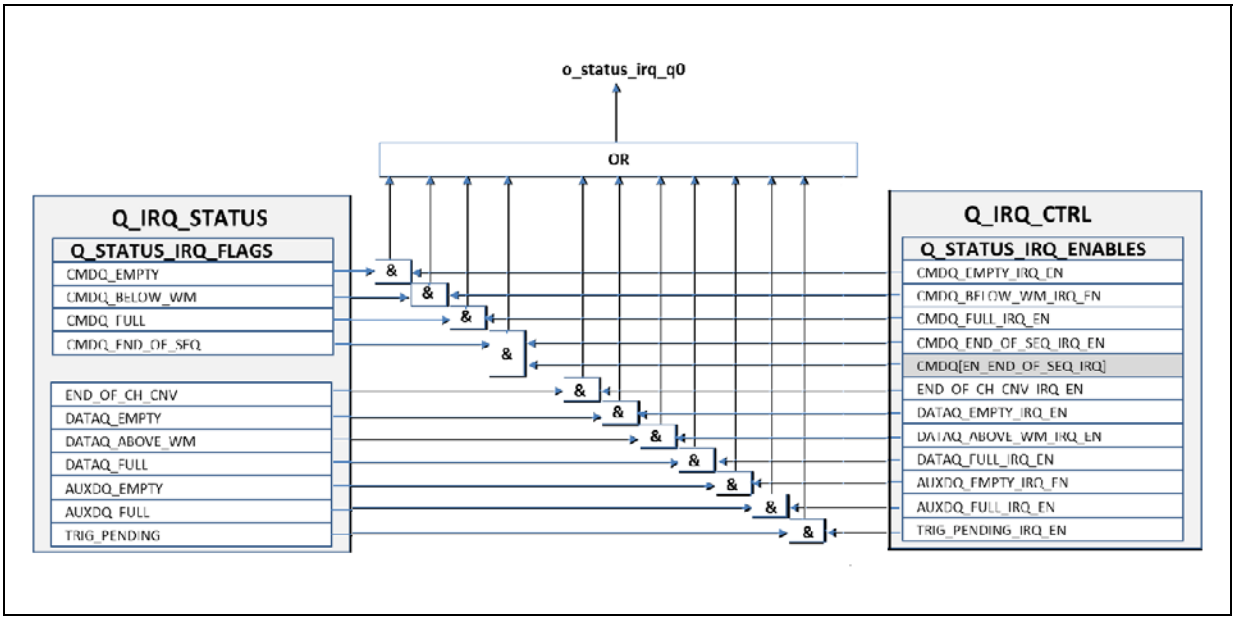

Figure 520. Queue error interrupts

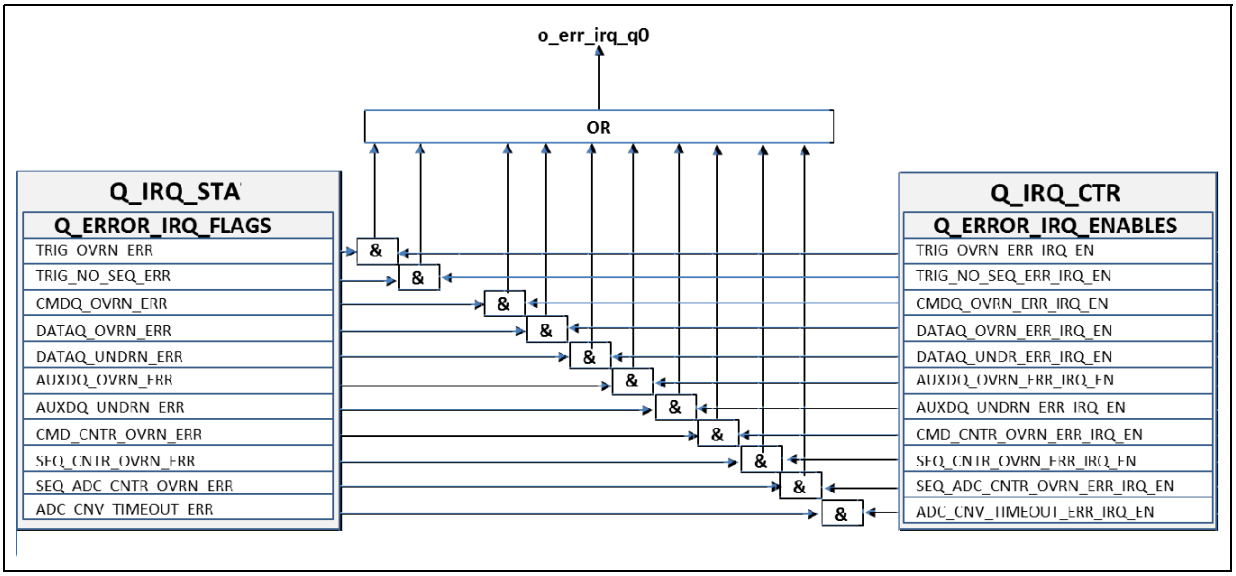

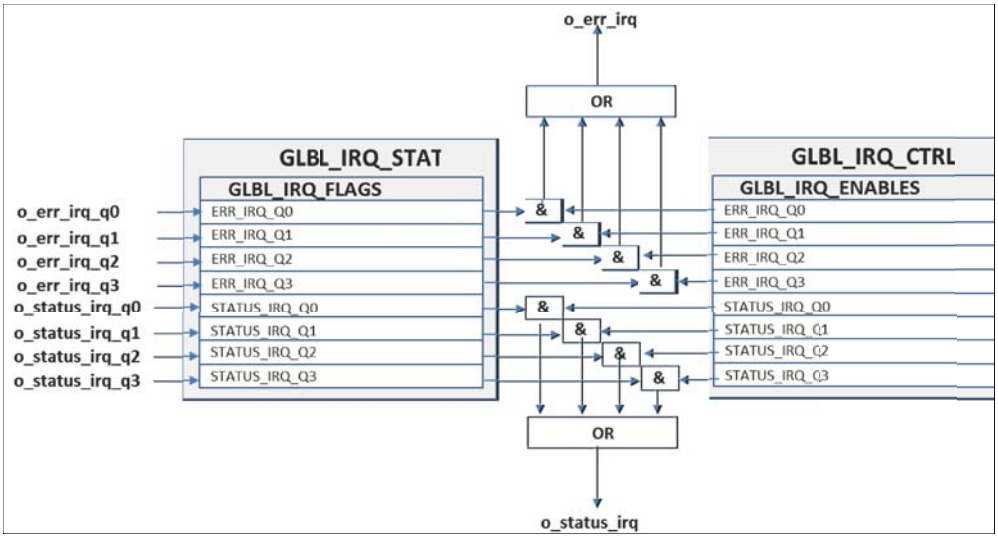

Figure 521. Global interrupt control

39.3.9 Queue abort

An ABORT operation is very much like a queue reset. Please refer to *Section 39.3.9.2: Outcome of ABORT operation* to check which controls are reset. The software also has to re-enable both the DMA and trigger to restart the queue.

39.3.9.1 Initiating ABORT operation

An individual queue can be aborted in the following two ways:

1. By writing a 1 to the Qn_CTRL[Q_ABORT] bit
2. By writing a 1 to the GLBL_Q_CTRL[Qn_ABORT] bit

Multiple queues within one ADCQ module can be aborted together by writing a 1 to all the required bits of the GLBL_Q_CTRL [Qn_ABORT] bits.

Multiple queues across ADCQ modules can be aborted by writing a 1 to the GLBL_OUTPUT[GLBL_OUT_Q_ABORT] bit. All the queues participating in the global abort operation are aborted. Participation in a global abort operation is enabled by setting Qn_SETUP[UMASK_GLBL_ABORT] to a 1.

After initiating an abort operation the SW must wait for the queue(s) to return to the IDLE state before starting the re-initialization.

If both FLUSH and ABORT bits are set together then ABORT takes precedence.

39.3.9.2 Outcome of ABORT operation

On an abort operation the following happens:

1. The active command sequence is aborted and CMDQ, DATAQ and AUXDQ are flushed and the FIFO pointers are reset.
   a) Qn_CMDQ_POINTERS = 0
   b) Qn_DATAQ_POINTERS = 0
   c) Qn_AUXDQ_POINTERS = 0
   d) Qn_DBG_RD_POINTERS = 0
2. If the normal queue is in SUSPENDED state then its sequence is also aborted and the FIFO is flushed.
3. Before issuing ABORT, the software has to disable the DMA interface by programming the following register bits:
   a) Q(#i)_CTRL[Q_DATAQ_DMA_ENABLE]
   b) GLBL_Q_CTRL[Q(#i)_DATAQ_DMA_ENABLE]
   c) Q(#i)_CTRL[Q_CMDQ_DMA_ENABLE]
   d) GLBL_Q_CTRL[Q(#i)_CMDQ_DMA_ENABLE]
4. An ongoing DATAQ/AUXDQ write is allowed to finish before flushing the FIFOs.
5. All error status flags associated with all the FIFOs are cleared.
6. All status flags associated with all the FIFOs go to their default state.
7. All the trigger sources of the queue are disabled by resetting the following bits:
   a) Qn_CTRL[Q_TRIGGER_EN] = 0
   b) GLBL_Q_CTRL[Qn_TRIG_EN] = 0
   c) Qn_SETUP [UMASK_GLBL_TRIG_EN] = 0
8. The CMDQ and DATAQ DMA is disabled by resetting the following bits:
   a) Qn_CTRL[Q_CMDQ_DMA_ENABLE] = 0
   b) GLBL_Q_CTRL[Qn_ CMDQ_DMA_ENABLE] = 0
   c) Qn_CTRL[Q_DATAQ_DMA_ENABLE] = 0
   d) GLBL_Q_CTRL[Qn_ DATAQ_DMA_ENABLE] = 0
9. All active and pending triggers are canceled and all trigger related flags are cleared.
   a) Qn_IRQ_STATUS[TRIG_NO_SEQ_ERR] = 0
   b) Qn_IRQ_STATUS[TRIG_OVRN_ERR] = 0
   c) Qn_IRQ_STATUS[TRIG_PENDING] = 0
10. All measurement counters are cleared.
    a) Qn_CMD_CNTRS = 0
    b) Qn_SEQ_STATUS = 0
11. If an ADC conversion is ongoing when a queue abort is received then the conversion is aborted and the pending sequence of a non-aborted queue is started.
12. While the above operations are ongoing the queue is in ABORT_IN_PROGRESS state and after completion of all the above operations the queue is brought to IDLE state.

39.3.10 Queue flush

FLUSH operation is similar to ABORT operation except that a FLUSH does not reset the DMA and trigger controls. So after a FLUSH operation the software does not have to initialize the queues again.

39.3.10.1 Initiating FLUSH operation

An individual queue can be flushed in the following two ways:

1. By writing a 1 to the Qn_CTRL[Q_FLUSH] bit
2. By writing a 1 to the GLBL_Q_CTRL[Qn_FLUSH] bit

Multiple queues within one ADCQ module can be flushed together by writing a 1 to all the required bits of the GLBL_Q_CTRL [Qn_FLUSH] bits.

Multiple queues across ADCQ modules can be flushed by writing a 1 to the GLBL_OUTPUT[GLBL_OUT_Q_FLUSH] bit. All the queues participating in the global flush operation are flushed. Participation in a global flush operation is enabled by setting Qn_SETUP[UMASK_GLBL_FLUSH] to a 1.

After initiating a flush operation the SW must wait for the queue(s) to return to IDLE state before starting the re-initialization.

If both FLUSH and ABORT bits are set together then ABORT takes precedence.

39.3.10.2 Outcome of FLUSH operation:

On a flush operation the following happens:

1. The active command sequence is aborted and CMDQ, DATAQ and AUXDQ are flushed and the FIFO pointers are reset.
   a) Qn_CMDQ_POINTERS = 0
   b) Qn_DATAQ_POINTERS = 0
   c) Qn_AUXDQ_POINTERS = 0
   d) Qn_DBG_RD_POINTERS = 0
2. If the normal queue is in SUSPENDED state then its sequence is also aborted and the FIFO is flushed.
3. Before issuing FLUSH, software has to disable the DMA interface by programming the following register bits:
   a) Q(#i)_CTRL[Q_DATAQ_DMA_ENABLE]
   b) GLBL_Q_CTRL[Q(#i)_DATAQ_DMA_ENABLE]
   c) Q(#i)_CTRL[Q_CMDQ_DMA_ENABLE]
   d) GLBL_Q_CTRL[Q(#i)_CMDQ_DMA_ENABLE]
4. All error status flags associated with all the FIFOs are cleared.
5. All status flags associated with all the FIFOs go to their default state.
6. All active and pending triggers are canceled and all trigger related flags are cleared.
   a) Qn_IRQ_STATUS[TRIG_NO_SEQ_ERR] = 0
   b) Qn_IRQ_STATUS[TRIG_OVRN_ERR] = 0
   c) Qn_IRQ_STATUS[TRIG_PENDING] = 0
7. If an ADC conversion is ongoing when a flush is received then the conversion is aborted and the pending sequence of the active queue is started.
8. While the above operations are ongoing the queue is in FLUSH_IN_PROGRESS state and after completion of all the above operations the queue is brought to IDLE state.

39.3.11 Queue debug mode

Upon a debug mode entry request, the ADCQ behaviour varies according to the setting of the DEBUG_EN bit of GLBL_Q_SETUP register. If DEBUG_EN is programmed to 0 then the debug mode entry request is ignored. If DEBUG_EN is programmed to 1 the ADCQ freezes its operation on debug mode entry request and enters debug mode.

Hereunder is described the behaviour of the queue during debug mode:

1. Does not accept any new command in the CMDQ (system writes to the Q_CMDQ_PUSH register are discarded).
2. Does not transfer any new command from the CMDQ to the ADC.
3. No new ADC conversion data is written to data queues (both DATAQ and AUXDQ).
4. An ongoing ADC conversion is allowed to finish but the converted data is not sent to the data queues. The ADC IF block holds the converted data till the debug mode is exited.
5. No new hardware or software trigger events are captured.
6. An ongoing DMA transfer is allowed to complete and after completion of the active DMA requests no new DMA requests are asserted.
7. All registers can be accessed normally during the debug mode. So the system can alter the module configuration during the debug mode. For example if the system issues a Q_ABORT command in the debug mode then it is executed and status flags are updated accordingly.
8. If an ADC command is in the ΔT phase then the ΔT is also frozen and will resume after exiting the debug state.
9. If an ADC command transfer is in process from the CMDQ to the ADC IF block then the command transfer is completed and the CMDQ FIFO status is updated.
10. If an ADC data transfer is in process from the ADC IF to the data queues then the data transfer is completed and the DATAQ/AUXDQ FIFO status is updated.

In the debug mode, using the Q_DBG_RD_POINTERS register, the system can read the contents of CMDQ, DATAQ and AUXDQ without destroying the FIFO pointers. On exiting debug mode the system resumes with the original pointers.

Follow the procedure below to read the data of various FIFOs in the debug mode:

1. Write the CMDQ FIFO address to CMDQ_DBG_RD_PTR and read the FIFO data on Q_CMDQ_PUSH register. If the data at that location is a valid entry then CMDQ_DBG_DATA_VALID bit is set.
2. Write the DATAQ FIFO address to DATAQ_DBG_RD_PTR and read the FIFO data on Q_DATAQ_POP register. If the data at that location is a valid entry then DATAQ_DBG_DATA_VALID bit is set.
3. Write the AUXDQ FIFO address to AUXDQ_DBG_RD_PTR and read the FIFO data on Q_AUXDQ_POP register. If the data at that location is a valid entry then AUXDQ_DBG_DATA_VALID bit is set.

39.3.12 Queue stop mode

The ADCQ acknowledges a stop mode entry request after taking the design to a stable state from which it can recover when returning to the normal mode. On acknowledgment the system can stop the clock input.

Following events happen on a stop mode entry request:

1. An ongoing ADC conversion is completed but the result is not written to the data queues. The ADC commands whose execution has not started do not execute until the stop mode exits.
2. The software should disable the DMA interface before requesting the STOP mode entry. To disable the DMA interface the following register bits must be programmed:
   a) Q(#i)_CTRL[Q_DATAQ_DMA_ENABLE]
   b) GLBL_Q_CTRL[Q(#i)_DATAQ_DMA_ENABLE]
   c) Q(#i)_CTRL[Q_CMDQ_DMA_ENABLE]
   d) GLBL_Q_CTRL[Q(#i)_CMDQ_DMA_ENABLE]
3. If an ADC command is in the ΔT phase then the ΔT is also frozen and will resume after exiting the stop state.
4. If an ADC command transfer is in process from the CMDQ to the ADC IF block then the command transfer is completed and the CMDQ FIFO status is updated.
5. If an ADC data transfer is in process from the ADC IF to the data queues then the data transfer is completed and the DATAQ/AUXDQ FIFO status is updated.
6. None of status flags are cleared.
7. Stop acknowledge is issued.

After exiting the stop mode, the module resumes from where it was stopped.

39.3.13 ADC conversion timeout

In order to avoid the hanging of the ADCQ state machine a conversion timeout counter has been implemented. Every time a conversion is launched this counter starts a countdown. If a conversion result does not appear before the countdown expires then a conversion timeout error flag is set and the system is notified about the problem. The DATAQ and AUXDQ entries for this channel are marked with a timeout error code.

39.3.14 Timestamp

The usage of this feature is completely SW defined. The SW can enable the timestamp capture per command in the command queue. The timestamp is captured for the ADC data only when it is enabled in the corresponding command in the command queue.

39.3.14.1 Timestamp capture goals

One of the primary goals of timestamping is to optimize the size of the data queues without losing important timing information. Not all the data in a sequence needs a timestamp. The following are important events when data in a sequence needs to be timestamped:

1. On a trigger event
2. Start of sampling or end of conversion of the first ADC Data
3. Start of sampling or end of conversion of the last ADC Data
4. Any conversion of the normal queue which got suspended due to an injected sequence

39.3.14.2 Timestamp and suspended command

An injected command sequence can suspend an ongoing normal sequence. The suspended normal sequence resumes after the completion of the injected sequence. An injected sequence can never be suspended. It is important to inform the SW at what point a

normal sequence encountered a suspension. Attaching a timestamp to the point where suspension occurred will assist the SW to do a correction.

Automatic timestamping of suspended data is avoided because sending the automatic timestamp data in the data queue will disrupt the SW data structure. Instead a suspended data in the data queue is appropriately marked and to calculate the duration of suspension the SW can enable the timestamp for the first and last data of the injected sequence.

If multiple commands of a normal sequence are suspended then every command which encountered suspension is marked appropriately.

39.3.14.3 Timestamp capture

For each data queue, the DATAQ and the AUXDQ, in a queue, the SW can enable the capture of the timestamp independently. Only when enabled, timestamps are captured in the corresponding data queues.

For each command in a command queue the SW can enable the timestamp capture. The timestamp is captured in the data queues only for the commands for which TS_CAPTURE_EN bit is set.

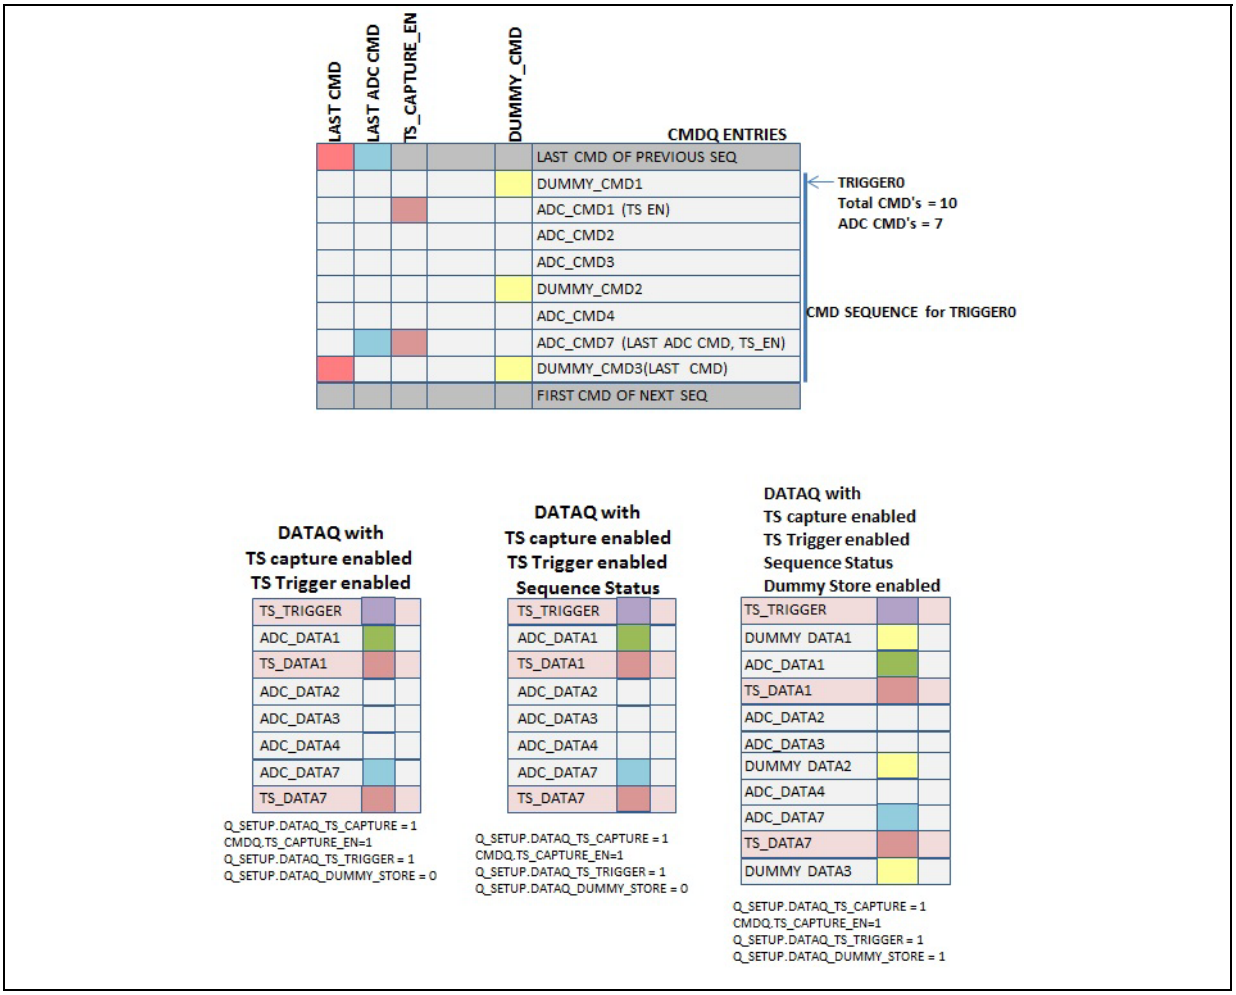
If the dummy command storage in data queues is enabled and the corresponding TS_CAPTURE_EN bit is set for the dummy command then the timestamp for the dummy command is also stored in the data queues.

39.3.14.4 Trigger timestamp

For each data queue, the DATAQ and the AUXDQ, in a queue, the SW can enable the capture of the trigger timestamp independently. Only when enabled, trigger timestamps are captured in the corresponding data queues and they are the first entries in a sequence.

Each pending trigger holds it is timestamp till its sequence starts executing.

For trigger overruns, timestamp values are not captured.



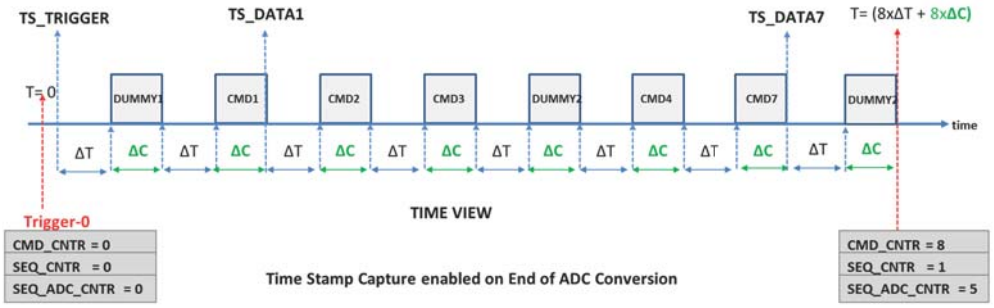
39.3.14.5 Data queue for timestamp entries

Figure 522. DATAQ/AUXDQ bit fields for timestamp data

	0:15	16:23	24	25	26	27	28	29:31		
	DATA[16:31]	ADC_CH_NUM[24:31]	TS_TRIGGER	TS_DATA	DUMMY DATA	LAST_ADC_DATA	FIRST_ADC_DATA	ERROR_CODE		
ADC data timestamp	TS[8:23]	TS[24:31]	0	1	0	0	0	0	0	0
Trigger Timestamp	TS[8:23]	TS[24:31]	1	0	0	0	0	0	0	0

Figure 523 illustrates the various timestamp capture scenarios for the DATAQ. The same scenarios are applicable for AUXDQ when the timestamp capture is enabled for AUXDQ.

Figure 523. Timestamp views of DATAQ/AUXDQ



39.3.14.6 Data timestamp sampling

The timestamps for ADC data are always sampled when an end of conversion is received.

Figure 524 illustrates both cases. The same timestamp sampling rule also applies to dummy commands.

Figure 524. Timestamp sampling

39.4 Memory map and register description

This section details all registers in the module.

Table 635 captures all the registers of ADCQ module. Any access to reserved registers will result in bus error.

Figure 525. Global Setup register (GLBL_Q_SETUP)

Table 636. GLBL_Q_SETUP field descriptions

Field	Description
30 DEBUG_EN	Refer to *Section 39.3.11: Queue debug mode* 1 The ADCQ freezes its operation on debug mode entry request and enters the debug mode. It is a non-destructive mode wherein the FIFO pointers are preserved while allowing inspection of their contents. But no new commands can be written to the CMDQ and no new ADC conversions can be initiated. 0 The ADCQ ignores the debug mode entry request and behaves normally. It is a destructive mode wherein the FIFO pointers are moved when the debugger reads the FIFO. New commands can be written to command the FIFO and ADC conversions can be initiated and the results read.
31 INJ_ABORT_EN	The injection queue can always suspend the active sequence of a normal queue. This bit controls the suspension mode. 1 The current conversion of the normal queue is aborted and the injected sequence starts. After the completion of the injection sequence the normal queue resumes with the aborted conversion. 0 The current conversion of the normal queue is completed before handing over control to the injected queue. After the completion of the injection sequence the normal queue resumes with the next conversion command in its queue.

39.4.2 Global Control Register (GLBL_Q_CTRL)

This register allows simultaneous control of all queues in an ADCQ module. For example to flush all queues simultaneously write a 1 to all Qn_FLUSH bits.

27 STATUS_IRQ_EN_Q0	When it is set it enables the assertion of status interrupt when the corresponding bit is set in the GLBL_IRQ_STATUS register.
28 ERR_IRQ_EN_Q3	When it is set it enables the assertion of error interrupt when the corresponding bit is set in the GLBL_IRQ_STATUS register. ***Exists:*** NUM_OF_QUEUES > 3
29 ERR_IRQ_EN_Q2	When it is set it enables the assertion of error interrupt when the corresponding bit is set in the GLBL_IRQ_STATUS register. ***Exists:*** NUM_OF_QUEUES > 2
30 ERR_IRQ_EN_Q1	When it is set it enables the assertion of error interrupt when the corresponding bit is set in the GLBL_IRQ_STATUS register. ***Exists:*** NUM_OF_QUEUES > 1
31 ERR_IRQ_EN_Q0	When it is set it enables the assertion of error interrupt when the corresponding bit is set in the GLBL_IRQ_STATUS register.

39.4.5 Global IRQ Status register (GLBL_IRQ_STATUS)

This read only register holds the status of interrupt requests raised by each queue.

When the system receives an interrupt then the SW first reads this register to identify the queue raising the interrupt and then reads the status register of the corresponding queue.

This bit is cleared by the HW when the corresponding status bits are cleared in the queue2. 1 Queue2 status interrupt is asserted. 0 Queue2 status interrupt is not asserted. ***Exists:*** NUM_OF_QUEUES > 2
26 STATUS_IRQ_Q1	If the corresponding bit in GLBL_IRQ_CTRL is set then the status interrupt of the ADCQ is asserted. This bit is cleared by HW when the corresponding status bits are cleared in the queue1. 1 Queue1 status interrupt is asserted. 0 Queue1 status interrupt is not asserted. ***Exists:*** NUM_OF_QUEUES > 1

Table 640. GLBL_IRQ_STATUS field descriptions (continued)

Field	Description
27 STATUS_IRQ_Q0	If the corresponding bit in GLBL_IRQ_CTRL is set then the status interrupt of ADCQ is asserted. This bit is cleared by the HW when the corresponding status bits are cleared in the queue0. 1 Queue0 status interrupt is asserted. 0 Queue0 status interrupt is not asserted.
28 ERR_IRQ_Q3	If the corresponding bit in GLBL_IRQ_CTRL is set then the error interrupt of ADCQ is asserted. This bit is cleared by the HW when the corresponding status bits are cleared in the queue3. 1 Queue3 error interrupt is asserted. 0 Queue3 error interrupt is not asserted. ***Exists:*** NUM_OF_QUEUES > 3
29 ERR_IRQ_Q2	If the corresponding bit in GLBL_IRQ_CTRL is set then the error interrupt of the ADCQ is asserted. This bit is cleared by the HW when the corresponding status bits are cleared in the queue2. 1 Queue2 error interrupt is asserted. 0 Queue2 error interrupt is not asserted. ***Exists:*** NUM_OF_QUEUES > 2
30 ERR_IRQ_Q1	If the corresponding bit in GLBL_IRQ_CTRL is set then the error interrupt of the ADCQ is asserted. This bit is cleared by the HW when the corresponding status bits are cleared in the queue1. 1 Queue1 error interrupt is asserted. 0 Queue1 error interrupt is not asserted. ***Exists:*** NUM_OF_QUEUES > 1
31 ERR_IRQ_Q0	If the corresponding bit in GLBL_IRQ_CTRL is set then the error interrupt of the ADCQ is asserted. This bit is cleared by the HW when the corresponding status bits are cleared in the queue0. 1 Queue0 error interrupt is asserted. 0 Queue0 error interrupt is not asserted.

39.4.6 Global ADC Interface Status register (GLBL_ADC_IF_STATUS)

This register captures the current state of ADC I/F. It holds the queue number and the ADC channel number that is currently being processed. If there is a suspension then this register also holds the queue number of the suspended queue.

offset: 0x014 Access: User Read-only

Figure 530. Global ADC Interface Status register (GLBL_ADC_IF_STATUS)

Table 641. GLBL_ADC_IF_STATUS field descriptions

Field	Description
8:11 SUSPENDED_Q_NUM	SUSPENDED_Q_NUM[4:1]: These one-hot encoded bits indicate the queue that is being held in suspension by the ADC interface. SUSPENDED_Q_NUM[1] is always 0. The injected queue can never be suspended. SUSPENDED_Q_NUM[2]= 1, means Q2 is under suspension at ADC interface. Valid when NUM_OF_QUEUES >1. SUSPENDED_Q_NUM[3]= 1, means Q3 is under suspension at ADC interface. Valid when NUM_OF_QUEUES >2. SUSPENDED_Q_NUM[4]= 1, means Q4 is under suspension at ADC interface. Valid when NUM_OF_QUEUES >3
16:23 ACTIVE_ADC_CH_NUM	This field holds the ADC channel number which is being currently served by the ADC interface. When [ACTIVE_Q_NUM] is 0 then ACTIVE_ADC_CH_NUM has no meaning.

Table 641. GLBL_ADC_IF_STATUS field descriptions (continued)

Field	Description
24:27 ACTIVE_Q_NUM	ACTIVE_Q_NUM[4:1]: These one-hot encoded bits indicate the queue that is currently being serviced by the ADC interface. ACTIVE_Q_NUM[1]= 1, means Q1 (injected queue) is currently being serviced by ADC interface. ACTIVE_Q_NUM[2]= 1, means Q2 is currently being serviced by ADC interface. Valid when NUM_OF_QUEUES >1. ACTIVE_Q_NUM[3]= 1, means Q3 is currently being serviced by ADC interface. Valid when NUM_OF_QUEUES >2. ACTIVE_Q_NUM[4]= 1, means Q4 is currently being serviced by ADC interface. Valid when NUM_OF_QUEUES >3.
31 ADC_IF_BUSY	This bit is set when an ADC conversion is ongoing and the interface is busy. When the ADC interface is idle this bit is 0.

39.4.7 Global ADC Conversion Timeout register (GLBL_ADC_CNV_TIMEOUT)

This register holds the reload value of ADC conversion timeout counter and the current value of the timeout counter.

offset: 0x018 Access: User Read/Write

Table 642. GLBL_ADC_CNV_TIMEOUT field descriptions

Field	Description
0:15 ADC_CNV_TO_VAL	This field reflects the current value of the ADC conversion timeout counter. If the ADC interface is idle then the value of this register field is 16'h0000.
16:31 ADC_CNV_TO_RELOAD	This field is used to program the number of ADC clocks the queue module will wait for after issuing a conversion command. If the ADC does not issue an end of conversion before this time then an error flag is set and system is notified. This field should always be programmed to a non zero value before starting any ADC conversion.

39.4.8 Global ADC Configuration registers (GLBL_ADC_CFG*n*)

These set of registers carry the configuration parameters of ADC. Each command in the measurement sequence can choose one of these registers based on the value of ADC_CFG_SEL field of the command descriptor.

Figure 532. Global ADC Configuration registers (GLBL_ADC_CFG*n*)

Table 643. GLBL_ADC_CFG*n* field descriptions

Field	Description
0 User	Reserved for future expansion
20:23 PRECHG	Pre-charging phase duration This bit field defines the pre-charging phase duration to be applied when this phase is enabled by ADC_PRECHG_EN bit of the command descriptor. This duration is calculated as (PRECHG X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for pre-charging phase, for most of the SARADC it is greater than 2.
24:31 INPSAMP	Sampling phase duration This bit-field defines the sampling phase duration to be applied. This duration is calculated as (INPSAMP X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for sampling phase.

39.4.9 Global Output register (GLBL_OUTPUT)

This register is used to control the global outputs of an ADCQ. These outputs can be used to trigger events across multiple ADCQs.

Note: This register exists if GLOBAL_OUTPUT = 1 (for this parameter value per ADCQ instance, see details in the Device Configuration chapter).

offset: 0x03C Access: User Read/Write

Figure 533. Global Output register (GLBL_OUTPUT)

Table 644. GLBL_OUTPUT field descriptions

Field	Description
27 GLBL_OUT_Q _RST_CNTRS	Whatever is written to this bit is reflected on the corresponding output pin. This can be used to provide a reset queue counters command to all participating queues across the ADCQs. Each queue can participate in this global operation by unmasking its global reset queue counter input. A value of 1 on this bit will be recognized as a reset queue counter command. So the SW has to bring it back to 0 to release "global reset queue counter".
28 GLBL_OUT_Q _FLUSH	Whatever is written to this bit is reflected on the corresponding output pin. This can be used to provide a queue flush to all participating queues across the ADCQs. Each queue can participate in this global operation by unmasking its global queue flush input. Only a 0-to-1 transition on this bit will be recognized as a queue flush. The bit clears to 0 after registering the flush operation.
29 GLBL_OUT_Q _ABORT	Whatever is written to this bit is reflected on the corresponding output pin. This can be used to provide a queue abort to all participating queues across the ADCQs. Each queue can participate in this global operation by unmasking its global queue abort input. Only a 0-to-1 transition on this bit will be recognized as a queue abort. The bit clears to 0 after registering the abort operation.
30 GLBL_OUT_Q _TRIG_EN	Whatever is written to this bit is reflected on the corresponding output pin. This can be used to provide a synchronized trigger enable to all participating queues across the ADCQs. Each queue can participate in this global operation by unmasking its global trigger enable input.
31 GLBL_OUT_Q _SW_TRIG	Whatever is written to this bit is reflected on the corresponding output pin. This can be used to provide a SW trigger to all participating queues across the ADCQs. Each queue can participate in this global operation by unmasking its global SW trigger input. Only a 0-to-1 transition on this bit will be recognized as a SW trigger. The bit clears to 0 after registering a software trigger.

39.4.10 Global module Configuration register (GLBL_CONFIG)

This global read only register holds the design configuration. The SW driver can be aligned based on the values present in this register. The reset value of this register will be based on the design configuration.

Figure 535. Global Queue Config register (GLBL_Q*n*_CONFIG)

Table 646. GLBL_Q*n*_CONFIG field descriptions

Field	Description
6 TRIGO_Q_PRESENT	1 The TRIGO feature is present in the queue and all the registers and bit fields associated with the trigger output feature are present. 0 The TRIGO feature is not present in the queue and all the registers and bit fields associated with the trigger output feature are not present.
7 AUXDQ_Q_PRESENT	1 The AUXDQ is present in the queue and all the registers and bit fields associated with the AUXDQ are present. 0 The AUXDQ is not present in the queue and all the registers and bit fields associated with the AUXDQ are not present.
8:15 DEPTH_Q_AUXDQ	This field is defined only when the AUXDQ is present for Qn. If not present then a read of this field will always return zeros. Number of 32-bit words supported by Qn AUXDQ. 0x0 AUXDQ Not Present 0x1 Depth of AUXDQ is one 32-bit WORD 0x2 Depth of AUXDQ is two 32-bit WORDS ... The width of the AUXDQ watermark field is governed by this parameter.

Table 646. GLBL_Q*n*_CONFIG field descriptions (continued)

Field	Description
16:23 DEPTH_Q_DATAQ	Number of 32-bit words supported by Qn DATAQ. 0x0 Reserved 0x1 Depth of DATAQ is one 32-bit WORD 0x2 Depth of DATAQ is two 32-bit WORDS ... The width of the DATAQ watermark field is governed by this parameter.
24:31 DEPTH_Q_CMDQ	Number of 32-bit words supported by Qn CMDQ. 0x0 Reserved 0x1 Depth of CMDQ is one 32-bit WORD 0x2 Depth of CMDQ is two 32-bit WORDS ... The width of the CMDQ watermark field is governed by this parameter.

39.4.12 Queue Setup register (Q*n*_SETUP)

This register is used to setup:

- The watermarks of command and data queues
- Whether additional information is pushed into a data queue
- Whether the queue participates in global events
- Whether to use the IRQ mode or the DMA mode for the CMDQ and the DATAQ

offset: 0x100 + *n**0x100 (*n* = 0 to 1) Access: User Read/Write

Figure 536. Queue Setup register (Q*n*_SETUP)

Table 647. Q*n*_SETUP field descriptions

Field	Description
3 UNMSK_GLBL _CNTR_RST	1 The queue participates in the global queue counters reset operation where queue counters of multiple queues across the ADCQs are synchronously reset. 0 The global queue counters reset input of the queue is masked and the queue does not participate in the global queue counters reset operation. By default the global queue counters reset input of the queue is masked.
4 UNMSK_GLBL _ABORT	1 The queue participates in the global queue abort operation where multiple queues across the ADCQs are synchronously aborted. 0 The global abort input of the queue is masked and the queue does not participate in the global queue abort operation. By default the global abort input of the queue is masked.
5 UNMSK_GLBL _FLUSH	1 The queue participates in the global queue flush operation where multiple queues across the ADCQs are synchronously flushed. 0 The global flush input of the queue is masked and the queue does not participate in the global queue flush operation. By default the global flush input of the queue is masked.
6 UNMSK_GLBL _TRIG_EN	1 The queue participates in the global trigger enable operation where the queue trigger of multiple queues across the ADCQs are synchronously enabled. 0 The global trigger enable input of the queue is masked and the queue does not participate in the global trigger enable operation. By default the global trigger enable input of the queue is masked.
7 UNMSK_GLBL _SW_TRIG	1 The queue participates in the global software trigger operation where multiple queues across the ADCQs are synchronously triggered by a single SW trigger command. 0 The global SW trigger is masked for the queue and the queue does not participate in the global SW triggering operation. By default the global SW trigger is masked.
8:15 CMDQ_WM	CMDQ watermark level. In the DMA mode a DMA request is asserted when the number of free entries in the CMDQ equals the watermark level. The DMA controller should be programmed to transfer an equal amount of data per DMA request. As an example, if the watermark level is set at 4 then a DMA request is asserted when there are 4 free entries in the CMDQ and the DMA controller should transfer 4 words for this DMA request. The watermark level programmed is a function of the number of commands and the DMA latency. The width of this field is governed by depth of the CMDQ. The unused bits are reserved and always read as 0.
20 DQ_DUMMY _STORE_EN	1 Enable the storage of the dummy data, corresponding to a dummy command, in the DATAQ. 0 Disable storage of the dummy data, corresponding to a dummy command, in the DATAQ. By default the storage of the dummy data, corresponding to a dummy command, in the DATAQ is disabled.
22 DQ_TRIGGER _TS_EN	1 Enable the timestamp capture for the trigger data in the DATAQ. When enabled every measurement data sequence in the DATAQ is prepended by the trigger timestamp value. 0 Disable the timestamp capture for the trigger data in the DATAQ. By default the timestamp capture for the trigger data in the DATAQ is disabled.

Table 647. Q*n*_SETUP field descriptions (continued)

Field	Description
23 DQ_CAPTURE_TS_EN	1 Enable the timestamp capture for the ADC data in the DATAQ. 0 Disable the timestamp capture for the ADC data in the DATAQ. When disabled then TS_CAPTURE_EN bit of the CMDQ has no effect. By default the timestamp capture for the ADC data in the DATAQ is disabled. If a dummy data is not stored in the FIFO then the corresponding timestamp is also not stored irrespective of this bit.
24:31 DATAQ_WM	DATAQ watermark level In the DMA mode a DMA request is asserted when the number of valid entries in the DATAQ equals the watermark level. The DMA controller should be programmed to transfer an equal amount of data per DMA request. If the watermark level is set at 4 then a DMA request is asserted when there are 4 free entries in the DATAQ and the DMA controller should transfer 4 words for this DMA request. The water mark level programmed is a function of the number of expected data and the DMA latency. the width of this field is governed by the depth of the DATAQ. the unused bits are reserved and always read as 0.

39.4.13 Queue AUXDQ Setup register (Q*n*_AUXDQ_SETUP)

This register is used to setup:

- The watermarks of the AUXDQ
- Whether additional information is pushed into the AUXDQ

Exists: AUXDQ_Qn_PRESENT = 0x1 (for n=0 to 1)

offset: 0x104 + *n**0x100 (n = 0 to 1) Access: User Read/Write

Figure 538. Queue Trigger Output Setup register (Q*n*_TRGO_SETUP)

Table 649. Q*n*_TRGO_SETUP field descriptions

Field	Description
24:31 TRGO_UNMASK	Using these bits the SW can allocate one or more of the 8 trigger outputs to a queue. 0 The corresponding trigger output of the queue is masked and held at zero. 1 The corresponding trigger output of the queue is unmasked and the TRIG_OUT bits of the CMDQ drive the trigger outputs of the queue. By default all trigger outputs are masked which means that none of the trigger outputs are allocated to the queue. ***Exists:*** TRIGO_Qn_PRESENT = 0x1

39.4.15 Queue Rise edge Enable register (Qn_RISEN)

This register is used to enable the rising edge of a hardware trigger input(s) to trigger the measurement sequence.

offset: 0x10C + *n**0x100 (*n* = 0 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 539. Queue Rise edge Enable register (Qn_RISEN)

Table 650. Q*n*_RISEN field descriptions

Field	Description
0:31 RISE_EDG_EN	A queue can support a maximum of 32 hardware trigger inputs. The width of this register is governed by the number of hardware trigger inputs enabled during the design configuration. The unused bits then become reserved and are always read as 0. RISE_EDG_EN [0] = 1. The rising edge of the hardware trigger input 0 is enabled to trigger the measurement sequence of the queue. RISE_EDG_EN [0] = 0. The rising edge of hardware trigger input 0 is disabled from triggering the measurement sequence of the queue. By default the rising edge of all hardware inputs are disabled from triggering the measurement sequence of the queue.

39.4.16 Queue Fall edge Enable register (Qn_FALLEN)

This register is used to enable the falling edge of hardware trigger input(s) to trigger the measurement sequence.

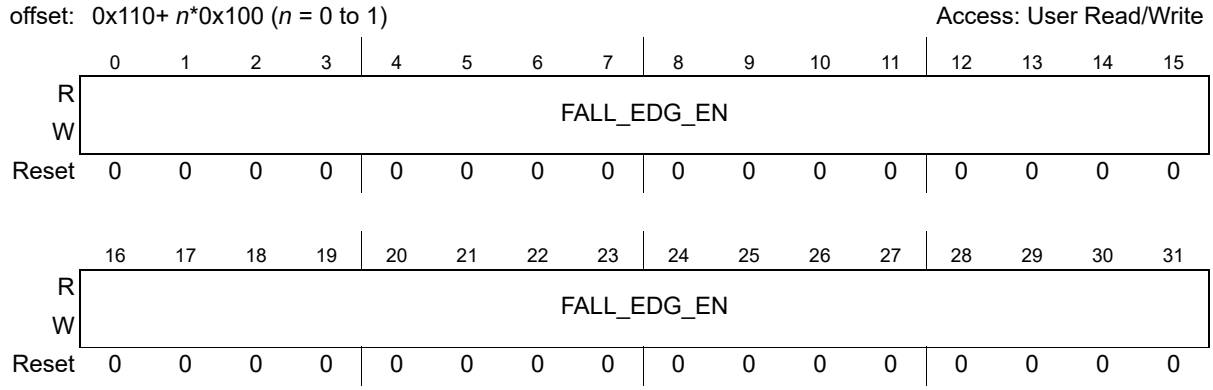

Figure 540. Queue Fall edge Enable register (Qn_FALLEN)

Table 651. Q*n*_FALLEN field descriptions

Field	Description
0:31 FALL_EDG_EN	A queue can support a maximum of 32 hardware trigger inputs. The width of this register is governed by the number of hardware trigger inputs enabled during the design configuration. The unused bits then become reserved and are always read as 0. FALL_EDG_EN [0] = 1. The falling edge of the hardware trigger input 0 is enabled to trigger the measurement sequence of the queue. FALL_EDG_EN [0] = 0. Falling edge of hardware trigger input 0 is disabled from triggering the measurement sequence of the queue. By default the falling edge of all hardware inputs are disabled from triggering the measurement sequence of the queue

39.4.17 Queue Measurement Timer register (Q*n*_MEAS_TIMER)

This register holds the measurement interval timer (ΔT) reload value and displays the current value of the timer if the queue is active or it shows the reload value.

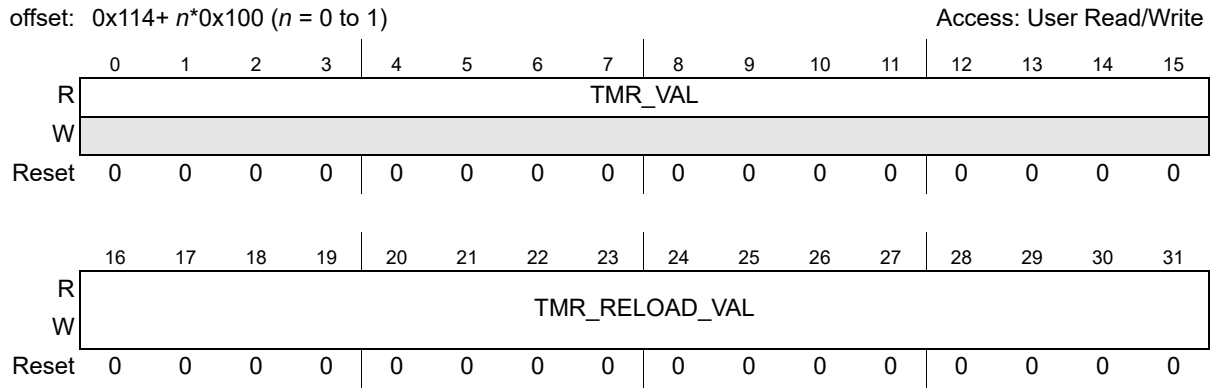

Figure 541. Queue Measurement Timer register (Q*n*_MEAS_TIMER)

Table 652. Q*n*_MEAS_TIMER field descriptions

Field	Description
0:15 TMR_VAL	Current value of the running measurement interval timer (ΔT) After the reset the timer is loaded with the reload value. This timer starts the countdown when a new command from the CMDQ is read.The command is passed for further processing after the expiry of this timer. After a queue abort operation or a queue flush operation this timer is reset to its reload value.
16:31 TMR_RELOAD_VAL	Reload value of Measurement interval timer. After the expiry of current measurement interval time this value is reloaded into the timer. This timer works at ADC clock. For an ADC clock frequency of 16 MHz the maximum time interval would be 4ms.

39.4.18 Queue Control register (Q*n*_CTRL)

This register controls the operation of a queue.

offset: 0x118+ *n**0x100 (*n* = 0 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 542. Queue Control register (Q*n*_CTRL)

Table 653. Q*n*_CTRL field descriptions

Field	Description
25 Q_DATAQ_DMA_ENABLE	1 DATAQ DMA enabled. 0 DATAQ DMA disabled.
26 Q_CMDQ_DMA_ENABLE	1 CMDQ DMA enabled. 0 CMDQ DMA disabled.
27 Q_RESET_CNTRS	Setting this bit will reset all the queue counters.

Table 653. Q*n*_CTRL field descriptions (continued)

Field	Description
28 Q_ABORT	Setting this bit will initiate a queue abort operation. This bit clears to 0 after the abort operation is registered. Refer to *Section 39.3.9: Queue abort* for a detailed description of the abort operation.
29 Q_FLUSH	Setting this bit will initiate a queue flush operation. This bit clears to 0 after flush operation is registered. Refer to *Section 39.3.10: Queue flush* for a detailed description of the flush operation.
30 Q_SW_TRIGGER	If the trigger is enabled then writing a 1 to this bit will trigger the queue. The bit is auto cleared when a software trigger is registered.
31 Q_TRIG_EN	1 Enable the queue to be triggered either by the HW trigger inputs or by the SW trigger. 0 Disable the queue trigger.

39.4.19 Queue Status register (Q*n*_STATE)

This read only register captures the current state of the queue.

offset: 0x11C+ *n**0x100 (*n* = 0 to 1) Access: User Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 543. Queue Status register (Q*n*_STATE)

Table 654. Q*n*_STATE field descriptions

Field	Description
28:31 Q_STATE	This field shows the current state of the queue. See *Table 655*.

Table 655. Q_STATE descriptions

Value	Queue state	Description
0x1	IDLE	Queue IDLE. The queue enters this state when: – There is no command in the CMDQ – This queue has not been serviced by the ADC interface – The queue is not triggered
0x2	NO_COMMAND	The queue is triggered but there is no command in the CMDQ.
0x3	WAIT TRIGGER	The command sequence is available and waiting for the trigger.
0x4	EXECUTE	The command execution is in progress.
0x5	SUSPENDED	A normal queue sequence is in suspended state due to the injected sequence.
0x6	TRIGGERED	A normal queue is triggered but waiting for the injected queue to relinquish control.
0x7	ABORT_IN_PROGRESS	A queue abort operation is in progress. After the completion of the abort the condition returns to the idle mode.
0x8	FLUSH_IN_PROGRESS	A queue flush operation is in progress. After the flush completion the queue state returns to the IDLE state if no trigger is pending. Otherwise it moves to the NO_COMMAND state.
0x9–0xF	RESERVED	Reserved for future.

39.4.20 Queue IRQ control register (Qn_IRQ_CTRL)

This register enables the generation of status and error interrupts if the corresponding bits in the Q_IRQ_STATUS register are set.

offset: 0x120+ *n**0x100 (*n* = 0 to 1) Access: User Read/Write

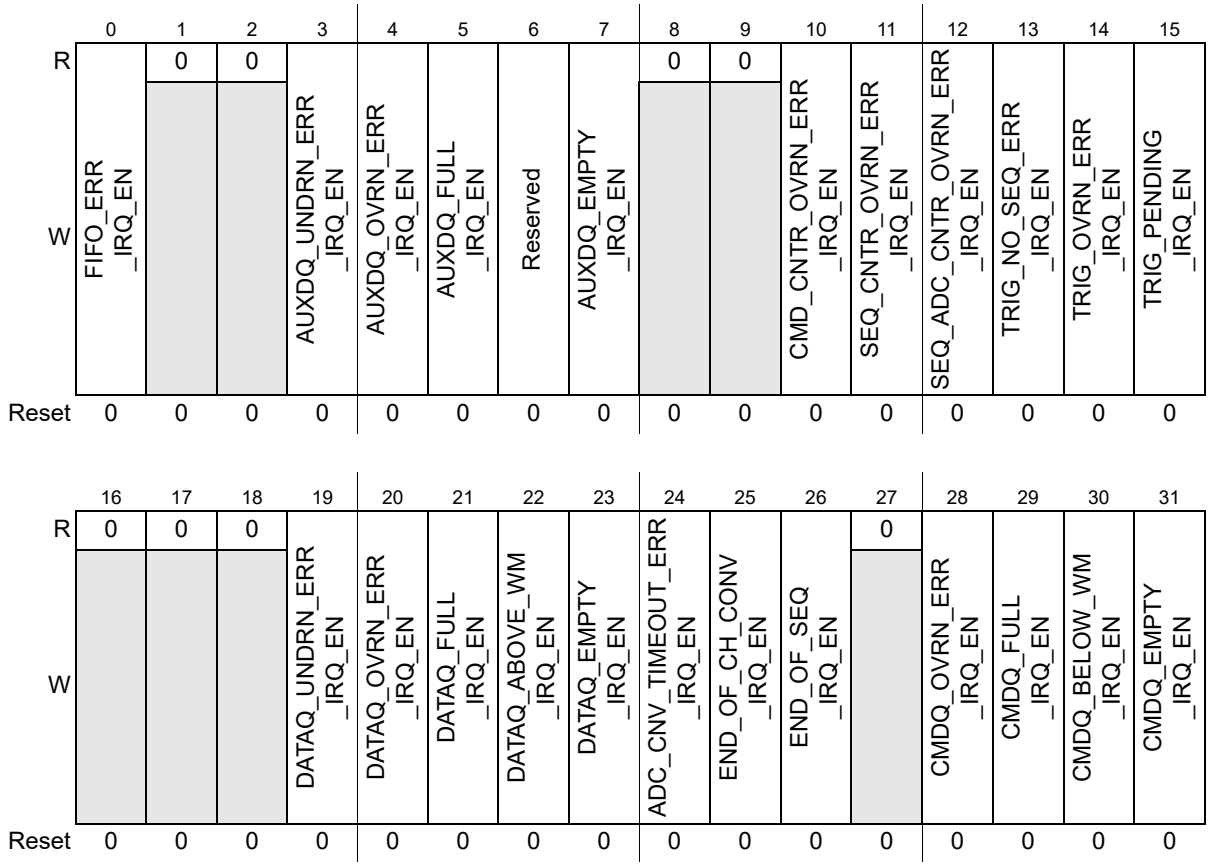

Figure 544. Queue IRQ control register (Q*n*_IRQ_CTRL)

31 CMDQ_EMPTY _IRQ_EN	Enables the assertion of the status interrupt when the corresponding bit is set in the Q_IRQ_STATUS register. ***Exists:*** Always

39.4.21 Queue IRQ Status register (Q*n*_IRQ_STATUS)

This register captures the status of a queue. It can either be a non-error status or an error status. Error status flags should be explicitly cleared by the SW by writing a 1 to the corresponding bits. Non-error status flags are cleared by the HW when the associated condition is cleared. If the corresponding enable bit in the Q_IRQ_CTRL register is set then an interrupt is generated. Error flags result in generation of error interrupts and non-error flags result in generation of status interrupts.

Figure 545. Queue IRQ Status register (Q*n*_IRQ_STATUS)

Table 657. Q*n*_IRQ_STATUS field descriptions

Field	Description
0 FIFO_ERR	When set it indicates the malfunctioning of the CMDQ or DATAQ or AUXDQ FIFO logic. Follow the ABORT or FLUSH procedure for recovery.
3 AUXDQ_UNDRN_ERR	This bit is set when the auxiliary read interface tries to read data from the AUXDQ even when the AUXDQ is empty. This may occur due to the SW programming error or auxiliary read interface design error. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared by writing a 1 to it. This bit is also cleared by a queue ABORT operation. ***Exists:*** AUXDQn_PRESENT = 0x1

Table 657. Q*n*_IRQ_STATUS field descriptions (continued)

Field	Description
4 AUXDQ_OVRN_ERR	This bit is set when there is no space in the AUXDQ and a new ADC data word arrives. The new data word does not overwrite any previous data and is lost. This may occur either due to a SW programming error or due to a very high read latency on the auxiliary interface. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation. ***Exists:*** AUXDQn_PRESENT = 0x1
5 AUXDQ_FULL	This bit is set when the AUXDQ is full and it cannot take any more data. This may occur either due to a SW programming error or due to a very high read latency on the auxiliary interface. This bit is cleared automatically when the full condition is removed by freeing some space by a read. In the IRQ mode if the corresponding enable bit is set in Q_IRQ_CTRL register then an interrupt is asserted. This bit is kept asserted even on an AUXDQ _OVRN_ERR. ***Exists:*** AUXDQn_PRESENT = 0x1
7 AUXDQ_EMPTY	This bit is set when the AUXDQ is empty otherwise it is 0 when any unread data is present in the AUXDQ. In IRQ mode if the corresponding enable bit is set in Q_IRQ_CTRL register then an interrupt is asserted. ***Exists:*** AUXDQn_PRESENT = 0x1
10 CMD_CNTR_OVRN_ERR	This bit is set when the command counter wraps around, if the SW does not clear this counter periodically. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.
11 SEQ_CNTR_OVRN_ERR	This bit is set when the sequence counter wraps around if the SW does not clear this counter periodically. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.
12 SEQ_ADC_CNTR_OVRN_ERR	This bit is set when the sequence ADC command counter wraps around.This can either be caused by a SW programming error in defining a very long measurement sequence or a design error. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.

Table 657. Q*n*_IRQ_STATUS field descriptions (continued)

Field	Description
13 TRIG_NO_SEQ_ERR	This bit is set in following two cases 1. When a valid trigger is registered on a queue but no command is available in the CMDQ FIFO. 2. When the CMDQ FIFO becomes empty while executing a sequence and the queue is stalled. It can happen either due to incorrect programming or due to high DMA latency. It can also happen when triggers are enabled along with DMA and a trigger occurs while the DMA engine is about to start sending the CMD to the queue. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit cleared by the software by writing a 1 to it. This bit is also cleared by a queue ABORT operation.
14 TRIG_OVRN_ERR	This bit is set when a trigger is already pending and a new one is detected while the CMDQ is executing a measurement sequence of a previous trigger. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit cleared by the software by writing a 1 to it. This bit is also cleared by a queue ABORT operation.
15 TRIG_PENDING	This bit is set when a new trigger occurs while the CMDQ is already executing a measurement sequence of a previous trigger. A status interrupt is generated if the corresponding enable bit is set in Q_IRQ_CTRL register is set. This bit is cleared by the hardware when the sequence corresponding to this trigger starts executing. This bit is also cleared on a queue ABORT operation.
19 DATAQ_UNDRN_ERR	This bit is set when the system tries to read data from the DATAQ even when the DATAQ is empty. This may occur due to a SW or a DMA programming error. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.
20 DATAQ_OVRN_ERR	This bit is set when there is no space in the DATAQ and a new ADC DATA arrives. The new data does not overwrite any previous data and is lost. This may occur due to a SW programming error or due to very high DMA latency. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.

Table 657. Q*n*_IRQ_STATUS field descriptions (continued)

Field	Description
21 DATAQ_FULL	This bit is set when the DATAQ is full and it can take no more data. This may occur due to a SW programming error or due to a very high DMA latency. This bit is cleared automatically when the full condition is removed by freeing some space by a read. In IRQ mode if the corresponding bit is set in the Q_IRQ_CTRL register then the system is informed about this condition. This bit is kept asserted even on a DATAQ_OVRN_ERR.
22 DATAQ_ABOVE_WM	This bit is set when the number of entries in the DATAQ is superior or equals the DATAQ water mark level. This bit is cleared automatically when the number of active entries in the DATAQ falls below the watermark level. In IRQ mode if the corresponding bit is set in the Q_IRQ_CTRL register then the system is informed about this condition and the SW can read the data from the DATAQ. In DMA mode when this condition is reached a DMA request is asserted.
23 DATAQ_EMPTY	This bit is set when the DATAQ is empty otherwise it is 0 when any unread data is present in the DATAQ. In IRQ mode if the corresponding enable bit is set in Q_IRQ_CTRL register then an interrupt is asserted.
24 ADC_CNV_TIMEOUT _ERR	This bit is set when the end of conversion for the command does not come back by the time defined by GLBL_ADC_CNV_TIMEOUT. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared by the software by writing a 1 to it. This bit is also cleared by a queue ABORT operation.
25 END_OF_CH_CONV	This bit is set on completion of every ADC channel conversion. This bit is cleared by the software writing a 1 to it. In IRQ mode if the corresponding enable bit is set in Q_IRQ_CTRL register then an interrupt is asserted. This bit is also cleared by a queue ABORT operation.
26 END_OF_SEQ	This bit is set when a measurement sequence is completed which is when the last command of the sequence has completed its execution and the queue moves to WAITING_FOR_TRIGGER state. This bit cleared by software writing a 1 to it or is cleared automatically when a new sequence is triggered. The corresponding bit should be set in Q_IRQ_CTRL register to raise an interrupt. This bit is also cleared by a queue ABORT operation.

Table 657. Q*n*_IRQ_STATUS field descriptions (continued)

Field	Description
28 CMDQ_OVRN_ERR	This bit is set when there is no space in the CMDQ and the system tries to push a new ADC command. The new command does not overwrite any previous entry and is lost. This may occur due to a SW programming error. It is an error condition and is reported to the system if the corresponding enable bit is set in Q_IRQ_CTRL register. This bit is cleared on writing a 1 to it. This bit is also cleared by a queue ABORT operation.
29 CMDQ_FULL	This bit is set when the CMDQ is full and it can take no more commands. This may occur due to a SW programming error. This bit is cleared automatically when the full condition is removed by freeing some space by a read. In IRQ mode if the corresponding bit is set in the Q_IRQ_CTRL register then the system is informed about this condition. This bit is kept asserted even on a CMDQ_OVRN_ERR.
30 CMDQ_BELOW_WM	This bit is set when number of free entries in the CMDQ is >= the CMDQ water mark level. This bit is cleared automatically when the number of free entries in CMDQ is below the watermark level. In IRQ mode if the corresponding bit is set in the Q_IRQ_CTRL register then the system is informed about this condition. In DMA mode when this condition is reached a DMA request is asserted.
31 CMDQ_EMPTY	This bit is set when the CMDQ is empty otherwise it is 0 when any valid entry exists in the CMDQ. In IRQ mode if the corresponding enable bit is set in Q_IRQ_CTRL register then an interrupt is asserted.

39.4.22 Queue Command Counter register (Q*n*_CMD_CNTR)

This read only register captures the command statistics. It captures the total number of sequences executed and the total number of commands (ADC + DUMMY) executed after the reset. If not explicitly cleared, then both counters will wrap around. The respective counter overflows are recorded in the queue status register.

Figure 546. Queue Command Counter register (Q*n*_CMD_CNTR)

Table 658. Q*n*_CMD_CNTR field descriptions

Field	Description
0:15 SEQ_CNTR	This read only 16-bit wraparound counter increments for every sequence completing execution. It is important to note that suspended sequences are resumed. So for resumed sequences the counter increments only after its execution. This counter allows the SW to synchronize the measurement counts across the queues in a multiple ADCQ environment. On a wraparound SEQ_CNTR_OVRN_ERR bit is set in the Q_IRQ_STATUS register. If SEQ_CNTR_OVRN_ERR_IRQ_EN bit is set in the Q_IRQ_CTRL register then the system is alerted. The counter is explicitly reset by the SW writing a 1 to RESET_Q_COUNTERS bit of the Q_CTRL register. This counter is also reset when a Q_ABORT operation is executed. If the queue unmasks the global reset queue counters input then a global reset queue counters operation will reset this counter.
16:31 CMD_CNTR	This read only 16-bit wraparound counter increments for every command completing execution. Even the dummy commands will increment this counter on its completion. It is important to note that suspended commands are resumed. So for resumed commands the counter increments only after its execution. This counter allows the SW to synchronize the measurement counts across the queues in a multiple ADCQ environment. On a wraparound CMD_CNTR_OVRN_ERR bit is set in the Q_IRQ_STATUS register. If CMD_CNTR_OVRN_ERR_IRQ_EN bit is set in the Q_IRQ_CTRL register then the system is alerted. The counter is explicitly reset by the SW writing a 1 to RESET_Q_COUNTERS bit of the Q_CTRL register. This counter is also reset when a Q_ABORT operation is executed. If the queue unmasks the global reset queue counters input then a global reset queue counters operation will reset this counter.

39.4.23 Queue Sequence Status register (Q*n*_SEQ_STATUS)

This read only register captures the number of ADC commands executed in a measurement sequence.

offset: 0x12C + *n**0x100 (*n* = 0 to 1) Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 547. Queue Sequence Status register (Q*n*_SEQ_STATUS)

Table 659. Q*n*_SEQ_STATUS field descriptions

Field	Description
24:31 SEQ_ADC_CMD_CNTR	This read only 8-bit wraparound counter increments for every ADC command of the measurement sequence completing execution. It is important to note that the suspended ADC commands are resumed. So for the resumed ADC commands the counter increments only after the completion of its execution. The contents of this field are held until a new sequence is triggered. At the beginning of a new sequence this field is reset. On a wraparound SEQ_ADC_CMD_CNTR_OVRN_ERR bit is set in the Q_IRQ_STATUS register. If SEQ_ADC_CMD_CNTR_OVRN_ERR_IRQ_EN bit is set in the Q_IRQ_CTRL register then the system is alerted. The wraparound of this counter is very unusual and can happen only when a measurement sequence has more than 256 ADC commands. The counter is explicitly reset by the SW writing a 1 to RESET_Q_COUNTERS bit of the Q_CTRL register. This counter is also reset when a Q_ABORT operation is executed. If the queue unmasks the global reset queue counters input then a global reset queue counters operation will also reset this counter.

39.4.24 Queue CMDQ Pointers register (Qn_CMDQ_POINTERS)

This read only register captures the current value of CMDQ FIFO read and write pointers and also the number of valid commands present in the CMDQ. This register is for debug purposes.

offset: 0x130+ *n**0x100 (*n* = 0 to 1) Access: User Read-only

39.4.27 CMDQ PUSH register (Q*n*_CMDQ_PUSH)

This register is used to push the data into the CMDQ. The data can be pushed by either the DMA or the CPU. It should always be a word push (32-bit write). A byte or half-word push will result in a data corruption. In the normal mode of operation this is a write only register.

If the DEBUG_EN bit is set then in debug mode this register is read/write:

1. Only a DMA can write the CMDQ in debug mode.
2. The CPU/SW can only read this register to read the CMDQ FIFO (non-destructive mode) in debug Mode.

Access: WO in normal mode and RW in enabled debug mode

Refer to *Section 39.3.1.3: Command Queue (CMDQ) descriptor* for details.

Field	Description
0 LAST_CMD_OF_SEQ	Denotes the last command in a sequence. The last command can also be a dummy command. The measurement sequence stops after this command and waits for a new trigger to start the next sequence in the CMDQ. For single conversion set the LAST_CMD and the LAST_ADC_CMD bits in the first command of the sequence.
1 LAST_ADC_CMD	Denotes that this command in the sequence is the last ADC command. Since a sequence can end with a dummy command and a dummy command is generally not stored in the data queues so there is no way to mark the last data in the data queues when the sequence ends with a dummy command. This bit allows marking the last ADC data in the DATAQ and the AUXDQ. This bit has no impact on the measurement sequence processing.
2 TS_CAPTURE_EN	Timestamp capture enable bit. When set the timestamp is captured for this command. Usually not all CMDs need a TS capture. The first command, the last command and the suspended commands in a sequence are the main targets for timestamp capture. The user can set this bit for the first, the last or any intermediate command to enable the timestamp capture for that command. This bit enables the capture of the timestamp in both the DATAQ and the AUXDQ. The queue specific control bits enable/disable the capture of the timestamps in the DATAQ and the AUXDQ.

Table 663. Qn_CMDQ_PUSH field descriptions (continued)

Field	Description
3 ALIGN_DATA_LEFT	ADC result data stored in data queues is by default aligned right. If ALIGN_DATA_LEFT bit is set in the command then the ADC data is aligned left in the data queues. This is true only when the result data width is less than 16-bits.
6 BYPASS_TIMER	When set then the command is executed immediately without waiting for the ΔT to elapse. This bit affects all the commands (ADC, dummy and trigger output commands).
7 DUMMY_CMD	When set, it denotes that the command is a dummy command which is not passed to the ADC.
10 ADC_VREF_SEL	To select one of the 2 ADC references for this CMD. Unused for dummy commands.
11 ADC_PRECHG_EN	When set then PRECHG phase is enabled for the channel. Unused for dummy commands.
12:13 ADC_CFG_SEL	To select one of the 4 ADC parameters for this command. These bits should also be defined for dummy commands so that the correct ΔC can be applied to the dummy commands.
14 DATA_TO_AUXDQ	Defined only when AUXDQ is present in the queue. When set the ADC result is routed to the AUX DATAQ.
15 DATA_TO_DATAQ	ADC Data routing bit. It is defined only when the AUXDQ is present in the queue. When the AUXDQ is not present then by default the ADC data is routed to the DATAQ only. When set the ADC result is routed to the DATAQ.
16:23 TRIG_OUT	One hot digital trigger output. One hot encoding allows driving them simultaneously from a single command. The SW has to manage the allocation of trigger outputs between the queues using the TRIG_OUT_UNMASK [7:0] bits of the Q_TRGO_SETUP register. The trigger output pulse width is defined by the SW in multiples of the ΔT value. When BYPASS_TIMER is set then the ΔT is skipped.
24:31 ADC_CH_NUM	Channel number of ADC for the current command. All values from 0 to 255 are valid. Use a dummy command to stop forwarding the command to the ADC in which case this field is unused.

39.4.28 DATAQ POP register (Q*n*_DATAQ_POP)

This read only register is used to pop some data out of the DATAQ. The data can be popped by either the DMA or the CPU. If DEBUG_EN bit is set then in debug mode the read of this register is non-destructive and the original FIFO pointers are restored after exiting the debug mode. If DEBUG_EN bit is not set then in debug mode the read of this register is destructive and the FIFO pointers are moved.

Refer to *Section 39.3.2.7: Data Queue (DATAQ) and Auxiliary Data Queue (AUXDQ) description* for details.

offset: 0x140 + *n**0x100 (*n* = 0 to 1) Access: User Read-only

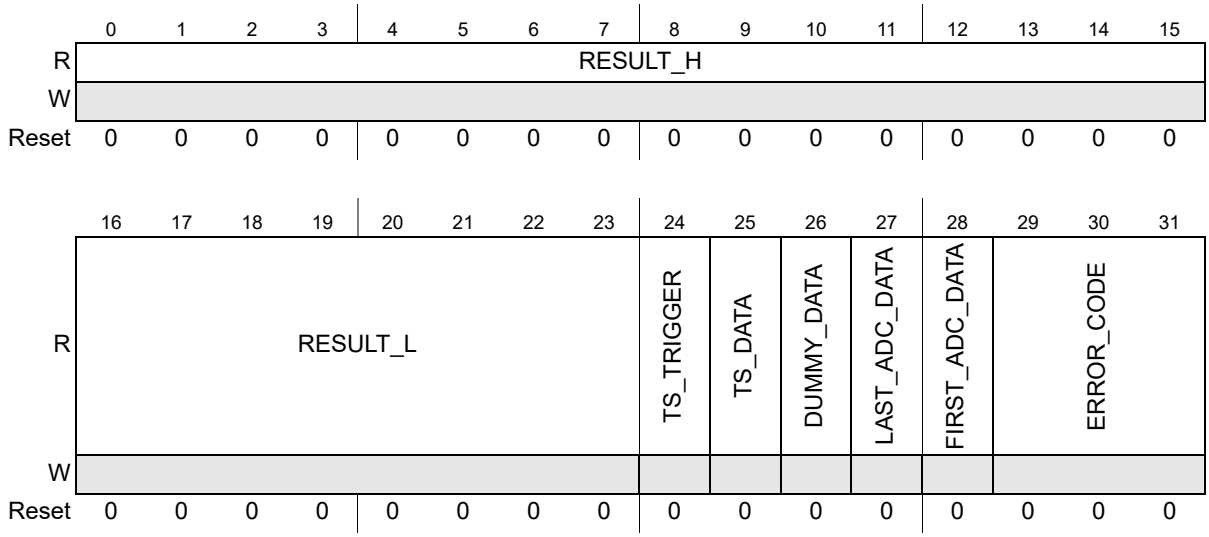

Figure 552. DATAQ POP register (Qn_DATAQ_POP)

Table 664. Qn_DATAQ_POP field description

Field	Description
0:15 RESULT_H	ADC_DATA, DATA_TS_H or TRIGGER_TS_H field For ADC data this field holds ADC conversion data for the channel specified in the ADC_CH_NUM field. If ADC data is less than 16-bits then the data alignment is defined by the corresponding bit in the command entry. For dummy data this field holds a 0xD0D0. For timestamps this field holds upper 16 bits of 24-bit timestamp. For sequence status this field holds the upper 16 bits of 24-bit timestamp for last ADC data.
16:23 RESULT_L	ADC_CH_NUM, DATA_TS_L or TRIGGER_TS_L field 8-bit ADC channel number corresponding to the data in the ADC Data field. For timestamps this field holds lower 8 bits of 24-bit timestamp. For sequence status this field holds the lower 8 bits of 24-bit timestamp for last ADC data.
24 TS_TRIGGER	When this field is set then the bits[0:23] contains the timestamp for the trigger.
25 TS_DATA	When this bit is set then the bits[0:23] contains the timestamp data for the channel.
26 DUMMY_DATA	Marker for denoting that this entry corresponds to a DUMMY CMD. This bit is significant only when DUMMY data dumping is enabled for a queue.
27 LAST_ADC_DATA	Marker for denoting the last ADC data of the sequence.

Table 664. Qn_DATAQ_POP field description (continued)

Field	Description
28 FIRST_ADC_DATA	Marker for denoting the first ADC data of the sequence.
29:31 ERROR_CODE	Every erroneous ADC result is marked with error codes. The *Table 634* captures different error codes.

39.4.29 AUXDQ POP register (Q*n*_AUXDQ_POP)

This read only register is accessible in debug mode only when DEBUG_EN bit is set. It is used to read the data from the AUXDQ. The read is non-destructive which means the original AUXDQ FIFO pointers are restored after exiting the debug mode. If DEBUG_EN bit is not set then in the debug mode the read of this register will result in a transfer error.

Access: RO in enabled debug mode

Exists: AUXDQ*n*_PRESENT = 0x1 (for n = 0 to 1)

Refer to *Section 39.3.2.7: Data Queue (DATAQ) and Auxiliary Data Queue (AUXDQ) description* for details.

offset: 0x144 + *n**0x100 (*n* = 0 to 1) Access: User Read-only

Field	Description
0:15 RESULT_H	ADC_DATA, DATA_TS_H or TRIGGER_TS_H field For ADC data this field holds ADC conversion data for the channel specified in the ADC_CH_NUM field. If ADC data is less than 16-bits then the data alignment is defined by the corresponding bit in the command entry. For dummy data this field holds a 0xD0D0. For timestamps this field holds upper 16 bits of 24-bit timestamp. For sequence status this field holds the upper 16 bits of 24-bit timestamp for last ADC data.
16:23 RESULT_L	ADC_CH_NUM, DATA_TS_L or TRIGGER_TS_L field 8-bit ADC Channel Number corresponding to the data in the ADC Data field. For timestamps this field holds lower 8 bits of 24-bit timestamp. For sequence status this field holds the lower 8 bits of 24-bit timestamp for last ADC data.
24 TS_TRIGGER	When this field is set then the bits[0:23] contains the timestamp for the trigger.
25 TS_DATA	When this bit is set then the bits[0:23] contains the timestamp data for the channel.
26 DUMMY_DATA	Marker for denoting that this entry corresponds to a DUMMY CMD. This bit is significant only when DUMMY data dumping is enabled for a queue.
27 LAST_ADC_DATA	Marker for denoting the last ADC data of the Sequence.
28 FIRST_ADC_DATA	Marker for denoting the first ADC data of the sequence.
29:31 ERROR_CODE	Every erroneous ADC result is marked with error codes.The *Table 634* captures different error codes.

39.4.30 Queue Debug Read Pointers register (Q*n*_DBG_RD_POINTERS)

All FIFOs provide non-destructive read operation. The SW can read the FIFO contents by programming this register with the pointer values. In the debug mode, on read request of the CMDQ/AUXDQ/DATAQ registers the data corresponding to this pointer location is read. The validity of the data is also highlighted in this register.

The width of this field is governed by the depth of the DATAQ. The unused bits are reserved and are always read as 0.
24:31 CMDQ_DBG_RD_PTR	This field allows to read the contents of CMDQ FIFO in debug mode. The content of the CMDQ FIFO location, pointed by CMDQ_DBG_RD_PTR is visible on the Q_CMDQ_PUSH register. The width of this field is governed by the depth of the CMDQ. The unused bits are reserved and are always read as 0.

40 Decimation Filter (DECFILTER)

40.1 Introduction

This chapter describes the Decimation Filter block.

40.1.1 Overview

The decimation filter is a dedicated hardware block, designed to decimate fixed point sample conversion results, generated by a master block, usually an Analog to Digital Converter. Two dedicated parallel side interfaces (PSI0 and PSI1) provide bi-directional communication between two master blocks and the filter. A third interface is provided for use by the CPU, allowing setup of the filter parameters and read/write of the configuration registers and filter samples.

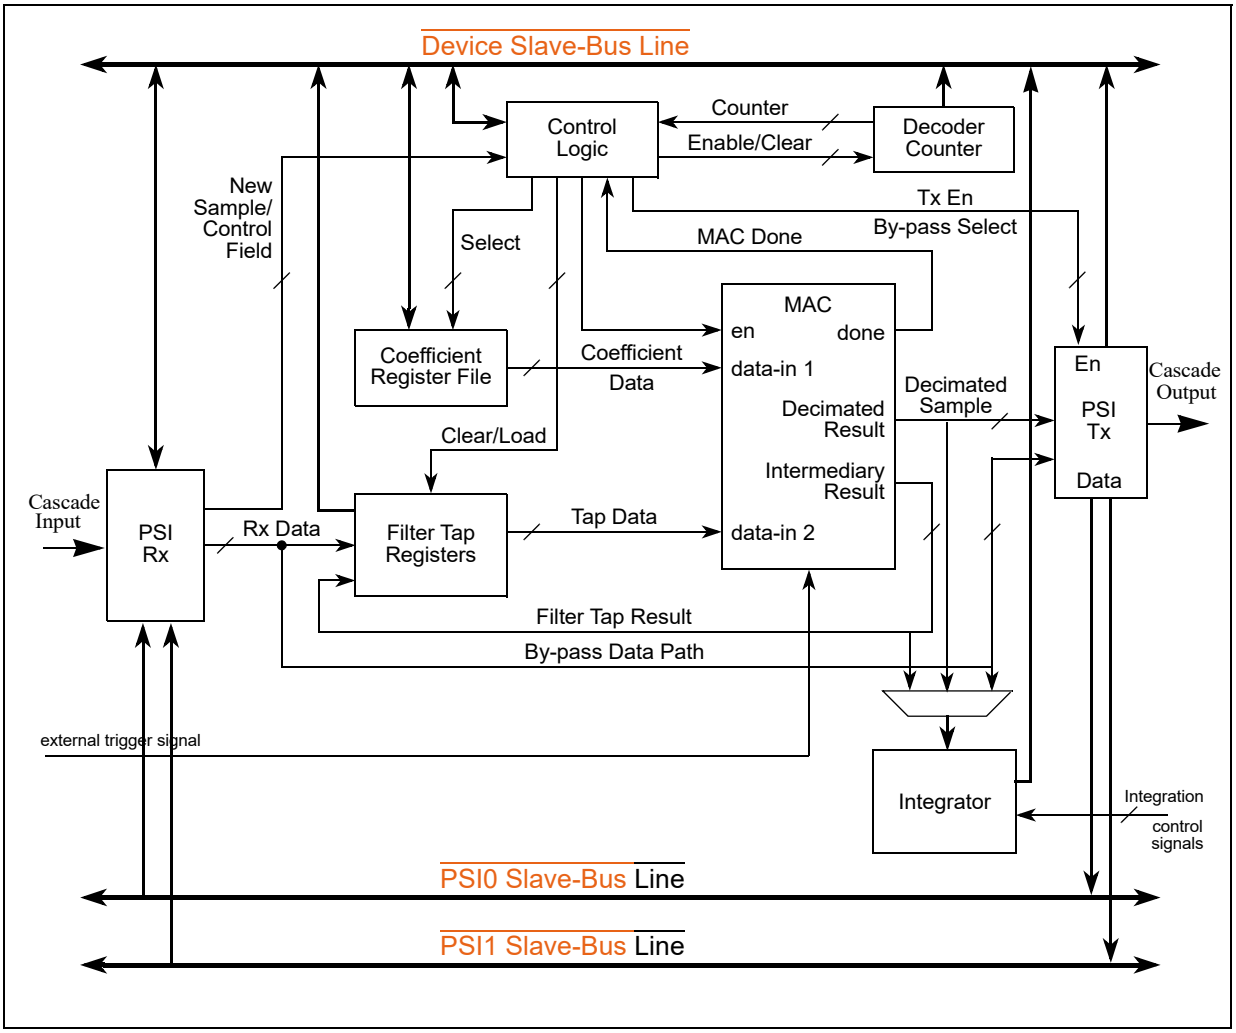
The Decimation Filter receives data samples from the master blocks in the PSI RX sub-block. Each sample arrives at the decimation filter with an identifier tag and associated commands. The input information is decoded by the PSI RX and control logic sub-blocks. When receiving a filtering command, the data is transferred to the filter tap register's sub-block and is processed by the filter using the MAC (Multiply and Accumulate) unit, the coefficient register, and the control logic sub-blocks. The result is then returned to the master block by the PSI TX sub-block, accompanied by the corresponding tag information that provides an address for the data.

To summarize normal mode, the decimation filter works as a slave block on the third slave-bus line, and there are up to two PSI master blocks such as the ADC to send and read data. This is illustrated in the application example in *Section 40.6: Application information*.

Note: The normal use is to receive the data stream from one specific PSI and transmit the results using one specific PSI. Input and output timing care is necessary if data is received from both PSI and output results are sent to both PSI alternately.

The decimation filter can also function in a standalone mode. In this mode, the input data is supplied and the output results are read by the chip core processor (CPU) using status and interrupt signals or DMA requests.

Mixed modes are also provided; allowing input data fed from the PSI interfaces and output results read by the CPU or DMA, or input fed from CPU or DMA and output directed to a selected PSI interface.



An integrator unit independently accumulates the values of filter outputs. The integration can be restricted to time windows defined by hardware signals or software.

Two or more decimation filter blocks can also be configured to work in the cascade mode of operation to obtain a more complex filtering function. The output result of a filter block is connected to the input of the next filter by means of a dedicated interface.

All signals in the interface are generated in the system clock domain.

Figure 555 shows the block diagram for the decimation filter.

Figure 555. Decimation Filter Block Diagram

40.1.2 Features

Each Decimation Filter block includes these distinctive features:

- Selectable 4th order IIR filter, or an 8th order FIR filter
  - Input/output with 16-bit (fixed point) two's complement signed values
  - Internal taps with 16-bit (feed-forward portion of first IIR) and 24-bit (feedback portion) resolutions (fixed point) for two's complement signed value
  - 24-bit programmable filter coefficients (fixed point) for two's complement signed value
  - MAC unit with 51-bit fixed point accumulator
  - Convergent rounding methodology
  - Two's complement overflow or saturation selection
  - 58 clock cycles to process the input
- Implements two local slave-bus interfaces to two master blocks (that is the eQADC blocks)
- Input and output buffers with DMA capability
- Slave-bus interface to device
- Filter taps access for debug
- Filter initialization (flush) and stabilization (pre-fill) commands
- Timestamp support
- Decimation controlled by an internal counter or from an on-chip independent trigger signal (triggered output result).
- Integrator unit accumulates filter output values, signaled or absolute, with 32-bit resolution. The integrator can be controlled by software or hardware signals.
- Cascade of two or more individual blocks to compose a more complex filter

40.1.3 Modes of operation

This section describes the operation modes of the Decimation Filter. The modes are selected using the following DECFILTER_MCR register fields: MDIS, FREN, FRZ, ISEL, MIXM, CASCD (see *Section 40.3.2.1: Decimation Filter Module Configuration Register (DECFILTER_MCR)*).

The mode selection is summarized in *Table 667*.

Table 667. Operation Mode Selection

Mode	MDIS	FREN, FRZ	ISEL	MIXM	CASCD
Normal	0	(0, 0) or (0, 1) or (1, 0)	0	0	00
Standalone	0	(0, 0) or (0, 1) or (1, 0)	1	0	00

Table 667. Operation Mode Selection (continued)

Mode	MDIS	FREN, FRZ	ISEL	MIXM	CASCD
PSI[1] Input Mixed	0	(0, 0) or (0, 1) or (1, 0)	0	1	00
PSI Output Mixed	0	(0, 0) or (0, 1) or (1, 0)	1	1	00
Cascade	0	(0, 0) or (0, 1) or (1, 0)	0 or 1	0	01 or 10 or 11
Freeze[2]	0	1, 1	X	X	X
Low Power	1	X	X	X	X
Reserved	All other combinations				

1. The physical input / output can be PSI0 or PSI1.
2. Freeze mode can also be activated from outside the Decimation Filter, depending on the MCU, if FREN=1.

40.1.3.1 Normal mode

This is the default operational mode of the decimation filter block. It corresponds to the pre-fill/filter operation with input data supplied through any of the two PSI slave-bus interfaces (that is its input data is the ADC conversion result), with output going to the same or to the other PSI interface.

40.1.3.2 Standalone mode

Standalone mode differs from normal mode because the input data is not supplied by the master blocks through the PSI interfaces. In this case, the data is provided by the central processor using the device slave-bus interface or DMA interface signals. Once the data is filtered the decimated result is available in the Output Buffer register. The filter output is also consumed by a CPU or DMA mastering the same device slave-bus interface. This operation mode can be used to debug the filter stability or to decimate data in System RAM.

40.1.3.3 PSI Input Mixed mode

In this mode the input is selected from any of the two PSI slave-bus interfaces, but the output is directed to the device slave-bus interface, where it can be read by the CPU or DMA.

40.1.3.4 PSI Output Mixed mode

This mode works inverted from the PSI Input Mixed Mode: the input is selected from the device slave-bus interface, fed either by the CPU or DMA, and the output is directed to one

of the two PSI slave-bus interfaces. If an SDADC is connected to one PSI interface, the output is directed to an RFIFO selected by the tag field in the DECFILTER_IB register (see *Section 40.3.2.5: Decimation Filter Interface Input Buffer register (DECFILTER_IB)*).

40.1.3.5 Cascade mode

Cascade mode is a filter structure mode with two or more individual filter blocks connected in a chain to form a more complex filter function. The output result of the first block (head block) is connected to the input of the next block (middle or tail block) to be filtered again. More details in *Section 40.4.16: Cascade mode description*.

40.1.3.6 Low Power mode

Low power mode corresponds to the module disable mode or stop mode. In the module disable mode the two PSI slave-bus lines are disabled and it is not possible to enter Freeze mode. The system clock is stopped. And in stop mode, the system clock is also stopped.

40.1.3.7 Freeze mode

This mode is also known as debug mode. All filter action is frozen, either through software or by the hardware SoC debug request signal. If a freeze request comes when the filter is processing an input, it enters freeze mode only after the processing finishes.

40.2 External signal description

Note: The Decimation Filter does not provide metastability protection or filtering for these signals.

40.2.1 Decimation trigger signal

This signal is used to control the output of the decimation filter, allowing decimation to be driven externally. For more details, see *Section 40.4.4.2: Triggered output result description*.

40.2.2 Integrator enable signal

This signal is used to enable the hardware integrator. For more details, see *Section 40.4.15.4: Integrator enabling and halting*.

40.2.3 Integrator halt signal

This signal is used to halt the hardware integrator. For more details, see *Section 40.4.15.4: Integrator enabling and halting*.

40.2.4 Integrator reset signal

This signal is used to reset the hardware integrator. For more details, see *Section 40.4.15.3: Integrator reset*.

40.2.5 Integrator output request signal

This signal is used to update the integrator output result. For more details, see *Section 40.4.15.2: Integrator outputs*.

40.3 Memory map and register definition

This section provides the memory maps and detailed descriptions of all registers. Accesses to reserved areas of the memory map can return a bus error, depending on the device integration.

This module communicates with three distinct slave-bus lines. One is related to the device integration and the two others are related to the PSI master blocks for data transfers. Below both memory maps are described.

40.3.1 Decimation filter device memory map

The addresses of the Decimation Filter registers are specified as offsets from the module's base address, described in *Table 668*. The registers allocated in this memory map are sufficient for a 4th order IIR filter implementation.

Table 668. Block memory map

Address offset	Register	Location
0x000	Module Configuration Register (DECFILTER_MCR)	*Section 40.3.2.1*
0x004	Module Status Register (DECFILTER_MSR)	*Section 40.3.2.2*

0x0E4	Final Integration Count Register (DECFILTER_FINTCNT)	*Section 40.3.2.11*
0x0E8	Current Integration Value Register (DECFILTER_CINTVAL)	*Section 40.3.2.12*
0x0EC	Current Integration Count Register (DECFILTER_CINTCNT)	*Section 40.3.2.13*
0x0F0–0x1FF	Reserved	

1. The TAP register stores, on each filter node, the input sample data and, for the IIR type, the filter intermediary results.

40.3.2 Decimation filter register descriptions

All registers are 32-bit wide.

40.3.2.1 Decimation Filter Module Configuration Register (DECFILTER_MCR)

The Decimation Filter module configuration register provides configuration control bits for the Decimation Filter internal logic.

Note: One must not modify this register contents when the status bit BSY is set, except for fields FREN, FRZ and IDIS. To guarantee that BSY does not set during the read-modify-write operation, set IDIS=1 and wait for BSY=0 beforehand.

Offset: 0x0000 Access: User read/write

Figure 556. Decimation Filter Module Configuration Register (DECFILTER_MCR)

Table 669. DECFILTER_MCR field descriptions

Field	Description
0 MDIS	Module Disable The MDIS bit puts the Decimation Filter in low power mode. Communication through the two PSI slave-bus Interfaces are ignored in this mode. Writes to the configuration register are allowed with the exception of writes to the FREN and SRES bits, which are ignored. Writes to the Coefficient registers are also allowed. The Decimation Filter cannot enter Freeze mode once in disable mode. Once the module is disabled it no longer receives the system clock. 1 Low Power Mode 0 Normal Mode
1 FREN	Freeze Enable The FREN bit enables the Decimation Filter to enter freeze mode if the SoC debug request signal or the FRZ bit is asserted. See *Section 40.4.13: Freeze mode description*, for more details. 1 Decimation Filter Freeze mode enabled 0 Decimation Filter Freeze mode disabled
3 FRZ	Freeze Mode The FRZ bit controls the freeze mode of the Decimation Filter. For this bit to take effect the FREN freeze enable bit also needs to be asserted. While in freeze mode the MAC operations are halted. See *Section 40.4.13: Freeze mode description*, for more details. 1 Decimation Filter in Freeze Mode 0 Decimation Filter in Normal Mode
4 SRES	Software-reset bit The SRES is a self-negated bit which provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. This bit always reads as zero. See *Section 40.4.10: Soft reset command description*, for more details. 1 Software-Reset 0 No action

Table 669. DECFILTER_MCR field descriptions (continued)

Field	Description
5:6 CASCD	Cascade Mode Configuration The CASCD bit field configures the block to work in cascade mode of operation according to *Table 667*. For more details about the cascade mode, see *Section 40.4.16: Cascade mode description*." 00 No cascade mode (single block) 01 Cascade Mode, Head block configuration 10 Cascade Mode, Tail block configuration 11 Cascade Mode, Middle block configuration **Note:** Any change to this field must follow the procedure described in the *Section 40.4.16.1: Cascade Freeze, Stop, and Configuration change procedures*.
7 IDEN	Input Data Interrupt Enable The IDEN bit enables the Decimation Filter to generate interrupt requests on all new input data written to the Interface Input Buffer register or Input/Output Buffers register. 1 Input Data Interrupt Enabled 0 Input Data Interrupt Disabled
8 ODEN	Output Data Interrupt Enable The ODEN bit enables the Decimation Filter to generate interrupt requests on all new data written to the filter Output buffer. It is independent of how ISEL and MIXM are set. 1 Output Data Interrupt Enabled 0 Output Data Interrupt Disabled
9 ERREN	Error Interrupt Enable The ERREN bit enables the Decimation Filter to generate interrupt requests based on the assertion of the DECFILTER_MSR register error flags OVF, DIVR, SVR, OVR or IVR. 1 Error Interrupts Enabled 0 Error Interrupts Disabled
11:12 FTYPE	Filter Type Selection bits The FTYPE[1:0] bits select the filter type according to the following values: 00 Filter Bypass 01 IIR Filter - 1 x 4th order 10 FIR Filter - 1 x 8th order 11 Reserved **Note:** In Bypass configuration the filter is disabled. Bypass must not be configured when in cascade mode (see field CASCD).
14:15 SCAL	Filter Scaling Factor The SCAL bit field selects the scaling factor used by the filter algorithm according to the following values: 00 Scaling Factor = 1 01 Scaling Factor = 4 10 Scaling Factor = 8 11 Scaling Factor = 16

Table 669. DECFILTER_MCR field descriptions (continued)

Field	Description
16 IDIS	Input Disable The IDIS bit disables the block input, so that writes to the input buffer have no effect (either from the device slave-bus or from the two PSI interfaces), and input DMA or interrupt requests are not issued. Input disabling is needed to change the block configuration to or from cascade mode. See *Section 40.4.17: Return PSI (RPSI) and PSI Output Selector (PSIOSEL)* for more details. 1 Input disabled 0 Input enabled **Note:** IDIS resets in 1 (hardware reset only), and the module configuration procedures for previous versions (without IDIS bit) are upward compatible provided that the DECFILTER_MCR register is written with 0 into the IDIS position (previously reserved).
17 SAT	Saturation Enable The SAT bit enables the saturation of the filter output. See *Section 40.4.6.2: Saturation*, for more details. 1 Enable Saturation 0 Disable Saturation
18 ISEL	Input Selection The ISEL bit selects the source of input data to the Filter. Possible data sources are the master block of any PSI slave-bus interface, or the CPU/DMA on the device slave-bus interface. Each device slave-bus write to the Interface Input Buffer register or DMA transfer to the input buffer is interpreted as a new sample to be processed by the filter. The output interface used is the same as the one selected by ISEL if the output selection bit MIXM=0. When MIXM=1, the output selection (slave-bus or device slave-bus) is contrary to the input selection (see *Table 670* and the MIXM bit definition), configuring a mixed mode operation. The slave-bus interface can always read the input/output buffers, however the PSI slave-bus interfaces can only read the output buffer by request of the decimation filter, in normal or input mixed modes. This behavior is outlined in detail in *Table 670*. 0 Filter input from any of the two PSI slave-bus interfaces 1 Filter input from the device slave-bus interface **Note:** There is no configuration register to select between the two PSI interfaces as the active one. Both are active when ISEL=0.
19 MIXM	Mixed Mode The MIXM field selects the interface used for filter output, either device slave-bus or the PSI slave-bus, in relation to the interface selected by ISEL (see ISEL bit definition and *Table 670* for more details): 0 Interface selected by ISEL is used for output, configuring normal or standalone mode. 1 Interface NOT selected by ISEL is used for output, configuring mixed mode. **Note:** MIXM must be set to 0 (zero) when the filter is configured as cascade mode.
20:23 DEC_RATE	Decimation Rate Selection The DEC_RATE[3:0] field selects the decimation rate used by the Decimation Filter. The decimation rate defines the number of data samples from the master block that is required to generate one decimated result in the Decimation Filter output. 0000 No Decimation: one filter output for each sample input 0001 One filter output for each (DEC_RATE+1) sample inputs ... 1111 One filter output for each (DEC_RATE+1) sample inputs

Table 669. DECFILTER_MCR field descriptions (continued)

Field	Description
24 SDIE	Integrator Data Interrupt Enable The SDIE field enables output buffer interrupts due to integrator data result being ready (at registers DECFILTER_FINTVAL and DECFILTER_FINTCNT): 0 Integration ready does not cause an output interrupt. 1 Integration ready causes an output interrupt.
25 DSEL	DMA Selection The DSEL bit determines whether the data transfers, to the input buffer (write to) and from the output buffer (read from), are performed by DMA requests or by interrupt requests. This bit can also be active when PSI inputs are selected with Enhanced Debug (ISEL=0, EDME=1), in which case the input buffer generates read requests only (see *Section 40.4.14: Enhanced Debug Monitor Description*"). 0 Interrupt requests are generated. 1 DMA requests are generated.
26 IBIE	Input Buffer Interrupt Request Enable The IBIE bit enables the Decimation Filter to generate interrupt requests when: – device slave-bus input is selected (ISEL=1) and DSEL=0 when the input buffer is available to receive new data; – PSI inputs are selected with Enhanced debug (ISEL=0, EDME=1) and DSEL=0 when the input buffer has data to be read by the device CPU. 0 Input Buffer Interrupt Request Disabled 1 Input Buffer Interrupt Request Enabled
27 OBIE	Output Buffer Interrupt Request Enable The OBIE bit enables the Decimation Filter interrupt requests when outputs are directed to the device slave-bus (ISEL != MIXM) and DMA is not selected (DSEL=0). 0 Output Buffer Interrupt Request Disabled 1 Output Buffer Interrupt Request Enabled
28 EDME	Enhanced Debug Monitor Enable The EDME bit defines the enhanced debug monitor when input selection is from any PSI (ISEL=0). In this case, the raw data fed from the PSI Master blocks is also, in parallel, made available in the register DECFILTER_EDID (see *Section 40.4.14: Enhanced Debug Monitor Description*), generating and input interrupt or DMA request. 0 Enhanced debug monitor disabled 1 Enhanced debug monitor enabled (read requests of input data from master block enabled)

Table 669. DECFILTER_MCR field descriptions (continued)

Field	Description
29 TORE	Triggered Output Result Enable The TORE bit enables an input trigger signal to force the decimation filter to send the next result of the filter back to the master block. For more details, see *Section 40.4.4.2: Triggered output result description*. 0 Output buffer update using an external signal is disabled 1 Output buffer update using an external signal is enabled **Note:** TORE must only be asserted when PSI is selected as output (normal or PSI output mixed modes). TORE must not be asserted with the filter bypassed (FTYPE=00).
30:31 TMODE	Trigger Mode The TMODE field selects the way the trigger signal controls the output result sampling function enabled by the TORE bit, as shown below. 00 output is posted at the rising edge of the trigger signal. 01 output is posted whenever the trigger signal is a logical 0. 10 output is posted at the falling edge of the trigger signal. 11output is posted whenever the trigger signal is a logical 1. **Note:** The TMODE definition replaces, and is upward compatible with, the TRFE bit definition found in previous versions of the Decimation Filter.

Table 670. ISEL/MIXM Definition — Read/Write from/to Input/Output Buffers

ISEL	MIXM	Mode	Operation	Device slave-bus Interface		PSI slave-bus interfaces	
				Input Buffer	Output Buffer	Input Buffer	Output Buffer
0	0	Normal	Read	Always, by DMA or interrupt(1) request if EDME=1	Always, no DMA or interrupt	forbidden, write only	By decfil request(2)
	1	PSI Input Mixed			Always, issues DMA or interrupt(1)		Disabled
	0	Normal	Write	Forbidden	no effect, read only	Enabled	(read only)
	1	PSI Input Mixed					
1	0	Standalone	Read	Always, no DMA or interrupt	Always, issues DMA or interrupt(1)	forbidden, write only	Disabled
	1	PSI Output Mixed			Always, no DMA or interrupt		By decfil request(2)
	0	Standalone	Write	Enabled, by DMA or interrupt request(1)	no effect, read only	Forbidden	read only
	1	PSI Output Mixed					

1. bit DSEL selects between interrupt or DMA request
2. Decimation filter issues a read request to the master block

Note: ISEL completely selects the output when the filter is configured as cascade tail, and is ignored when it is configured as cascade middle.

ISEL must not be modified during the filter operation (when the status bit BSY is set). In addition, the interface not selected by ISEL must not be used to write into the input buffer.

40.3.2.2 Decimation Filter Module Status Register (DECFILTER_MSR)

Offset: 0x0004 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BSY	0	DEC_COUNTER				0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 557. Decimation Filter Status Register (DECFILTER_MSR)

Table 671. DECFILTER_MSR field descriptions

Field	Description
0 BSY	Decimation Filter Busy indication The BSY bit indicates that the Decimation Filter is processing new input data from the master block in normal mode or from the device core in standalone mode. BSY is not asserted when the filter is disabled (FTYPE = 00). However, the BSY bit is asserted when the soft reset is executed. 0 Decimation Filter Idle 1 Decimation Filter Busy
2:5 DEC_COUNTER	Decimation Counter The DEC_COUNTER field indicates the current value of the DEC_COUNTER Decimation Counter (see *Figure 555*), which counts the number of input data samples received by the Decimation Filter. When the value of this counter matches the DEC_RATE[3:0] Configuration Register field, one decimated result is generated and the DEC_COUNTER counter is re-initialized at zero. This register is cleared by a soft reset or a flush command.
6 IDFC	Input Data Flag Clear bit The IDFC bit clears the IDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IDF
7 ODFC	Output Data Flag Clear bit The ODFC bit clears the ODF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears ODF

Table 671. DECFILTER_MSR field descriptions (continued)

Field	Description
9 IBIC	Input Buffer Interrupt Request Clear bit The IBIC bit clears the IBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IBIF
10 OBIC	Output Buffer Interrupt Request Clear bit The OBIC bit clears the OBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OBIF
12 DIVRC	DIVR Clear bit The DIVRC bit clears the DIVR Debug Filter Input Data Read Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears DIVR
13 OVFC	OVF Clear bit The OVFC bit clears the OVF Output Overflow bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVF
14 OVRC	OVR Clear bit The OVRC bit clears the OVR Output Overrun bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVR
15 IVRC	IVR Clear bit The IVRC bit clears the IVR Filter Input Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IVR
22 IDF	Input Data Flag The IDF bit flag indicates when new data is available at the DECFILTER_IB register or at the DECFILTER_IOB register. This flag generates an Interrupt Request if enabled by the IDEN bit in the Configuration Register. This Flag is cleared by the IDFC Status bit or by a soft reset of the decimation filter. 0 Sample not received 1 New Sample received **Note:** OBS: This flag is not used for read / write requests. It is used only to announce the input data event. For read / write request flag, refer to IBIF.

Table 671. DECFILTER_MSR field descriptions (continued)

Field	Description
23 ODF	Output Data Flag The ODF bit flag indicates when a new decimated sample is available at the DECFILTER_OB register or at the DECFILTER_IOB register. This flag generates an Interrupt Request if enabled by the ODEN bit in the Configuration Register. This Flag is cleared by the ODFC Status bit or by a soft reset of the decimation filter. 0 No new Decimated Output Sample available 1 New Decimated Output Sample available **Note:** OBS: This flag is not used for read requests. It is used only to announce the output data event. For read request flag, refer to OBIF.
25 IBIF	Input Buffer Interrupt Request Flag The IBIF bit flag indicates that the input buffer DECFILTER_IB is available to be filled with new data, when Enhanced Debug Monitor is off. In Enhanced Debug Monitor, it indicates the input buffer DECFILTER_IB was filled with a new sample and is ready to be read. IBIF assertion also asserts the interrupt signal when enabled by the IBIE bit in the Configuration Register when DMA is not selected (DSEL=0) and the input buffer requires access from the device slave-bus (ISEL != EDME). This Flag is cleared by the IBIC Status bit or by a soft reset of the decimation filter. 0 No action 1 New Sample is requested (ISEL = 1, EDME=0) or new sample is available in Enhanced Debug Monitor (ISEL=0, EDME=1).
26 OBIF	Output Buffer Interrupt Request Flag The OBIF bit flag indicates that a new decimated sample is available at the DECFILTER_OB register. This flag generates an Interrupt Request if enabled by the OBIE bit in the Configuration Register and with ISEL!=MIXM and DSEL=0. This Flag is cleared by the OBIC Status bit or by a soft reset of the decimation filter. 0 No new Decimated Output available 1 New Decimated Output available
28 DIVR	Enhanced Debug Monitor Input Data Read Overrun The DIVR bit indicates that a received sample in the Filter Interface Input Register was overwritten by a new sample and was not read by the Core. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the DIVRC Status bit or by a soft reset of the decimation filter. 0 Input Data Read Overrun did not occur in Enhanced Debug monitor. 1 Enhanced Debug Monitor Input Data Read Overrun occurred
29 OVF	Filter Overflow Flag The OVF bit indicates that an overflow occurred in the filtered sample result. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVFC Status bit or by a soft reset of the decimation filter. 0 No overflow 1 Overflow occurred

Table 671. DECFILTER_MSR field descriptions (continued)

Field	Description
30 OVR	Output Interface Buffer Overrun The OVR bit indicates that a decimated sample was overwritten by a new sample in the Interface Output Buffer Register. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVRC Status bit or by a soft reset of the decimation filter. 0 No Output Overrun 1 Filter Output Overrun occurred
31 IVR	Input Interface Buffer Overrun The IVR bit indicates that a received sample in the Filter Interface Input Register was overwritten by a new sample. This was probably caused by a violation of the Decimation Filter maximum throughput. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the IVRC Status bit or by a soft reset of the decimation filter. 0 Input Buffer Overrun did not occur. 1 Input Buffer Overrun occurred **Note:** IVR does not set due to input register writes when input is disabled (DECFILTER_MCR bit IDIS=1).

40.3.2.3 Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SISEL	0	SZROSEL		0	0	SHLTSEL		0	SRQSEL			0	0	SENSEL	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 558. Decimation Filter Extended Configuration Register (DECFILTER_MXCR)

Table 672. DECFILTER_MXCR field descriptions

Field	Description
0 SDMAE	Integrator DMA Enable The SDMAE bit enables the DMA request when an integrator output is requested (see *Section 40.4.15.2: Integrator outputs*). 0 integrator DMA request disabled 1 integrator DMA request enabled **Note:** The DMA channel used is the same one used for filter outputs, and any configuration that generates DMA requests from both of those sources is not allowed.
1 SSIG	Integrator Signal operation selection The SSIG bit defines how the filtered data signal is treated for integration: 0 integrator input takes the absolute value of filter output. 1 integrator input takes signaled filter output.
2 SSAT	Integrator Saturated operation selection The SSAT bit defines how the integrator accumulator behaves in case of an overflow. 0 integrator accumulator holds a modulo 2^{17} value (considering the 15-bit fractional part) on an overflow. 1 integrator accumulator saturates on an overflow. **Note:** In saturated operation the overflowed integration sum holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). Non-saturated mode is not supported with signaled integration, therefore one must not configure SSIG=1 and SSAT=0.
3 SCSAT	Integrator Counter Saturated operation selection The SCSAT bit defines how the integrator sample counter behaves in case of an overflow. 0 integrator sample counter holds a modulo 2^{32} value on an overflow. 1 integrator sample counter saturates on an overflow, holding a value of 0xFFFFFFFF.
14 SRQ	Integrator Output Request The SRQ bit is used to command the update of the integrator output, reflected in the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT. It may also cause a DMA or interrupt request, depending on the DECFILTER_MCR bit SDIE and DECFILTER_MXCR bit SDMAE. This is a write-only bit, so reads always return 0. For more details see *Section 40.4.15.2: Integrator outputs*. 0 no integrator output update request 1 requests integrator output update
15 SZRO	Integrator Zero The SZRO bit is used to zero the integrator sum. This is a write-only bit, reads always return 0. For more details see *Section 40.4.15.3: Integrator reset*. 0 does not zero integrator sum 1 zeros integrator sum **Note:** If bits SRQ and SZRO are both written 1 at the same time, the integrator is reset only after the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT are updated.

Table 672. DECFILTER_MXCR field descriptions (continued)

Field	Description
16 SISEL	Integrator Input Selection The SISEL bit selects the input of the integrator. For more details see *Section 40.4.15.1: Integrator inputs*. 0 decimated filter outputs feed the integrator 1 filter outputs before the decimation feed the integrator
18:19 SZROSEL	Integrator Zero Control Mode Selection The SZROSEL field defines the use of the integrator zero hardware input signal, according to the parameters below. For more details see *Section 40.4.15.3: Integrator reset*. 00 hardware integrator zero request disabled 01 integrator zero on toggle of hardware signal 10 integrator zero on rising edge of hardware signal 11 integrator zero on falling edge of hardware signal
22:23 SHLTSEL	Integrator Halt Control Selection The SHLTSEL field defines the integrator halting mechanism, according to the list below. When the integrator is halted, the integration accumulator remains unaltered on filter outputs independently of the enabling selected by SENSEL. For more details see *Section 40.4.15.4: Integrator enabling and halting*. 00 hardware halt control signal disabled 01 integrator halted, independently of the hardware signal 10 integrator halted when signal is at logical 0 11 integrator halted when signal is at logical 1

Table 672. DECFILTER_MXCR field descriptions (continued)

Field	Description
25:27 SRQSEL	Integrator Output Read Request Mode Selection The SRQSEL field defines the use of the integrator output request hardware input signal, according to the parameters below. An integrator output request updates the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT, also causing a DMA or interrupt request. Note that DMA or interrupt requests due to integrator output updates depend on the DECFILTER_MXCR bit SDMAE and DECFILTER_MCR bit SDIE. When continuous output is on, an integrator output request is issued whenever a new filter output is accumulated. For more details see *Section 40.4.15.2: Integrator outputs*. 000 hardware output request disabled 001 integrator output request on toggle of hardware signal 010 integrator output request on rising edge of hardware signal 011 integrator output request on falling edge of hardware signal 100 reserved 101 continuous output request on, independently of hardware signal 110 continuous output request on when signal is at logical 0 111 continuous output request on when signal is at logical 1
30:31 SENSEL	SENSEL — Integrator Enable Control Selection The SENSEL field defines the integrator enabling mechanism, according to the parameters below. When the integrator is enabled, filter outputs selected by the SISEL bit are added to the integration accumulator. When the integrator is disabled, the integration accumulator remains unaltered on filter outputs. For more details see *Section 40.4.15.4: Integrator enabling and halting*. 00 integrator disabled, independently of the hardware enable control signal 01 integrator enabled, independently of the hardware signal 10 integrator enabled when signal is at logical 0 11 integrator enabled when signal is at logical 1

40.3.2.4 Decimation Filter Module Extended Status Register (DECFILTER_MXSR)

Offset: 0x000C Access: User read/write

Figure 559. Decimation Filter Extended Status Register (DECFILTER_MXSR)

Table 673. DECFILTER_MXSR field descriptions

Field	Description
7 SDFC	Integrator Output Data Flag Clear bit The SDFC bit clears the SDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SDF
10 SSEC	Integrator Sum Exception Clear bit The SSEC bit clears the SSE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SSE
11 SCEC	Integrator Count Exception Clear bit The SCEC bit clears the SCE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCE
13 SSOVFC	Integrator Sum Overflow Clear bit The SSOVFC bit clears the SSOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SSOVF
14 SCOVFC	Integrator Count Overflow Clear bit The SCOVFC bit clears the SCOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCOVF
15 SVRC	SVR Clear bit The SVRC bit clears the SVR Integrator Data Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SVR
23 SDF	Integrator Data Flag The SDF bit flag indicates when a new integrator result is available at the DECFILTER_FINTVAL register. This flag generates an Interrupt Request if enabled by the SDIE bit in the Configuration Register. This Flag is cleared by the SDFC Status bit or by a soft reset of the decimation filter. 0 no new integrator result available 1 new integrator result available
26 SSE	Integrator Sum Exception flag The SSE bit indicates an exceptional condition of the integrator accumulator. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SSEC bit or by a soft reset. Integrator exceptions are defined in *Section 40.4.15.5: Integrator exceptions*. 0 No exception in the integrator accumulator 1 Integrator accumulator exception

Table 673. DECFILTER_MXSR field descriptions (continued)

Field	Description
27 SCE	Integrator Count Exception flag The SSE bit indicates an exceptional condition of the integrator counter. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SCEC bit or by a soft reset. Integrator exceptions are defined in *Section 40.4.15.5: Integrator exceptions*. 0 No exception in the integrator counter 1 Integrator counter exception
29 SSOVF	Integrator Sum Overflow Flag The SSOVF bit flag indicates an overflow of the integrator accumulator. This Flag is cleared by the SSOVFC bit or by a soft reset. 0 No overflow in the integrator sample counter 1 Integrator sample counter overflowed **Note:** The SCOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/DECFILTER_CINTCNT) must be used by the application, in order to avoid races.
30 SCOVF	Integrator Count Overflow Flag The SCOVF bit flag indicates an overflow of the internal integrated sample counter. This Flag is cleared by the SCOVFC bit or by a soft reset. 0 No overflow in the integrator sample counter 1 Integrator sample counter overflowed **Note:** The SCOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/DECFILTER_CINTCNT) must be used by the application, in order to avoid races.
31 SVR	Integrator Data Overrun The SVR bit indicates that an integration value and count in the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT was overwritten by a new integrator output request and was not read by the CPU or DMA. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the SVRC bit or by a soft reset. 0 Integrator Data Overrun did not occur. 1 Integrator Data Overrun occurred

40.3.2.5 Decimation Filter Interface Input Buffer register (DECFILTER_IB)

The Input Buffer Register provides access to the Input buffer of the decimation filter when the filter is in the standalone or PSI output mixed modes of operation. Writes to this register are interpreted as requests to the Decimation Filter to process new sample data. Writes to this register when ISEL=0 are not allowed.

Offset: 0x0010 Access: User read/write

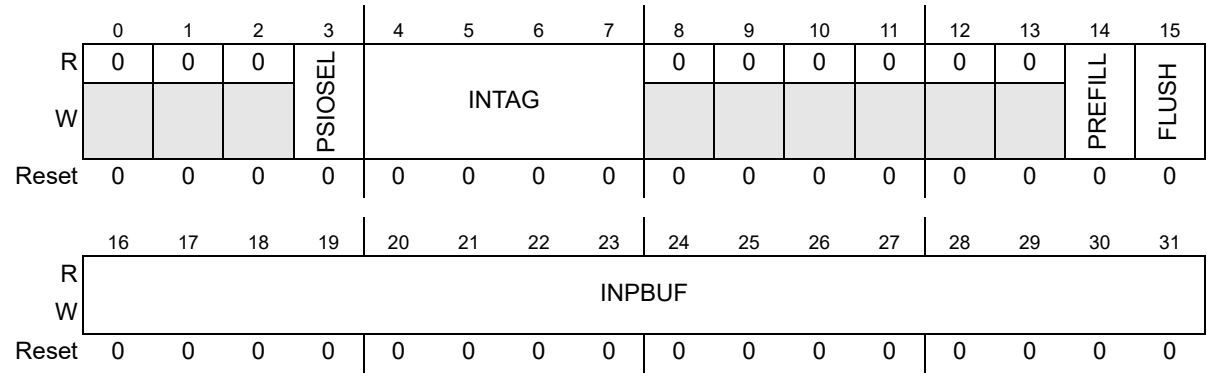

Figure 560. Decimation Filter Interface Input Buffer register (DECFILTER_IB)

Table 674. DECFILTER_IB field descriptions

Field	Description
3 PSIOSEL	PSI Output Selection The PSIOSEL bit selects the output PSI to send result filter in PSI output mixed mode. In standalone mode this bit has no effect. For more details, see *Section 40.4.17: Return PSI (RPSI) and PSI Output Selector (PSIOSEL)*. 0 PSI0 is selected to send result data (in PSI output mixed mode). 1 PSI1 is selected to send result data (in PSI output mixed mode). **Note:** The value of PSIOSEL should be constant for some data stream when in output mixed mode. Therefore, the output data is sent to a specific PSI and avoids undesired output overrun events.
4:7 INTAG	Decimation filter input tag bits The INTAG bit field is defined as a selector signal and it is used to identify different destinations for the INBUF[15:0] data.
14 PREFILL	Decimation Filter Pre-fill/Filter control bit The PREFILL bit selects the Decimation Filter operation mode. For more details, see *Section 40.4.7: Filter pre-fill control description*. 0 Decimation Filter normal sample 1 Decimation Filter pre-fill sample
15 FLUSH	Decimation Filter Flush control bit Assertion of the FLUSH bit initializes the Decimation Filter to a initial state, as defined in *Section 40.4.9: Flush command description*. This bit is self negated and it is cleared only when the data is read and the flush is executed. 0 no flush request 1 flush request
16:31 INPBUF	Input Buffer Data The INPBUF bit field carries the sample data to be filtered. This data buffer can be written from the two PSI slave-bus interfaces or by the device slave-bus interface. See *Section 40.4.3: Input buffer description*, for more details.

40.3.2.6 Decimation Filter Interface Output Buffer register (DECFILTER_OB)

Offset: 0x0014 Access: User read only

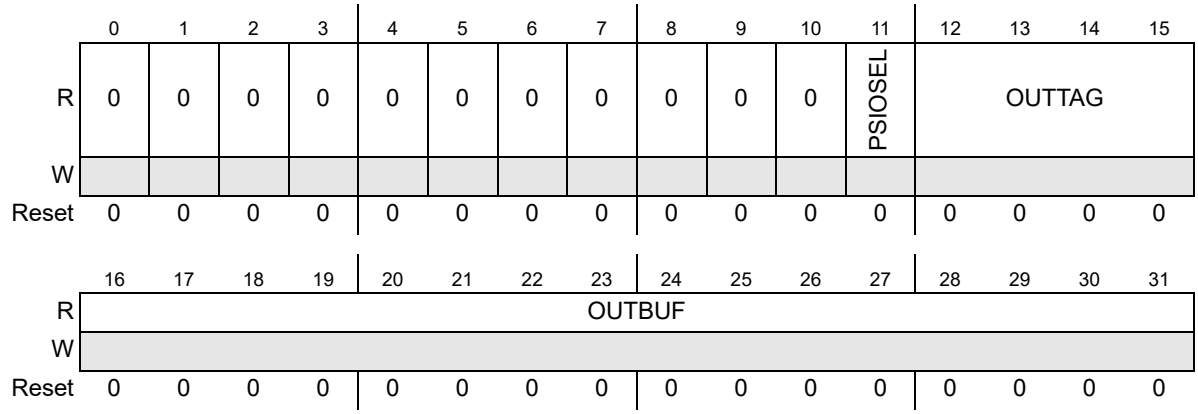

Figure 561. Decimation Filter Interface Output Buffer register (DECFILTER_OB)

Table 675. DECFILTER_OB field descriptions

Field	Description
11 PSIOSEL	Selected PSI Output The PSIOSEL bit indicates the selected PSI output that sends the filter result back to the master block. This field has no meaning when in standalone mode or PSI input mixed mode. For more details, see *Section 40.4.17: Return PSI (RPSI) and PSI Output Selector (PSIOSEL)*. 0 PSI0 is selected to send result data. 1 PSI1 is selected to send result data.
12:15 OUTTAG	Decimation filter output tag bits The OUTTAG bit field is defined as a selector signal and it is used to identify different destinations for the OUTBUF data.
16:31 OUTBUF	Output Buffer Data The OUTPBUF bit field is the result data in the decimation filter Output Buffer. It represents a fixed point signed number in two's complement format and is updated only when a decimated result is ready to be transmitted, meaning it contains the last decimated result from the filter.

40.3.2.7 Decimation Filter Coefficient *n* register (DECFILTER_COEF*n*)

Offset: 0x0020 +*n**0x4 (*n* = 0 to 8) Access: User read/write

8:31 TAP*n*	The read-only TAP*n*[8:31] bit fields shows the contents of the digital filter tap registers, as fractional signed values in two's complement format, in the range (-1 ≤ coef < 1). **Note:** The content of these registers is meaningless when BSY=1.

40.3.2.9 Decimation Filter Interface Enhanced Debug Input Data register (DECFILTER_EDID)

The Enhanced Debug Input Data Register provides read-only access to the sample data received by the decimation filter when the input is selected from the device slave-bus (ISEL=0), allowing the monitoring of filter operation. See *Section 40.4.14: Enhanced Debug Monitor Description* for more details. Writes to this register are not allowed.

Table 679. DECFILTER_FINTVAL field descriptions

Field	Description
0:31 SUM_VALUE	Integration Sum Value The SUM_VALUE field holds the sum of filtered output values. The 17 most significant bits hold the integer part, and the 15 least significant ones the fractional part of the integration value. The control of the integration sum and update of this register is determined by the register DECFILTER_MXCR (see *Section 40.3.2.3: Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)*). The register is updated only upon an integration output request. SUM_VALUE should be taken as an unsigned number when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0), and a two's complement signed number otherwise. **Note:** If the DEFILTER_MXCR bit SSAT=1, the integration sum is saturated, so that if the accumulation overflows DECFILTER_FINTVAL holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). If SSAT=0, DECFILTER_FINTVAL holds the integration sum modulo 2^{17} (considering the 15-bit fractional part).

40.3.2.11 Decimation Filter Final Integration Count Value register (DECFILTER_FINTCNT)

Field	Description
0:31 COUNT	Integration Count Value The COUNT field holds the count of filtered outputs integrated. The value is updated only when register DECFILTER_CINTVAL is read, to keep the coherency between the integration and count values.

40.3.3 Decimation filter memory map for parallel side interfaces

The Decimation Filter exchanges data with the master blocks through the two PSI (PSI0 and PSI1). The master blocks send data to the input buffer and reads data from the output buffer of the filter. To implement this exchange, only a single register is required as described in *Table 683*, therefore the PSI addresses are ignored.

Table 683. Parallel side interface memory map for decfilter data exchange

Decimation Filter Address	Description	Access
0x0	DECFILTER_IOB - Decimation Filter(1) input/output Registers	R/W

1. The input registers are addressed for write only and output registers are addressed for read only.

40.3.4 PSI register description

This register is defined as 24-bit.

40.3.4.1 Decimation Filter Input/Output Buffers register (DECFILTER_IOB)

The Input/Output Buffers Register is used by the PSI master block to access the Input and Output buffers of the decimation filter. Writes to this register are interpreted as requests to the Decimation Filter to process new sample data or to bypass timestamp data. Reads from this register frees the decimation filter output buffer from filtered data or from bypass timestamp data.

Address: PSI_BASE + 0x0000

Access: User read/write

Figure 569. Decimation Filter Interface Input/Output Buffers register (DECFILTER_IOB)

Table 684. DECFILTER_IOB field descriptions

Field	Description
0 M_FLUSH	Master block Flush request/control bit Assertion of the M_FLUSH bit initializes the Decimation Filter to a initial state, as defined in *Section 40.4.9: Flush command description*. The sample or timestamp data written with a flush request in the same IOB register write is processed normally after the flush. 0 no flush request 1 flush request
1:2 M_CTRL[1:0]	Decimation Filter mode control bits The values below define the M_CTRL[1:0] field functions. This field is used for control of the Decimation Filter. 00 PREFILL: A pre-fill indicates to the Decimation Filter to accept INP_BUFF[15:0] as valid data but no decimated samples are generated out of these master samples. The pre-fill function is used to initialize and stabilize the Decimation Filter without generating decimated samples. 01 CONVERSION RESULT: A conversion result indicates that the INP_BUFF[15:0] field is data to be treated as valid sample data and it is considered for decimation counting and output buffer update. 10 TIMESTAMP: A timestamp indicates that the INP_BUFF[15:0] field has data that bypasses the flow in the decimation filter logic, returning back to the master block without any modification when: – the previous accompanying data is not for pre-fill, and – when the previous accompanying input data is generating decimated filter output. Also, bit M_FLUSH is always 0 for timestamp data type. 11 Reserved
3 RPSI	Return Parallel Side Interface The RPSI bit is used in the module that has two PSI interfaces (PSI0 and PSI1) which can be connected to two master blocks. It specifies if the data received from one PSI should be transmitted to the same PSI connected to this master block or to the other one. For more details refer to *Section 40.4.17: Return PSI (RPSI) and PSI Output Selector (PSIOSEL)*. 0 Results from this input sample must be transmitted back using the same PSI (master block). 1 Results from this input sample must be transmitted to the other PSI (master block).

Table 684. DECFILTER_IOB field descriptions (continued)

Field	Description
4:7 INP_TAG[3:0]/ OUT_TAG[3:0]	Decimation filter input tag bits The INP_TAG[3:0] field indicates the destination associated with the INPBUFF[15:0] sample. This value is stored by the Decimation Filter and used to address the destination register when a decimated sample is available to be read by the master block. Since several input data samples can be received before a decimated result is generated, the INP_TAG[3:0] used for the decimated sample corresponds to the latest INP_TAG[3:0] received. Therefore it is expected that the tag field be constant during the decimation process. Decimation filter output tag bits The OUT_TAG[3:0] bit field is used to address the appropriate destination register in the master block for the accompanying OUTBUF[15:0] data. When this value is updated, it is a copy of the INP_TAG[3:0] value that was received with the last processed input data.
8:23 INP_BUFF[15:0]/ OUT_BUFF[15:0]	INP_BUFF[15:0]: Input Buffer Data The INP_BUFF[15:0] bit field is the data input from the master block. The input register can be written with this data when ISEL=0. This data can be timestamp information that is not processed by the filter, or sample data that is processed by the digital filter. In this case, the information is a signed signal in two's complement format. OUT_BUFF[15:0]: Output Buffer Data The OUT_BUFF[15:0] bit field corresponds to the data result of the decimation filter that has been processed to the master block. This data can be timestamp information or a digital filter result. In this case, the information is a signed signal in two's complement format.

40.4 Functional description

40.4.1 Overview

Figure 555 shows the block diagram of the Decimation Filter. The control logic provides the control signals for all other sub-modules. The PSI data interface is sub-divided into two sub-modules, transmitter and receiver, that are accessed by two PSI slave-bus interfaces. The bypass path is used when the filter is disabled and the incoming data can be transmitted back to the master block without being processed by the Filter algorithm. The Filter hardware is implemented in such a way that an IIR (1 x 4 poles) or FIR filter type can be implemented. The selection between the two types of filter algorithms is implemented by the Control Logic sub-block.

The Coefficient register file provides the digital filter coefficients. This block is a register bank with read/write access by the device slave-bus interface. The Filter TAP registers are also accessed through the device slave-bus line interface, providing additional debug capabilities to the Decimation Filter block. The MAC (Multiply Accumulate) sub-block executes the filter arithmetic operations controlled by the Control Logic. The MAC results are routed to the Filter TAP registers and to the output buffer when the result is a decimated filter sample.

40.4.2 Parallel Side Interface (PSI) sub-block description

This section describes the operation of the Parallel Side Interface (PSI) sub-block which is responsible for communication and data exchange between two master blocks (for instance, two eQADC blocks) and the Decimation Filter block. It is important to note that there are two

PSI lines (PSI0 and PSI1) but there are only one internal input buffer and only one internal output buffer.

The decimation filter receives sample data from up to two master blocks. The input data bus format is the same for both buses and are presented in *Figure 569*. The sample data arrives along with the control bits. These control bits are decoded and the proper action is decided in the Control Logic sub-block. When the decimation filter finishes its processing and a result is available, the read request signal is issued to the selected master block. This data transfer request remains set until the result is read by the master block.

When using two or more decimation filter blocks in the device, the output of the second block is connected to the input data of the next block, and the output of the first block is connected to the read data input of the corresponding PSI master block.

40.4.3 Input buffer description

The decimation filter receives data samples for filtering from two master blocks (for instance two eQADCs) using the dual PSI interface, or from the CPU using the device slave-bus interface. The data source is selected by the ISEL bit of the module configuration register DECFILTER_MCR. When ISEL selects the PSI interfaces, the user can send data from any of the two master blocks because both are enabled. However, it is necessary to consider the characteristics of the PSI interface itself as described below.

When the device slave-bus interface is selected and DMA operation is chosen (DECFILTER_MCR bit DSEL=1), the input data request signal is asserted when the input buffer is empty. When DMA operation is not chosen (DSEL=0) in standalone or PSI output mixed modes, the logic asserts an input interrupt request and the input buffer waits for data from the device slave-bus.

Input buffer filling is flagged by the DECFILTER_MSR bit IDF. The IDF flag remains set, even after the input data has been consumed and the buffer is free, until it is cleared by software.

Input buffer overrun is detected and flagged by the DECFILTER_MSR bit IVR. The idle (BSY=0) Decimation Filter is able to receive two consecutive input writes without input overrun. For more details, see *Section 40.4.3.1: Input buffer overrun*.

Note: There is no buffer / control to separate or select data from each PSI interface. The user should know which PSI is being served by the filter module to avoid undesired overrun caused by the two PSI inputs.

When the selected input source is any PSI master block, the PSI master may send timestamp data after related sample data for filtering. The timestamp is sent back to the PSI following the respective filter output, using the same request mechanism. As the decimation filter takes several clock cycles to process a sample, the timestamp is copied into an internal timestamp register until the filtered output is sent out, therefore freeing the input buffer for yet another sample data.

When the input buffer is loaded with a sample data coming from any PSI interface and enhanced debug monitor is enabled (DECFILTER_MCR bits ISEL=0, EDME=1), input DMA or interrupt requests are asserted so that the PSI input samples can be monitored from the device slave-bus interface. These interrupt sor DMA requests result in input read accesses from the DECFILTER_IB register and the DECFILTER_EDID needs to be read by CPU polling to allow DECFILTER_IB to be processed by the DMA. On the opposite, write accesses are needed when the same requests are made and the device slave-bus interface

is selected for input (ISEL=1). Only the sample data input (not timestamps), can be monitored in this way. See also *Section 40.4.14: Enhanced Debug Monitor Description*.

Soft reset clears the input buffer indication flags and any data write/read request that was generated in any mode.

40.4.3.1 Input buffer overrun

An input overrun occurs when the input buffer is holding input data and new data is received by the filter. See *Section 40.4.3: Input buffer description*, for details of the input buffer.

The input buffer overrun can occur only when the input is enabled (DECFILTER_MCR bit IDIS=0), and in the following cases:

- When the input buffer has sample data to be processed but the filter is busy and another input (data or timestamp) is received.
- When the input buffer has a timestamp, the internal timestamp register is loaded and the next input data is received.
- When the two PSI interfaces try to write the input buffer at the same time.

As an example of the input data sequence, assume that the filter is enabled and not busy, and all registers are empty. Then a word of sample data is received followed by a timestamp and another word of sample data. No input overrun occurs in this case, because the first sample is immediately transferred to the tap input register, the timestamp is immediately transferred to the internal timestamp storage register, and the second sample can be held in the input buffer until the end of the processing of the sample data by the filter. The input overrun may occur if more input is received before the end of the processing, or if the filter is busy at the beginning of the received sequence.

When the filter is in bypass/disable mode (DECFILTER_MCR field FTYPE=00), the data from the input buffer is transferred to the output buffer, if it is not already full. If the output buffer is full, the input buffer is loaded, and another word of input data is sent, then an input overrun occurs.

Note: Configuring ISEL=1, MIXM=1 and FTYPE=00 (bypass), writes to the DECFILTER_IB are routed directly to the PSI output.

40.4.4 Output buffer description

The decimation filter has an output buffer to send filtering results to a master block using any PSI, or to the CPU using the device slave-bus, as selected through the DECFILTER_MCR bits ISEL and MIXM bits.

Note: There is only one output buffer to serve the two PSI outputs. The PSI output selection is controlled by the PSI input field RPSI or by the bit field PSIOSEL in the DEC_FILTER_IB register.

Filtering of pre-fill inputs do not update the output buffer, so the flag ODF is not set.

When filter types IIR and FIR are selected and the input source is any PSI master block (normal or PSI input mixed modes), the output buffer receives data from the MAC sub-block or from the timestamp storage register. The result from the MAC is written immediately after the processing if the decimation is enabled. However, the timestamp data is enabled to be written in the output buffer only when the output buffer is empty, the decimation count is reached, and the corresponding data was also ready to be transmitted. When a new word of data is available in the output buffer, a read request signal is sent to a master block. The master block has to send the corresponding read commands to clear the read request

signal. In this configuration, the core can always read the output buffer. The flag ODF is set when the buffer is updated.

When in filter operation mode with input from the device slave-bus (ISEL=1), only sample data is processed by the filter, as there is no way to input timestamps. When the filter result from the MAC is ready, this is immediately written to the output buffer when the decimation count is reached. The flag ODF is set when the buffer is updated. It also generates a DMA read request if DSEL=1 in standalone or PSI input mixed modes.

When the filter is bypassed (FTYPE=00), and a PSI is selected as output (normal mode or PSI output mixed mode), the data written into the input buffer waits until the output buffer is empty before passing the data. This is needed because the master block takes some clock cycles to send the read commands to the decimation filter after the read request signal is asserted. When the filter is bypassed and the device slave-bus is selected as output (standalone mode or PSI input mixed mode), the data written into the input buffer is immediately written into the output buffer. The flag ODF is set when the buffer is updated and a DMA read request is asserted if DSEL=1.

Soft reset clears the output buffer, as well as any data read request generated in any mode.

40.4.4.1 Output buffer overrun

An output overrun occurs when the output buffer is holding output data (sample or timestamp) that has not been read is overwritten with another word of data (sample or timestamp).

Output overruns are flagged by the DECFILTER_MSR bit OVR, if the output buffer is updated when not empty. The output buffer empty condition depends on the mode and output selection as follows:

- if PSI0 or PSI1 is selected as output (normal mode or PSI output mixed mode), the output buffer is considered empty when the last output has been read.
- if cascade mode is selected, the output buffer is considered empty if the last output request was acknowledged.
- if the device slave-bus is selected (standalone or PSI input mixed mode) for output and DMA is selected (DSEL=1), the output buffer is considered empty if the last output has been read.
- if the device slave-bus is selected (standalone or PSI input mixed mode) for output and DMA is not selected (DSEL=0), the output buffer is considered empty when the ODF flag is negated.

Note: When the device slave-bus is selected (standalone or PSI input mixed *mode) for output and DMA is not selected (DSEL=0), the ODF flag must be cleared to avoid overrun, even if its corresponding interrupt is not used (ODEN=0).*

Note: The normal use is to receive the data stream from one specific PSI and transmit the results using one specific PSI. Input and output timing care are necessary to avoid output overrun when output results are sent to both PSI alternately.

Pre-fill inputs do not cause IIR or FIR output overrun in standalone, normal, and cascade tail modes, but can cause overruns in cascade head or middle configurations (see *Section 40.1.3.5: Cascade mode*).

When bypass is selected, the output overrun does not occur because the data written into the input buffer is written into the output buffer only when this buffer is empty, but an input overrun may still occur (see *Section 40.4.3.1: Input buffer overrun*).

40.4.4.2 Triggered output result description

The posting of a filter output, either to a PSI interface or to the device slave-bus can be controlled by an additional input trigger signal (see *Section 40.2.1: Decimation trigger signal*). It allows the decimation to be controlled by another circuit, instead of the internal decimation counter.

Triggered output operation is enabled by the bit TORE in the configuration register DECFILTER_MCR. When triggered output is enabled, the decimation count configured by DECFILTER_MCR field DEC_COUNTER is ignored. The decimation filter detects the rising edge or the falling edge of the trigger signal as selected by the configuration field TMODE in the DECFILTER_MCR register. When the corresponding edge is detected, the output buffer is enabled to receive the next filter result. This means if a filtering process is occurring, the output buffer read request is only set when the filtering ends and a new result is available.

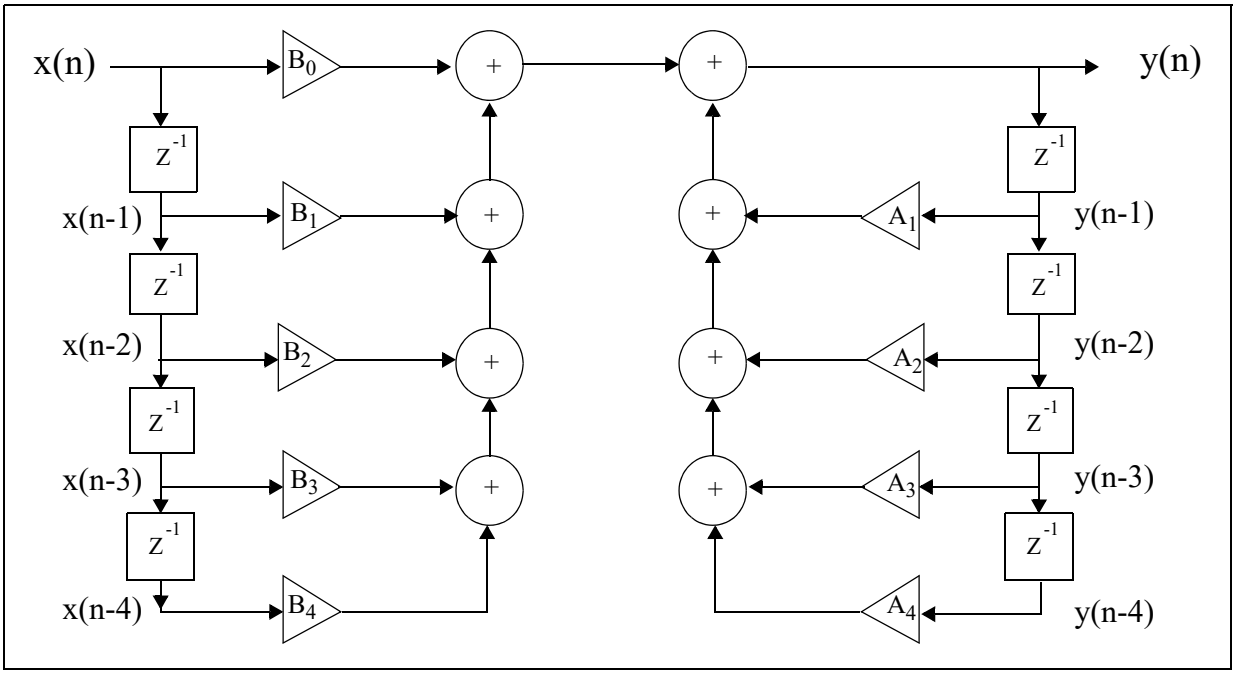
Note: This mode is not affected by the pre-fill sample indication then a result is pulled into the output buffer when TORE is enabled and a trigger is detected. Therefore, the initialization phase of the digital filter need to be controlled by the timing of asserting the TORE bit or by discarding the initial sampled results.

Note: The time interval between two consecutive trigger events should be greater than 60 clock cycles. This is necessary to avoid possible trigger overruns.

The input trigger signal can also be used as a simple filtered output enable: in this trigger mode, when the input trigger signal is asserted, every filtered output is posted to the output buffer; no output is posted when the signal is negated. This trigger mode and the assertion polarity (active 0 or 1) of the input trigger signal is also defined in the DECFILTER_MCR field TMODE.

40.4.5 Bypass configuration description

Bypass operation is configured by setting the field FTYPE[1:0] of module configuration register DECFILTER_MCR to 00. In this case, the input sample and tag are sent to the output with no change. This behavior is independent of the ISEL/MIXM setting. The following applies to the bypass configuration:



- Flush is ignored
- Pre-fill is ignored
- Trigger or Counted decimation is ignored
- BSY bit is not set
- The input and output flags are set

Note: Bypass must not be configured in cascade mode (see Section 40.4.16: Cascade mode description).

40.4.6 IIR and FIR Filter

This section describes the IIR filters implemented in the Decimation Filter block. *Figure 570* shows the filters functional diagrams. The figure shows a IIR filter of fourth order (4poles). The filter topology, not the hardware, is represented. The hardware implementation is based on a MAC unit controlled by an FSM which implements the filter algorithm.

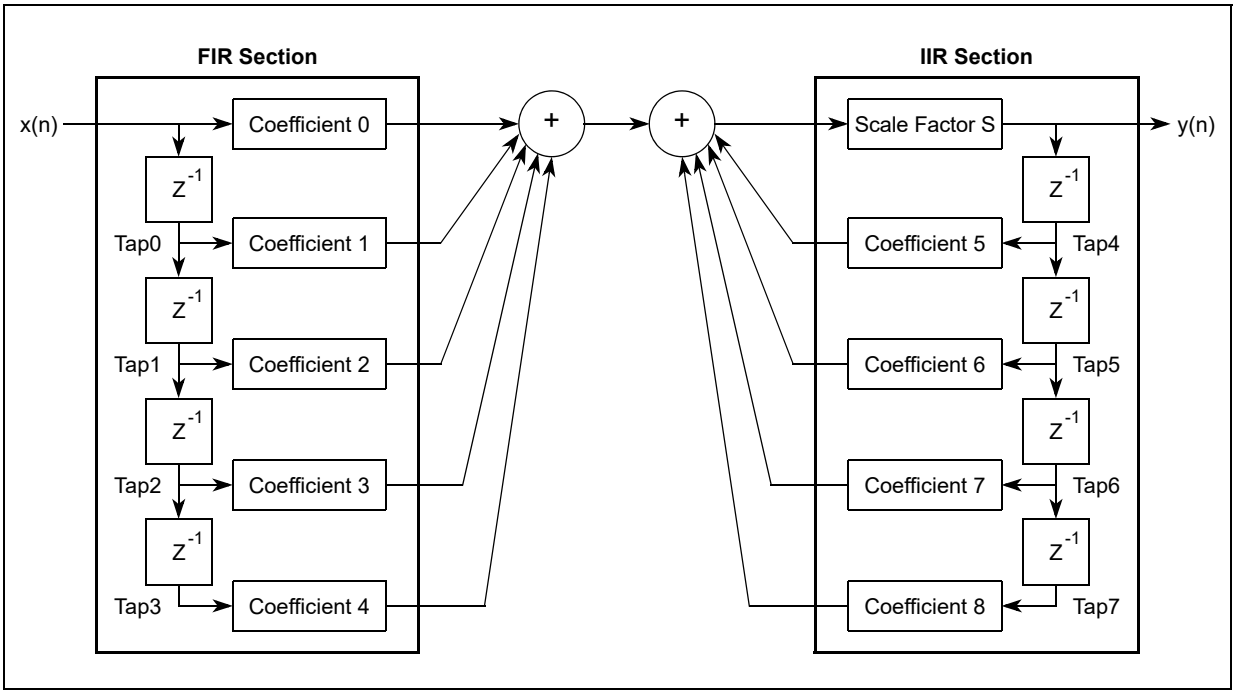
Figure 570. 1 x 4 Poles IIR Filter Functional Diagram

The difference equation for the IIR filter of *Figure 570* can be written as:

Equation 24

$$y(n) = \sum_{i=0}^{N} B_i x(n-i) + \sum_{j=1}^{M} A_j y(n-j)$$

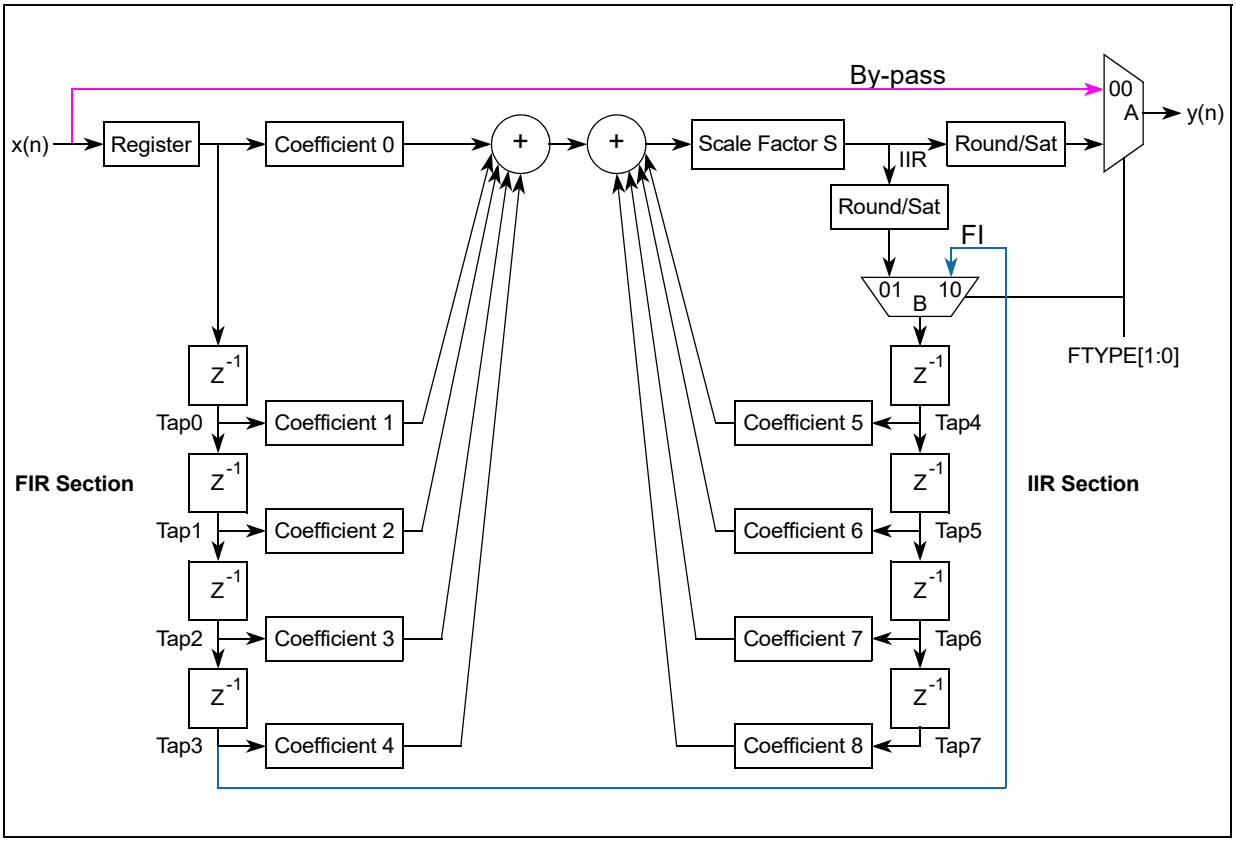
where *x(n)* is the filter input at time *n, y(n)* is the filter output at time *n*, *N* is the number of feed-forward filter coefficients minus one, B_i are the feed-forward filter coefficients, *M* is the number of feed-back filter coefficients, and A_j are the feedback filter coefficients.



Equation 24 can be written as:

Equation 25

$$y(n) = S\left\{ \sum_{i=0}^{N} \frac{B_i}{S} x(n-i) + \sum_{j=1}^{M} \frac{A_j}{S} y(n-j) \right\}$$

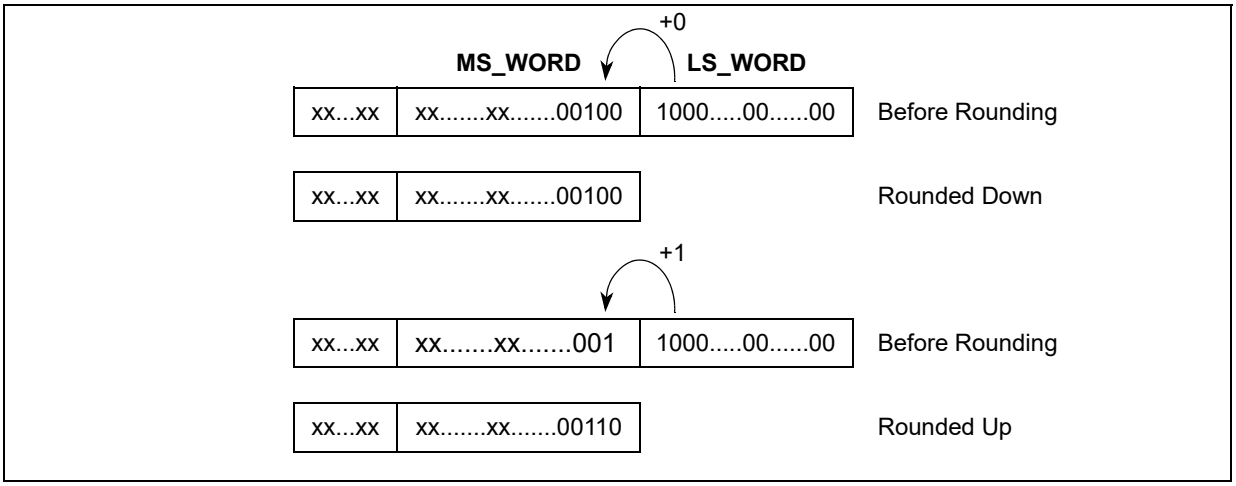


Where all the coefficients are scaled down by S. The block diagram for *Equation 25* is shown in *Figure 571* in a fourth-order IIR filter implementation where the coefficients A_j and B_i are called *coefficient n*, where *n*=0-8.

Figure 571. Fourth Order IIR Filter Implementation Block Diagram

The fourth order IIR filter is implemented with a FIR section followed by an IIR section. If the FIR type filter mode is selected, the IIR section is converted into an FIR section. In this case the order of the FIR filter is twice the IIR filter order, since all the TAP and coefficient registers are allocated for the FIR section. The Filter configuration paths are shown in *Figure 572*. Multiplexer A controls the *bypass* filter path and multiplexer B controls/selects the filter mode of operation, to either IIR mode or FIR mode. The selection is controlled by the FTYPE[1:0] bits in the Filter Module Configuration register. The order of the filter can be controlled by setting the appropriate *filter coefficients* to *zero.*

Figure 572. Filter Configuration Paths (FIR or 1x4Poles IIR)



40.4.6.1 Rounding

The Decimation Filter performs rounding operations in two different locations, as shown in *Figure 572*:

- to obtain the filter output result with 16 bits
- to obtain the IIR feedback result to be stored in tap4 registers with 24 bits

The rounding mechanism implements the Convergent Rounding methodology (also known as round-to-nearest even number), which makes the decision on rounding up or down based on the value of the lower portion of data to be rounded (LS_WORD). The rounding up/down condition is equal to the traditional rounding except when the LS_WORD has the format {1000...00}. In this particular case, the rounding procedure is like the example of *Figure 573*. If the MS_WORD is odd, the value is rounded up. Otherwise the value is rounded down.

Figure 573. Convergent Rounding Methodology

40.4.6.2 Saturation

Filter output saturation occurs when an overflow or underflow condition of the filter is detected by dedicated logic, and if it is enabled by the SAT control bit of the configuration register DECFILTER_MCR. In this condition, the filter output is set to a saturated value equal to the maximum or minimum value that can be represented by the 16-bit output port. Also, for the IIR filter an equivalent logic is used to assert the saturation for the 24-bit feedback result.

40.4.7 Filter pre-fill control description

A pre-fill indicates that the input data should be accepted by the Decimation Filter, but no decimated output should be generated while the control field indicates pre-fill. Therefore the pre-fill function is used in the beginning of the filter operation to initialize and stabilize the Decimation Filter without generating decimated samples. In addition, the pre-fill does not operate when the filter is in bypass (FTYPE=0b00).

The pre-fill is controlled by the value in the M_CTRL[1:0] field in the DECFILTER_IOB register. When ISEL=0, the M_CTRL[1:0] field in the DECFILTER_IOB register controls the pre-fill. When ISEL=1, it is controlled by the PREFILL field in the DECFILTER_IB register. The pre-fill control is usually activated only in a certain number of words of sample data in the beginning of the input data sequence.

When the pre-fill control is set, the decimation filter block operates as follows:

- Input data is processed normally by the digital filter and tap values are updated.
- The decimation counter is maintained in reset value.
- The output buffer is not updated and no output interrupt or read request is generated.
- The accompanying timestamp for the identified pre-fill conversion data is not bypassed.
- The overflow detector/flag operates normally and the error interrupt request is set if enabled.

In Cascade Mode, pre-fill control is ignored in all cascaded filters except the Tail one: the pre-fill samples are filtered, decimated and forwarded to the next block with the pre-fill indication. The Tail block takes the samples with pre-fill indication, filter them and discard the result.

Note: The combined decimation count of the cascade combo may not be reset after the last pre-fill sample. Unlike in a single (non-cascaded) filter, the number of non-pre-fill inputs until an output comes out depends on the number of past pre-fill inputs.

40.4.8 Timestamp data transmission

The timestamp information is identified by the master block using the M_CTRL[1:0] bit field of the register DECFILTER_IOB. For timestamp data, the input data and tag values that come with M_CTRL[1:0] bits set to 0b10 are sent back to the master block without changing. However, some additional conditions are considered:

- The timestamp is additional information that accompanies a sample conversion data. The PSI master block sends the decimation filter the conversion data with control bits for either pre-fill or filter operation. This data may optionally be followed by the corresponding timestamp data. When the corresponding conversion data is marked for pre-fill, the timestamp data is not sent to the output buffer. This occurs because the filter result is not sent to the output buffer.
- Similarly, when the filter is decimating the results, the timestamp is only sent to the output buffer if the corresponding received conversion data has generated a filter output that is selected by the decimation counter to be sent to the output buffer. Other received timestamps that come with data not selected by the decimator are discarded.
- Sending two consecutive words of timestamp data is not allowed: there must be at least one conversion data between two timestamp inputs. In normal operation, the filter should receive only one timestamp for each word of conversion data to be filtered.
- Timestamps are not allowed in PSI Input Mixed Mode.
- When both PSI are sending data / timestamp to the same decimation filter, the user should control the timing between the two PSIs to avoid loss of information and erroneous mixing of data and timestamp.

40.4.9 Flush command description

The flush signal is used by the Decimation Filter to execute a partial reset of the filter. This is useful when the same filter is used on a new set of data samples after finishing the filtering of another set of data.

When the flush control is detected, all filter TAPs are cleared and the DEC_COUNTER[3:0] field in the status register DECFILTER_MSR is reset.

The flush function does not clear the Coefficient registers file in the Decimation Filter, thus it is not required to re-write these registers after a flush. The integrator accumulator and sample count are not cleared either. The output buffer also keeps the last result and may be retrieved until the next output is posted.

The flush control precedes the input data to be filtered. Therefore, the corresponding sample data is processed by the block after the flush. When ISEL=0, the field M_FLUSH in the DECFILTER_IOB register is processed. When ISEL=1, the field FLUSH in the DECFILTER_IB register is processed. Note that a word of valid sample data can be available at the same time the flush signal is asserted. In this case the flush is executed and the sample is processed after the flush.

When ISEL=0, flush bit M_FLUSH must not be asserted when the input data is a timestamp (M_CTRL=10).

When the filter is disabled by the FTYPE[1:0] control bit field, the flush command is not executed.

Note: In Cascade Mode, the flush command is forwarded to the next cascaded block together with the output, after the decimation count. Therefore it is possible that, in a given moment, the taps of a cascaded block are zeroed after a flush input, while the following ones still retain the old values.

40.4.10 Soft reset command description

The soft reset command is requested through the self-negated bit SRES of the DECFILTER_MCR register and provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. The procedure below must be performed for a software reset when the filter is active:

1. Disable filter inputs, writing DECFIL_MCR bit IDIS = 1.
2. Poll the register DECFIL_MSR until the bit BSY is 0.
3. Repeat the step 2 polling; this is necessary to cover the case when a sample is left in the input buffer.
4. Write DECFILTER_MCR bit SRES = 1.

After the software reset is issued, all internal Filter TAP registers, the decimation counter, the integrator outputs (except DECFILTER_CINTCNT) and the state machine are put in the initial state. The status register DECFILTER_MSR is also cleared. The Coefficient registers are not affected by the SRES. In case there is some filter processing, the filter process is aborted and the last sample is discarded. In addition, data in the input buffer waiting to be processed, and data in the output buffer waiting to be read, are discarded (the requests of service are cleared). The software reset command has high priority and the BSY bit is set during its operation.

The configuration registers DECFILTER_MXCR and DECFILTER_MCR are also not affected by a soft reset, except the bit SRES that is self-negated and is always read as zero.

When in debug or freeze mode, the soft reset is executed but the filter remains in debug or freeze mode.

Note: It is recommended to clear the IBIE bit before a software reset, especially if ISEL changes, in order to avoid unwanted interrupt requests.

DMA transfers must not be active during soft reset. Data loss can occur.

40.4.11 Interrupts requests description

40.4.11.1 Block interrupt request

There are several interrupt request events that can be enabled using the module configuration register DECFILTER_MCR. Basically, the interrupt request can be issued under any of the following conditions:

- when a word of input data is received.
- when a word of output data is available.
- when an error has occurred.

The input data flag IDF is set when a word of data is received from the CPU when in standalone mode, or when a word of data is received from any PSI when it is not in standalone mode (normal mode). It is not used to generate the read or write requests (as defined in *Section 40.4.11.2: Input buffer interrupt request*) when DSEL=0.

Output data is available and its flag (ODF) is set when the input data sample is processed by the filter and the decimation counter matches the decimation rate value. It is not used to generate the read requests (as defined in *Section 40.4.11.3: Output buffer interrupt request*) when DSEL=0.

An error event in the decimation filter block is defined as one of these events:

- Overflow in the filter, flagged by OVF
- Overrun in the decimation filter input, flagged by IVR
- Overrun in the decimation filter output, flagged by OVR
- Overrun in enhanced debug monitor, flagged by DIVR
- Integrator overrun, flagged by SVR
- Integrator value exception, flagged by SSE
- Integrator count exception, flagged by SCE

An overflow occurs when the two's-complement result value from the MAC accumulator is out of the range of values that can be stored in tap register 4 (IIR) or in the output register.

An input overrun occurs when the input buffer is holding a word of input data and one more word of data is received by the filter. See *Section 40.4.3.1: Input buffer overrun*, for more details.

An output overrun occurs when a new word of data is sent to the output buffer but the previous word of data has not been handled yet. See *Section 40.4.4.1: Output buffer overrun*, for more details.

These flags can be set by the PSI events, however they are only cleared by:

- The CPU, or
- By the soft reset command in the DEC_FILTER_MCR, or
- By the clear flag registers in the DEC_FILTER_MSR register.

40.4.11.2 Input buffer interrupt request

This interrupt is enabled by the register IBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is flagged in the DECFILTER_MSR by field IBIF.

In standalone and PSI output mixed mode, the input buffer interrupt request is asserted when the input buffer is available to receive a conversion sample and DMA operation is not selected (DSEL=0), meaning the block is requesting data to be written into the input buffer. The interrupt request is cleared when the CPU writes a one in field IBIC of the DECFILTER_MSR register, or by the soft reset command.

When in normal, cascade or PSI input mixed modes with enhanced debug enabled (ISEL=0 and EDME=1, DSEL=0), the input sample data can be read by the CPU when this interrupt request is asserted. The interrupt is asserted just when a new word of sample data is supplied to the filter sub-block to be processed. As this filter register is overwritten by the next word of sample data, an input read overrun event can occur (the DIVR bit in DECFILTER_MSR register is asserted) if the interrupt request is not cleared before, or at the same time as, the new sample arrives to set the interrupt. This DIVR bit is cleared by the DIVRC bit in the status register DECFILTER_MSR. However, in enhanced debug monitoring, the set condition has higher priority than the clear. This means that if the set condition and the clear bit IBIC occur at the same time, the interrupt remains asserted.

40.4.11.3 Output buffer interrupt request

This interrupt is enabled by the register OBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is also indicated in the field OBIF of the DECFILTER_MSR register.

When in standalone mode, the output buffer can be read by the CPU with the DMA disabled. The output buffer interrupt request is asserted when the output buffer receives a new result from the filter sub-block. This means the block is requesting data to be read by the CPU.

The output buffer interrupt request can also be asserted due to an integrator result being ready, as flagged by the DECFILTER_MXSR bit SDF, when the DECFILTER_MCR bit SDIE=1. Note that both the filter output and integrator share the same interrupt source.

This interrupt request is cleared when a one is written in the bit OBIC or bit SDFC (or both) of the DECFILTER_MXSR register, or by the soft reset command.

40.4.12 DMA requests description

The DMA function for input and output buffers is enabled using DSEL=1 in the DECFILTER_MCR register. The DMA function for integrator result is described in another section.

40.4.12.1 Input buffer DMA request

This DMA request is enabled by the ISEL and DSEL bits in the DECFILTER_MCR register.

When in standalone mode (ISEL=1), the input buffer can be written by the DMA. The input buffer DMA request is asserted when the input buffer is available to receive a conversion sample (it is not holding a word of data). This DMA request is cleared when an input data word is written in the input buffer. Therefore, the DMA request is always cleared before it is asserted again.

When in normal mode with enhanced debug enabled (EDME=1 and DSEL=1), the input sample data can be read by the DMA when this DMA request is asserted. The request is asserted when a new word of sample data is written into the input buffer to be processed. As this filter register is overwritten by the next word of sample data, a DMA read overrun event can occur (the DIVR bit in DECFILTER_MSR register is asserted) if the DMA request is not cleared before, or at the same time as, a new sample arrives to set the DMA request. This DIVR bit is cleared by the DIVRC bit in the status register DECFILTER_MSR or by soft reset.

This DMA request is cleared when the DMA transfer is complete or by soft reset.

40.4.12.2 Output buffer DMA request

This DMA request is enabled by the ISEL, MIXM and DSEL bits in the DECFILTER_MCR register.

When in standalone mode, the output buffer can be read using the DMA. The output buffer DMA request is asserted when the output buffer receives a new result from the internal filter sub-block. This DMA request is cleared when the output buffer is read by the processor.

The output buffer DMA request is also asserted when an integrator output is ready, if DECFILTER_MXCR bit SDMAE=1 and the filter output is directed to a PSI interface (ISEL=MIXM).

The DMA request is also cleared by soft reset.

40.4.13 Freeze mode description

The freeze mode operation is asserted using the FREN enable bit and FRZ bit in the DEC_FILTER_MCR register or by the modules debug input.

It is not possible to enter freeze mode when the module is disabled by the configuration bit MDIS.

In case of a freeze mode request during the processing of an input sample, the current processing is finished and then the module enters freeze mode.

Access to input and output buffers remain operational in freeze, as well as their related flags.

Note: For cascaded blocks (see Section 40.4.16: Cascade mode description), it is recommended to freeze only the Head block. If it is really necessary to freeze all the blocks, it is recommended that they are frozen sequentially starting from the Head block towards the Tail one. Unfreezing is recommended to be done sequentially from the Tail block towards the Head one.

40.4.14 Enhanced Debug Monitor Description

This feature is enabled by the EDME bit in the configuration register DECFILTER_MCR. The monitoring operation works either in normal or cascade modes, when the sample data is supplied by a master block through the PSI slave-bus interfaces (ISEL=0) or another cascaded block (see *Section 40.4.16: Cascade mode description*). The Enhanced Debug Monitor feature makes the input sample data also available in the DECFILTER_EDID register. A DMA or interrupt request (selected by DSEL) indicates a new input was fed and DECFILTER_EDID was updated. The input is processed normally by the filter.

An Enhanced Debug Input Data Register (DECFILTER_EDID) overrun can occur if a sample is not read by the CPU or DMA before overwritten by a new sample. The overrun is indicated in a separate flag DIVR in the status register DECFILTER_MSR. If the ERREN bit is set in the DECFILTER_MCR configuration register, this overrun asserts the module interrupt request.

40.4.15 Integrator

The hardware sample integrator accumulates the filter output values for determined periods.

40.4.15.1 Integrator inputs

The integrator can be fed either by raw or decimated filter outputs, selected by the DECFILTER_MXCR bit SISEL (see *Section 40.3.2.3: Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)*). The accumulated input value taken can be the filtered sample “as is” (signaled), or its absolute value, depending on the DECFILTER_MXCR register bit SSIG.

Note: The integrator accumulates input samples when bypass is selected.

40.4.15.2 Integrator outputs

The integrator output is either:

- the 32-bit, fixed point unsigned accumulation of the absolute values from the filter output, when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0). This resolution allows a minimum of 131071 samples to be integrated before an overflow occurs in absolute operation, or 65536 samples in signed operation.
- the 32-bit, fixed point signed two's complement accumulation of the signed values from the filter output, when the integrator is configured for signed operation (SSIG=1).

The fractional part of the accumulation is 15 bits wide in both cases.

An accumulation overflow is flagged by the DECFILTER_MXSR bit SSOVF. The accumulator can overflow in either of the ways below, selected through the DECFILTER_MXCR bit SSAT:

- Saturated accumulation (SSAT=1), so that an overflow results in the value of 0xFFFFFFFF for absolute value accumulation (SSIG=0), or 0x7FFFFFFF (positive) and 0x80000000 (negative) for signaled accumulation (SSIG=1).
- Non-saturated accumulation (SSAT=0), so that an overflow results in the modulo 2^{17} accumulation value. This operation is only allowed in absolute accumulation (SSIG=0).

The integrator output value becomes available in register DECFILTER_FINTVAL (see *Section 40.3.2.10: Decimation Filter Final Integration Value register (DECFILTER_FINTVAL)*) when an integrator output request is issued. The integrator output request can be issued in the following ways:

- By hardware, controlled by an external signal; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR field SRQSEL (see *Section 40.3.2.3: Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)*);
- By software, writing 1 to the DECFILTER_MXCR bit SRQ;

The SSOVF flag is asserted upon an integrator output request, based on the overflow state of the internal accumulator. This internal overflow state is cleared upon an output request, just after SSOVF is asserted, or upon an integrator reset (see *Section 40.4.15.3: Integrator reset*). The internal overflow state is also cleared by writing SSOVFC to 1, but only in saturated accumulation. Therefore, a non-saturated overflow that occurs before an SSOVF clear is still flagged in the next output request.

The integrator output request also updates the register DECFILTER_FINTCNT, which holds the number of samples accumulated into the register DECFILTER_FINTVAL. This internal accumulated sample counter can operate either in a saturated or "wrapped" count mode, as selected by the DECFILTER_MXCR bit SCSAT. In both cases, the counter overflow is flagged by the DECFILTER_MXSR bit SCOVF.

The SCOVF flag is asserted upon an integrator output request, based on the overflow state of the internal counter. This internal overflow state is negated upon an output request, just after SCOVF is asserted, or upon an integrator reset (see *Section 40.4.15.3: Integrator reset*). The internal overflow state is also negated by writing SCOVFC to 1, but only in saturated count. Therefore, a non-saturated overflow that occurs before an SCOVF clear is still flagged in the next output request.

An integrator output update can also issue a DMA or interrupt request. The interrupt and DMA requests are the same ones used for the filter output buffer (see *Section 40.4.11.3: Output buffer interrupt request* and *Section 40.4.12.2: Output buffer DMA request*). The DECFILTER_MCR bit SDIE is used to enable integrator interrupts, and the

DECFILTER_MXCR bit SDMAE enables the DMA integrator requests. The integrator DMA request uses the same signal as the filter output DMA request, so one must never use any configuration that allows both the integrator and filter output to make DMA requests.

Integrator output updates are flagged by the DECFILTER_MXSR bit SDF. The integrator overrun is detected in the same way as a filter output buffer overrun, and is flagged by DECFILTER_MXSR bit SVR. An integrator overrun also generates an error interrupt if the DECFILTER_MCR bit ERREN=1 (see *Section 40.4.4.1: Output buffer overrun*).

Registers DECFILTER_CINTVAL and DECFILTER_CINTCNT provide a way to poll intermediate integration values and sample counts, respectively (see *Section 40.3.2.12: Decimation Filter Current Integration Value register (DECFILTER_CINTVAL)* and *Section 40.3.2.13: Decimation Filter Current Integration Count Value register (DECFILTER_CINTCNT)*). DECFILTER_CINTVAL is updated whenever the integrator is reset or a new sample is accumulated. DECFILTER_CINTCNT is updated only when DECFILTER_CINTVAL is read, so that coherency between the value and count values is guaranteed. Therefore, the read access order of that pair of registers must be DECFILTER_CINTVAL first, followed by DECFILTER_CINTCNT.

Note: The flags SSOVF and SCOVF can also asserted when DECFILTER_CINTVAL is read. The SSOVF and SCOVF set and clearing rules apply for the DECFILTER_CINTVAL read the same way as for an integrator output request.

40.4.15.3 Integrator reset

The integration value is reset to the value of zero, in the following ways:

- By hardware: on hardware reset, or controlled by an external signal; the enabling and the selection of the zero signal modes is done through the DECFILTER_MXCR field SZROSEL (see *Section 40.3.2.3: Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)*);
- By software: on software reset, or writing 1 to the DECFILTER_MXCR bit SZRO;

The integrator reset also zeros the internal counter of accumulated samples and the internal overflow state (but not SSOVF and SCOVF). Software and hardware reset resets all integrator registers immediately. Integrator zero command from external signal or by software (SZRO) affects the integrator registers and flags as follows:

- DECFILTER_CINTVAL resets immediately;
- DECFILTER_CINTCNT does not reset immediately; it is updated only upon a DECFILTER_CINTVAL read, loaded with the number of integrated samples occurred after the reset;
- DECFILTER_FINTVAL and DECFILTER_FINTCNT do not reset immediately; being updated only upon a new output request (see *Section 40.4.15.2: Integrator outputs*); if a integrator software zero command (through SZRO bit) and an integrator output request (through SRQ bit) are made at the same time, the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT are updated with the last internal values before reset; the same applies to simultaneous integrator zero command and output request by hardware signal;
- the SSOVF and SCOVF flags do not negate; however, the internal overflow states which assert SSOVF and SCOVF do reset immediately, so that the next output update (either by hardware request, software request or DECFILTER_CINTVAL read) before an overflow does not assert SSOVF/SCOVF.

Note: The integrator reset does not depend on the integrator enabling (see Section 40.4.15.4: Integrator enabling and halting).

40.4.15.4 Integrator enabling and halting

Two mechanisms, enabling and halting, drive the integrator accumulation, allowing it to be controlled by a combination of two distinct sources: both software, both hardware, or one hardware and the other software. Values are accumulated when the integrator is enabled and not halted. The integrator halt and enable states can be controlled in the following ways:

- By hardware, through external signals; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR fields SENSEL and SHLTSEL, respectively (see *Section 40.3.2.3: Decimation Filter Module Extended Configuration Register (DECFILTER_MXCR)*);
- By software, through the same DECFILTER_MXCR fields SENSEL and SHLTSEL. Note that these fields are in different bytes, so that two distinct, concurrent software tasks can avoid coherency problems by changing the fields using byte read-modify-write accesses.

Note: Enabling and halting does not affect output requests or integrator reset.

40.4.15.5 Integrator exceptions

Integrator may run into exception states due to the overflow of either the accumulated value or the sample counter. Exceptions are flagged by the DECFILTER_MXSR bits SSE for sum value exception, and SCE for counter exception. These flags generate an error interrupt if it is enabled (see *Section 40.4.11.1: Block interrupt request*).

The accumulator exception condition depends on whether or not it operates in saturated mode as follows:

- In Saturated operation (DECFILTER_MXCR bit SSAT=1): a sum exception occurs (SSE=1) whenever an overflow is flagged; SSE asserts together with SSOVF.
- In Non-saturated operation (DECFILTER_MXCR bit SSAT=0): a sum exception occurs (SSE=1) when an overflow is flagged and the DECFILTER_MXSR bit SSOVF is already set to 1.
- In Non-saturated operation, an accumulator exception also occurs if the accumulator overflows twice without any update of the final integrator value DECFILTER_FINTVAL or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integrator reset occurs. The SSOVF flag does not assert in this situation.

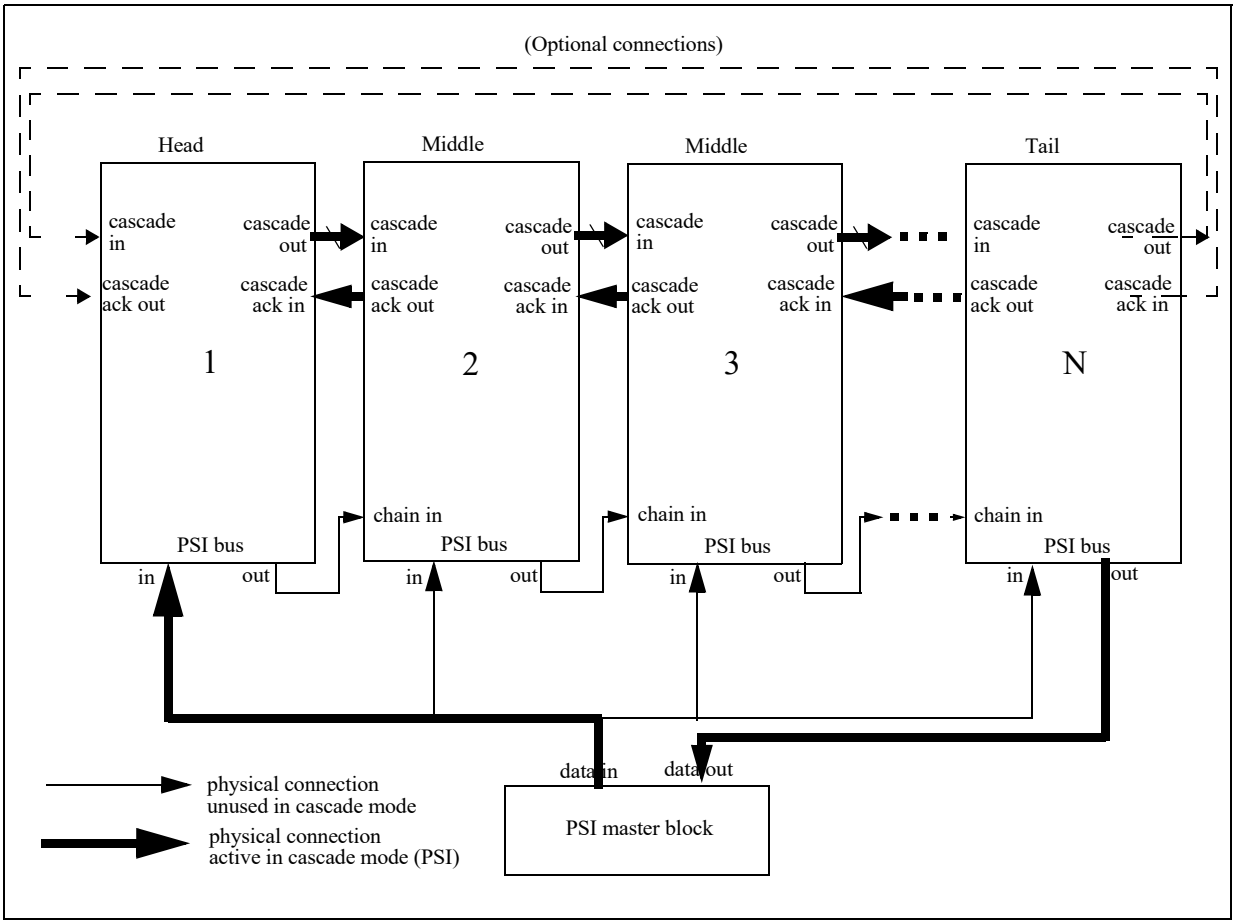
Note: The SSOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read, based on the internal accumulator overflow state.

Similarly, the sample counter exception condition depends on whether or not it operates in saturated mode as follows:

- In Saturated operation (DECFILTER_MXCR bit SCSAT=1): a counter exception occurs (SCE=1) whenever an overflow is flagged; SCE asserts together with SCOVF.
- In Non-saturated operation (DECFILTER_MXCR bit SCSAT=0): a counter exception occurs (SCE=1) when an overflow is flagged and the DECFILTER_MXSR bit SCOVF is already set to 1.
- In Non-saturated operation, a counter exception also occurs if the counter overflows twice without any update of the final count DECFILTER_FINTCNT or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integration reset occurs. The SCOVF flag does not assert in this situation.

Note: The SCOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read (also updating DECFILTER_CINTCNT), based on the internal counter overflow state.

40.4.16 Cascade mode description



The cascade mode is defined as a configuration mode of the decimation filter to work together with other ones in a chain arrangement. All blocks in the arrangement, hereafter called a **cascade combo**, are configured to operate in cascade mode by the CASCD[1:0] field in the DECFILTER_MCR register. *Figure 574* shows an example of cascade combo:

- The figure shows PSI being used for both data input and output, but cascade can also work in standalone or mixed modes.
- The left most block, named Head. receives the raw data to be filtered from a PSI master block (or from the device slave-bus interface in standalone/PSI output modes). The head type is configured using CASCD[1:0] = 01 in the configuration register DECFILTER_MCR.
- The right most block, named Tail, is the last filter block in the chain. It sends the output result back to a PSI master block (or to the device slave-bus interface in standalone/PSI input modes). This type of cascaded block is configured using CASCD[1:0] = 10.
- The blocks in between, named Middle, do not exchange data (receive / transmit) with a PSI master, only with other decimation filter blocks. This type of block is configured by setting CASCD[1:0] = 11. Middle blocks are optional in a cascaded combo: two blocks, one Head block feeding a Tail one, can be used in cascade.

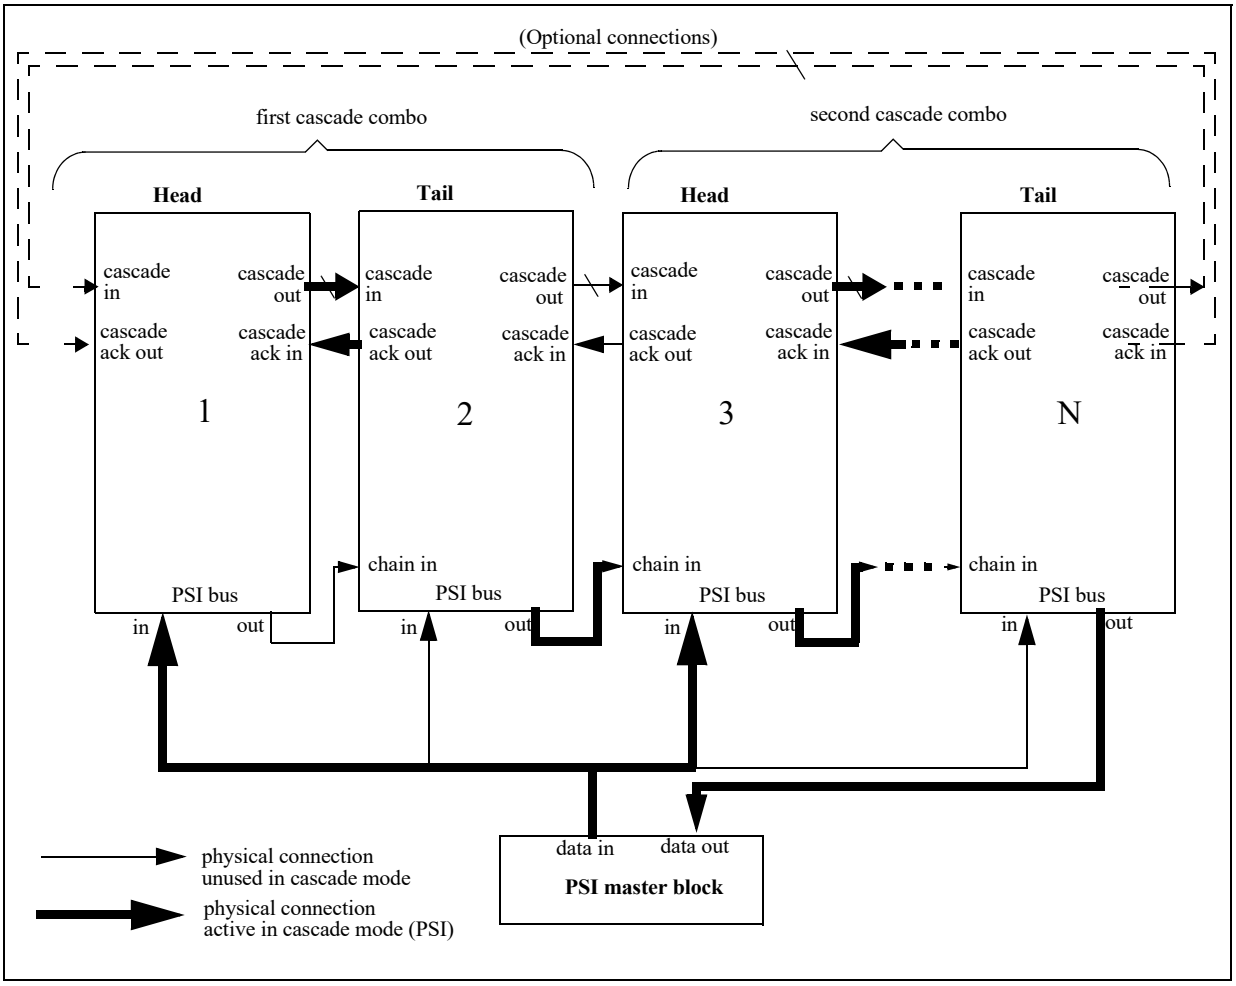
Note: The values passed between cascaded blocks can be monitored using Enhanced Debug Monitor (see Section 40.4.14: Enhanced Debug Monitor Description).

- Each decimation filter block has one cascade-in and one cascade-out ports, besides the PSI connections used in normal mode. The format of the cascade bus is described in *Section 40.4.16.2: Cascade mode data/control bus description*. The arrows show how they are physically connected. The bold arrows show the connections used in cascade mode.
- The block configurations as Head, Tail or Middle must respect their physical connections such that all the following apply:
  - a Head block feeds a Middle or Tail one
  - a Middle block feeds another Middle block or a Tail one
  - Tail feeds no other block, and Head is fed by no other block.
- As a consequence of the conditions above, there must be one and only one Head block and one and only one Tail block in a cascade combo.
- A group of physically chained blocks can form more than one cascade combo. For instance, *Figure 575* shows the same physical chain, but now with blocks 1 and 2 configured as Head and Tail, respectively, forming one combo. The remaining blocks form another combo starting with block 3 (Head), and ending with block N (Tail). Note that the chain-in inputs of blocks from block 3 on are used to carry output data from the first cascaded combo (Tail block 2) to a PSI master block.
- Blocks not used in a cascaded chain can be used normally, isolated (DEFILTER_MCR field CASCD[1:0] = 00), as exemplified in *Figure 576*.
- The optional connection shown from block N to block 1 in *Figure 574* allows block N to be configured as Head or Middle, feeding block 1 configured as Middle or Tail, yielding more flexibility, as in the last example of *Figure 576*.

Figure 574. Cascade mode chain structure

The input to a cascaded configuration is selected by the DECFILTER_MCR bit ISEL of the Head block. The output target of the cascaded blocks is selected by the DECFILTER_MCR bit ISEL of the Tail block, with the same values used for input selection (ISEL=0 for PSI, ISEL=1 for device slave-bus). DECFILTER_MCR bit MIXM must be written 0 for all cascaded blocks.

Figure 575. Multiple Cascade mode chain structure



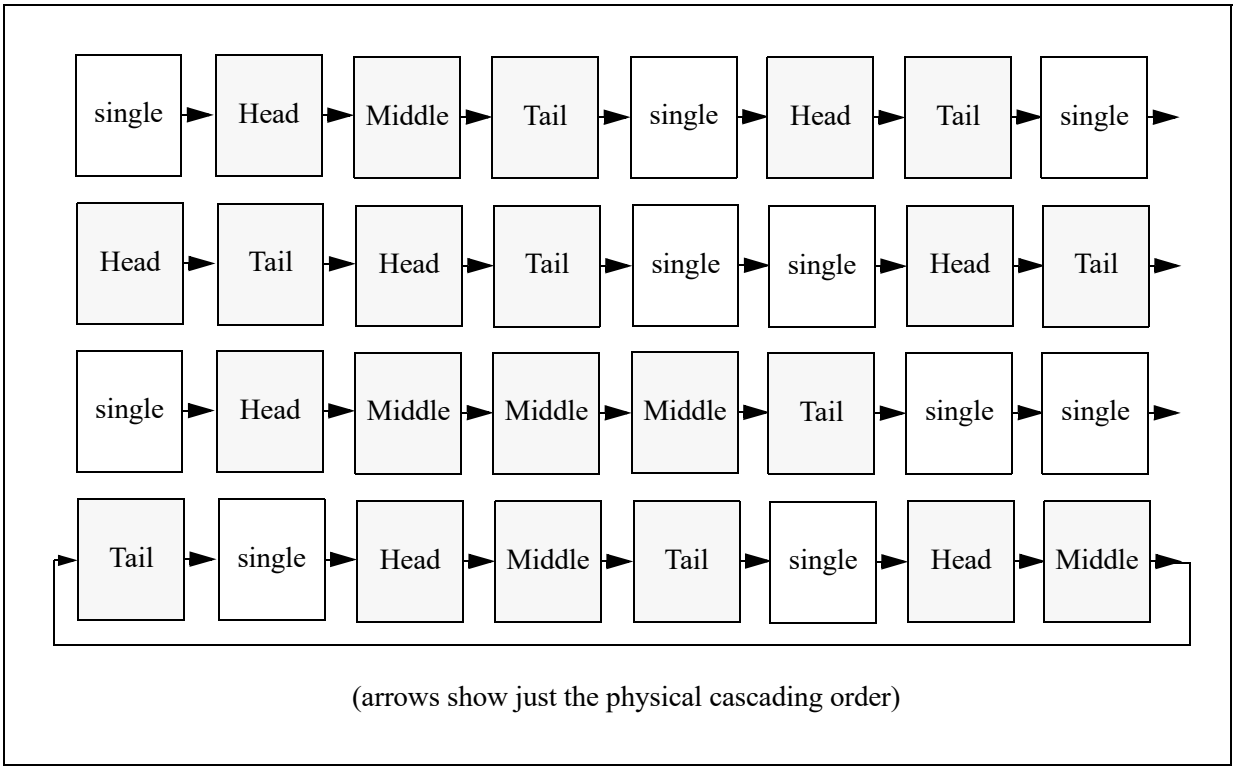


Figure 576. Examples of mixed cascaded and single blocks

40.4.16.1 Cascade Freeze, Stop, and Configuration change procedures

To change a block configuration mode to or from cascade mode, the following safe procedures must be observed:

- To modify a cascade combo, either to single or any other cascade combo combination, all the cascade combo blocks must have their inputs disabled (using DECFILTER_MCR bit IDIS), in order, from the Head to the Tail block. After a block IDIS bit has been set to 1 (one), one must wait for its DECFILTER_MSR bit BSY to be 0 (zero) before disabling the input of the next block in the sequence.
- Each block in a new cascade combo must be configured with its input disabled. When the mode configuration is done, the combo blocks must have their inputs enabled in order, from the Tail towards the Head block.
- A single block must also be reconfigured the same way, to or from a cascade combo configuration: first disabling its input, and then waiting for a non-busy state before writing DECFILTER_MCR field CASCD.

To take cascade combo blocks to or from freeze or low power modes, a similar procedure must be used:

- Take the Head to freeze or low-power first, wait for DECFILTER_MSR bit BSY=0, and repeat the procedure for the other blocks in the chain in sequence, towards the Tail block.
- Take the blocks out of freeze or low-power modes in the inverse sequence, from Tail to Head.

40.4.16.2 Cascade mode data/control bus description

A separate data bus is used to cascade the filters. The bus content is presented in *Figure 577* and the signals descriptions are present below.

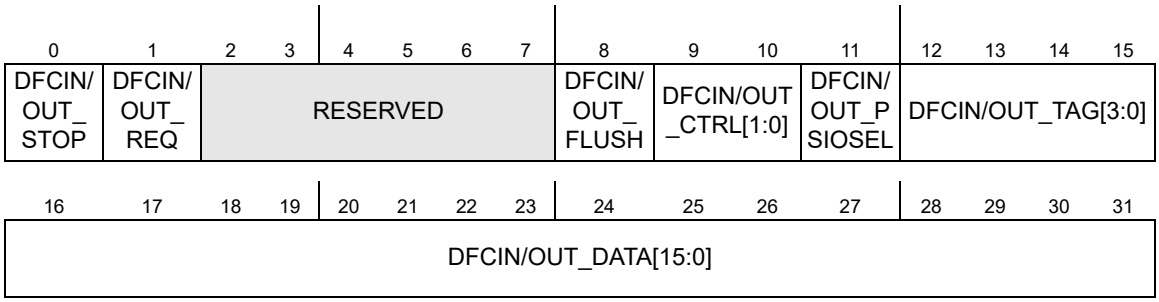

Figure 577. Decimation filter cascade mode data bus

Table 685. DECFILTER_IOB field descriptions

Field	Description
0 DFCIN/OUT_STOP	Decimation Filter Cascade Input/Output Stop flag The DFCIN/OUT_STOP bit indicates that a cascade bus driver block in a cascade configuration is stopped. When the block is configured as Cascade Middle or Tail, it only stops (asserting ipg_stop_ack) when this bit is asserted.
1 DFCIN/OUT_REQ	Decimation Filter Cascade Request The DFCIN/OUT_REQ bit indicates that a cascade bus driver block in a cascade configuration has data ready to be sent. The driven block responds to the request asserting its decfil_cascade_ack signal at the same time it copies the relevant cascade data bus fields.
8 DFCIN/OUT_FLUSH	Decimation Filter Cascade Input/Output Flush control bit The DFCIN/OUT_FLUSH bit indicates to the receiver Decimation Filter block that it should execute a flush command, thus some internal registers are placed in the initial state.
9:10 DFCIN/OUT_CTRL[1:0]	Decimation Filter Cascade Input/Output Control bits The DFCIN/OUT_CTRL[1:0] field has the same function as the M_CTRL[1:0] control bits described in *Table 684*. This field defines the operation to be executed with the DFCIN/OUT_DATA[15:0] data.
11 DFCIN/OUT_PSIOSEL	Decimation Filter Cascade Input/Output PSI Selector The DFCIN/OUT_PSIOSEL field indicates which PSI output should send data back to the master block. This bit has only meaning in the Tail blocks.
12:15 DFCIN/OUT_TAG[3:0]	Decimation Filter Cascade Input/Output Tag bits The DFCIN/OUT_TAG[3:0] field indicates the destination associated with the DFCIN/OUT_DATA[15:0] data. This value is stored by the Decimation Filter and used to address the destination register when a decimated sample is available to be read by the master block.
16:31 DFCIN/OUT_DATA[15:0]	Decimation Filter Cascade Input/Output Data The DFCIN/OUT_DATA[15:0] bit field carries the data to be transmitted in the chain of cascaded decimation filter blocks.

Cascade Middle and Tail blocks do not make input feed requests, either on PSI or device slave-bus interfaces. Similarly, cascade Head and Middle block do not make filtered (not integrator) output data requests, either on PSI or device slave-bus interfaces.

Cascaded blocks can be configured with different filter types (DECFILTER_MCR field FTYPE), except bypass. *Table 686* shows how Decimation Filter features work in each of the Cascade Mode configurations.

Table 686. Features in cascade mode

Feature	Head	Middle	Tail
Pre-fill	Output and pre-fill command are forwarded to the next cascaded block		Effective
Flush	Effective, and forwarded to the next cascaded block		Effective
Decimation	Effective in each block		
Timestamp	Forwarded to the next cascaded block		Effective
Enhanced Debug	Effective in each block		
Integrator	Effective in each block		

40.4.17 Return PSI (RPSI) and PSI Output Selector (PSIOSEL)

This block can be connected to two master blocks through two separated Parallel Side Interfaces - PSI0 and PSI1. The input data can come from any of these PSIs and can also come from the device slave-bus by DMA or interrupt request. And the filter output result can be sent to any of these PSIs or can be read by the device slave-bus by DMA or interrupt request.

The input data can come from PSI0 or PSI1. The PSI data bus structure is presented in *Section 40.4.2: Parallel Side Interface (PSI) sub-block description*, and it contains the bit field RPSI that defines which PSI output should send the filter result back to its master block. This means the filter result correspondent to some sample data from a PSI input can be sent to any PSI output by the received RPSI value. For example, when the input data comes from PSI1 with RPSI=0 (=1) the filter result is sent back by using PSI1 (PSI0) by asserting the read request signal.

In case of PSI output mixed mode, the input data is supplied by writes to the DEC_FILTER_IB register and the output PSI is directly selected by the bit field PSIOSEL. This is different from RPSI because the sample data does not come from a PSI. For example, when the input data comes with PSIOSEL=0 (=1) the filter result is sent back by using PSI0 (PSI1) by asserting the read request signal.

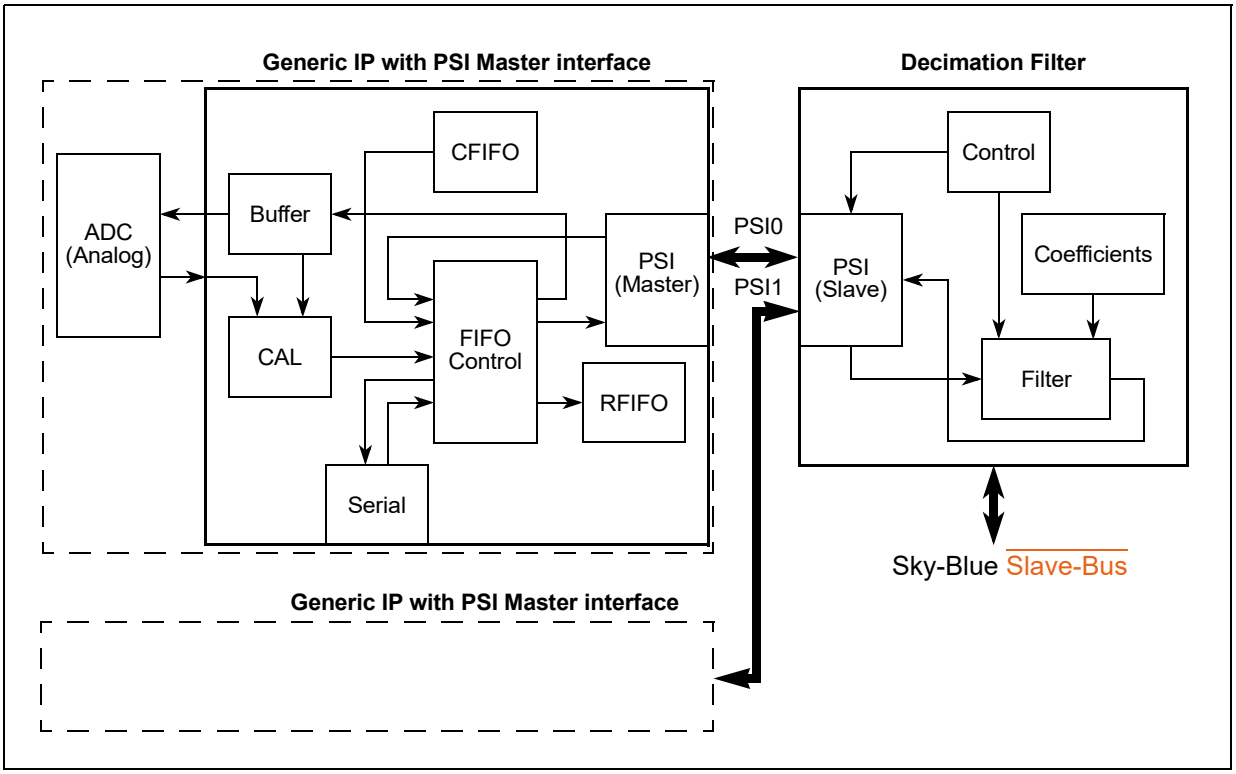
40.5 Initialization Information

Following are some simple initialization steps to be performed before using the decimation filter block. These steps assume that the user has already calculated the filter coefficients using a filter design tool.

40.5.1 Initialization Procedure

The sequence of steps for the block initialization is as follows:

1. Program the configuration registers DECFILTER_MCR and DECFILTER_MXCR as desired for your application.
2. Write all filter coefficient registers DECFILTER_COEFn with the previously calculated values.
3. Enable the filter input, writing DECFILTER_MCR bit IDIS=0.
4. Run a soft-reset cycle if necessary.
5. The module is ready to receive data from PSI0/PSI1 or from the device slave-bus interface.



40.6 Application information

40.6.1 Generic IP as the PSI Master Block

The system block diagram for a generic application is shown in *Figure 578*. In this case, the Decimation Filter receives conversion results generated by one Master block using PSI0 interface.

The data received by PSI interface is either filtered by the decimation filter or bypassed and sent back to the Master block.

Figure 578. Decimation Filter/eQADC interface

40.7 Filter example simulation

The decimation filter block operation was checked in a Verilog simulation using calculated filter coefficient values and noisy input data. The expected output values and the RMS error were then calculated.

40.7.1 Coefficients calculation

The coefficients were calculated using a digital filter design tool. We have supplied some hypothetical filter parameters to the tool and obtained the filter coefficients. The input parameters are:

- filter characteristics: elliptic/low pass
- filter type: 4th order IIR
- input sample rate: 800k sample/s
- passband edge: 100 kHz
- stopband edge: 150 kHz
- passband attenuation: ≤ 1 dB

The software tool gives the IIR filter coefficients in the Z-transform format expressed by *Equation 26*:

Equation 26

$$\frac{Y(s)}{X(s)} = \frac{B_0 + B_1 s + B_2 s^2 + B_3 s^3 + B_4 s^4}{A_0 + A_1 s + A_2 s^2 + A_3 s^3 + A_4 s^4}$$

The coefficient results in fixed point decimal representation are shown in *Table 687*.

Table 687. Coefficient values given by SPW digital filter design tool

Coefficient	Decimal Value	Coefficient	Decimal Value
B0	0.0221455	A0	1.0
B1	0.00445582948893748	A1	-2.69772868375858
B2	0.0318517846509088	A2	3.234056294853
B3	0.00445582948893748	A3	-1.92028561712454
B4	0.0221455	A4	0.47939080709495

Comparing *Equation 25* with *Equation 26*, we obtain the relationship between the calculated values of coefficients and the values to be loaded in the DECFILTER_COEFn registers. Note that A0=1 in both cases and that the coefficients A1 to A4 in *Equation 26* has the opposite signal from *Equation 25*.

See *Table 688* below to obtain the coefficients. A scale factor of eight is used, being the smallest divider factor to have all coefficient values in the range (–1 ≤ Coef < +1).

Table 688. Coefficient values for decimation filter

SCALE	S=1	S=8	
COEF*n*	Decimal Value	Decimal Value	Hexadecimal Values (24 bits)
Coef0 = B0/S	0.0221455	0.00276815891266	0x005AB5
Coef1 = B1/S	0.00445582948893748	0.00055694580078	0x001240
Coef2 = B2/S	0.0318517846509088	0.00398147106171	0x008277
Coef3 = B3/S	0.00445582948893748	0.00055694580078	0x001240
Coef4 = B4/S	0.0221455	0.00276815891266	0x005AB5
Coef5 = –A1/S	2.69772868375858	0.33721613883972	0x2B29E6
Coef6 = –A2/S	–3.234056294853	–0.40425717830658	0xCC414E
Coef7 = –A3/S	1.92028561712454	0.24003565311432	0x1EB97D
Coef8 = –A4/S	–0.47939080709495	–0.05992400646210	0xF8546A

40.7.2 Input data calculation

The 24-bit words of input data are samples of a sum of two tones: one tone of 30 kHz and another tone of 250 kHz. The samples were calculated at the rate of 800k samples per second. The tones have the same amplitude and it is assured that the resultant amplitude is smaller than ‘1’ so as to obtain samples in the range ($-1 \leq$ sample $< +1$). It is supposed the input data are signed values in the two’s complement format in the range ($-1 \leq$ sample $< +1$).

40.7.3 Filter results

The decimation filter block was used in a Verilog simulator using the calculated coefficients and the input data samples. A scaling factor of eight in the configuration register DECFILTER_MCR, and no decimation factor, were used to obtain the maximum of output results from the filter.

The theoretical expected values from this filter were also calculated, and these results were compared with those from the decimation filter. The resultant RMS error when considering about 500 samples was about –97 dB.

41 Temperature Sensor

41.1 Introduction

The device includes an onboard temperature sensor that monitors device temperature and delivers two analog output signals and three digital output signals.

The analog outputs consist of two voltage signals which vary linearly with the internal junction temperature: a voltage signal that is linearly increasing (PTAT: proportional to absolute temperature) and a voltage signal that is linearly decreasing (CTAT: complementary proportional to absolute temperature). The analog outputs are connected to an input channel of an ADC on the device. The internal junction temperature must be calculated by software based on the converted temperature values.

The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions. These signals notify the device to take action to appropriately adjust the device temperature in response to an out of specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

41.1.1 Signal Descriptions

This module has no external signals.

41.2 Functional description

The temperature sensor generates two analog outputs voltage, PTAT and CTAT which are proportional to the absolute current junction temperature of the device.

An on-chip ADC module is used to convert the analog outputs voltage, PTAT and CTAT, into a digital representation. These values, along with parameter values stored in onboard flash memory, are used by software to calculate the device junction temperature.

41.2.1 Linear temperature sensor (analog output generation)

The temperature sensor outputs two voltage proportional and complementary proportional to the internal junction temperature of the chip. These analog voltage signals are converted into digital values by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programed into flash memory.

41.3 Temperature formula

41.3.1 Equations for converting TSENS voltages to junction temperature

Table 689. Calibration constants (1) (2)

Constant	Description
P1	Code from the ADC converting PTAT output voltage at 150^0C
P2	Code from the ADC converting PTAT output voltage at -40^0C
C1	Code from the ADC converting CTAT output voltage at 150^0C
C2	Code from the ADC converting CTAT output voltage at -40^0C

1. It is mandatory to keep the ADC reference constant while measuring P1, P2, C1, and C2
2. Flash locations for P2, C2, P1 and C1 are respectively 0x400000, 0x400002, 0x400004 and 0x400006.

In the equations below:

- Pn and Cn are the calibration constants described in *Table 689*
- T is the unknown device temperature in ^{0}C
- Px is the code from the ADC converting PTAT output voltage at the temperature T with any ADC reference voltage Vref
- Cx is the code from the ADC converting CTAT output voltage at the temperature T with the same ADC reference voltage Vref.
- T2 = -40^0C
- T1 = 150^0C

Equation 27 $$A = Px \cdot C2 - (Cx \cdot P2)$$

Equation 28 $$B = Cx \cdot P1 - (Px \cdot C1)$$

The temperature T is calculated as

Equation 29 $$T = T2 + \frac{A \cdot (T1 - T2)}{A + B}$$

Caution: It is mandatory to have the same value as the ADC reference, while measuring Px and Cx.

41.3.2 Equations for converting TSENS voltages into constant reference (Digital Bandgap Voltage)

By converting the two outputs of the Temperature Sensor through ADC, one can find out a constant reference code (REFCODE) which does not change with temperature.

- Pn and Cn are the calibration constants described in *Table 689*.
- Px is the code from the ADC converting PTAT output voltage at any temperature T with any ADC reference voltage Vref.
- Cx is the code from the ADC converting CTAT output voltage at the same temperature T with the same ADC reference voltage Vref.

Equation 30

$$REFCODE = Px + \left(\frac{(P2 - P1)}{(C1 - C2)}\right) \times Cx$$

Caution: It is mandatory to measure Px and Cx at the same ADC reference voltage and at the same temperature.

Note: Software calculation must be made with negligible precision loss associated with limited bit representation of intermediate calculated results.

42 System Timer Module (STM)

42.1 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

Note: For chip-specific implementation details of this module's instances, see the chip configuration information.

42.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the FBRIDGE clock divided by an 8-bit prescale value (1 to 256).

42.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

42.1.3 Modes of operation

The STM supports two device modes of operation: Normal and Debug. When the STM is enabled in Normal mode, its counter runs continuously. In Debug mode, operation of the counter is controlled by the FRZ bit in the STM Control Register (STM_CR). If STM_CR[FRZ] is set, the counter is stopped in Debug mode, otherwise it continues to run.

42.2 External signal description

The STM does not have any external interface signals.

42.3 Memory map and register definition

The STM programming model includes a group of 32-bit registers: a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

42.3.1 Memory map

The STM memory map is shown in *Table 690*.

Table 690. STM memory map

42.4 Functional description

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the FBRIDGE clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode the counter operation is controlled by the STM_CR[FRZ] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode, otherwise it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*) and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing a 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

Note: The STM counter does not advance when the FBRIDGE clock is stopped.

43 Software Watchdog Timer (SWT)

43.1 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

Note: For chip-specific implementation details of this module's instances, refer to the chip configuration information.

43.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

43.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

43.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR *Section 43.2.1.1: SWT Control Register (SWT_CR)*. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit of the SWT_CR register. Refer to *Section 43.2.1.1: SWT Control Register (SWT_CR)*. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

43.2 Memory map and register definition

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access, otherwise a bus error is generated. If either the HLK or

SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in *Table 696*.

Table 696. SWT memory map

43.2.1 Register descriptions

The following sections detail the individual registers within the SWT programming model.

Note: Refer to the memory map for the base address of SWT registers.

43.2.1.1 SWT Control Register (SWT_CR)

The SWT_CR contains fields for configuring and controlling the SWT. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

1. SWT_CO will reflect the internal value of the counter when WEN=0, and will be read as 0x0000_0000 when WEN=1

Figure 589. SWT Counter Output Register (SWT_CO)

Table 702. SWT_CO field descriptions

Field	Description
0:31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

43.2.1.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Offset: 0x0018 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 590. SWT Service Key Register (SWT_SK)

Table 703. SWT_SK field descriptions

Field	Description
16:31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] = 01, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^16.

43.3 Functional description

43.3.1 Introduction

The SWT is a 32-bit timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- A control register (SWT_CR)
- An interrupt register (SWT_IR)
- A time-out register (SWT_TO)
- A window register (SWT_WN)
- A service register (SWT_SR)
- A counter output register (SWT_CO)
- A service key register (SWT_SK)

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

43.3.1.1 SWR_CR register

The SWT_CR register includes bits to enable the timer, set configuration options and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific[o]. If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

43.3.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100 in which case the time-out period is set to 0x100.When the SWT is enabled, this time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed.The source used to drive the down counter and the reset value of the SWT_TO register is device specific, refer to the device configuration chapter.

43.3.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

o. Refer to SWT section in device configuration chapter.

43.3.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

43.3.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

43.3.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

43.3.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

43.3.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation which is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- Fixed service sequence
- Keyed service sequence
- Fixed execution address
- Incremental execution address

43.3.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected which requires writing 0xA602, 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

43.3.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected which requires writing two pseudo-random keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudo-random key generator defined in *Equation 31*. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

Equation 31

$$SK_{n+1} = (17*SK_n+3) \bmod 2^{16}$$

43.3.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

43.3.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected in which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

43.3.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to ‘1000’ then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

43.3.5 Time-out

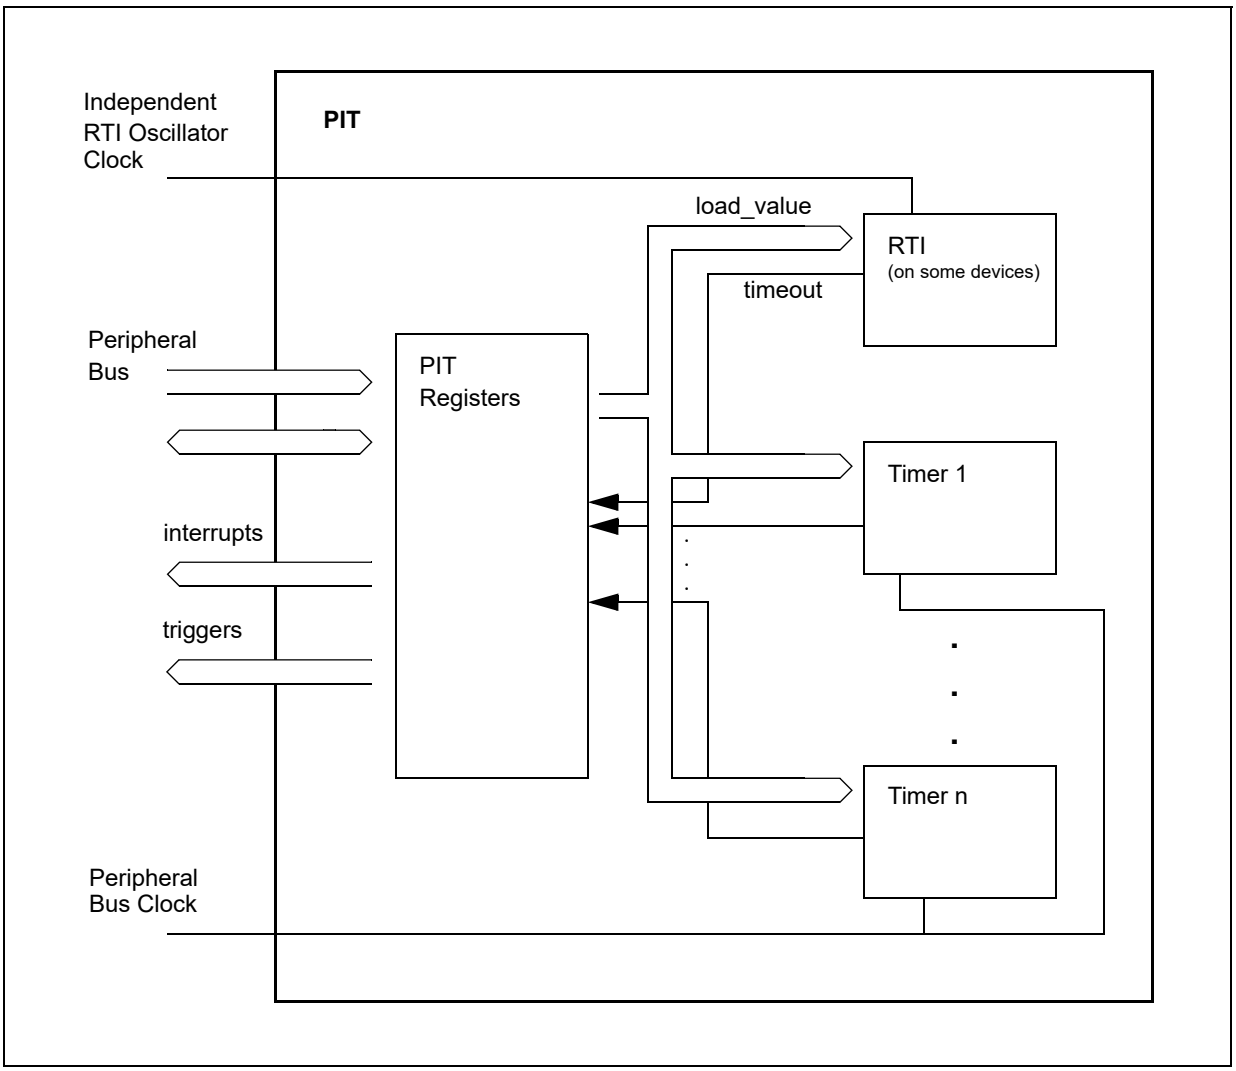
The SWT_CR[ITR] (“Interrupt Then Reset” bit) controls the action taken when a time-out occurs. If the SWT_CR[ITR] bit is not set, a reset is generated immediately on a time-out. If the SWT_CR[ITR] bit is set, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period. If the service sequence is not written before the second consecutive time-out, the SWT generates a system reset. The interrupt is indicated by the time-out interrupt flag (SWT_IR[TIF]). The interrupt request is cleared by writing a one to the SWT_IR[TIF] bit.

43.3.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

44 Periodic Interrupt Timer (PIT)

44.1 Introduction



The PIT timer module is an array of timers that can be used to raise interrupts and trigger DMA channels. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup.

Note: For the chip-specific implementation details of this module's instances refer to the Device Configuration chapter.

44.1.1 Block diagram

Figure 591 shows the PIT block diagram.

Figure 591. Block diagram of the PIT

Note: Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

44.1.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wake up the CPU in Stop mode
- Timers can generate DMA trigger pulses
- Timers can generate interrupts
- All interrupts are maskable
- RTI interrupt can be raised, even when the bus clock is switched off
- Power saving with a separate input clock for the RTI timer (all other timers share one common core clock)
- Independent timeout periods for each timer

44.2 Signal description

This module has no external pins.

44.2.1 Memory map/register description

This section provides a detailed description of all registers accessible in this module.

Note: Reserved registers will read as 0, writes will have no effect.

Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

The RTI registers should be programed only when the RTI clock is running.

Figure 592. PIT Module Control Register (MCR)

Table 705. MCR field descriptions

Field	Description
29 MDIS_RTI	Module Disable - RTI section This is used to disable the RTI timer. This bit must be enabled before any RTI setup is done. 0 Clock for RTI timers is enabled. 1 Clock for RTI timers is disabled.
30 MDIS	Module Disable This is used to disable the module clock. The RTI timer is not affected by this bit. This bit must be enabled before any other setup is done. 0 Clock for PIT timers is enabled. 1 Clock for PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters debug mode. 0 Timers continue to run in debug mode. 1 Timers are stopped in debug mode.

44.2.1.2 PIT Upper Lifetime Timer Register (LTMR64H)

The PIT Upper Lifetime Timer Register (LTMR64H) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

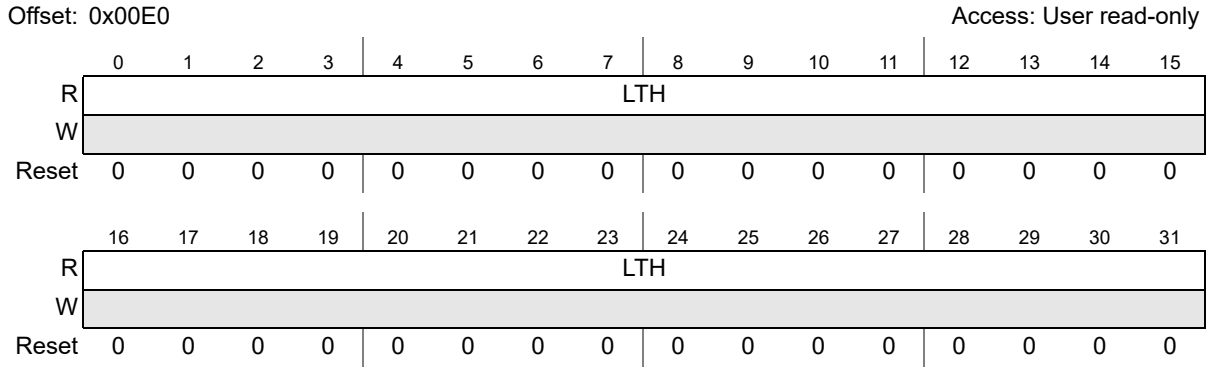

Figure 593. PIT Upper Lifetime Timer Register (LTMR64H)

Table 706. LTMR64H field descriptions

Field	Description
0:31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

44.2.1.3 PIT Lower Lifetime Timer Register (LTMR64L)

The PIT Lower Lifetime Timer Register (LTMR64L) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

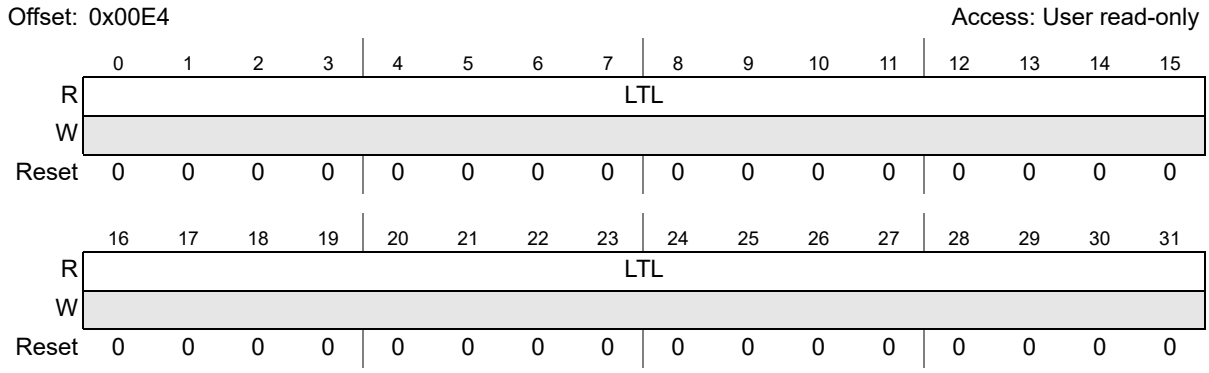

Figure 594. PIT Lower Lifetime Timer Register (LTMR64L)

Table 707. LTMR64L field descriptions

Field	Description
0:31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

44.2.1.4 PIT RTI Timer Load Value Register (RTI_LDVAL)

This register selects the timeout period for the timer interrupts.

In case of the RTI, it takes several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronization mechanism allows 0 wait states for RTI in this case.

Figure 595. PIT RTI Timer Load Value Register (RTI_LDVAL)

Table 708. RTI_LDVAL field descriptions

Field	Description
0:31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. **Note:** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.

44.2.1.5 PIT RTI Current Timer Value Register (RTI_CVAL)

This register indicates the current timer position.

For the RTI timers, it shows a value which is several cycles old, since it originates from a potentially different clock domain.

Figure 599. PIT Timer Load Value Register *n* (LDVAL*n*)

Table 712. LDVAL*n* field descriptions

Field	Description
0:31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

44.2.1.9 PIT Current Timer Value Register *n* (CVAL*n*)

Offset: 0x0104 + *n**0x10 (n = 0 to 7) Access: User read-only

Field	Description
31 TIF	Timer Interrupt Flag TIF is set to '1' at the end of the timer period. This flag can be cleared only by writing it with 1. Writing 0 has no effect. If enabled (TIE = 1), TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

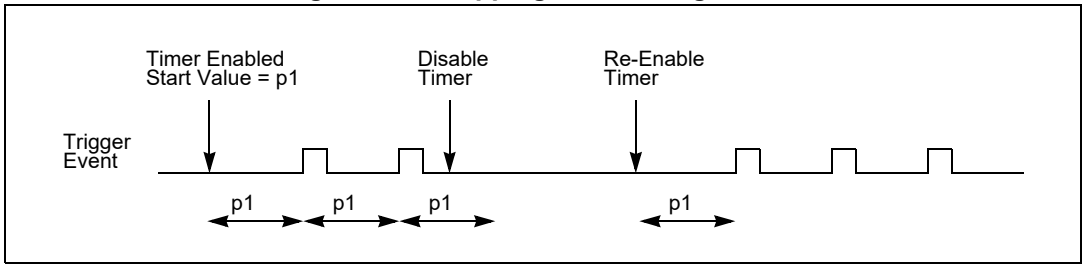
44.3 Functional description

This section provides the functional description of the module.

44.3.1 General

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses as well as to generate interrupts. Each interrupt is available on a separate interrupt line.

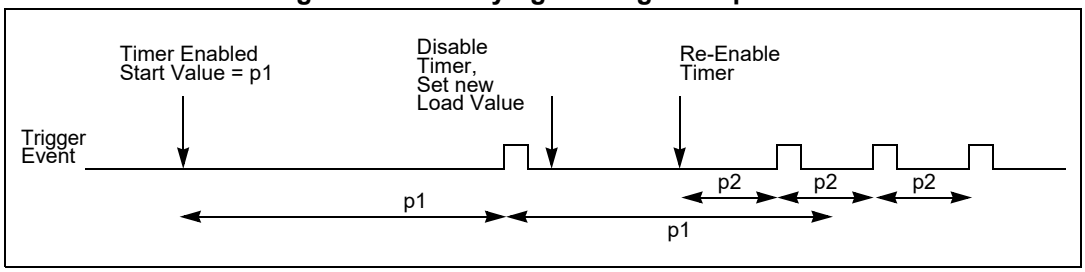
44.3.1.1 Timers/RTI



The timers generate triggers at periodic intervals, when enabled. They load their start values, as specified in their LDVAL registers, then count down until they reach 0. Then they load their respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

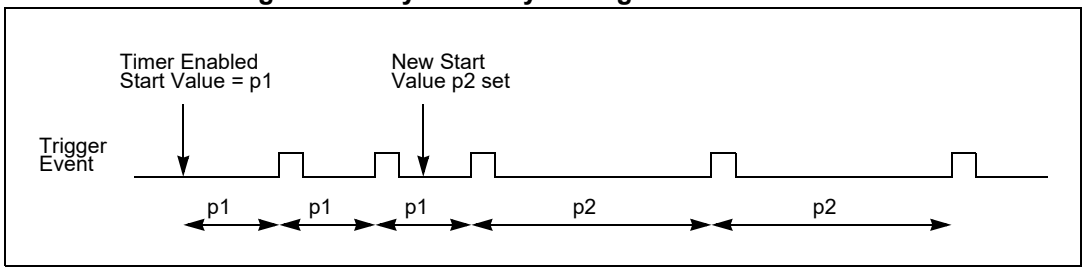
All interrupts can be enabled or masked (by setting the TIE bits in the TCTRL registers). A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 should be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.



The counter period can be restarted, by first disabling, then enabling the timer with the TEN bit (refer to the following figure).

Figure 603. Stopping and starting a timer



The counter period of a running timer can be modified, by first disabling the timer, setting a new load value and then enabling the timer again (refer to the following figure).

Figure 604. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing the LDVAL register with the new load value. This value will then be loaded after the next trigger event (refer to the following figure).

Figure 605. Dynamically setting a new load value

44.3.1.2 Debug mode

In debug mode, the timers will be frozen based on field MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system (for example, the timer values) and then continue the operation.

44.3.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. Refer to the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting the TIE bits. The timer interrupt flags (TIF) are set to ‘1’ when a timeout occurs on the associated timer, and are cleared to ‘0’ by writing a ‘1’ to that TIF bit.

The PIT RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting the TIE bit to zero. The real time interrupt flag (TIF) is set to ‘1’ when a timeout occurs, and is cleared by writing a ‘1’ to the TIF bit. (The flag will be set regardless whether the interrupt is enabled.)

The RTI can be used for periodic wakeup from a low power mode. It can also be used to generate a general purpose interrupt.

44.3.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer *n*-1 has counted down to 0, counter *n* will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

44.4 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

First the PIT module must be activated by writing a 0 to field MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5000000 cycles.

Timer 1 needs to trigger every 5.12 ms/20 ns = 256000 cycles and timer 3 every 30 ms/20 ns = 1500000 cycles.

The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) - 1

This means RTI_LDVAL will be written with 004C4B3F hex, LDVAL1 should be written with 0x0003E7FF, and LDVAL3 should be written with 0x0016E35F.

To generate the wakeup interrupt, the interrupt line must be enabled by writing a ‘1’ to bit RTI_TCTRL[TIE]. To start the RTI, bit RTI_TCTRL[TEN] must also be set.

The interrupt for Timer 1 is enabled by setting bit TCTRL1[TIE]. The timer is started by writing ‘1’ to bit TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore Timer 3 is started by writing a ‘1’ to bit TCTRL3[TEN]; bit TIE stays at 0.

The following example code matches the described setup:

Example 7

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE;    // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN;   // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;        // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;         // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3for 1500000 cycles
PIT_TCTRL3 |= TEN;         // start Timer 3
```

44.5 Example Configuration for the Lifetime Timer

To configure the life timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a ‘0’ to field MCR[MDIS], then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

Example 8

```
// turn on PIT
PIT_CTRL = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0;        // disable timer 2 interrupts
PIT_TCTRL1 |= CHN;       // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN;         // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0for maximum counting period
PIT_TCTRL0 = TEN;          // start timer 0
```

To access the lifetime read first LTMR64H then LTMR64L.

Equation 32

current_uptime = PIT_LTMR64H << 32;

current_uptime = current_uptime + PIT_LTMR64L

The timer is a down counter.

45 GTM344 Integration (GTMINT) Module

45.1 Introduction

This chapter specifies the functionality of the GTMINT module. The GTMINT is integrated IP with timer and debug functions and is comprised of:

- The GTM-IP_344 timer module (also called GTM-IP)
- The GTMDI debug interface IP
- 14 ECC error correction encoder / decoders for the RAMs required by the timer.

The timer GTM-IP_344 is a very powerful module that can be configured to perform several timer functions. The debugger module is the GTMDI IP (GTM Development Interface IP) that is a Nexus based interface that is connected to the chip level NAR and used to monitor the software and hardware activities of GTM-IP. The ECC sub-blocks generate the parity bits on RAM writes and detect errors in the data read from the RAMs.

Note: This chapter does not intend to present details of GTM-IP nor GTMDI. For full information about the timer and the debugger, refer to the GTMDI subsection in the "Calibration and Debug" chapter of the SPC58xNx Reference Manual and the GTM344 documentation set.

45.1.1 Features

The GTMINT module features include:

- GTM-IP timer features
  - Time base generators
  - Advanced data signal / time base router
  - Input signal processors (48 inputs)
  - Simple output signal generators (48 outputs)
  - Microprocessed output signal generators (48 outputs)
  - Digital PLL
  - BLDC support
  - Safety features - GTM is a non-safety relevant module

    Output compare unit

    Monitoring unit
  - CPU bus interface clock operates asynchronously to timer section clock allowing CPU low power operation.
- GTMDI debug block features
  - Full duplex pin interface for medium and high visibility throughput

    Pin interface shared among all Nexus-based development interfaces on the device

    Auxiliary Output Port

    DATA with MDO (Message Data Out) and MSEO (Message Start/End)

    2 $\overline{\text{EVTO}}$ (Event Out) pin for GTM real time signal monitoring

    Auxiliary Input Port

    1 $\overline{\text{EVTI}}$ (Event In) pin

    IEEE 1149.1 (JTAG) Test Access Port (TAP)

    Support for optional Multi-JTAG TAP Linking Module (TLM)

    4 pins (TDI, TDO, TMS, and TCK)

    Reset input $\overline{\text{TRST}}$ driven by either the Nexus Port Controller or an external pin
  - GTM Development Support

    Read/Write registers in debug mode from JTAG port

    Ability to enter debug mode at reset negation or during normal execution

    Breakpoint and Watchpoint Configuration

    Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This allows the development tool to trace reads and writes to selected RAM address ranges

    Two data trace windows for each MCS core with programmable address ranges and access attributes are provided. Data trace windowing reduces the

requirement on the Aurora port bandwidth by constraining the number of trace locations.

Fetch trace capability controlled by two programmable Watchpoints.

Private messages are used to indicate special MCS core cases not covered by public messages. Up to two[p] MCS cores can be debugged at the same time.

Watchpoint Messaging (WPM)

– Trigger Control

The GTMDI provides selection of trigger signals that will generate debug actions at system level such as Halt GTM itself or cores in the same device.

Trace enable signals are provided to control the start/stop of trace messages for each one of the GTM Nexus message sources, such as TIM, TOM, ATOM,...

– GTMDI Clock operation

The module is able to operate in any frequency ratio considering GTMDI and JTAG frequency. The GTMDI should operate in the same clock source as the GTM IP module.

- ECC encoder / decoder for each of 14 RAM interfaces
  - Parity calculation using the whole word and the target memory address value
  - Detection and correction of single error on the read data value
  - Detection of single bit error on address field but no need for correction
  - Double error detection on data or address field without error correction
  - ECC report generation for each RAM containing:

    Address of the error in the register map (see *Section 45.2: Memory Map and Register Definition*)

    Non-correctable error indication (not correctable data + address ECC detected errors)

    Correctable error indication (correctable data error)
- Generation of 151 interrupt requests and or DMA requests.
- Debugger is allowed to read all GTM registers through the peripheral bus even when the timer is running. Read-access of the debugger is possible without destroying or changing the contents of these registers.
- Debugger is allowed to read all GTM addresses read-/writeable from the peripheral bus when GTM is running or halted.

45.1.2 Modes of Operation

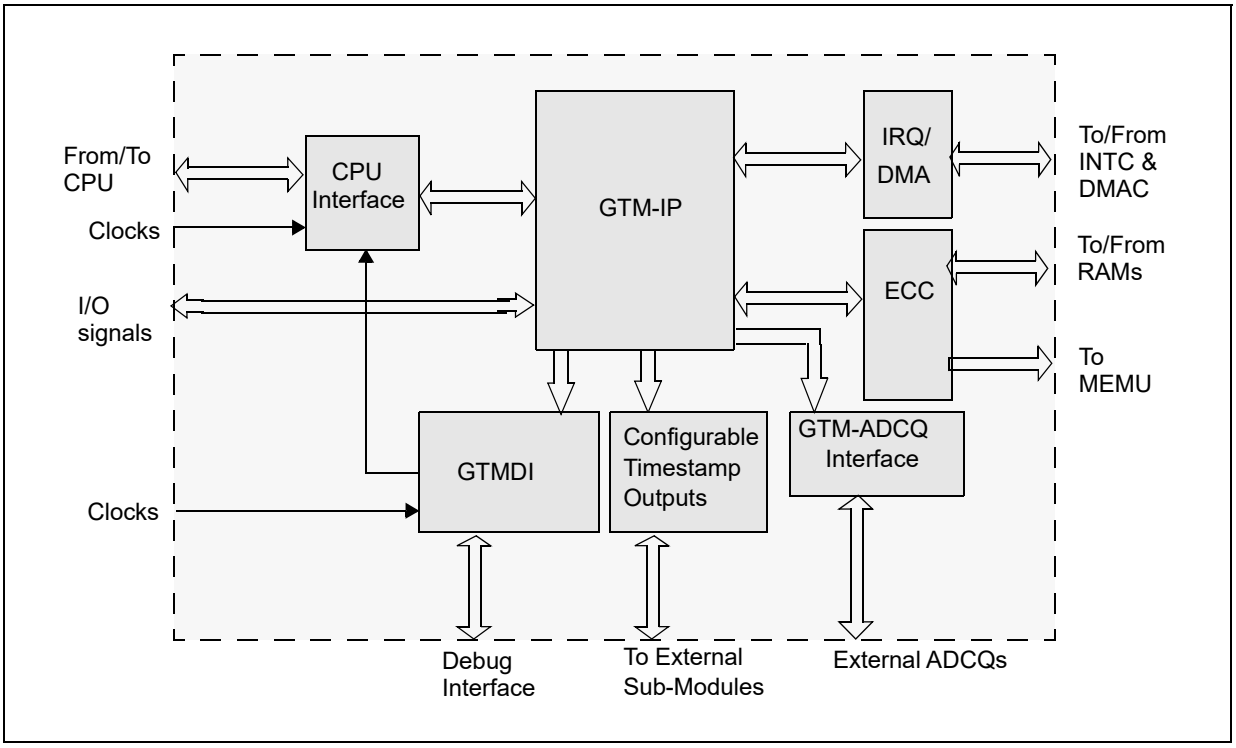
45.1.2.1 Normal Mode

The normal mode is the mode in which the GTMINT module is after a reset is applied. In this mode the timer IP is functional and processes input timing signals and generates timed outputs based on the input timing signals or controlled by the internal channels software. The GTMDI development interface is also active.

p. Note that by enabling two MCS cores at the same time for data trace can exceed the capacity of the Nexus Aurora Router throughput thus information can be lost.

45.1.2.2 Stop Mode

This mode is set when the global stop input is received or when the bit field MDIS on the GTMMCR register is asserted. In this case functional clock is disabled (ipg_clk), but the slave bus clock is not disabled. See more details on *Section 45.3.4: Stop Mode Description*.



45.1.2.3 Debug Mode (or Halt Mode)

The debug mode or GTM-IP halt mode is externally requested through the GTMDI. In this mode, the GTM-IP internally gates its Kernel clock and the bus interface clocks remain running to access all registers and memories. It is possible to read the registers not interfering into the logic status, even for FIFOs, by configuring the debug access controls on GTMDI.

45.1.3 Block Diagram

Figure 606 shows the interconnections in the GTMINT Module.

Figure 606. GTMINT block diagram

45.2 Memory Map and Register Definition

This section provides a reference table to the GTM-IP sub-module registers. Details of each register are found in the GTM344 documentation set. Additional registers from those used in the GTM-IP are described in this section.

45.2.1 Module Memory Map

The GTMINT simplified memory map is shown in *Table 716*. Offsets are relative to the GTMINT base address. See the device memory map for the module base address.

Note: The GTMINT module has only a few registers, detailed in Section 45.2.2: Register Descriptions. The module also acts as an interface to all implemented GTM-344 control registers. For details see the GTM344 documentation set.

1. Default value when in reset state.
2. These values are device specific and will change with every device.
3. For detailed information see the *GTM-IP Specification* document.
4. Reset value depends on configuration parameters.
5. The old address areas of modules are marked with LEG_ (Legacy). These legacy areas are mapped to the normal areas.
6. RAM reserved position for GTM-IP internal use. No error occurs when accessed.

45.2.2 Register Descriptions

This section contains the description of additional registers on the top integration module. Description of GTM-IP registers, or GTMDI registers are found in their respective specification document.

45.2.2.1 GTM Module Configuration Register (GTMMCR)

The GTMMCR contains the control bits to configure the general operation of the GTMINT and GTM-IP Module.

Offset 0x000C0 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	—(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 607. GTM Module Configuration Register (GTMMCR)

1. Reset value is SoC dependent (see *Table 717*).

GTMMCR register functions are as shown in *Table 718*.

Table 718. GTMMCR field descriptions

Field	Description
1 MDIS	MDIS Module Disable. The MDIS bit puts the GTMINT Module in stop/disabled mode. Communication through the slave-bus Interface is ignored in this mode except reads/writes to the GTMMCR register and reads from other integration registers which are allowed. 1 Module disable request 0 Normal Mode.
15 AEISREN	AEISREN AEI interface soft-reset control enable. The AEISREN bit enables the soft-reset of the AEI interface that is controlled by AEISRST bit on GTMMAEICR register. Refer to *Section 45.3.7: AEI Interface Software Reset Description* for more details. 1 AEI soft-reset control is enabled. 0 AEI soft-reset control is disabled.
17 STPS	STPS Stop Mode Status. The STPS bit indicates the GTM-IP Module is in stop mode, or by MDIS bit field setting or by stop line request. Refer to *Section 45.3.4: Stop Mode Description* for more details. 1 GTM is in Stop Mode. 0 Normal Mode.

45.2.2.2 GTM Interrupts Clear Register (GTMINTCLR)

The GTMINTCLR contains the control bits to clear some specific interrupt request output.

Offset 0x000C8 Access: User read/write

Figure 609. GTM AEI Control Register (GTMMAEICR)

GTMMAEICR register functions are as shown in *Table 721*.

Table 721. GTMMAEICR field descriptions

Field	Description
31 AEISRST	AEISRST AEI interface soft-reset control. The AEISRST bit when set applies a reset on the GTM-IP AEI interface. The set is enabled by the AEISREN bit on GTMMCR register. This is a self clear bit and is always read as 0. Refer to *Section 45.3.7: AEI Interface Software Reset Description* for more details.

45.2.2.4 External ADC Select Register (EXT_ADC_SEL)

EXT_ADC_SEL register contains the mapping of GTM MCS sub-modules with external ADCQ modules. Two MCS modules can't be mapped to a same ADCQ module so each field of this register should have different value programmed.For detailed information see *Section 45.3.9: GTM-ADC interface*.

Offset 0x000D0 Access: User read/write

Figure 610. External ADC Select Register

Table 722. EXT_ADC_SEL field descriptions

Field	Description
0 MCS_ADC_SEL_EN	This bit enables the GTM-ADCQ interface logic present in GTMINT module. By default this bit is 0 and should be set to 1 only after the ADCQ mapping is completed in bits [19:0] of this register. 1 Enable GTM-ADCQ Interface. 0 Disable GTM-ADCQ Interface.
1 MCS_ADC_EN_ACK	This bit is the acknowledgment that GTM-ADCQ interface logic is now enabled. The transaction on MCS ADC interface should be done only when this bit is 1. 1 GTM-ADCQ interface block is enabled. 0 GTM-ADCQ interface block is disabled.

Table 722. EXT_ADC_SEL field descriptions (continued)

Field	Description
12:15 MCS4_ADC_SEL	External ADCQ mapped with MCS4(1) 0000 ADC0 selected 0001 ADC1 selected 0010 ADC 2 selected 0011 ADC 3 selected 0100 ADC 4 selected 0101 ADC 5 selected 0110 ADC 6 selected 0111 Reserved ... 1111 Reserved
16:19 MCS3_ADC_SEL	External ADCQ mapped with MCS3(1) 0000 ADC0 selected 0001 ADC1 selected 0010 ADC 2 selected 0011 ADC 3 selected 0100 ADC 4 selected 0101 ADC 5 selected 0110 ADC 6 selected 0111 Reserved ... 1111 Reserved

Field	Description
24:27 MCS1_ADC_SEL	External ADCQ mapped with MCS1(1) 0000 ADC0 selected 0001 ADC1 selected 0010 ADC 2 selected 0011 ADC 3 selected 0100 ADC 4 selected 0101 ADC 5 selected 0110 ADC 6 selected 0111 Reserved ... 1111 Reserved
28:31 MCS0_ADC_SEL	External ADCQ mapped with MCS0(1) 0000 ADC0 selected 0001 ADC1 selected 0010 ADC 2 selected 0011 ADC 3 selected 0100 ADC 4 selected 0101 ADC 5 selected 0110 ADC 6 selected 0111 Reserved ... 1111 Reserved

1. These bits should be programmed only when MCS_ADC_SEL_EN is low (0). For more details refer to *Section 45.4.2: GTM - ADC Interface Programming*.

In SPC58xNx GTMINT module is connected with SAR ADC modules present on device. The SAR ADCQ instance corresponding with ADC0-6 is captured in *Table 723*

Table 723. SAR ADC Instances

ADC Number	SAR ADCQ Instance
ADC0	SAR ADC_12bit_0
ADC1	SAR ADC_12bit_1
ADC2	SAR ADC_12bit_2
ADC3	SAR ADC_12bit_3
ADC4	SAR ADC_10bit_0
ADC5	SAR ADC_10bit_1
ADC6	SAR ADC_12bit_B

45.2.2.5 Timestamp Configuration registers

GTMINT module provides three timestamp outputs for usage in external modules like CAN, Flexray, SD ADC, SAR ADC. Timestamp configuration registers are used to map the TBU channels of GTM with these three timestamp outputs. It also programs the number of GTM clock cycles by which the Timestamp update signal is stretched. For more details on time stamp configuration refer to *Section 45.3.10: Configurable Time Stamp*.

45.2.2.5.1 TBU_OUT1_CFG register (TBU_OUT1_CFG)

Timestamp output 1 configuration register.

Offset 0x000D4 Access: User read/write

45.3 Functional Description

The following sections describe the GTMINT Module functionality.

The GTMINT Module is designed to accommodate the multipurpose timer (GTM-IP) and the debugger block (GTMDI). The GTM-IP can generate timed signals and also can handle external signals to obtain their timing information. The GTMDI provides several features to help the development of programs to be run on GTM-IP. Refer to *Figure 619* for the integration architecture.

The GTMINT Module integrates the following internal sub-modules into the SPC58xNx platform:

- GTM-IP timer
- GTMDI debug interface
- ECC error correction sub-blocks
- Interface match logic

The following sections describe each one of these sub-modules and their combined operation.

45.3.1 GTM-IP Timer

The Generic Timer Module (GTM) is composed of several submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic. The scalability and configurability is reached with an architecture philosophy where dedicated hardware submodules are located around a central routing unit called Advanced Routing Unit (ARU). The ARU can connect the submodules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM-IP is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM-IP can run (once set up by an external CPU) independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum. In addition, the timer section of GTM-IP runs at a variable clock frequency of 200MHz or 100MHz to allow real time period counting, but the interface to CPU can work with a frequency variable clock

45.3.1.1 GTM-IP Timer Architecture

The hardware submodules have dedicated functions, for instance there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several submodules through the ARU complex functions can be established. For example, the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called infrastructural components further on. These components are present in all GTM variants. However, the number of these components may vary from device to device. Other submodules have a more general architecture and can fulfill typical timer functions, for instance there are PWM generation units. The third class of submodules are those fulfilling a dedicated functionality for a certain application domain, for instance the DPLL serves engine management applications. A fourth group of submodules is responsible for supporting the implementation of safety functions to fulfill a defined safety level.

Each GTM-IP is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM-IP.

A list of submodules is given in *Table 727* below.

Table 727. Submodules of GTM-IP

Item	Submodule	Group
1	Advanced Routing Unit (ARU)	Infrastructural components
2	Broadcast Module (BRC)	
3	First In First Out Module (FIFO)	
4	AEI-to-FIFO Data Interface (AFD)	
5	FIFO-to-ARU Interface (F2A)	
6	Clock Management Unit (CMU)	
7	Time Base Unit (TBU)	
8	Timer Input Module (TIM)	IO Modules
9	Timer Output Module (TOM)	
9	Dead Time Module (DTM)	
10	ARU-connected Timer Output Module (ATOM)	
11	Multi Channel Sequencer (MCS)	Signal generation and processing
12	Memory Configuration Module (MCFG)	Infrastructural component for MCS
13	TIM0 Input Mapping Module (MAP)	Dedicated
14	Digital PLL (DPLL)	
15	Sensor Pattern Evaluation Module (SPE)	BLDC support
16	Interrupt Concentrator Module (ICM)	Interrupt services
17	Output Compare Unit (CMP)	Safety features
18	Monitoring Unit (MON)	

For more details, refer to the *GTM344 documentation set*.

45.3.2 GTMDI Debug Interface

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including MCS cores, ARU data trace, Input Channel Filters trace, Output Timer channels, DPLL and SPE sub-modules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules in order to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and Nexus Aurora router on-chip modules. Note that the Nexus standard is only used for the physical interfaces. In order to implement the debug features such as breakpoint and messages required for the GTM debug, the Nexus standard could not be followed.

For detailed architecture and features description, refer to the GTMDI chapter of this reference manual.

45.3.2.1 Peripheral Slave Bus Read Debug Access

Debugger is able to read all GTM registers, which are visible from the peripheral bus even when the timer is running. Read-access of the debugger is possible without destroying or changing the contents of these registers. A read debug access using the slave bus has no side effects on the timer. The main example is a read access to the FIFO that does not update the FIFO pointers.

45.3.3 Error Detection on GTM Memories Accesses

The GTM-IP architecture requires 14 RAM units that should be placed on the SoC. Each RAM is connected with separated input and output ports to the GTM-IP for safety purposes.

Memories of this block are equipped with error detection features for safety improvement. The following procedures detect errors on memory accesses:

- Memory write data and its address are considered in the parity bits calculation. These parity bits are stored in that memory address as part of the written data.
- Memory read data and its address are considered in the error detection. The parity bits are part of the data read from the specified memory address.
- Error Correcting Code (ECC), that corrects single errors and detects double errors on each read access

45.3.3.1 ECC Description

The Error Correcting Code (ECC) for GTM RAMs provides guaranteed single bit error correction and double bit error detection (without correction) per accessed word. On write accesses, the parity bits are calculated and appended to the original data bits to be written into the specified memory address. And error detection and correction are performed on read accesses.

Note: In case of error detection (with correction or not), no write operation is done here to fix possible errors in the memory content.All memories must be initialized with write operations in all addresses because the ECC parity bits need to be stored in each memory address before any read operation.

Note: GTM-IP sub-block does this initialization automatically for all memories, except for FIFO0 RAM. In this case, the user must be careful to execute writes before reads.

Table 728 presents a summary of GTM memories and the necessary ECCs for single error correction / double error detection.

Table 728. ECC Characteristics for GTM Memories

Memory	MEM Number of Words	MEM Address Width (bits)	Uncoded Data Width (bits)	ECC (bits)	MEM Data In/Out (Data + ECC) (bits)	Matrix Size (N.o Synd.)
FIFO0 RAM	1024	10	29	7	36	46
DPLL RAM1A	96	7	24	7	31	38
DPLL RAM1B	384	9	24	7	31	40
DPLL RAM2	2048	11	24	7	31	42
MCS0 RAM0	2048	11	32	7	39	50

Table 728. ECC Characteristics for GTM Memories (continued)

Memory	MEM Number of Words	MEM Address Width (bits)	Uncoded Data Width (bits)	ECC (bits)	MEM Data In/Out (Data + ECC) (bits)	Matrix Size (N.o Synd.)
MCS1 RAM0	2048	11	32	7	39	50
MCS2 RAM0	2048	11	32	7	39	50
MCS3 RAM0	2048	11	32	7	39	50
MCS4 RAM0	2048	11	32	7	39	50
MCS0 RAM1	1024	10	32	7	39	49
MCS1 RAM1	1024	10	32	7	39	49

MCS3 RAM1	1024	10	32	7	39	49
MCS4 RAM1	1024	10	32	7	39	49

45.3.3.1.1 Error Correcting Code (ECC) and Syndrome Definition

This ECC is based on the Hsiao code with 7 parity bits for each data word.

Table 729 shows the definition of the syndrome field for each bit position. Note that the ECC data vector width can be different for each memory, so we consider only the necessary positions for each one, not all the table positions.

Table 729. 42 bits Word Based Syndrome Definition

SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)	SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)
40	error on **code** bit 6	—	54	error on data bit 23	element 23

1C	error on data bit 26	element 26	51	error on data bit 1	element 1
58	error on data bit 25	element 25	61	error on data bit 0	element 0
0B	error on data bit 24	element 24	—	—	—
—	—	—	—	—	—
00	no error	—	any other(4)	non-correctable error	—

1. Actually the data can be data or address bit.
2. Actually the data can be data or address bit.
3. Actually the data can be data or address bit.
4. For the FIFO0 RAM with 29 data bits and 10 address bits, the valid error positions are from bit 0 to bit 38, only. The syndromes with values for bit 39 to 41 of the table are considered also for non-correctable errors.

45.3.3.2 Error Report Description

Each RAM generates a defined number of information to report an error on an access. Each of them is described below.

- Error Address - this is the mapped address of the RAM as defined in *Section 45.2.1: Module Memory Map*. This field has only meaning when an error occurs and is flagged by the two error signals below. It is reported on read or write operations.
- Non-correctable Error - this one bit width error indicates that:
  - The ECC detected errors in the read access and it is not possible to correct them because the ECC can only fix single bit error. The error can occur in the RAM read data bus (parity bits + data) or in the address value that the RAM has received.
- Correctable Error - this one bit width error indicates that:
  - The ECC detected and corrected a single bit error on the RAM read data bus (parity bits + data). The parity bits are discarded after the ECC decoder but this error report includes these bits to obtain the performance of the whole RAM data storage sector.

This Error Report remains active for only one RAM clock cycle and should be captured by the external RAM Error Monitor module.These error indications are also available for the GTM-IP timer module that is the block that requests the RAM accesses. Uncorrectable ECC error indication are provided to GTM-IP but the reaction to the error depends on this block itself. Refer to its specification for more details.

45.3.4 Stop Mode Description

The stop mode is characterized by the stopping of the functional clock and the timer configuration registers clock. Therefore, the timers become stopped and almost all registers access are not allowed. This mode can be requested by two ways:

- By asserting the bit field MDIS in the GTMMCR configuration register.
- By receiving the SoC stop request signal ipg_stop.
  - the minimum waiting time to a new stop request is about 20 bus clock cycles.

However, it is important to note that to confirm the stop request was granted, it is necessary to read the stop status bit field STPS in the GTMMCR register.

45.3.4.1 Stop Mode by MDIS

The stop mode is requested by asserting this bit field with a write operation on the GTMMCR mapped register. The module only requests to stop the clocks when no slave bus accesses are pending in the GTM-IP. When in stop mode:

- The clocks are disabled to feed the whole GTM-IP and peripheral functions like the ECC
- The stop status bit field STPS in GTMMCR register is set.
- Read or write accesses to all mapped registers are not allowed and generates an access error indication, except accesses for the GTMMCR register.
- The slave bus clock is not affected by stop mode.

This stop mode ends by clearing the MDIS bit field. The STPS stop status bit is automatically cleared after a while (it is considered that the SoC stop request is not set).

45.3.5 Debug / Halt Mode Description

The debug / halt mode is requested via GTMDI and is used to debug the GTM-IP sub-block. In this mode it is required that the core of GTM-IP becomes halted by stopping its clock. Therefore all time bases and counters are frozen.

Debug or halt mode requests should be enabled by setting the bit field DBE on the GTMDI GTMDI_DC register that is accessible by the JTAG interface (refer to GTMDI block guide for more details). GTM halt is only activated when no read- or write-access to GTM over AEI are taking place in parallel. Only in this condition the GTM is released to change to debug / halt mode read.

It is important to notice that any peripheral slave bus access is active in this mode. Debugger is able to read all GTM addresses read-/writeable from the peripheral bus when GTM is running or halted. All registers in the register map can be accessed by the peripheral bus, even the RAMs because they are in the register map. Of course, the clocks for the RAMs are not stopped in debug mode. GTM IP also provides an additional output signal (gtm_restore) which indicates restore phase of functional memory accesses after any GTM Halt phase.

For more details about the debug mode, refer to GTMDI documentation.

Note: If this module is in disable mode by setting the MDIS bit at the GTMMCR register, the debug request is not considered until the MDIS bit is cleared.

45.3.6 GTM-IP Timer Software Reset Description

The GTM-IP timer portion has the software reset possibility by writing a 1 in the RST bit field on the GTM_RST register. This bit is self cleared and is always read as zero. In addition, this bit is write protected by the bit field RF_PROT in the GTM_CTRL register.

This is a global reset to GTM-IP block only. The GTMDI is not affected by this soft-reset.

45.3.7 AEI Interface Software Reset Description

The GTM-IP has software reset control for the AEI interface sub-block only. This block is the slave bus interface of GTM-IP and is not reset by the GTM-IP timer soft-reset. The AEI soft-reset occurs by writing a 1 in the AEISRST bit field on the GTMMAEICR register. This bit is self cleared and is always read as zero. In addition, this bit is write protected by the bit field AEISREN in the GTMMCR register.

A soft-reset in the AEI interface is equivalent to the hard-reset. It occurs in the next clock cycle of the request and takes one bus clock cycle. The AEI buffer and configuration registers are cleared, and some slave bus access can be aborted. Therefore, access commands in the buffer memory are lost and the configuration registers of the AEI interface change to their reset values.

45.3.8 Interrupt and DMA Support Logic

The GTM-IP provides several interrupts / DMA request signals to signalize internal events to other external modules. The list of all signals are provided in the GTM-IP documentation and all have the same type of controls and configuration options.

Each interrupt / DMA request line represents a set of internal interrupt / DMA request signals, and each of this internal signal has its own set of status / control / configuration registers: IRQ_EN, IRQ_NOTIFY, IRQ_FORCINT, and IRQ_MODE registers. Refer to GTM344 documentation set, for more details.

It is required to maintain the configuration register IRQ_MODE=00 that is the Level Interrupt Mode, the default mode to be compatible with the chip standard. the IRQ_NOTIFY register is the internal flag and can be enabled to set an external signal by the IRQ_EN register. For more details, refer to the GTM-IP documentation.

The GTM integration module provides the same GTM-IP set of signals as interrupt requests and as DMA requests and the real functionality on the chip can be configured later. However, if a signal is configured to start a DMA request, the request can be cleared by the respective DMA answer, but it can be also cleared by software as occurs for interrupt requests.

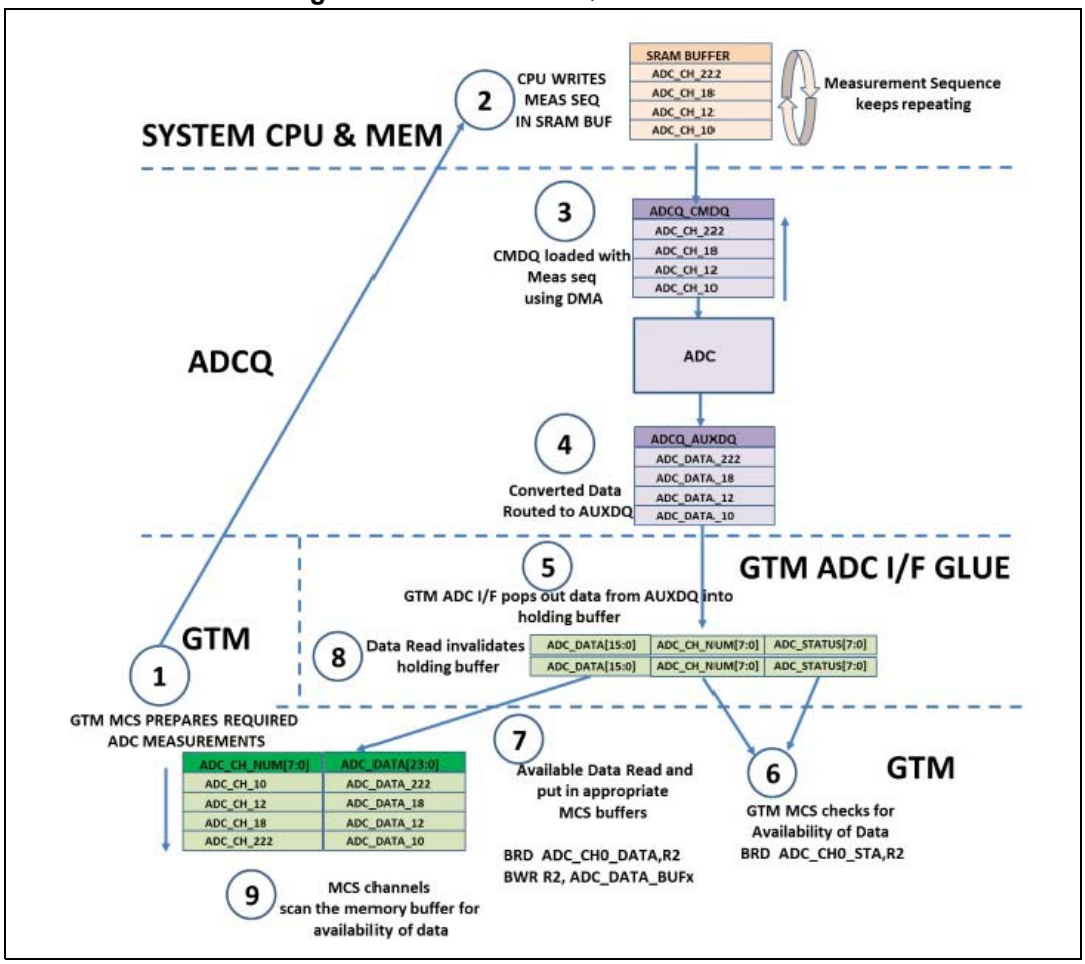
45.3.8.1 Interrupt Request Clear Controls

Each interrupt request output can be a composition of several internal events flags that are enabled by configuration registers. After an interrupt request is recognized by the chip interrupt controller and it is serviced, the interrupt routine must clear the flags that originated that service request. The GTM integration module provides two ways to clear those flags, but each method has its limitations that are described below.

The first way to clear the events flags that originated the interrupt request is by a slave bus write operation in the interrupt mapped registers named *_IRQ_NOTIFY in *Table 717*. The main characteristics are listed below:

- For example, writing a 1 in the bit field DEST_ERR on the register BRC_IRQ_NOTIFY is going to clear this bit to clear the ipi_int_gtm_brc interrupt output signal
- Several flags in this register could have generated the interrupt request, therefore all of them can be cleared with this write operation.
- There is a delay between the reception of the clear command and the actual clear of the flags. This time interval can vary and depends on the number of commands inside the AEI buffer. Therefore it is not possible to know easily when the flags were cleared.
- This method of interrupt clear can generate a new service request if we are using write masked response mode for AEI interface.

The second way to clear the events flags of the interrupt requests is by using the mapped register GTMINTCLR that is described in *Section 45.2.2.2: GTM Interrupts Clear Register (GTMINTCLR)*. The main characteristics of this method are listed below:



- For example, to clear the ipi_int_gtm_brc interrupt output signal, we execute a write operation in the GTMINTCLR register with data value 0x05 in the INTCLR_PTR bit field. This value selects to execute a clear in all flags that are used to generate that interrupt request.
- There is a delay between the reception of the clear command and the actual clear of the flags. This time interval can vary and depends on the number of commands inside the AEI buffer. However, the flags clear instant is well defined and can be seem by the integration module.
- As this method clear all flags for an interrupt request output, some flag that is set during the interrupt service is also cleared, and then some event can be lost.

45.3.9 GTM-ADC interface

Each MCS sub-module of the GTM IP provides a dedicated read interface for connection with external ADCQ modules present on the device. Converted data can be read from these external ADCQ modules using the instruction set of GTM IP. GTMINT module contains an interface block between the ADC interface of GTM IP and external ADCQ modules.

GTM MCS prepares the list of required ADC measurements in form of external ADC channel IDs and this channel list is programmed into the ADCQ modules by the software. External ADCQ will start the conversion on these channels and provides the digital data in a 32-bit wide FIFO. The steps involved in this process are captured in *Figure 614*.

Figure 614. GTM - ADCQ Read Data Flow

This 32-bit data will be read from the external FIFO along with some additional signals which are captured in *Table 730*.

Table 730. External ADC Signals

ADC Signal	Description
ADC_DISABLED	External ADC channel is disabled
ADC_READY	Data is present in the external ADC FIFO
ADC_VALID	Data read from external FIFO is valid
ADC_DATA [31:0]	32 bits ADC conversion data

GTM-ADC interface block present inside GTNMINT module keeps on polling the external FIFO to check when the converted data is available. As soon as the data is present in FIFO it will be read and stored into a holding buffer inside the GTMINT module.

Table 731. Holding Buffer Fields

Bit #	Field	Description
0	ADC CH INV	Conversion requested for the ADC channel is not present or it is disabled
1	BUFFER ENTRY VALID	The ADC data entry stored in Holding buffer is valid
2	FIRST ADC DATA	Marker for denoting the first ADC data of the Sequence
3	LAST ADC DATA	Marker for denoting the last ADC data of the Sequence
4:7	Reserved	Read returns zero
15:8	ADC CH NUM[7:0]	8 bit ADC Channel Number corresponding to the data in the ADC Data field.
31:16	DATA [15:0]	16-bit data field. This field holds ADC conversion data for the channel specified in the ADC_CH_NUM field.

GTM IP reads the conversion data as 30 bit input (ADC_DATA[29:0]) using its ADC read instructions as shown in *Figure 614*. It will take two instructions to read one complete conversion data of an ADC channel. **BRD ADC_CHn_STA** instruction will provide the ADC channel number and status to the GTM. Another read instruction **BRD ADC_CHn_DATA** provides the 16bit ADCQ data for the channel number read previously as given in *Table 732*.

Table 732. ADC_DATA [29:0] for GTM IP

Instruction	ADC_DATA [29]	ADC_DATA [28]	ADC_DATA [27:24]	ADC_DATA [23:16]	ADC_DATA [15:0]
BRD ADC_CHn_STA	FIRST_ADC_ DATA	LAST_ADC_ DATA	XXXX(1)	ADC_CH_NUM	XXXX(1)
BRD ADC_CHn_DATA	FIRST_ADC_ DATA	LAST_ADC_ DATA	XXXX(1)	DATA [23:16](2)	DATA [15:0]

1. These data bits will be read as all 0s.
2. As the ADCQ converted data is only 16bit wide these remaining MSBs will be read as 0s.

Note: In current GTM-ADC interface scheme the channel ID provided by GTM IP instruction is not considered. The GTM-ADC interface reads the data present in the ADCQ FIFO and sends it to GTM IP irrespective of its channel ID.

GTM ADC interface block supports two types of access:

1. Normal access - In this only one converted data is read from an ADC channel at a time. GTM reads channel number and status followed by the channel data for a particular ADCQ channel. In normal access the holding buffer data will be overwritten only when

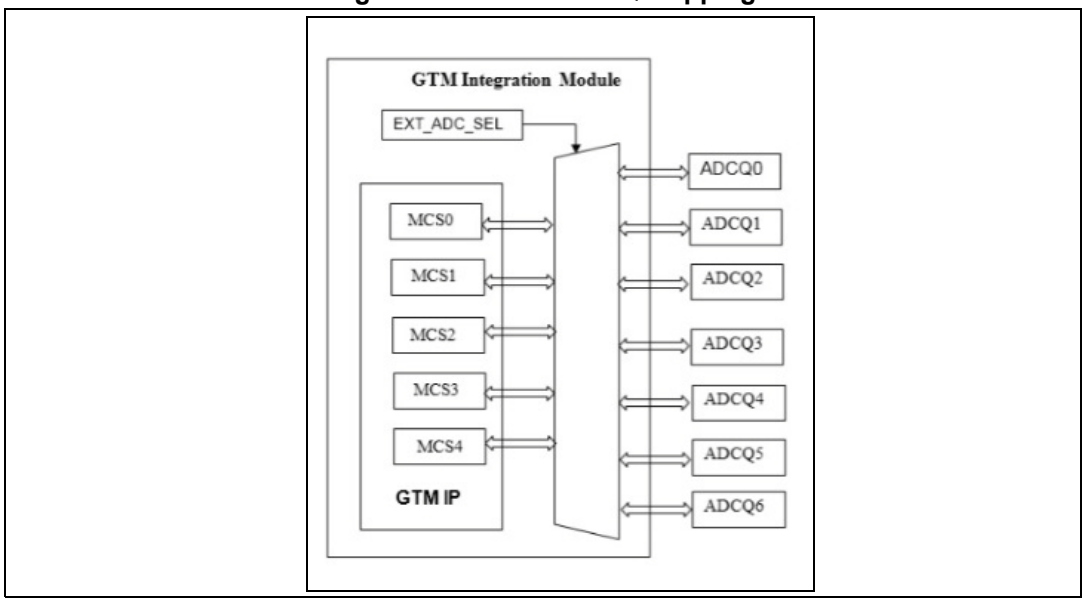
both channel number and channel data is read by the GTM. *Table 733* shows the list of instructions for completing one normal access.

Table 733. GTM Instruction List For Normal Access

Instruction	Description
BRD ADC_CHn_STA, R2	Read ADC channel number and status
BRD ADC_CHn_DATA, R2	Read ADC data for the channel number read earlier
BWR R2, ADC_DATA_BUFx	Write this ADC data in the internal buffer

2. Burst access - If a GTM MCS sub-module is programmed to read a list of channels from a single ADCQ then it can access the data using burst mode. In this mode the first channel ID and status are read followed by the data. For the remaining access only channel data is read. Table shows an example list of instructions for burst access. During the burst access first and last channel data is signified by ADC data bits 29 and 28 respectively. *Table 734* shows an example set of instructions for a burst access which contains 4 channels in the conversion list.

Table 734. GTM Instruction List For Burst Access



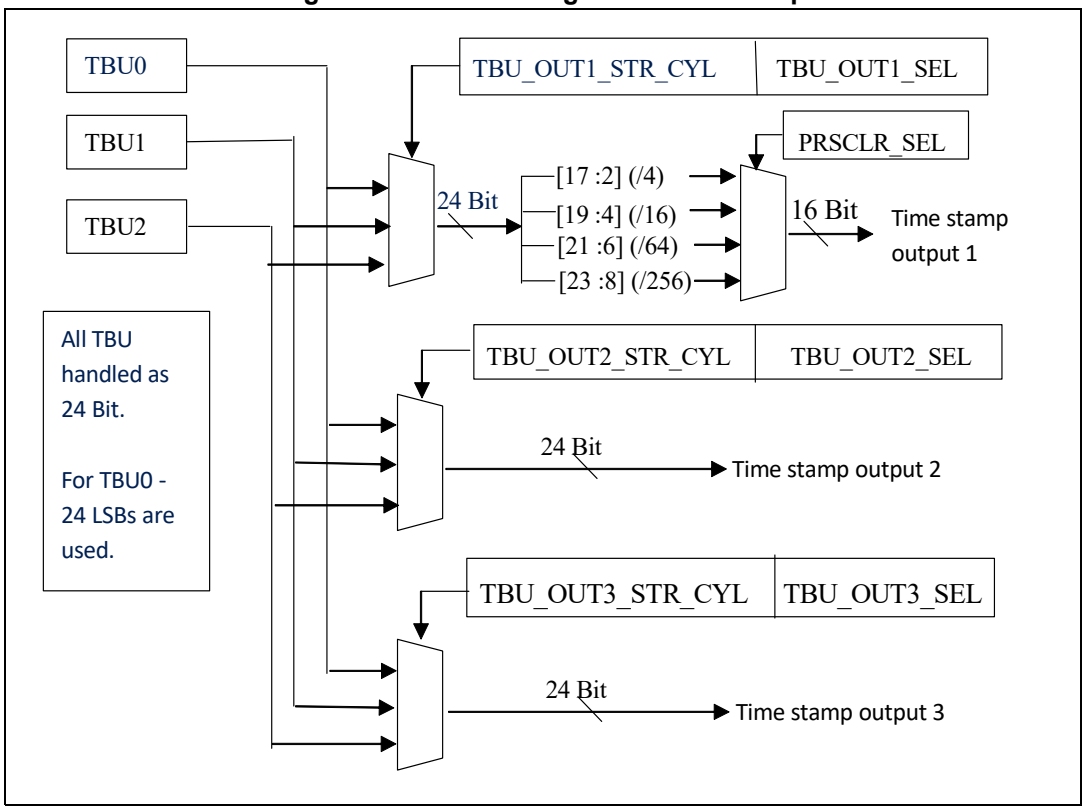
Instruction	Description
BRD ADC_CHn_STA, R2	Read ADC Channel number and status. This will be the first channel to be read from mapped ADCQ.
BRD ADC_CHn_DATA, R2	Read ADC data for the channel number read earlier. This will be the first channel to be read from mapped ADCQ.
BWR R2, ADC_DATA_BUFx	Write this first channel data in the internal buffer
BRD ADC_CHn+1_DATA, R2	Read ADC data for the next channel number in the list.
BWR R2, ADC_DATA_BUFx	Write this channel data in the internal buffer
BRD ADC_CHn+5_DATA, R2	Read ADC data for the next channel number in the list.
BWR R2, ADC_DATA_BUFx	Write this channel data in the internal buffer
BRD ADC_CHn+x_DATA, R2	Read ADC data for the last channel number in the list.
BWR R2, ADC_DATA_BUFx	Write this last channel data in the internal buffer

This GTM-ADC interface present in the GTMINT module will remain disabled if the GTMINT goes into Stop or Halt mode.

45.3.9.1 MCS-External ADCQ Mapping

The clusters present in GTM IP contains a MCS sub-module and each MCS sub-module is associated with an ADC read interface. These MCS modules can be mapped to any of the external ADCQ module present on the device by programming *External ADC Select Register (EXT_ADC_SEL)* register. This mapping should be written into the register when MCS_ADC_SEL_EN bit is low. After programming the ADCQ mapping in the register bits MCS_ADC_SEL_EN bit should be set high. After writing 1 to MCS_ADC_SEL_EN bit wait for MCS_ADC_EN_ACK bit to go high. MCS_ADC_EN_ACK bit going high signifies that the GTM-ADCQ interface is now enabled and the normal transactions can be done on this interface.

Figure 615. MCS - ADCQ Mapping



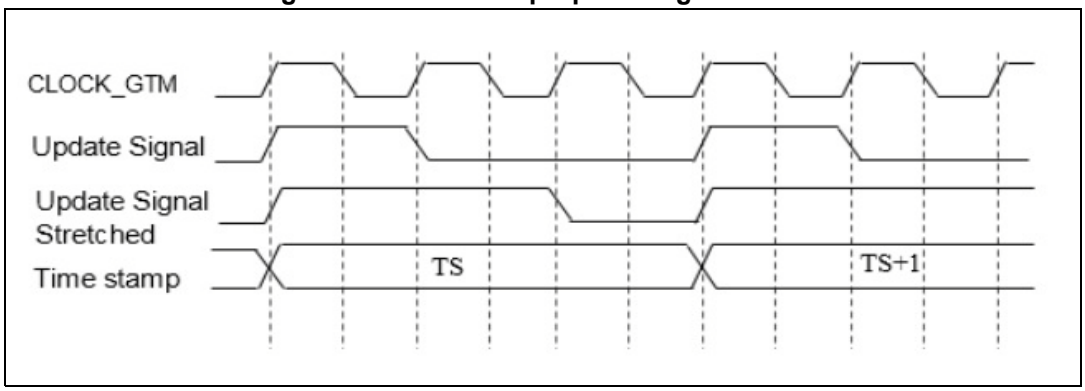
Note: This is mapping is one-to-one so each ADCQ can be mapped to only one of the MCS sub-module.

45.3.10 Configurable Time Stamp

GTM IP has a timebase unit (TBU) block which is further organized into three channels. All the three channels can be individually configured to provide different time stamps. GTMINT module provides three time stamp outputs for usage in external modules like CAN, FlexRay, SAR ADC and SD ADC.

Out of these three, first Timestamp output is 16 bits wide and remaining two outputs are 24 bits wide. The timetamp and update signal coming from any of the three TBU channels can be provided to any of the three outputs by programming *Timestamp Configuration registers*. First 16bits wide timestamp output has a prescalar option which can be programmed to get different resolutions of timestamp. Based on the programming it can select bits [17:2], [19:4], [21:6] or [23:8] from any of the TBU channels.

Figure 616. GTM Configurable Timestamp



Note: From TBU channel 0 only 24LSB bits are used for timestamp.

45.3.10.1 Timestamp Update Signal Stretching

The time stamp from each TBU channel can be configured to update at a fraction of GTM clock frequency. GTM IP provide a time base update signal (TBU_UP) along with each channel which goes high for one GTM clock cycle when the time stamp bus is getting updated. This update signal is stretched by a number of GTM clock cycles so that it can be easily detected by external modules using the time stamp which are running at lower frequency than the GTM. The number of clock cycles by which this signal is stretched is configured using *Timestamp Configuration registers*.

Figure 617 shows an example in which the TBU_OUTx_STR_CYL is programmed as 1 so the update signal is stretched by 1 GTM clock cycle.

Figure 617. Timestamp Update Signal Stretch

45.4 Programming Guidelines

45.4.1 Initialization/Application Information

The GTM integration module receives two active low reset signals, one on the slave bus clock domain, and the other in the peripheral clock domain. The last one resets all the timer logic, and registers inside the GTM-IP block. Just after this reset signal is negated, the GTM-IP is in the following condition:

- The GTM bridge is in asynchronous mode.
- after reset, write operations waits the response status (write response is not masked).
- If MDIS_DEFAULT is 1, a write access to GTMMCR is necessary to clear the MDIS bit register and have the GTM-IP clocks toggling.
- DPLL RAMs and MCSs RAMs starts the write initialization cycles. This is necessary for ECC parity bits storage on each RAM address.
- FIFO0 RAM is not automatically initialized. In normal operation mode, the initialization is not required because the FIFO memory always have to written first to be read later.

Refer to GTM-IP and GTMDI documentation to initialize the GTMINT module.

45.4.2 GTM - ADC Interface Programming

While programming the external ADCQ modules and the GTM MCS sub-modules the system should follow the steps given in *Figure 614*.

- First the conversion list should be prepared which contains the list of ADC channels.
- Then this conversion list should be programmed in the external ADCs.
- After programming the external ADCs software should program *External ADC Select Register* to map the MCS interfaces with the external ADCQ modules.
- This mapping of MCS modules with external ADCQ should be done when MCS_ADC_SEL_EN bit is low. During the first write to this register only bits [19:0]

should be programmed and in second write GTM-ADCQ interface can be enabled by writing MCS_ADC_SEL_EN bit as 1.

- Special care should be taken while programming this register so that no two MCS sub-modules are mapped to the same ADCQ. Hence no two MCS*x*_ADC_SEL fields can have the same value programmed.
- After writing 1 to MCS_ADC_SEL_EN bit wait for MCS_ADC_EN_ACK bit to go high. The transactions should be done on MCS-ADC interface only when this MCS_ADC_EN_ACK bit is high.
- GTM MCS-ADCQ mapping should not be changed during run-time when the GTM-ADC interface is in operation.
- After this the conversion data should be read by MCS instructions using either normal access or burst access.
- Match the channel numbers from the data read and store the conversion data in internal buffers accordingly.

45.4.3 Timestamp Configuration Programming

The GTM module updates its different TBU channels with timestamps generated based on internal CMU Clocks.

- This CMU clock is basically a divided version of GTM main clock.
- The timestamp counter from GTM is updated at the frequency of CMU clock inside GTM.
- First calculate the value of GTM clock divider for generating the CMU clock.

  $F_{CMU_CLK} = F_{GTM_CLK}/(Z/N)$
- Z/N values are required to be programmed in GTM for CMU clock generation as given in Clock Management Unit description of GTM344 documentation set.
- This value of Z/N should be calculated according to the frequency of the module where this timestamp will be used and number of clock cycles between two consecutive outputs/samples.

  (CEILING [F_{GTM} / F_{MODULE}]) * 3 < Z/N < (FLOOR [F_{GTM} / F_{MODULE}]) * [No. of module clock cycles between two consecutive samples]
- It is assumed that the operating frequency of external module will be less than the frequency of GTM.
- Example:

  F_{GTM} = 100MHz

  F_{MODULE} = 7.5MHz

  No of module cycles between two consecutive samples = 48 cycles

  (CEILING [100 / 7.5]) * 3 < Z/N < (FLOOR [100 / 7.5]) * 48

  14 * 3 < Z/N < 13 * 48

  42 < Z/N < 624

  Hence, the value of Z/N should lie between 42 and 624.
- All TBU channels can have different CMU clocks so they can operate at different frequencies.
- Now select one of the TBU output as the timestamp output by programming TBU_OUT*x*_SEL bit in Timestamp Configuration registers (*Section 45.2.2.5: Timestamp Configuration registers*).
- Next program the value by which the TBU update signal should be stretched as shown in *Figure 617* by programming TBU_OUT*x*_STR_CYL bits in *Timestamp Configuration registers*.
- The TBU_OUT*x*_SEL and TBU_OUT*x*_STR_CYL bits should be programmed only when respective timestamp output is disabled (TBUOUT*x*_EN bit is low).
- Only after programming these register fields the timestamp output should be enabled by writing TBUOUT*x*_EN bit as 1.
- The update signal should be stretched such that the falling edge lies in the middle of timstamp update cycle so that the receiver module can capture the timestamp on falling edge of update signal. So the valid range for TBU_OUT*x*_STR_CYL can be from 0 to (|Z/N|/2) -1 clock cycles, where Z/N is divider value calculated above.

Note: First program the required fields in External ADC Select Register (EXT_ADC_SEL) followed by Timestamp Configuration registers, then enable these interfaces in the same order by writing 1 into their respective enable bits.

46 Generic Timer Module (GTM344)

46.1 About this module

GTM344 is a programmable timer that can perform complex timing and I/O management independently of the chip's processor cores.

46.2 For more information

For more information on GTM344, see the Generic Timer Module 344 (GTM344) documentation set.

47 GTM Development Interface (GTMDI)

47.1 Introduction

The GTMDI debug module unit is a hardware module that:

- Monitors the software and hardware activities of GTM-IP
- Read the registers without interfering with the logic status, even for FIFOs, by configuring the debug access controls

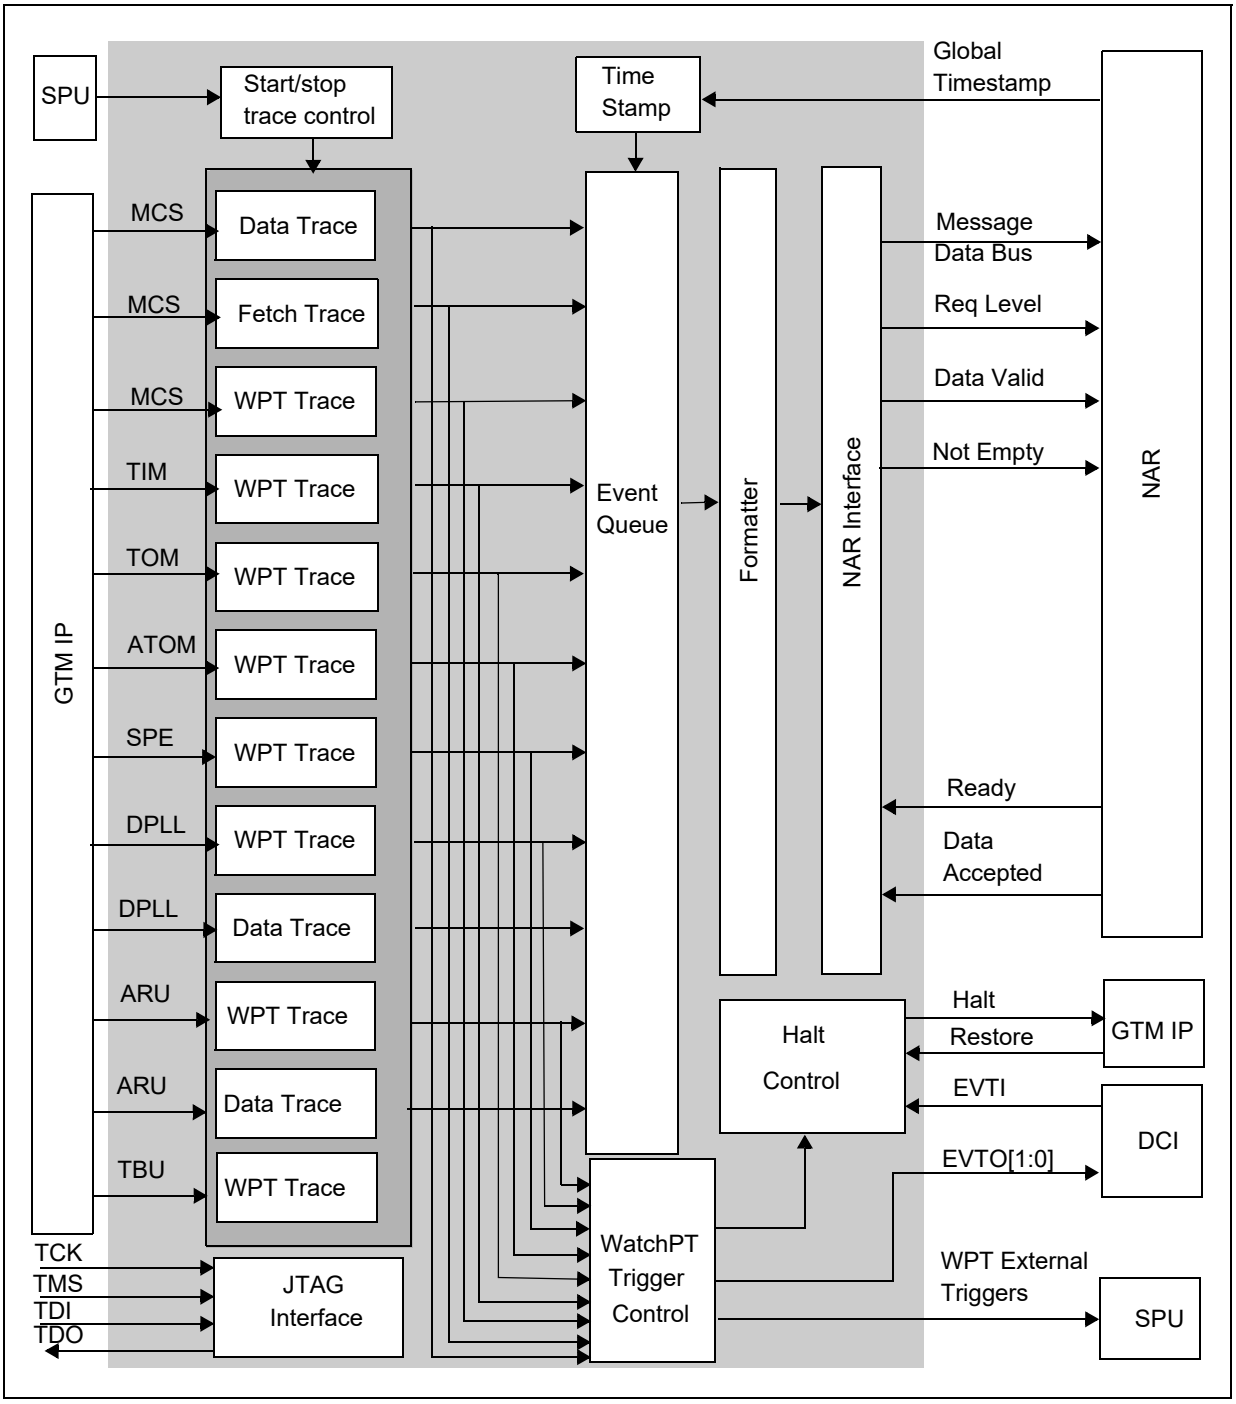
47.2 Overview

Figure 618 shows a block diagram of the Generic Timer Module (GTM) Development Interface.

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-Channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, input channel filters trace, output timer channels, DPLL and Sensor Pattern Evaluation (SPE) sub-modules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and NAR on-chip modules. The Nexus standard is only used for the physical interfaces. Due to specific requirements for the GTM debug, the Nexus standard is not followed.

Figure 618. GTMDI block diagram



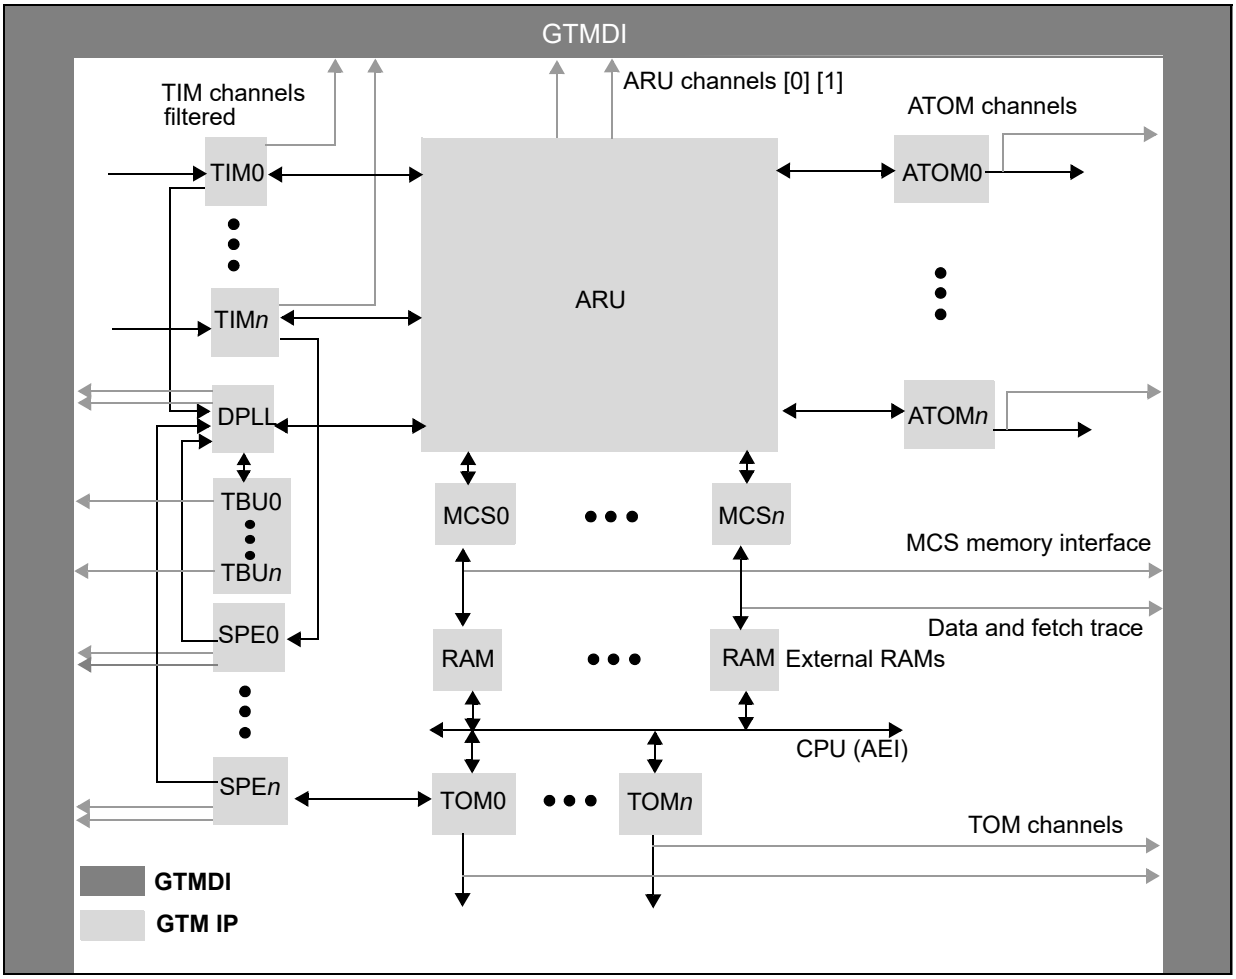


Figure 619 describes the interconnection between the GTMDI and GTM modules. The GTMDI selects which signal or bus to monitor since it does not have the capability to monitor all signals in parallel. The multiplexing architecture is described in the following sections.

Figure 619. GTMDI and GTM interface

Note: Figure 619 does not show all of the GTM internal modules. It shows only the modules that interface to the GTMDI debug module.

The number of ATOM, TIM, TOM, MCS and SPE modules in *Figure 619* is shown in *Table 735*.

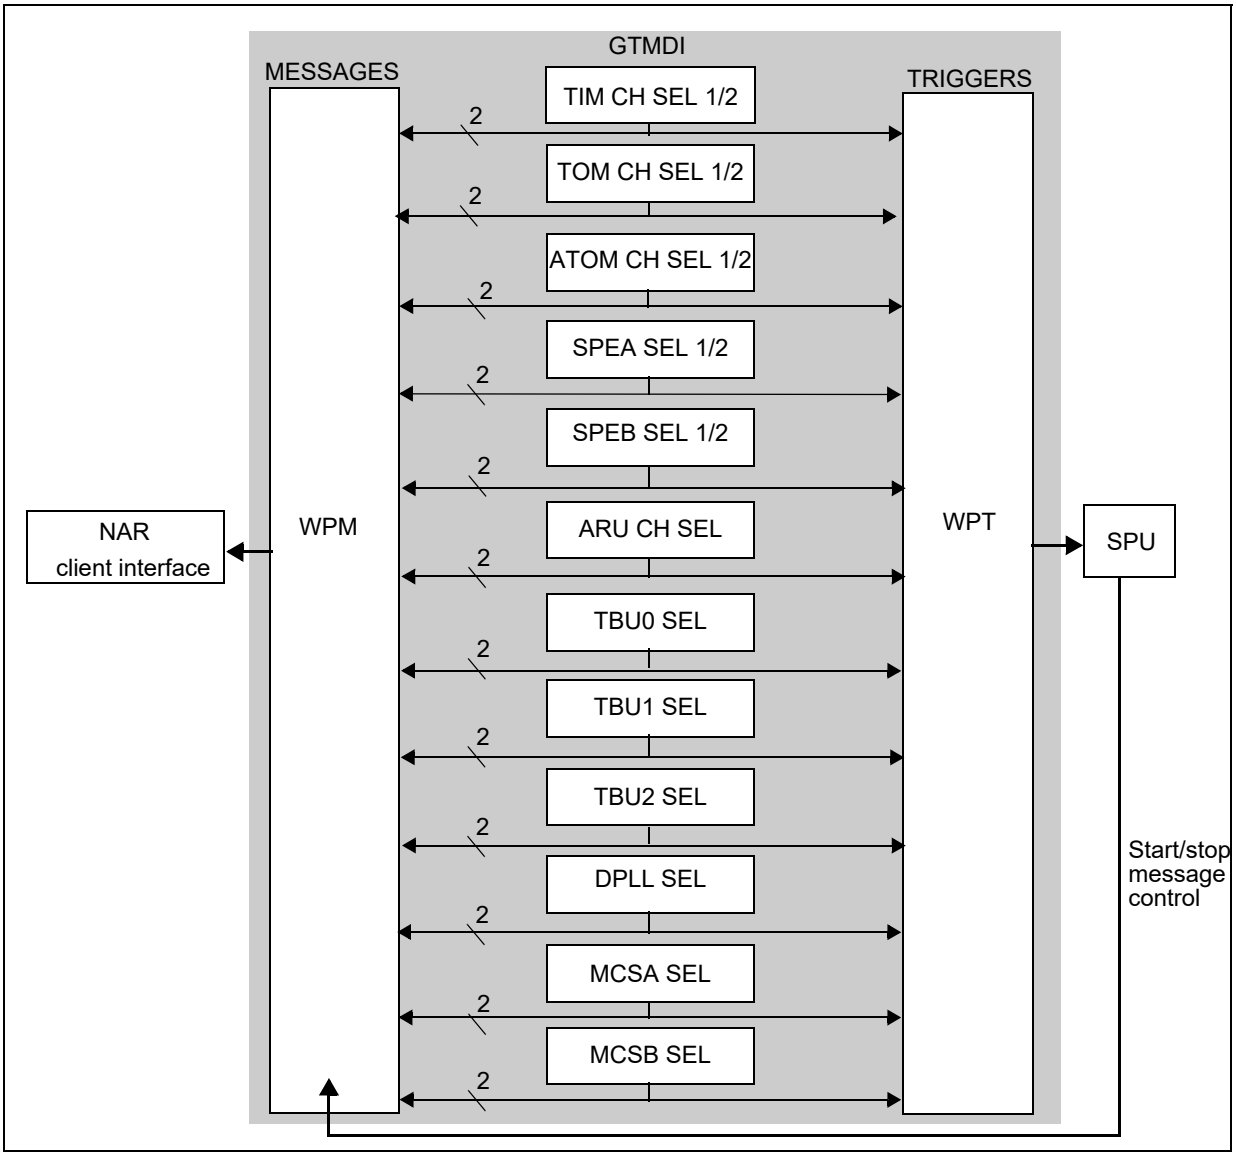

Table 735. GTM Sub-module instances

Module	Number of instances
ATOM	6
TIM	6
TOM	3
MCS	5
SPE	2

Figure 620 shows the Watchpoint Triggers (WPT) and Watchpoint Messages (WPM). Each GTM sub-module generates two watchpoints which can be routed internally to the GTMDI and generate watchpoint triggers or routed to the message formatter and generate watchpoint messages. The selection between watchpoint triggers and messages is

implemented per sub-module. Messages and watchpoint triggers can also be generated at the same time based on the same event within a sub-module, thus a TIM channel transition can generate a watchpoint trigger and a watchpoint message. The watchpoint triggers may be sent to the Sequence Processing Unit (SPU) outside the GTMDI if enabled by appropriate control register bits for each sub-module, such as Timer Input Module (TIM), Timer Output Module (TOM) and ARU-connected Timer Output Module (ATOM). The watchpoint messages, if enabled, are sent to the NAR through the Nexus Client interface.

Figure 620. Watchpoint triggers and watchpoint messages

The SPU provides external control of the watchpoint messages generated by the GTMDI thus controlling the bandwidth over the Nexus Client interface. This functionality is implemented through Start/Stop control signals from the SPU. These signals are connected to the sub-module register bit that enables the message transmission implementing a dual control over these registers, either by JTAG interface programing or by SPU Start/Stop

signals. See *Section 47.5: Functional description* for more details about register control and general architecture.

47.2.1 Features

The GTMDI block implements the following features:

- Full duplex pin interface for medium and high visibility throughput
  - 2 $\overline{\text{EVTO}}$ (Event Out) for GTM real time signal monitoring
  - 1 $\overline{\text{EVTI}}$ (Event In)
  - IEEE 1149.1 (JTAG) Test Access Port (TAP)

    4 pins (TDI, TDO, TMS, and TCK)

    Reset input $\overline{\text{TRST}}$ driven by either the Nexus Port Controller or an external pin
- GTM Development Support
  - Read/Write registers in debug mode from JTAG port
  - Ability to enter debug mode at reset negation or during normal execution

Note: Enter debug out-of-reset is provided through the SoC system level debug control signal. In order to allow this functionality the GDE and SDBE control bits in the GTMDI_DC register should be set.

  - Halt and Watchpoint Configuration
  - MCS Data Trace Messaging (DTM) and Watchpoint Messaging (WPM) allows the development tool to trace reads and writes to selected MCS RAM address ranges

    Two data trace windows for each MCS core with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the Aurora port bandwidth by constraining the number of trace locations.

    Fetch trace capability controlled by two programmable Watchpoints.

    Private messages are used to indicate special MCS core cases not covered by public messages. Two MCS cores can be debugged at the same time.

Note: Enabling two MCS cores at the same time for data trace can exceed the capacity of the NAR Client interface throughput thus information can be lost.

  - DPLL Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace reads and writes to selected DPLL RAM addresses and selected data value.
  - ARU Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace selected ARU channels.
  - Watchpoint Messaging (WPM)
- Trigger Control
  - The GTMDI provides selection of trigger signals that generate debug actions at system level such as Halt GTM itself or cores in the same device.
  - Trace enable signals are provided to control the start/stop of trace messages for each one of the GTM Nexus message sources, such as Timer Input Module (TIM), Timer Output Module (TOM), ARU-connected Timer Output Module (ATOM).
- GTMDI clock operation
  - The module is able to operate in any frequency ratio considering GTMDI and JTAG frequency. The GTMDI operates from the same clock source as the GTM IP module.

47.2.2 Modes of operation

The GTMDI block is placed in reset when the Nexus reset signal is asserted. The JTAG registers controlled by the TCK clock are also put into the reset state if the TAPcontroller is in the TEST-LOGIC-RESET state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the TEST-LOGIC-RESET state regardless of the initial TAP controller state. Asserting the Nexus reset signal *nex_reset_b* results in asynchronous entry into the reset state not only of the TCK controlled registers but all registers in the GTMDI. The GTMDI is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the TEST-LOGIC-RESET state
- The auxiliary output port pins are negated
- The auxiliary output port enable outputs are negated
- The TDI, TMS, and TCK TAP inputs are ignored (The TMS and TCK signal are ignored only while the Nexus reset signal *nex_reset_b* is asserted.)
- Registers default back to their reset values

Note: The GTMDI is not reset by the system reset signal. It is reset during device Power On reset or by a dedicated Nexus reset thus preserving internal registers state and programming during system reset.

Debug Mode can be controlled by on-chip logic through the system debug signal. The level on this signal defines if the GTM module is in debug mode, meaning that it is in Halt state and accepts write and read accesses to internal registers that do not modify the state of those registers. If asserted, the GTM enters Halt state. If negated, the GTM debug mode is controlled by other sources, internal to the GTMDI. The GTM may enter debug out of reset by asserting the system debug signal while the device is being reset. By detecting this condition, the GTMDI puts the GTM into the Halt state. The GDE and SDBE bits described in *Figure 622* must be set during reset allowing the GTM to enter debug state.

47.2.3 DATA port

GTMDI messages are sent through the Message Data Bus. The Message Data Bus has a fixed width of 32 bits which defines one BEAT of data. There are three BEATS per NAR clock thus 96 bits(MDO[89:0] + $\overline{\text{MSEO}}$[5:0]) are transmitted in parallel in the DATA port.

47.3 External signal description

The GTMDI pinout provides interface for the transmission of messages and for accessing Nexus registers. The GTMDI pin definition is outlined in *Table 736*.

Table 736. GTMDI signal properties

Name	Port	Function	Reset State
EVTI	Auxiliary	Event In pin	—
$\overline{\text{EVTO}}$[1:0]	Auxiliary	Event Out pin	[11]
TCK	TAP	Test Clock Input	—
TDI	TAP	Test Data Input	—
TDO	TAP	Test Data Output	0
TMS	TAP	Test Mode Select Input	—
TRST	TAP	Test Reset Input	—

Each of the signals listed in *Table 736* is described in more detail in the following sections.

47.3.1 Event in ($\overline{\text{EVTI}}$)

Event In ($\overline{\text{EVTI}}$) is used to generate a Halt if enabled by the corresponding control bit. $\overline{\text{EVTI}}$ is an edge-sensitive signal. It is synchronized at the GTMDI input and a falling edge is detected.

47.3.2 Event out $\overline{\text{EVTO}}$[1:0]

Event Out ($\overline{\text{EVTO}}$) are two outputs from GTMDI for development tools with exact timing for a two watchpoints or Halt occurrence. $\overline{\text{EVTO}}$ is asserted for one system clock cycle when Halt or watchpoints are monitored. When internal GTM signals are monitored, such as TIM filtered signals or TOM/ATOM outputs, the $\overline{\text{EVTO}}$ represent the exact signal shape with a certain delay. In this monitoring mode the signal is not inverted through the $\overline{\text{EVTO}}$ output. The real time monitoring mode is intended for oscilloscope type of monitoring thus allowing the user to evaluate the actual shape of the signals. The source selection for the $\overline{\text{EVTO}}$ is centralized in the Development Control register GTMDI_DC.

47.3.3 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the JTAG port.

47.3.4 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

47.3.5 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is actively driven in the SHIFT-IR and SHIFT-DR states of the JTAG state machine. TDO changes on the falling edge of TCK and is sampled on the rising edge of TCK.

47.3.6 Test Mode Select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the JTAG state machine. TMS is sampled on the rising edge of TCK.

47.4 Register definition

This section provides a detailed description of all GTMDI registers accessible to the development tool. Individual bit-level descriptions and reset states of each register are included. *Table 737* shows the GTMDI registers and index values. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 737. GTMDI registers

47.4.1 Register descriptions

This section consists of GTMDI register descriptions . The registers are shown in *Table 737*. The MCS cores selected for debugging are named MCSA and MCSB thus two MCS cores can be debugged at the same time. See registers GTMDI_MCSA_DC and GTMDI_MCSB_DC which specify the real number of the MCS associated with MCSA and MCSB.

47.4.1.1 Device identity register (DID)

The DID register contains the unique identification information as shown in *Figure 621*.

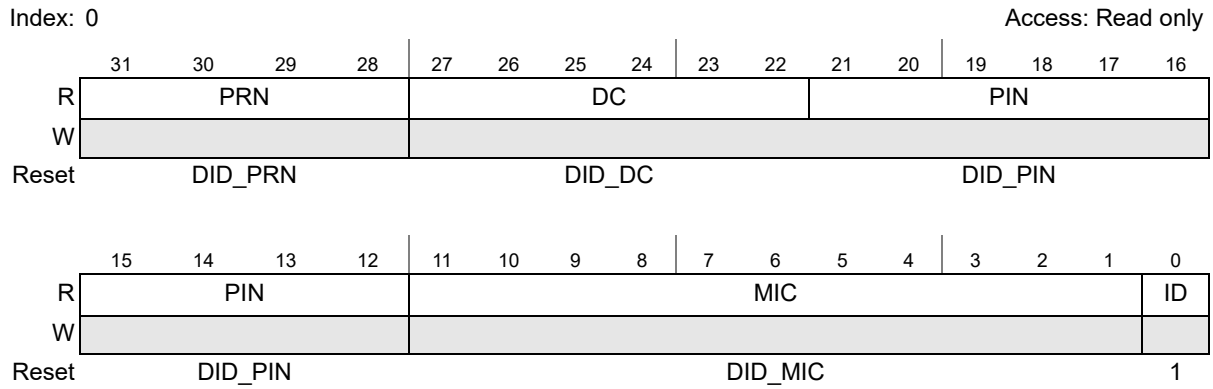

Figure 621. Device identity register (DID)

Table 738 describes the device identification register functions.

Table 738. DID field descriptions

Field	Description
31:28 PRN	Part Revision Number. Contains the revision number of the part.
27:22 DC	Design Center. Indicates the design center.
21:12 PIN	Part Identification Number. Contains the part number of the device. Value is 0x3E3.
11:1 MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x020.
0 ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

47.4.1.2 GTMDI development control register (GTMDI_DC)

The GTMDI_DC register controls various trace and debug features of the GTM modules as described in *Figure 622*.

Table 739 describes the GTMDI_DC register functions.

Table 739. GTMDI_DC field descriptions

Field	Description
31 GDE	Global Debug Enable. This control bit disables all debug features of the GTMDI module including ability to put GTM IP in Halt state, modify EVTO output, send messages to the DATA bus and set triggers to the SPU module. Before changing the GTMDI configuration it is recommended to clear GDE bit to prevent spurious behavior of the module outputs. See *Figure 678* for details about debug enable logic. 0 GTMDI Global debug is disabled 1 GTMDI Global debug is enabled
27:24 EOS0	$\overline{\text{EVTO0}}$ Output Selection. This signal is dedicated to sel 1 which is the selection 1 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output $\overline{\text{EVTO0}}$ remains at one 0001 Halt Indication, If $\overline{\text{EVTO0}}$ is zero indicates that GTM is halted 0010 TIM, Map EVTO0 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO0 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO0 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO0 from SPEA, controlled by TSS1 described in *Figure 630* 0110 SPEB, Map EVTO0 from SPEB, controlled by TSS1 described in *Figure 632* 0111 ARU CH0, Map EVTO0 from ARU CH0I 1000 DPLL, Map EVTO0 from DPLL according to TSEL1 in *Figure 634* 1001 MCSA, Map EVTO0 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO0 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved
19:16 EOS1	$\overline{\text{EVTO1}}$ Output Selection. This signal is dedicated to sel 2 which is the selection 2 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output $\overline{\text{EVTO1}}$ remains at one 0001 Halt Indication, If $\overline{\text{EVTO1}}$ is zero indicates that GTM is halted 0010 TIM, Map EVTO1 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO1 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO1 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO1 from SPEA, controlled by TSS2 described in *Figure 630* 0110 SPEB, Map EVTO1 from SPEB, controlled by TSS2 described in *Figure 632* 0111 ARU CH1, Map EVTO1 from ARU CH1 1000 DPLL, Map EVTO1 from DPLL according to TSEL2A/B in *Figure 634* 1001 MCSA, Map EVTO1 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO1 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved

Table 739. GTMDI_DC field descriptions (continued)

Field	Description
8 CHR	Clear Halt Request. Writing this bit to one clears halt requests., which means GTM resumes normal operation out of halt state. The status bits of the GTMDI_DS register are cleared. This bit is self-cleared thus read always as zero. 0 No action 1 Clear halt requests
6 EIDR	EVTI Debug Request enable. The EIDR bit enables EVTI input to request the GTM to enter Halt state. After the GTM enters Halt state due to a pulse in EVTI signal, the EIDR bit state is not meaningful, thus it may be cleared and the GTM continues in Halt state. See *Figure 678* for details about debug enable logic. 0 Disable EVTI to control GTM to enter Halt state 1 Enable EVTI to control GTM to enter Halt state
4 DBE	Debug Enable. DBE enables debug mode thus allowing the GTM to enter debug mode which means halt regular operation. The debug events controlled by this register are the ones generated internally to the GTMDI, excluding ipg_debug and EVTI which have their dedicated enable control. See *Figure 678* for details about debug enable logic. 0 Debug mode disabled 1 Debug mode enabled
3 DBR	Debug Request. Mechanism to allow development tool to request modules to enter debug mode directly. See *Figure 678* for details about debug enable logic. 0 Does not modify GTM IP debug state 1 Request GTM IP to enter debug mode
2 SDBE	System Debug Enable. The SDBE bit enables the GTM to enter halt state if system level debug enable signal is asserted. This bit allows the debug controller to select specific sub-groups of cores or modules to halt, while others continue to operate. GDE bit must also be set to allow GTM to halt. See *Figure 678* for details about debug enable logic. 0 GTM does not enter halt state due to system debug enable signal assertion 1 GTM is enabled to enter halt state due to system debug enable signal assertion
0 TSFT	Timestamp Force Transmission Forces the transmission of the Timestamp value along with the Nexus message data for all messages transmitted by the GTMDI Client module. When Timestamp inclusion is not forced into the client message, its inclusion depends upon the NAR settings. 0 Does not force transmission of Timestamp value 1 Forces transmission of Timestamp along with Nexus message

47.4.1.3 GTMDI development status register (GTMDI_DS)

The GTMDI_DS register described in *Figure 623* shows the status of various conditions that impact GTM development support. All status bits are dynamic and do not require clearing. Debug Status Event is queued due to a change in the Halt or Stop modes and a Debug Status Message is generated as soon as there is an opportunity in the NAR interface. If any status bit changes before the Status message is sent, this change is reflected in the message. The GTMDI_DS register dynamically tracks the debug condition status even when several of them are simultaneously set.

Figure 623. GTMDI development status register (GTMDI_DS)

Table 740 describes the GTMDI_DS register functions.

Note: The HS1 and HS2 bit fields are cleared as soon as the GTM resumes normal operation which is controlled by the CHR bit in the GTMDI_DC register. One exception is HS1[0] that indicates system debug request, which is not cleared by CHR. This bit is cleared when system debug request is negated.

Table 740. GTMDI_DS field descriptions

Field	Description
31 HLT	Halt Indication. The HLT bit indicates if the GTM IP is in Halt state, ready to receive debug accesses. 0 GTM is running 1 GTM is in Halt state (GTM Halt or Restore is high)
28:16 HS1	Halt Status1. The HS1 field shows which source generated the halt condition. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt sources that occurred immediately when the halt mode is entered. 0000000000000 No Trigger generated 1xxxxxxxxxxxx TIM x1xxxxxxxxxxx TOM xx1xxxxxxxxxx ATOM xxx1xxxxxxxxx SPEA xxxx1xxxxxxxx SPEB xxxxx1xxxxxxx ARU xxxxxx1xxxxxx DPLL xxxxxxx1xxxxx MCSA xxxxxxxx1xxxx MCSB xxxxxxxxx1xxx TBU0 Watchpoint 1 xxxxxxxxxx1xx TBU1 Watchpoint 1 xxxxxxxxxxx1x TBU2 Watchpoint 1 xxxxxxxxxxxx1 External through system debug enable signal

Table 740. GTMDI_DS field descriptions (continued)

Field	Description
15 STP	Stop Status. Indicates if the GTM is in stop mode with no active clocks. Besides the system level stop mode mechanism, the GTM may independently be programmed for STOP mode by setting the Module Disable Control bit. Thus, the STP field indicates if the GTM is in stop mode no matter if due to the system stop mode assertion or due to the MDIS bit in the GTM module control register. 0 GTM not stopped 1 GTM is stopped in low power mode
12:0 HS2	Halt Status2. Similarly to HS1 this field indicates the source for the halt condition selection 2. See *Figure 679* for reference about source selection 1 and 2. The HS2 field shows which source generated the halt condition 2. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt condition source that occurred when the halt mode is entered. 0000000000000 No Trigger generated 1xxxxxxxxxxxTIM x1xxxxxxxxxxTOM xx1xxxxxxxxxATOM xxx1xxxxxxxxSPEA xxxx1xxxxxxxSPEB xxxxx1xxxxxxARU xxxxxx1xxxxxDPLL xxxxxxx1xxxxx MCSA xxxxxxxx1xxxxMCSB xxxxxxxxx1xxx TBU0 Watchpoint 2 xxxxxxxxxx1xx TBU1 Watchpoint 2 xxxxxxxxxxx1x TBU2 Watchpoint 2 xxxxxxxxxxxx1 $\overline{\text{EVTI}}$

47.4.1.4 TIM watchpoint control register 1 (GTMDI_TIM_WPC1)

The GTMDI_TIM_WPC1 register shown in *Figure 624* controls the Watchpoint Triggers WPT issued by TIM channels. These triggers are used by the GTM internal modules in order to control GTM Halt mode entering and also at SoC level. See *Figure 679* which describes the use of this register.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG . The SEN1 and SEN2 control bits from the GTMDI_TIM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Table 741 describes the GTMDI_TIM_WPC1 register functions.

Table 741. GTMDI_TIM_WPC1 field descriptions

Field	Description
29:28 TSS1	TIM Channel Slope Selection 1. The TSS1 field selects the slope for the TIM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
26:24 SSEL1	TIM sub-module Source Selection 1. Selects which TIM sub-module is the source for watchpoint generation. 000 TIM0 001 TIM1 010 TIM2 011 TIM3 100 TIM4 101 TIM5 110 Reserved 111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

Table 741. GTMDI_TIM_WPC1 field descriptions (continued)

Field	Description
18:16 CHSEL1	TIM channel selection 1. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7
13:12 TSS2	TIM Channel Slope Selection 2. The TSS2 field selects the slope for the TIM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
10:8 SSEL2	TIM sub-module Source Selection 2. Selects which TIM sub-module is the source for watchpoint generation. 000 TIM0 001 TIM1 010 TIM2 011 TIM3 100 TIM4 101 TIM5 110 Reserved 111 Reserved
7 HEN2	Halt Enable 2. The HEN1 Halt Enable 2 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC1 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
2:0 CHSEL2	TIM channel selection 2. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7

47.4.1.5 TIM watchpoint control register 2 (GTMDI_TIM_WPC2)

The GTMDI_TIM_WPC2 register shown in *Figure 625* controls the Watchpoint Triggers WPT issued by TIM channels. These watchpoint triggers are used to control GTM Halt state entering, watchpoint messages and control external logic to the GTMDI. See *Figure 679* for details of the logic that uses the bits in this register.

Figure 625. TIM watchpoint control 2 register (GTMDI_TIM_WPC2)

Table 742 describes the GTMDI_TIM_WPC2 register functions.

Note: The SHARED_WPT and SHARED_WPT_ST signals mentioned in Table 742 and in other tables in this document, refer to the GTMDI top level connections. They correspond to Watchpoint trigger outputs of GTMDI and Stop/Start input signals respectively.

Table 742. GTMDI_TIM_WPC2 field descriptions

Field	Description
30:28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same WTSEL1 value, in this case the result watchpoint signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21:20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a Watchpoint external trigger is issued. This enable refers to the output selected by the WTSEL1 field. 0 Disable Watchpoint Trigger Generation 1 Enable Watchpoint Trigger Generation

Table 742. GTMDI_TIM_WPC2 field descriptions (continued)

Field	Description
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected TIM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same watchpoint trigger, in this case the result signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used to control the watchpoint trace messages for the selected TIM channel. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TIM channel. This enable refers to the output selected by the WTSEL2 field. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.6 TOM watchpoint control register 1 (GTMDI_TOM_WPC1)

The GTMDI_TOM_WPC1 register shown in *Figure 626* controls the Watchpoint Triggers issued by TOM channels. These Watchpoint triggers are used to control the GTM requests to enter Halt, issue watchpoint messages and also by logic external to the GTMDI at SoC level.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAGJTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Table 744. GTMDI_TOM_WPC2 field descriptions

Field	Description
30:28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TOM Channel. Other modules can select the same WTSEL1 value, in this case the result watchpoint signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21:20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a Watchpoint external trigger is issued by the TOM Channel output selected by WTSEL1. 0 Disable Trigger Generation 1 Enable Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected TOM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_TOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available Watchpoint trigger outputs which one is connected to the TOM selected channel. Other modules can select the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used for the watchpoint message control. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 744. GTMDI_TOM_WPC2 field descriptions (continued)

Field	Description
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TOM channel. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs of the GTMDI to control Watchpoint trace messages generated by the TOM selected channel. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.8 ATOM watchpoint control 1 register (GTMDI_ATOM_WPC1)

The GTMDI_ATOM_WPC1 register shown in *Figure 628* controls the Watchpoint Triggers issued by ATOM channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ATOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Table 745 describes the GTMDI_ATOM_WPC1 register functions.

Table 745. GTMDI_ATOM_WPC1 field descriptions

Field	Description
29:28 TSS1	ATOM Channel Slope Selection 1. The TSS1 field selects the slope for the ATOM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
27:24 SSEL1	ATOM sub-module Source Selection 1. Selects which ATOM sub-module is the source for watchpoint generation. 0000 ATOM0 0001 ATOM1 0010 ATOM2 0011 ATOM3 0100 ATOM4 0101 ATOM5 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the selected ATOM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected ATOM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected ATOM Channel output to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
18:16 CHSEL1	ATOM channel selection 1. Selects which channel in an ATOM module generates watchpoints. 000 ATOM CH0 001 ATOM CH1 010 ATOM CH2 011 ATOM CH3 100 ATOM CH4 101 ATOM CH5 110 ATOM CH6 111 ATOM CH7
13:12 TSS2	ATOM Channel Slope Selection 2. The TSS2 field selects the slope for the ATOM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved

Table 745. GTMDI_ATOM_WPC1 field descriptions (continued)

Field	Description
11:8 SSEL2	ATOM sub-module Source Selection 2. Selects which ATOM module is the source for watchpoint generation. 0000 ATOM0 0001 ATOM1 0010 ATOM2 0011 ATOM3 0100 ATOM4 0101 ATOM5 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the ATOM selected channel is enabled to HALT the GTM module. If this bit is set and an event occurs on the ATOM selected channel, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected ATOM Channel output to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
2:0 CHSEL2	ATOM channel selection 2. The CHSEL2[2:0] field selects a channel within the TOM selected sub-module to generate watchpoints. 000 ATOM CH0 001 ATOM CH1 010 ATOM CH2 011 ATOM CH3 100 ATOM CH4 101 ATOM CH5 110 ATOM CH6 111 ATOM CH7

47.4.1.9 ATOM watchpoint control 2 register (GTMDI_ATOM_WPC2)

The GTMDI_ATOM_WPC2 register shown in *Figure 629* controls the Watchpoint Triggers issued by ATOM channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected ATOM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_ATOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table 746. GTMDI_ATOM_WPC2 field descriptions (continued)

Field	Description
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available Watchpoint trigger outputs which one is connected to the ATOM selected channel. Other modules can selected the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used for the watchpoint message control. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected ATOM channel. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs of the GTMDI to control Watchpoint trace messages generated by the ATOM selected channel. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_ATOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.10 SPEA watchpoint control 1 register 1 (GTMDI_SPEA_WPC1)

The GTMDI_SPEA_WPC1 register shown in *Figure 630* controls the Watchpoint Triggers issued by SPEA channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and to control logic outside of the GTMDI module, such as SPU interface.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_SEP0_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Table 749 describes the GTMDI_SPEB_WPC1 register functions.

Table 749. GTMDI_SPEB_WPC1 field descriptions

Field	Description
26:24 SSEL	SPEB sub-module Source Selection(1) Selects which SPE sub-module is the source for watchpoint generation. 000 SPE1 001 Reserved 010 Reserved 011 Reserved 100 Reserved 101 Reserved 110 Reserved 111 SPE0
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on SPEB NIPD to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
21:20 TSS1	SPEB NIPD Slope Selection. The TSS1 field selects the slope for the NIPD signal. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
17 HEN1	Halt Enable 1. The HEN1 Halt Enable 1bit controls if the SPEB NIPD active slope event is enabled to HALT the GTM module. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on SPEB DIR output to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0Watchpoint Messages disabled 1 Watchpoint Messages enabled
5:4 TSS2	SPEB DIR Slope Selection. The TSS2 field selects the slope for the DIR signal. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
1 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the SPEB DIR active slope event is enabled to HALT the GTM module. 0 Disables Halt GTM 1 Enables Halt GTM

1. The SSEL field for SPEB starts from SPE1 selection, differently from the equivalent field for SPEA which selects SPE0 instead.

47.4.1.13 SPEB watchpoint control 2 register (GTMDI_SPEB_WPC2)

The GTMDI_SPEB_WPC2 register shown in *Figure 633* controls the Watchpoint Triggers issued by SPEB. These watchpoints are used for GTM to enter Halt state, generate

watchpoint trace messages and to control logic outside the GTMDI module, such as SPU interface.

Table 750. GTMDI_SPEB_WPC2 field descriptions (continued)

Field	Description
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the DIR SPEB signal. Other modules can selected the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used for the watchpoint message control. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a watchpoint external trigger is issued by the SPEB DIR selected event. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the SPEB DIR selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_SPEB_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.14 DPLL watchpoint control 1 register (GTMDI_DPLL_WPC1)

The GTMDI_DPLL_WPC1 register shown in *Figure 634* controls various trace and debug features of the DPLL modules as described below.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_DPLL_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Figure 634. DPLL watchpoint control 1 register (GTMDI_DPLL_WPC1)

Table 751 describes the GTMDI_DPLL_WPC1 register functions.

Table 751. GTMDI_DPLL_WPC1 field descriptions

Field	Description
25:24 TSEL1	Watchpoint Selection 1. The TSEL1[1:0] field selects if a watchpoint trigger is issued based on TASI or SASI events. 00 Watchpoint on TASI event 01 Watchpoint on SASI event 10 Reserved 11 Reserved
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on DPLL SASI or TASI to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
21:20 TSS1	TASI/SASI Slope Selection. The TSS1 field selects the slope for TASI or SASI depending on TSEL1 selection. The selected slope is monitored by watchpoints. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
17 HEN1	The HEN1 Halt Enable 1 bit controls if the DPLL SASI or TASI selected signal is enabled to HALT the GTM module. If this bit is set and an event occurs on the DPLL selected signal, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
13:12 TSEL2B	Watchpoint Selection 2B. The TSEL2B field selects the RAM access type to mach on 00 Watchpoint is issued on any access (read or write) 01 Watchpoint is issued based on write accesses 10 Watchpoint is issued based on read accesses 11 Reserved

Table 751. GTMDI_DPLL_WPC1 field descriptions (continued)

Field	Description
9:8 TSEL2A	Watchpoint Selection 2A. The TSEL2A field selects if a watchpoint is issued based on the RAM1a, RAM1bc or RAM2 access. 00 Watchpoint is issued based on RAM1a access 01 Watchpoint is issued based on RAM1b access 10 Watchpoint is issued based on RAM2 access 11 Reserved
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables selected accesses on DPLL RAMs to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
1 HEN2	Halt Enable 2. The HEN Halt Enable bit controls if watchpoint from TSEL2 selection is enabled to HALT the GTM module. If this bit is set and an event occurs on an DPLL selected RAM, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM

47.4.1.15 DPLL watchpoint control 2 register (GTMDI_DPLL_WPC2)

The GTMDI_DPLL_WPC2 register shown in *Figure 635* controls the Watchpoint Triggers issued by DPLL. These triggers are used for GTM to enter Halt state and by GTMDI external logic at SoC level. This register also controls the Watchpoint Trace messages WPM.

Table 752 describes the GTMDI_DPLL_WPC2 register functions.

Table 752. GTMDI_DPLL_WPC2 field descriptions

Field	Description
30:28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL SASI or TASI signal. Other modules can select this same WTSEL1 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21:20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages related to DPLL SASI or TASI signals. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a watchpoint external trigger is issued by the DPLL TASI or SASI selected event. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enable the DPLL TASI or SASI selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL RAM access signal. Other modules can select this same WTSEL2 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used by the watchpoint trace messages related to DPLL RAM access events for RAM1A, RAM1B and RAM2. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 752. GTMDI_DPLL_WPC2 field descriptions (continued)

Field	Description
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a watchpoint external trigger is issued by the DPLL RAM selected access. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the DPLL RAM selected access event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.16 DPLL watchpoint control 3 register (GTMDI_DPLL_WPC3)

The GTMDI_DPLL_WPC3 register shown in *Figure 636* defines the data value observed in the selected DPLL RAM access. A match to this value causes a Watchpoint.

Index: 43 Access: Read/Write

Table 753 describes the GTMDI_DPLL_WPC3 register functions.

Table 753. GTMDI_DPLL_WPC3 field descriptions

Field	Description
28 DMASK	Data Mask. The DMASK field is a mask for the data comparator. If set, the data read or written to the memory should not be considered for watchpoint generation. 0 RAM_DATA should be compared with data from RAM access 1 RAM_DATA is masked and should not be compared
23:0 RAM_DATA	Data value. The RAM_DATA[23:0] field defines the data value that is compared against the data accessed from the selected DPLL RAM.

47.4.1.17 DPLL watchpoint control 4 register (GTMDI_DPLL_WPC4)

The GTMDI_DPLL_WPC4 register shown in *Figure 637* defines the RAM address mask for the DPLL selected RAM address comparisson.

Index: 44 Access: Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 754 describes the GTMDI_DPLL_WPC4 register functions.

Table 754. GTMDI_DPLL_WPC4 field descriptions

Field	Description
11:0 RAM_ADDR_MASK	RAM Address mask. The RAM_ADDR_MASK[11:0] field is a mask applied bit by bit to the RAM_ADDR defined in the GTMDI_DPLL_WPC5 register. If mask is 1, the corresponding RAM_ADDR bit is not valid for comparison, thus it always returns a match when compared to the selected RAM address.

47.4.1.18 DPLL watchpoint control 5 register (GTMDI_DPLL_WPC5)

The GTMDI_DPLL_WPC5 register shown in *Figure 638* defines the address value that is monitored during DPLL selected RAM access. Once this address value matches with the DPLL RAM address a Watchpoint is issued.

Index: 45 Access: Read/Write

Table 755 describes the GTMDI_DPLL_WPC5 register functions.

Table 755. GTMDI_DPLL_WPC5 field descriptions

Field	Description
11:0 RAM_ADDR	RAM Address Compare. The RAM_ADDR[11:0] field defines the address value that is compared against the address for write and read DPLL RAM accesses. Before the comparison is executed the RAM_ADDR_MASK should be considered thus masking corresponding bits. A masked bit is always considered a match. **Note:** DPLL module has three RAM modules with different address widths. The address value in the RAM_ADDR field and the RAM address should be right aligned in order to be compared.

47.4.1.19 DPLL data trace control register (GTMDI_DPLL_DTC)

The GTMDI_DPLL_DTC register shown in *Figure 639* controls data trace message transmission.

Index: 46 Access: Read/Write

Figure 639. DPLL data trace control register (GTMDI_DPLL_DTC)

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the DMC control bit thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit from the GTMDI_DPLL_DTC register need to be set in order to allow external Start/Stop signals to control the DMC bit.

Table 756 describes the GTMDI_DPLL_DTC register functions.

Table 756. GTMDI_DPLL_DTC field descriptions

Field	Description
13:12 RWC	Read/Write Control. This bit controls DPLL data trace message transmission. 00 Transmits only memory reads 01 Transmits only memory writes 10 Transmits all memory accesses 11 Reserved
9:8 RAMSEL	RAM Module Selection. This field selects a DPLL memory module for data tracing. 00 RAM1a selected for data tracing 01 RAM1b selected for data tracing 10 RAM2 selected for data tracing 11 Reserved

Table 756. GTMDI_DPLL_DTC field descriptions (continued)

Field	Description
6 DMC	Data Trace Message Control. This bit is written by JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
5:4 STSEL	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
0 SEN	Start/Stop Enable. The SEN bit field enables the DPLL data trace message generator to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DMC Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.20 ARU watchpoint control 1 register (GTMDI_ARU_WPC1)

The GTMDI_ARU_WPC1 register shown in *Figure 640* controls the Watchpoint Triggers issued by ARU Debugging Channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ARU_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Table 757 describes the GTMDI_ARU_WPC1 register functions.

Table 757. GTMDI_ARU_WPC1 field descriptions

Field	Description
28 TSS1	ARU Debugging Channel 0 Data Activity Selection 1. The TSS1 bit selects the type of data activity to monitor on ARU Debugging Channel 0. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel 0 1 Compare data with expected value
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the ARU Debugging Channel 0 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 0, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches on the ARU Debugging Channel 0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
12 TSS2	ARU Debugging Channel 1 Data Activity Selection. The TSS2 bit selects the type of data activity to monitor on the ARU Debugging Channel 1. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel Monitor 1 1 Compare data with expected value
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the ARU debugging Channel 1 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 1, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match on the ARU Debugging Channel 1 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

47.4.1.21 ARU watchpoint control 2 register (GTMDI_ARU_WPC2)

The GTMDI_ARU_WPC2 register shown in *Figure 640* controls the Watchpoint Triggers issued by ARU Debugging Channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_ARU_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table 758. GTMDI_ARU_WPC2 field descriptions (continued)

Field	Description
14:12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the ARU Debugging Channel 1. Other modules can selected the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5:4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used for the watchpoint message control for ARU Debugging Channel 1. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a watchpoint external trigger is issued by the ARU Debugging Channel 1 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the ARU Debugging Channel 1 to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_ARU_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.4.1.22 ARU watchpoint DATA0H register (GTMDI_ARU_DATA0H)

The ARU Watchpoint DATA0H high word shown in *Figure 642* is used for comparison against the high word of the ARU Debugging Channel 0. The address of the channel to be monitored is defined by the Host CPU in the GTM IP ARU_DBG_ACCESS0 register.

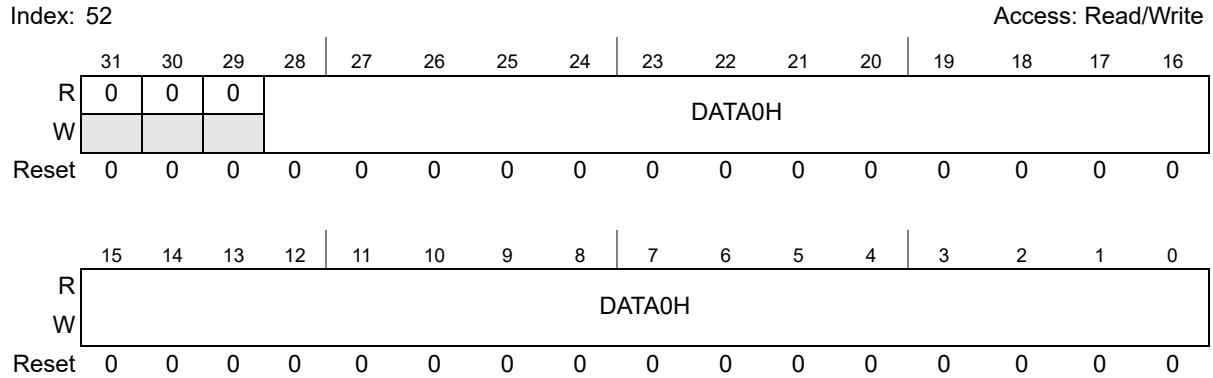

Figure 642. ARU watchpoint DATA0H register (GTMDI_ARU_DATA0H)

Table 759 describes the GTMDI_ARU_DATA0H register functions.

Table 759. GTMDI_ARU_DATA0H field descriptions

Field	Description
28:0 DATA0H	Watchpoint DATA0H. This field is compared against the high word of the ARU Debugging Channel 0.

47.4.1.23 ARU watchpoint DATA0L register (GTMDI_ARU_DATA0L)

The ARU Watchpoint DATA0H low word shown in *Figure 643* is used for comparison against the low word of the ARU Debugging Channel 0. The address for the channel to be monitored is defined by the Host CPU in the GTM IP ARU_DBG_ACCESS0 register.

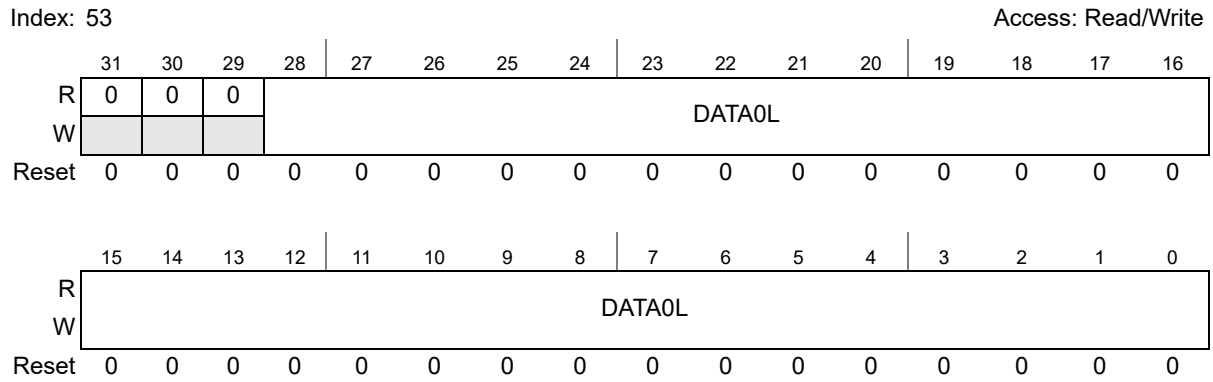

Figure 643. ARU watchpoint DATA0L register (GTMDI_ARU_DATA0L)

Table 760 describes the GTMDI_ARU_DATA0L register functions.

Table 760. GTMDI_ARU_DATA0L field descriptions

Field	Description
28:0 DATA0L	Watchpoint DATA0L. This field is compared against the low word of the ARU Debugging Channel 0.

47.4.1.24 ARU watchpoint DATA1H register (GTMDI_ARU_DATA1H)

The ARU Watchpoint DATA1H high word shown in *Figure 644*. is used for comparison against the high word of the ARU Debugging Channel 1. The address for the channel to be monitored is defined by the Host CPU in the GTM IP ARU_DBG_ACCESS1 register.

Field	Description
28:0 DATA1L	Watchpoint DATA1L. This field is compared against the low word of the ARU Debugging Channel 1.

47.4.1.26 ARU data trace control register (GTMDI_ARU_DTC)

The GTMDI_ARU_DTC register shown in *Figure 646* controls the ARU data trace message transmission. The GTM Module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1. The data trace for these two channels is controlled by DMC1/2 bits in this register. Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the DMC1 and DMC2 control bits thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC1 or DMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits need to be set in order to allow external Start/Stop signals to control the DMC1/2 bits.

Field	Description
11:8 MCSA_SEL	MCSA Selection field. The MCSA_SEL[3:0] selection field selects which one of the MCS cores in the GTM module are assigned as MCSA. 0000 MCS0 0001 MCS1 0010 MCS2 0011 MCS3 0100 MCS4 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

47.4.1.28 MCSA watchpoint control register (GTMDI_MCSA_WPC)

The MCSA Watchpoint Control Register shown in *Figure 648* is used to configure MCSA watchpoints. This register can be configured for halt/watchpoint based on instruction fetch, data read or data write, with address and data masking options.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC control bit thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit needs to be asserted in order to allow external Start/Stop signals to control the WMC bit.

Note: The watchpoint channel selection is made through the GTMDI_MCSA_CE by the WPCE field.

Figure 648. MCSA watchpoint control register (GTMDI_MCSA_WPC)

Table 765 describes the GTMDI_MCSA_WPC register functions.

Table 765. GTMDI_MCSA_WPC field descriptions

Field	Description
25:24 HACH	Halt/Watchpoint on Active Channel. The HACH field selects which type of MCS RAM access generates a watchpoint or halt. Combining this field with HWO gives GTMDI the capability of monitoring channel activity as well as accesses to specific addresses or data. 00 Match on Instruction Fetch 01 Match on Data Read 10 Match on Data Write 11 Match on Data Read or Write
22 WMC	Watchpoint Message Control. The WMC Watchpoint Message Control bit controls the watchpoint message sent through the Message Data bus. If this bit is asserted it enables MCSA Watchpoints to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
19:16 HME	Halt/Watchpoint Data Mask Enable. The HME field selects which data bytes are used for hardware halt/watchpoint generation when comparing to HWD register. This register field is only meaningful if HWO bit field is [x1], otherwise the data comparison is disabled independent of HME value. 0000 All bytes of data compared xxx1 Least significant byte of data masked out xx1x Second least significant byte of data masked out x1xx Second most significant byte of data masked out 1xxx Most significant byte of data masked out
15:14 HWO	Halt/Watchpoint Operand. The HWO field selects if address or data matching , or both, is done. Registers WPA and WPD are used for address and data comparison, respectively. If address is not compared WPA is not use. If data is not compared then WPD is not used. 00 Comparison Disabled for address or data x1 Compare data with HWD field 1x Compare address with HWA field
8 EOC	$\overline{\text{EVTO}}$ Control. The EOC bit controls the indication on the $\overline{\text{EVTO}}$ output. See *Figure 651*, *Figure 652*, *Figure 653* and *Figure 654* for definition about watchpoint 1 and 2. 0 Indicates Watchpoint 2 occurrence 1 Indicates Watchpoint 1 occurrence
7 HEN	Halt Enable. The HEN Halt Enable bit controls if the MCSA Watchpoint is enabled to HALT the GTM IP module. If this bit is set and watchpoint occurs on the MCSA a Halt signal is generated to the GTM IP which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
5:4 STSEL	Start/Stop input signal selection. Selects the Start/Stop input that is used to control the watchpoint messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 765. GTMDI_MCSA_WPC field descriptions (continued)

Field	Description
1 TEN	Watchpoint Trigger Enable.The TEN field controls if a external trigger is issued by the MCSA when a watchpoint occurs. 0 Disables Trigger Generation 1 Enables Trigger Generation
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA Watchpoint message to consider the Start/Stop inputs for watchpoint message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC Watchpoint Trace Message Control bit. 0 Disables trace control from Start/Stop inputs 1 Enables trace control from Start/Stop inputs

47.4.1.29 MCSA program fetch trace control register (GTMDI_MCSA_PTC)

The GTMDI_MCSA_PTC register shown in *Figure 649* allows program fetch traces to be enabled or disabled on the occurrence of a watchpoint. If the same watchpoint is programed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags. If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags also toggle.

Table 766. GTMDI_MCSA_PTC field descriptions

Field	Description
13:12 PFTS	Program Fetch Trace Start. This bit field allows Program fetch trace to be enabled at a watchpoint occurrence. See *Figure 651*, *Figure 652*, *Figure 653* and *Figure 654* for definition about watchpoint 1 and 2. 00 No watchpoint selected (do not start Program Fetch Trace) 01 Program Fetch Trace enabled on MCSA Program Watchpoint 1 occurrence 10 Program Fetch Trace enabled on MCSA Program Watchpoint 2 occurrence 11 Reserved
9:8 PFTE	Program Fetch Trace End. This bit field allows program trace to be disabled at a watchpoint occurrence. 00 No watchpoint selected 01 Program Fetch Trace disabled on MCSA Program Watchpoint 1 occurrence 10 Program Fetch Trace disabled on MCSA Program Watchpoint 2 occurrence 11 Reserved
6 FTC	Fetch Trace Control. This bit controls the Fetch Trace message sent through the Message Data bus. If this bit is asserted it enables MCSA Fetch access to generate a trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI 0 Fetch Messages disabled 1 Fetch Messages enabled
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA Fetch message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the FTC Fetch Trace Message Control bit. 0 Disable fetch trace control from Start/Stop inputs 1 Enable fetch trace control from Start/Stop inputs

47.4.1.30 MCSA data trace control register (GTMDI_MCSA_DTC)

The GTMDI_MCSA_DTC register shown in *Figure 650* controls which address ranges are enabled for data trace, and if reads and writes are traced in that range.

Table 767 describes the GTMDI_MCSA_DTC register functions.

Table 767. GTMDI_MCSA_DTC field descriptions

Field	Description
17 RC0	Range Control 0. Controls the range on data trace window 0. The window 0 is defined by DTAR1 register. See *Figure 656*. 0 Trace addresses outside (exclusive) of data trace window 0 1 Trace address inside (inclusive) of data trace window 0
16 RC1	Range Control 1. Controls the range on data trace window 1. The window 1 is defined by DTAR2 register. See *Figure 657*. 0 Trace addresses outside (exclusive) of data trace window 1 1 Trace address inside (inclusive) of data trace window 1
13:12 RWT0	MCSA Read/Write Trace Control 0. RWT0 controls whether data trace messages are generated for MCSA RAM read or write accesses. 00 No MCSA data trace messages generated for data trace window 0 01 Enable MCSA data read trace for MCS window 0 10 Enable MCSA data write trace for MCS window 0 11 Enable MCSA data read and write trace for data trace window 0
9:8 RWT1	MCSA Read/Write Trace Control 1. RWT1 controls whether data trace messages are generated for MCSA accesses inside MCS data trace window, and if so, whether reads, writes, or both generate the data trace messages. 00 No MCSA data trace messages generated for data trace window 1 01 Enable MCSA data read trace for MCS window 1 10 Enable MCSA data write trace for MCS window 1 11 Enable MCSA data read and write trace for data trace window 1
6 DTC	Data Trace Control. This bit controls the Data Trace message sent through the Message Data bus. If this bit is asserted it enables MCSA Data access to generate a data trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI 0 Data Messages disabled 1 Data Messages enabled
5:4 DTS	Data Trace Start. This bit field allows data trace to be enabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace enabled on MCSA Watchpoint 1 occurrence 10 Data Trace enabled on MCSA/B Watchpoint 2 occurrence 11 Reserved
2:1 DTE	Data Trace End. This bit field allows data trace to be disabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace disabled on MCSA Watchpoint 1 occurrence 10 Data Trace disabled on MCSA Watchpoint 2 occurrence 11 Reserved
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA Data message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DTC Data Trace Message Control bit. 0 Disable data trace control from Start/Stop inputs 1 Enable data trace control from Start/Stop inputs

47.4.1.31 MCSA watchpoint address 1 register (GTMDI_MCSA_WPA1)

The MCSA Watchpoint Address 1 Register shown in *Figure 651* is used to configure the MCSA halt/watchpoint hardware. It isused for data and instruction fetch accesses.

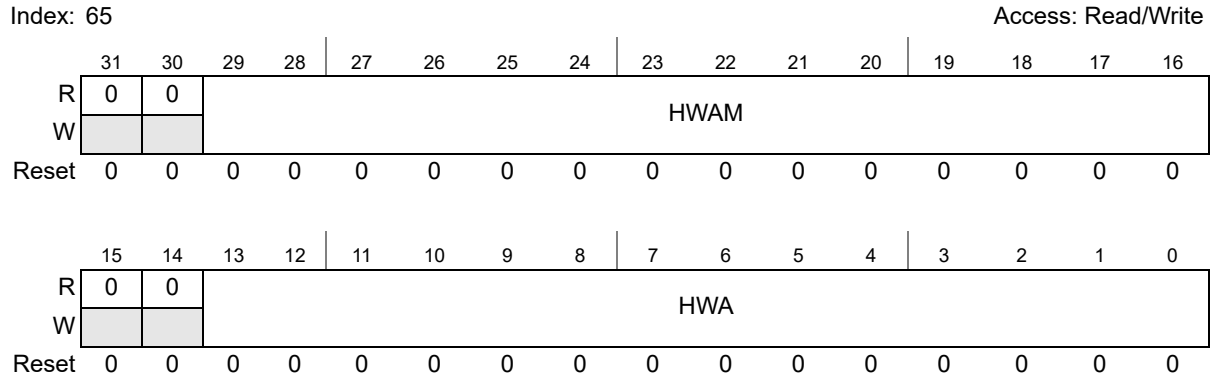

Figure 651. MCSA watchpoint address 1 register (GTMDI_MCSA_WPA1)

Note: The HWA field represents word addresses relative to the MCS address map, not the CPU address map. This applies to the GTMDI_MCSA_WPA1 and GTMDI_MCSA_WPA2 registers.

Table 768 describes the GTMDI_MCSA_WPA1 register functions.

Table 768. GTMDI_MCSA_WPA1 field descriptions

Field	Description
29:16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13:0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data ddresses. The HWA field represents a word address.

47.4.1.32 MCSA watchpoint address 2 register (GTMDI_MCSA_WPA2)

The MCSA Watchpoint Address 2 Register shown in *Figure 652* is used to configure the MCSA halt/watchpoint hardware. It is used for data and instruction fetch accesses.

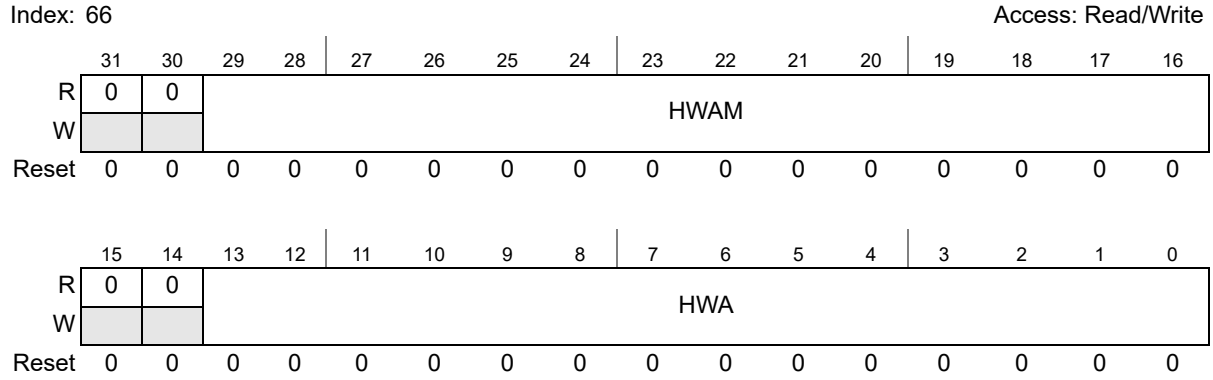

Figure 652. MCSA watchpoint address 2 register (GTMDI_MCSA_WPA2)

Table 769 describes the GTMDI_MCSA_WPA2 register functions.

Table 769. GTMDI_MCSA_WPA2 field descriptions

Field	Description
29:16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13:0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data addresses. The HWA field represents a word address.

47.4.1.33 MCSA watchpoint data 1 register (GTMDI_MCSA_WPD1)

The MCSA Halt/Watchpoint Data 1 Register shown in *Figure 653* is used to configure the MCSA halt/watchpoint hardware. It is used for data accesses selection only.

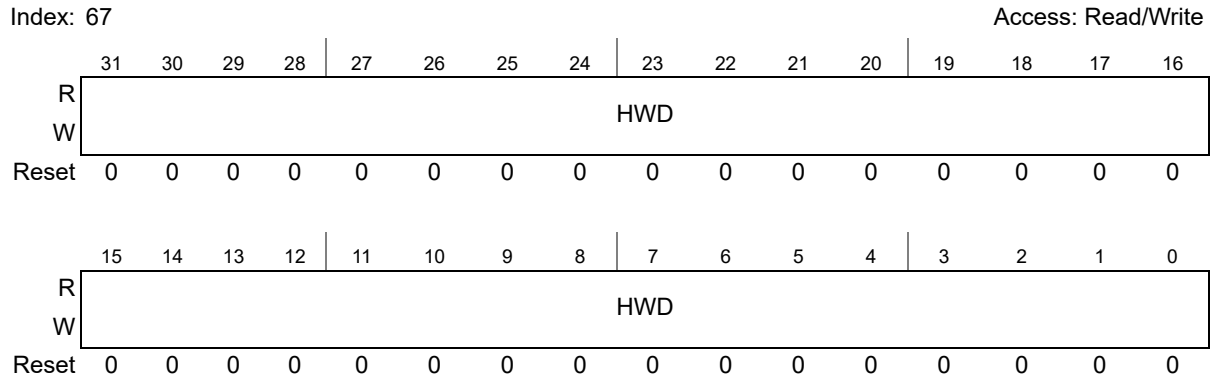

Figure 653. MCSA watchpoint data 1 register (GTMDI_MCSA_WPD1)

Table 770 describes the GTMDI_MCSA_WPD1 register functions.

Table 770. GTMDI_MCSA_WPD1 field descriptions

Field	Description
31:0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

47.4.1.34 MCSA watchpoint data 2 register (GTMDI_MCSA_WPD2)

The MCSA Watchpoint Data 2 Register shown in *Figure 654* is used to configure the MCSA halt/watchpoint hardware. It is used for data accesses selection only.

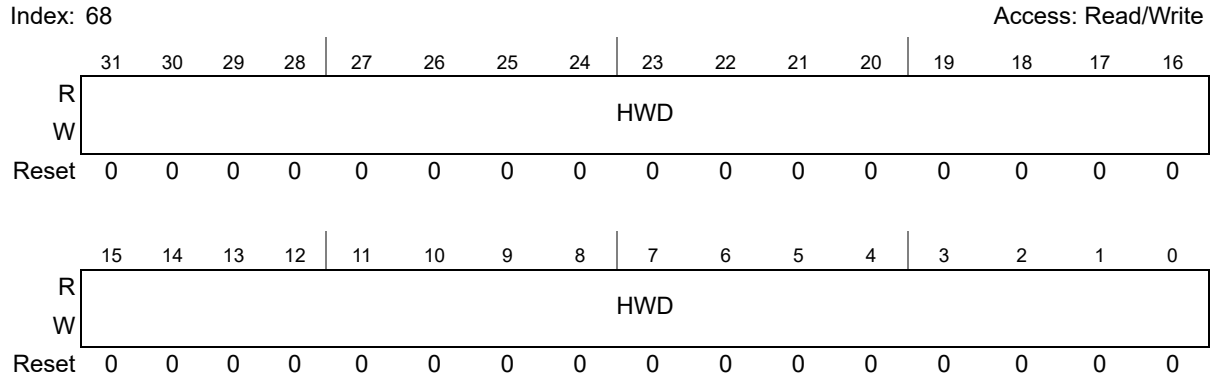

Figure 654. MCSA watchpoint data 2 register (GTMDI_MCSA_WPD2)

Table 771 describes the GTMDI_MCSA_WPD2 register functions.

Table 771. GTMDI_MCSA_WPD2 field descriptions

Field	Description
31:0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

47.4.1.35 MCSA channel enable register (GTMDI_MCSA_CE)

The GTMDI_MCSA_CE register shown in *Figure 655* enables the monitoring for 8 MCSA channels independently.

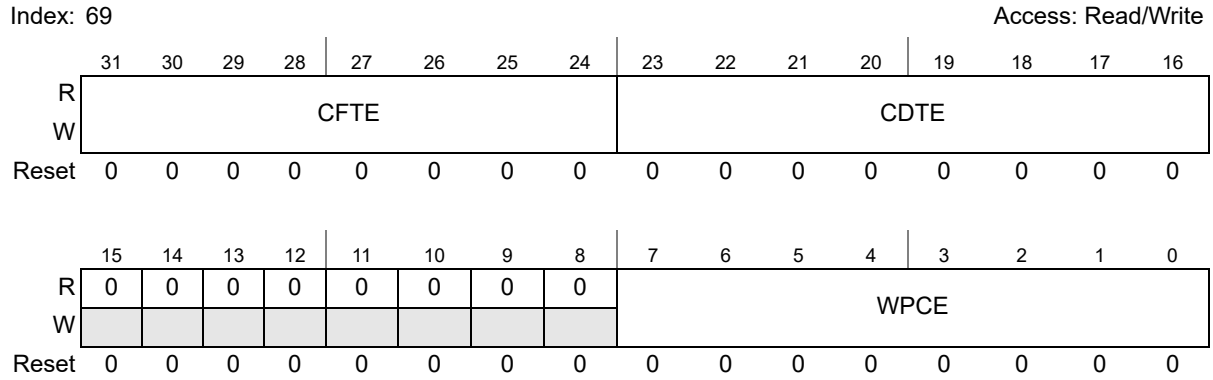

Figure 655. MCSA channel enable register (GTMDI_MCSA_CE)

Table 772 describes the GTMDI_MCSA_CE register functions.

Table 772. GTMDI_MCSA_CE field descriptions

Field	Description
31:24 CFTE	MCSA Channel Fetch Trace Enable. The CFTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for fetch traces. If enabled, the corresponding channel Fetches are monitored by Fetch Trace messages. Start and Stop message controls are controlled by the FTC bit in the GTMDI_MCSA_PTC registers (*Section 47.4.1.29: MCSA program fetch trace control register (GTMDI_MCSA_PTC)*. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111All Channels selected
23:16 CDTE	MCSA Channel Data Trace Enable. The CDTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for data trace messages. If enabled, the corresponding channel Data Accesses are monitored by Data Trace messages. Start and Stop message are controlled by the DTC bit in the GTMDI_MCSA_DTC registers (*Section 47.4.1.30: MCSA data trace control register (GTMDI_MCSA_DTC)* and by the Data trace window. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111 All Channels selected
7:0 WPCE	MCSA Channel Enable. The WPCE[7:0] is a one hot bit field which defines the channel or channels to be monitored for watchpoint, data and fetch traces. The messages controlled by this bit must be also enabled and disabled according to occurrence of Watchpoints and Address Ranges. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111 All Channels selected

47.4.1.36 MCSA data trace address range 1 register (GTMDI_MCSA_DTAR1)

The GTMDI_MCSA_DTAR1 register shown in *Figure 656* defines a data trace address range. The address range is used by the MCSA and enables the range for reads and writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.

Index: 71 Access: Read/Write

Figure 656. MCSA Data trace address range 1 register (GTMDI_MCSA_DTAR1)

Note: The DTSA and DTEA fields represent word addresses relative to the MCS address map, not the CPU address.

Table 773 describes the GTMDI_MCSA_DTAR1 register functions.

Table 773. GTMDI_MCSA_DTAR1 field descriptions

Field	Description
29:18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSA data trace window.
13:2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSA data trace window.

47.4.1.37 MCSA data trace address range 2 register (GTMDI_MCSA_DTAR2)

The GTMDI_MCSA_DTAR2 register shown in *Figure 657* defines a data trace address range. The address range is used by the MCSA and enables the range for reads and writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 1.

Table 775. GTMDI_MCSB_DC field descriptions

Field	Description
11:8 MCSB_SEL	MCSB Selection field. The MCSB_SEL[3:0] selection field selects which one of the MCS cores in the GTM module are assigned as MCSB. 0000 MCS0 0001 MCS1 0010 MCS2 0011 MCS3 0100 MCS4 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

47.4.1.39 MCSB watchpoint control register (GTMDI_MCSB_WPC)

The MCSB Watchpoint Control Register shown in *Figure 659* is used to configure MCSB watchpoints. This register can be configured for halt/watchpoint based on instruction fetch, data read or data write, with address and data masking options.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC control bit thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit needs to be asserted in order to allow external Start/Stop signals to control the WMC bit.

Note: The watchpoint channel selection is made through the GTMDI_MCSB_CE by the WPCE field.

Figure 659. MCSB watchpoint control register (GTMDI_MCSB_WPC)

Table 776 describes the GTMDI_MCSB_WPC register functions.

Table 776. GTMDI_MCSB_WPC field descriptions

Field	Description
25:24 HACH	Halt/Watchpoint on Active Channel. The HACH field selects which type of MCS RAM access generates a watchpoint or halt. Combining this field with HWO gives GTMDI the capability of monitoring channel activity as well as accesses to specific addresses or data. 00 Match on Instruction Fetch 01 Match on Data Read 10 Match on Data Write 11 Match on Data Read or Write
22 WMC	Watchpoint Message Control. The WMC Watchpoint Message Control bit controls the watchpoint message sent through the Message Data bus. If this bit is asserted it enables MCSA/B Watchpoints to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

Table 776. GTMDI_MCSB_WPC field descriptions (continued)

Field	Description
19:16 HME	Halt/Watchpoint Data Mask Enable. The HME field selects which data bytes are used for hardware halt/watchpoint generation when comparing to HWD register. This register field is only meaningful if HWO bit field is [x1], otherwise the data comparison is disabled independent of HME value. 0000 All bytes of data compared xxx1 Least significant byte of data masked out xx1x Second least significant byte of data masked out x1xx Second most significant byte of data masked out 1xxx Most significant byte of data masked out
15:14 HWO	Halt/Watchpoint Operand. The HWO field selects if address or data matching (or both) is done. Registers WPA and WPD are used for address and data comparison, respectively. If address is not compared WPA is not use. If data is not compared then WPD is not used. 00 Comparison Disabled for address or data x1 Compare data with HWD field 1x Compare address with HWA field
8 EOC	$\overline{\text{EVTO}}$ Control. The EOC bit controls the indication on the $\overline{\text{EVTO}}$ output. See *Figure 662*, *Figure 663*, *Figure 664* and *Figure 665* for definition about watchpoint 1 and 2. 0 Indicates Watchpoint 2 occurrence 1 Indicates Watchpoint 1 occurrence
7 HEN	Halt Enable. The HEN Halt Enable bit controls if the MCSA/B Watchpoint is enabled to HALT the GTM IP module. If this bit is set and watchpoint occurs on the MCSA/B a Halt signal is generated to the GTM IP which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
5:4 STSEL	Start/Stop input signal selection. Selects the Start/Stop input that is used to control the watchpoint messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN	Watchpoint Trigger Enable.The TEN field controls if a external trigger is issued by the MCSB when a watchpoint occurs. 0 Disables Trigger Generation 1 Enables Trigger Generation
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSB Watchpoint message to consider the Start/Stop inputs for watchpoint message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC Watchpoint Trace Message Control bit. 0 Disables trace control from Start/Stop inputs 1 Enables trace control from Start/Stop inputs

47.4.1.40 MCSB program fetch trace control register (GTMDI_MCSB_PTC)

The GTMDI_MCSB_PTC register shown in *Figure 660* allows program fetch traces to be enabled or disabled on the occurrence of a watchpoint. If the same watchpoint is programed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags. If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags also toggle.

Table 778. GTMDI_MCSB_DTC field descriptions

Field	Description
17 RC0	Range Control 0. Controls the range on data trace window 0. The window 0 is defined by DTAR1 register. See *Figure 667*. 0 Trace addresses outside (exclusive) of data trace window 0 1 Trace address inside (inclusive) of data trace window 0
16 RC1	Range Control 1. Controls the range on data trace window 1. The window 1 is defined by DTAR2 register. See *Figure 668*. 0 Trace addresses outside (exclusive) of data trace window 1 1 Trace address inside (inclusive) of data trace window 1
13:12 RWT0	MCSB Read/Write Trace Control 0. RWT0 controls whether data trace messages are generated for MCSB RAM read or write accesses. 00 No MCSB data trace messages generated for data trace window 0 01 Enable MCSB data read trace for MCS window 0 10 Enable MCSB data write trace for MCS window 0 11 Enable MCSB data read and write trace for data trace window 0
9:8 RWT1	MCSB Read/Write Trace Control 1. RWT1 controls whether data trace messages are generated for MCSB accesses inside MCS data trace window, and if so, whether reads, writes, or both generate the data trace messages. 00 No MCSB data trace messages generated for data trace window 1 01 Enable MCSB data read trace for MCS window 1 10 Enable MCSB data write trace for MCS window 1 11 Enable MCSB data read and write trace for data trace window 1
6 DTC	Data Trace Control. This bit controls the Data Trace message sent through the Message Data bus. If this bit is asserted it enables MCSB Data access to generate a data trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI 0 Data Messages disabled 1 Data Messages enabled

Table 778. GTMDI_MCSB_DTC field descriptions (continued)

Field	Description
5:4 DTS	Data Trace Start. This bit field allows data trace to be enabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace enabled on MCSB Watchpoint 1 occurrence 10 Data Trace enabled on MCSB Watchpoint 2 occurrence 11 Reserved
2:1 DTE	Data Trace End. This bit field allows data trace to be disabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace disabled on MCSB Watchpoint 1 occurrence 10 Data Trace disabled on MCSB Watchpoint 2 occurrence 11 Reserved
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Data message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DTC Data Trace Message Control bit. 0 Disable data trace control from Start/Stop inputs 1 Enable data trace control from Start/Stop inputs

47.4.1.42 MCSB watchpoint address 1 register (GTMDI_MCSB_WPA1)

The MCSB Watchpoint Address Registers 1 shown in *Figure 662* are used to configure the MCSB halt/watchpoint hardware. They are used for data and instruction fetch accesses.

Index: 82 Access: Read/Write

Figure 662. MCSB watchpoint address 1 register (GTMDI_MCSB_WPA1)

Note: The HWA field represents word addresses relative to the MCS address map, not the CPU address map. This applies to GTMDI_MCSB_WPA1 and GTMDI_MCSB_WPA2 registers.

Table 779 describes the GTMDI_MCSB_WPA1 register functions.

Table 779. GTMDI_MCSB_WPA1 field descriptions

Field	Description
29:16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13:0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data ddresses. The HWA field represents a word address.

47.4.1.43 MCSB watchpoint address 2 register (GTMDI_MCSB_WPA2)

The MCSB Watchpoint Address 2 Registers shown in *Figure 663* are used to configure the MCSB halt/watchpoint hardware. They are used for data and instruction fetch accesses.

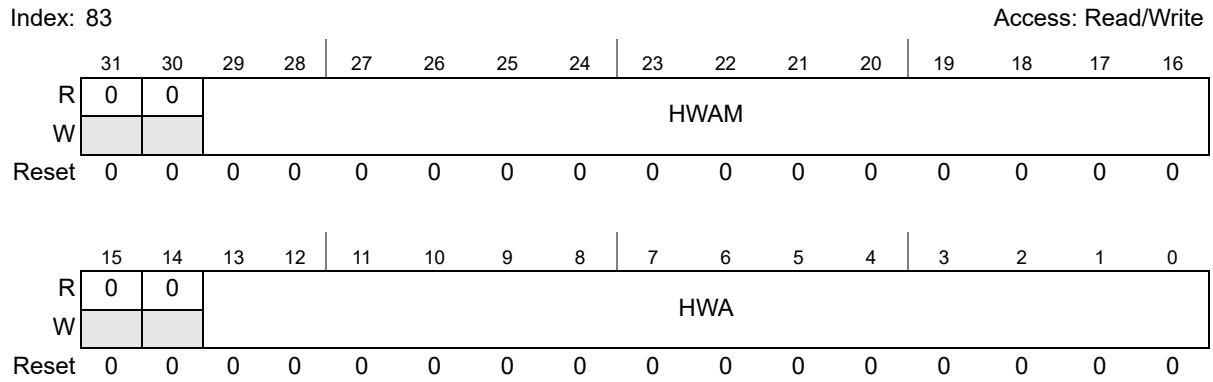

Figure 663. MCSB watchpoint address 2 register (GTMDI_MCSB_WPA2)

Table 780 describes the GTMDI_MCSB_WPA2 register functions.

Table 780. GTMDI_MCSB_WPA2 field descriptions

Field	Description
29:16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13:0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data addresses. The HWA field represents a word address.

47.4.1.44 MCSB watchpoint data 1 register (GTMDI_MCSB_WPD1)

The MCSB Halt/Watchpoint Data 1 Register shown in *Figure 664* is used to configure the MCSB halt/watchpoint hardware. It is used for data accesses selection only.

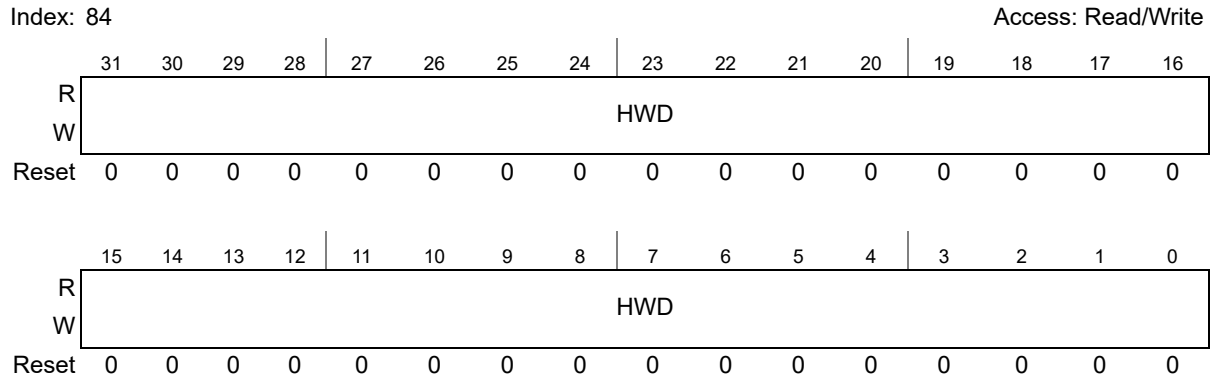

Figure 664. MCSB watchpoint data 1 register (GTMDI_MCSB_WPD1)

Table 781 describes the GTMDI_MCSB_WPD1 register functions.

Table 781. GTMDI_MCSB_WPD1 field descriptions

Field	Description
31:0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

47.4.1.45 MCSB watchpoint data 2 register (GTMDI_MCSB_WPD2)

The MCSB Watchpoint Data 2 Register shown in *Figure 665* is used to configure the MCSB halt/watchpoint hardware. It is used for data accesses selection only.

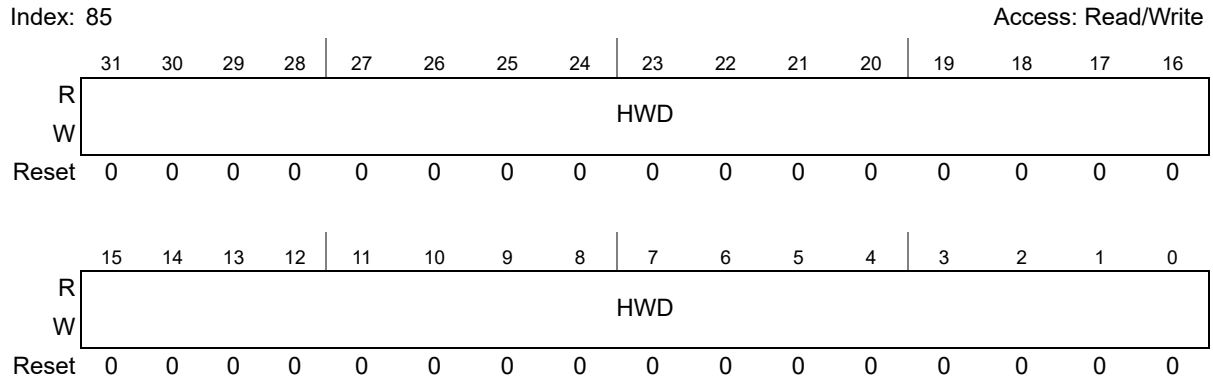

Figure 665. MCSB watchpoint data 2 register (GTMDI_MCSB_WPD2)

Table 782 describes the GTMDI_MCSB_WPD2 register functions.

Table 782. GTMDI_MCSB_WPD2 field descriptions

Field	Description
31:0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

47.4.1.46 MCSB channel enable register (GTMDI_MCSB_CE)

The GTMDI_MCSB_CE register shown in *Figure 666* enables the monitoring for 8 MCSB channels independently.

Table 783. GTMDI_MCSB_CE field descriptions

Field	Description
31:24 CFTE	MCSB Channel Fetch Trace Enable. The CFTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for fetch traces. If enabled, the corresponding channel Fetches are monitored by Fetch Trace messages. Start and Stop message controls are controlled by the FTC bit in the GTMDI_MCSB_PTC registers (*Section 47.4.1.40: MCSB program fetch trace control register (GTMDI_MCSB_PTC)*. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111All Channels selected
23:16 CDTE	MCSB Channel Data Trace Enable. The CDTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for data trace messages. If enabled, the corresponding channel Data Accesses are monitored by Data Trace messages. Start and Stop message are controlled by the DTC bit in the GTMDI_MCSB_DTC registers (*Section 47.4.1.41: MCSB data trace control register (GTMDI_MCSB_DTC)* and by the Data trace window. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111 All Channels selected

Table 783. GTMDI_MCSB_CE field descriptions (continued)

Field	Description
7:0 WPCE	MCSB Channel Enable. The WPCE[7:0] is a one hot bit field which defines the channel or channels to be monitored for watchpoint, data and fetch traces. The messages controlled by this bit must be also enabled and disabled according to occurrence of Watchpoints and Address Ranges. 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111 All Channels selected

47.4.1.47 MCSB data trace address range 1 register (GTMDI_MCSB_DTAR1)

The GTMDI_MCSB_DTAR1 register shown in *Figure 667* defines a data trace address range. The address range is used by the MCSB and enables the range for reads and writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.

Table 785 describes the GTMDI_MCSB_DTAR2 register functions.

Table 785. GTMDI_MCSB_DTAR2 field descriptions

Field	Description
29:18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSB data trace window.
13:2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSB data trace window.

47.4.1.49 TBU0 watchpoint control 1 register (GTMDI_TBU0_WPC1)

The GTMDI_TBU0_WPC1 register shown in *Figure 669* controls the Watchpoint issued by TBU0 GTM Time Base Units (TBU). These watchpoints are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TBU0_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Field	Description
30:28 TSS1	TBU0 Watchpoint 1 Compare Selection. The TSS1[2:0] field controls the type of comparison used for TBU0 watchpoint generation. 000 TBU0 24-bit update (do not compare data) 001 TBU 27-bit update (do not compare data) 010 Compare TBU0 value in 24-bit mode with expected data(1) 011 Compare TBU0 value in 27-bit mode with expected data 100 Reserved 101 Reserved 110 Reserved 111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the TBU0 event is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU0 a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches or increment on selected TBU0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
14:12 TSS2	TBU0 Watchpoint 2 Compare Selection 2. The TSS2[2:0] field controls the type of comparison used for TBU0 watchpoint generation. 000 TBU0 24-bit update (do not compare data) 001 TBU 27-bit update (do not compare data) 010 Compare TBU0 value in 24-bit mode with expected data1 011 Compare TBU0 value in 27-bit mode with expected data 100 Reserved 101 Reserved 110 Reserved 111 Reserved

Table 786. GTMDI_TBU0_WPC1 field descriptions (continued)

Field	Description
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the TBU0 valid event, which is a match or increment, is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU0, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match or increment on TBU0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signal inputs to GTMDI. 0Watchpoint Messages disabled 1 Watchpoint Messages enabled

1. Only bits from 26 to 3 from register GTMDI_TBU0_DATA are used for comparison

47.4.1.50 TBU0 watchpoint control 2 register (GTMDI_TBU0_WPC2)

The GTMDI_TBU0_WPC2 shown in *Figure 670* register controls the Watchpoint Triggers issued by TBU0. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Field	Description
26:0 TBU0_DATA	TBU0 Watchpoint DATA. The field TBU0_DATA is used to compare against the TBU0 data.

47.4.1.52 TBU1 watchpoint control 1 register (GTMDI_TBU1_WPC1)

The GTMDI_TBU1_WPC1 register shown in *Figure 672* controls the Watchpoint issued by TBU1 GTM Time Base Units. These watchpoints are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signal inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the

same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TBU1_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

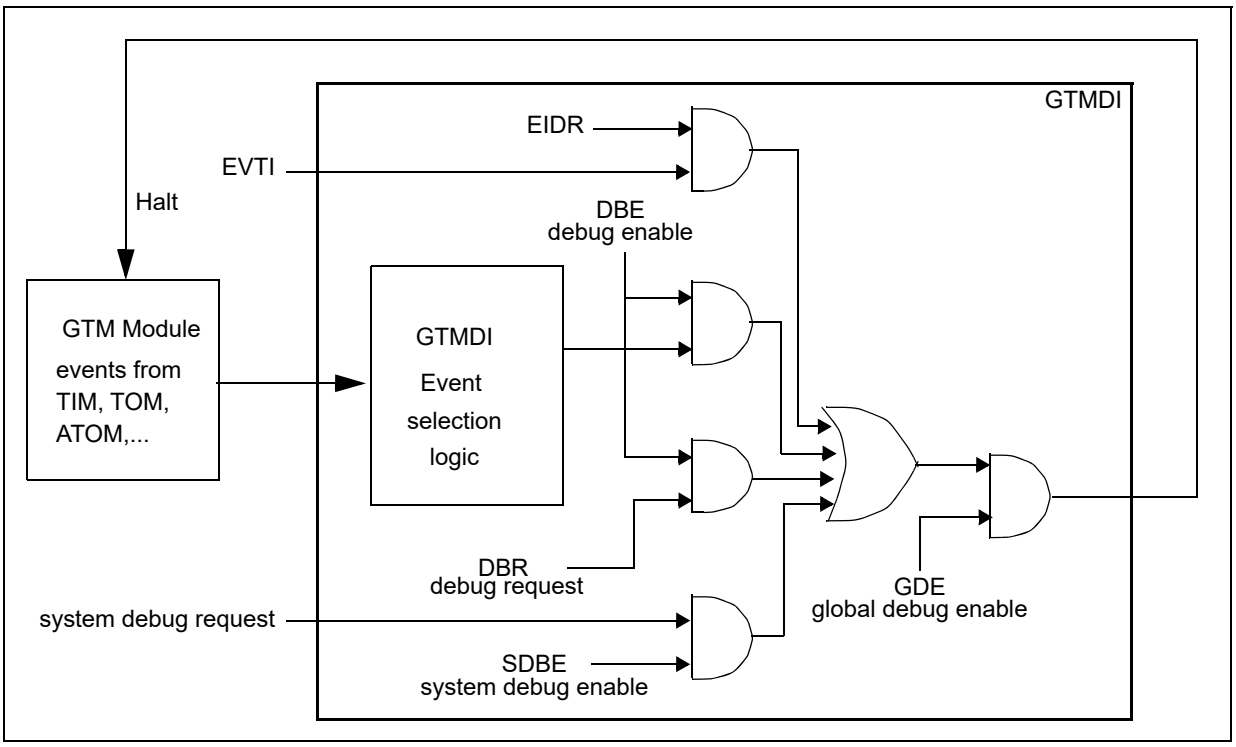
47.5 Functional description



This section describes in detail the main functionality of the GTMDI module.

47.5.1 Debug enable logic

In order to enable the GTM to enter Halt state, which is the module debug state, there are some registers that need to be set. The sources that can put GTM in halt state are events

from TIM, TOM, ATOM, MCS and several other internal GTM modules that are selected and controlled by the GTMDI_DC register bits shown in *Figure 622*. The system debug request external signal is also a source of halts, as well as direct JTAG write to control register. *Figure 678* describes the logic behind the Halt signal generated by GTMDI. See *Figure 622* for a description of the register bits mentioned in *Figure 678*.

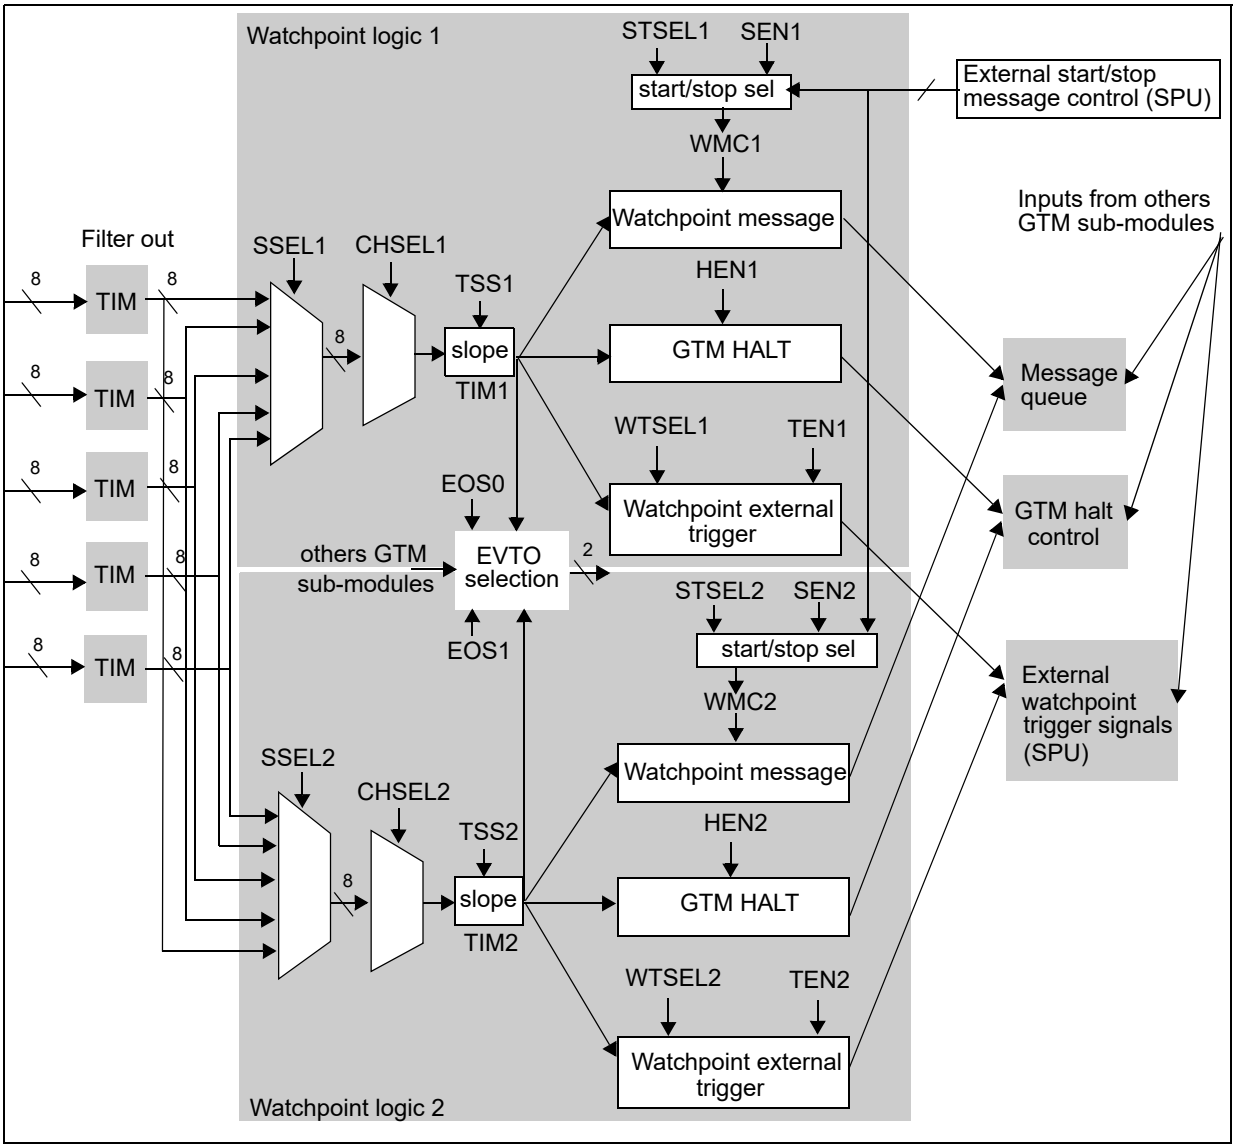


Figure 678. GTM Halt signal enable logic

47.5.2 TIM-TOM-ATOM selection and control logic

The TIM sub-modules can be selected to generate signals that control the watchpoint messages, Halt GTM and watchpoint outputs from the GTMDI module. *Figure 679* describes the TIM selection logic for generation of watchpoint messages, GTM halt and external watchpoint triggers. This logic is duplicated thus allowing independent selection of two TIM filtered inputs. *Figure 679* also shows the register bits that control the selection process. Watchpoint Logic 1 and Watchpoint Logic 2 are two implementations for the same logic.

Figure 679. TIM selection logic

Note: Figure 679 shows five instances of the TIM sub-module as an example of a GTM configuration. Different configurations may have different number of TIM sub-modules, thus SSEL1/2 signals have to be able to select different number of TIM sub-modules.

The selection logic for TOM and ATOM sub-modules is similar to the TIM logic. The register names are also kept the same for easy correlation of functionality.

47.5.3 GTMDI reset configuration

47.5.3.1 Enabling GTMDI class 1 operation

The GTMDI Class 1 features are always enabled after exiting the JTAG TEST-LOGIC-RESET state. But they are disabled while the JTAG is in this state. Thus, allowing low power mode. The registers are always reset while in the JTAG TEST-LOGIC-RESET state.

47.5.3.2 Enabling GTMDI class 3 operation

After exiting JTAG TEST-LOGIC-RESET state, the GTMDI classes 1 and 3 are enabled, otherwise the GTMDI class 3 features are disabled, entering in the Disable-Port Mode, thus no trace output is provided, and auxiliary port output pins are disabled.

47.5.4 Message Data Bus —interface with NAR module

47.5.4.1 Output messages

Table 795 describes the messages that the GTMDI can transmit on the Message Data Bus.

Table 795. GTMDI Nexus trace message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Debug Status Message	6	6	fixed	TCODE	Value = 0
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	32	32	fixed	STATUS	Value of the Development Status register GTMDI_DS, see *Table 796*
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message	6	6	fixed	TCODE	Value = 8
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	4	4	fixed	ETYPE	Always 0 for GTMDI
	15	15	fixed	ECODE	Error Code, see *Table 797*
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
MCS Data Trace, Data Write with Sync Message	6	6	fixed	TCODE	Value = 56
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location written
	32	32	fixed	DATA	Data value written
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
MCS Data Trace, Data Read with Sync Message	6	6	fixed	TCODE	Value = 57
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location read
	32	32	fixed	DATA	Data value read
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

Table 795. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Watchpoint Hit Message(1)	6	6	fixed	TCODE	Value = 15
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	15	15	fixed	WPHIT	Number indicating watchpoint source (binary coded), see *Table 798*, *Table 799* and *Table 800*
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace	6	6	fixed	TCODE	Value = 58
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT(2)	Fetch Sequential Counter. Value 0 indicates there is no relationship between the last fetch trace message and the current message. The counter rolls back to one when a non sequential address is fetched. The counter increments every time a sequential address is fetched. When counter reaches 63 a message is sent and the counter rolls back to one. If an ERROR message is sent the counter rolls back to zero.
	14	14	fixed	FADDR	First element address of the next fetch sequence
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace End (fetch trace was turned off, no faddr field is sent)	6	6	fixed	TCODE	Value = 59
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT	The message is sent with the current value in the FSCNT counter and the counter rolls back to zero after the message is sent.
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
ARU Data Trace	6	6	fixed	TCODE	Value = 60
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	CHN	ARU Debugging Channel number (0/1)
	58	58	fixed	DATA	Data value read {ARU_DATAH, ARU_DATAL}
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

Table 795. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
DPLL Data Trace, Data Read/Write	6	6	fixed	TCODE	Value = 61
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	24	24	fixed	DATA	Data value read/written
	12	12	fixed	ADDR	Full address of the memory location written
	1	1	fixed	RW	Read 1, Write 0
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Watchpoint Hit Message conforms to the IEEE-ISTO 5001-2003 standard, however, other messages conform to the IEEE-ISTO 5001-2011 standard.
2. FSCNT is the sequential instruction fetch counter that indicates the number of sequential instruction fetches executed by the MCS core for a channel. See *Section 47.5.9.2: Fetch trace state machine* for more information.

47.5.4.1.1 Temporal ordering of transmitted messages

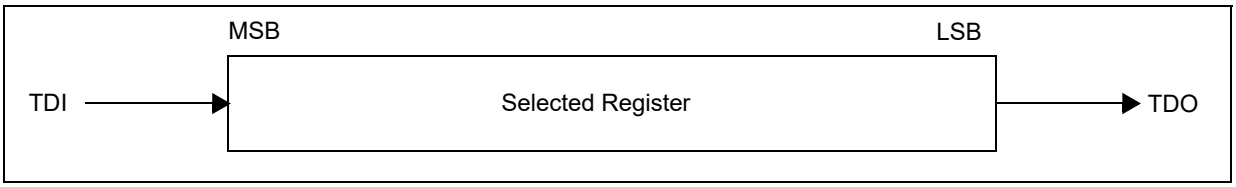
All messages are sent out in the sequence their related event actually occurred. The GTM interface with the GTMDI provides the GTM signals to be monitored and captured. At the occurrence of any event that would cause a message, a snapshot of all information needed by the message formatter to generate a message is queued. Doing so, several events from either MCS, TIM, ATOM, ARU, or others, can be queued at the same time.

47.5.4.1.2 Interleaved messages

Two MCS cores, TIM channels and other sources can be enabled for trace. The GTMDI formats and queues all messages in the order they are generated. Since there can be message inversion among sources during the send process, if enabled by the TSFT bit in *Figure 622* or by the NAR, the messages are sent along with a timestamp. This timestamp is globally synchronized among all Nexus clients at SoC level.

47.5.5 IEEE 1149.1 (JTAG) input port

The GTMDI block uses the IEEE 1149.1 TAP for accessing registers. This port is shared among all TAP controllers on the SoC. This sharing is controlled by the value in the instruction register and client select control register. The GTMDI implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1 state machine shown in *Figure 681*. The Nexus controller state machine, shown in *Figure 682*, is defined by the IEEE-ISTO 5001-2002 standard.



The instructions implemented by the GTMDI TAP controller are listed in *Table 802*. If any other instruction is received it is treated as a BYPASS.

Table 802. Implemented instructions

Instruction name	Private / public	Opcode	Description
NEXUS-ENABLE	Public	4b0000	Activate Nexus controller state machine to read and write GTMDI registers
BYPASS	Public	4b1111	Implements a single shift register stage providing a minimum serial length between TDI and TDO

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in *Figure 680*. This applies for the instruction register and all Nexus tool-mapped registers.

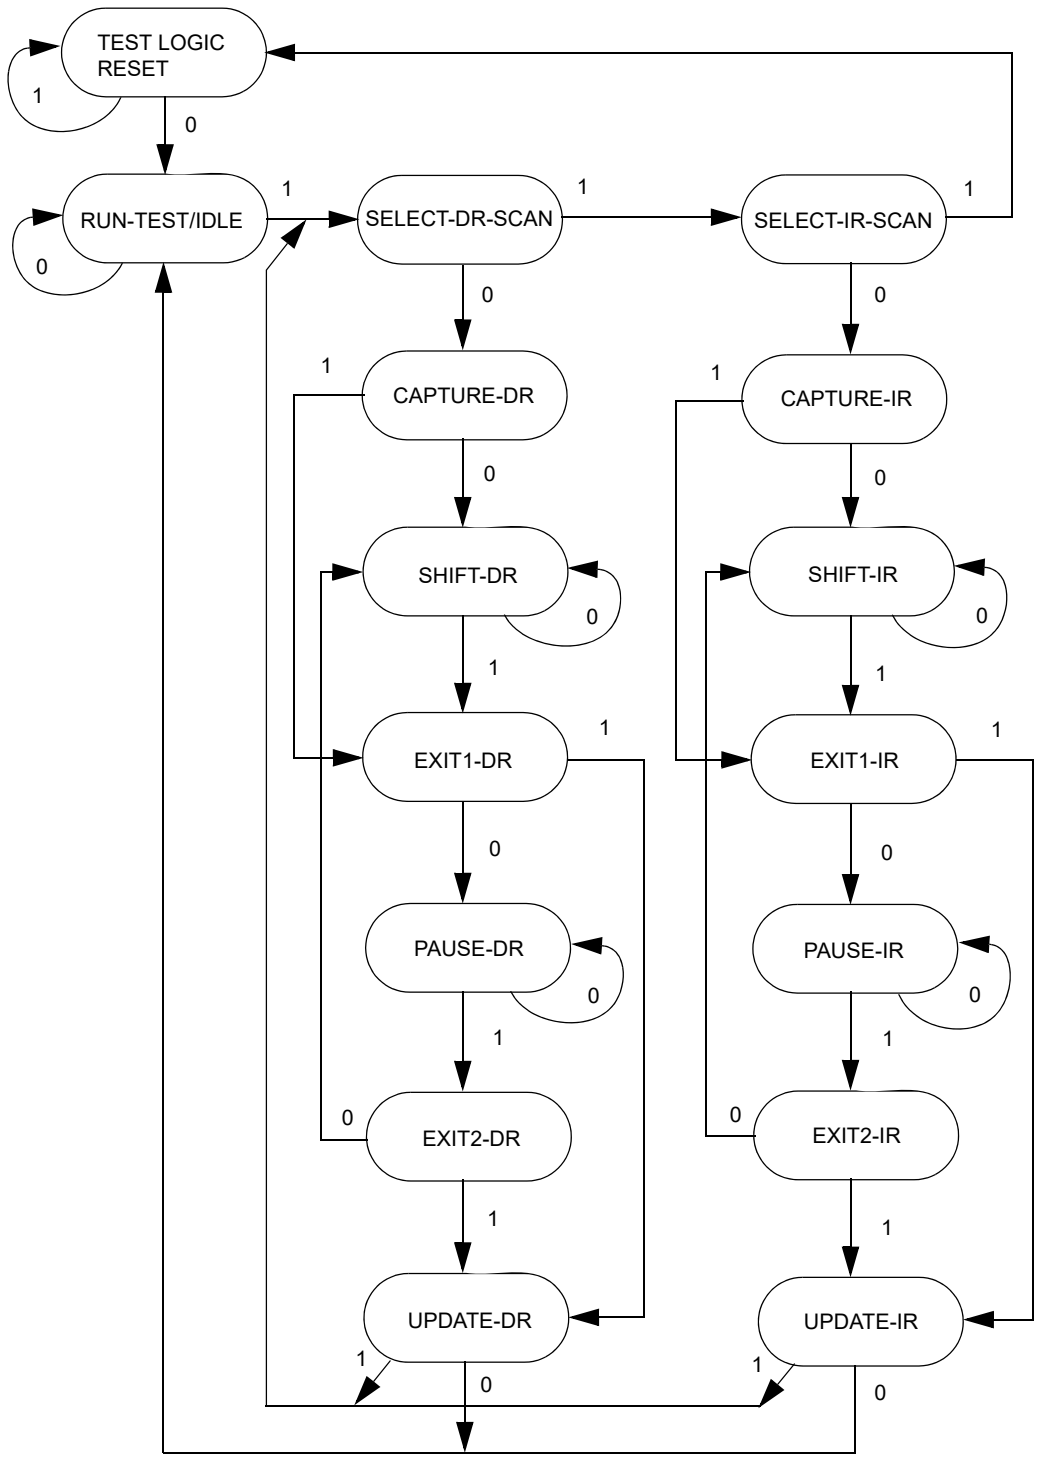


Figure 680. Shifting data into register

47.5.5.1 Enabling the GTMDI TAP controller

Assertion of the $\overline{\text{TRST}}$ input resets all TAP controllers on the SoC. The controllers are loaded with the BYPASS instruction upon exit of the TEST-LOGIC-RESET JTAG controller state. Loading the NEXUS-ENABLE instruction grants access to Nexus debug. GTMDI acts as BYPASS by loading any other instruction. The TDO bit is driven with the value of the instruction register while in SHIFT-IR state.

Figure 681. IEEE 1149.1 16-State finite state machine

NOTE: The value shown adjacent to each state transition in this figure represents the value of the TMS bit at the time of a rising edge of TCK.

47.5.5.2 Loading NEXUS-ENABLE instruction

Access to the GTMDI registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. The current instruction value is loaded into the IEEE 1149.1 shifter in the CAPTURE-IR state. The instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 682*, transitions to the REG_SELECT state. *Table 803* illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 682. Nexus controller state machine

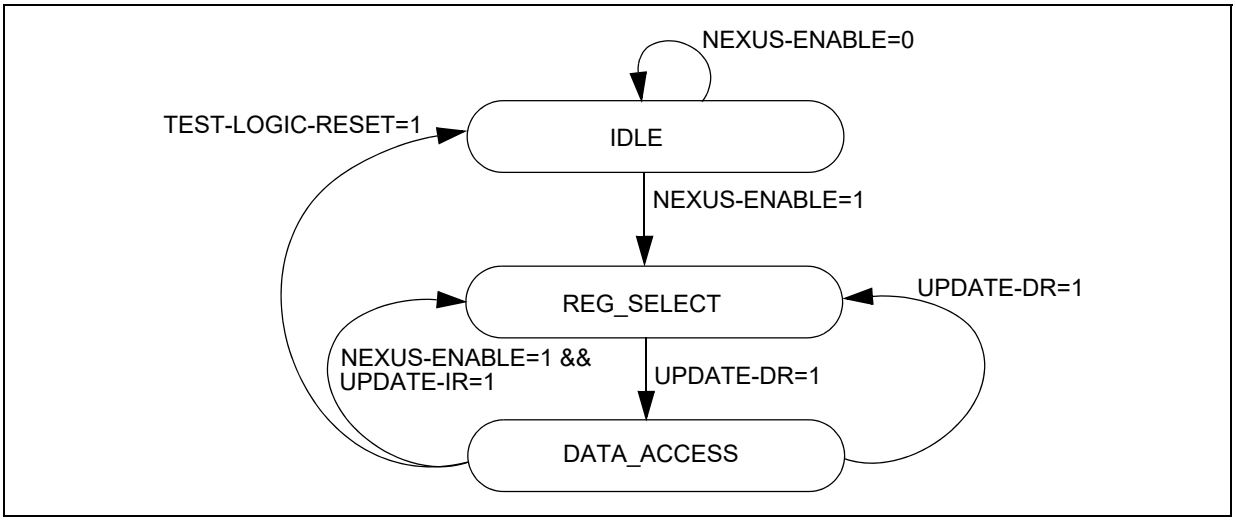

Table 803. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction
4 TCKs				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	NEXUS-ENABLE ready to be read

47.5.5.3 Selecting an IEEE 1149.1 register

When the NEXUS-ENABLE instruction is loaded in the GTMDI TAP controller instruction register, the input port allows development tool access to all GTMDI registers. Each register has a 7-bit address index. Some clients have registers with the same index as registers in other clients. Therefore, to access the registers of a particular client, the Client Select Control register must be set for that client.

All register access is performed via the SELECT-DR-SCAN path. The Nexus state machine defaults to the register select state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 683*. The read/write control bit is set to 1 for writes and 0 for reads. The current value of the Controller Command Input is captured into the IEEE 1149.1 shifter during the CAPTURE-DR state while the Nexus controller state machine is in the REG_SELECT state.

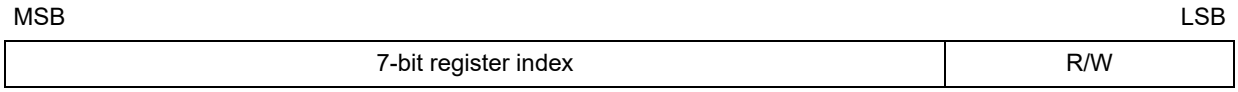

Figure 683. IEEE 1149.1 controller command input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the current register value is loaded into the IEEE 1149.1 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

Table 804 illustrates a sequence which writes a 32-bit value to a register.

Table 804. Writing to a register

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register

47.5.6 Nexus Class 1 development support

The GTMDI contains a number of hardware hooks that aid in the development of software for the GTM MCS cores. This features described in this section are compliant with the following Nexus Class 1 features:

- Enter a debug mode at reset negation
- Enter a debug mode during normal execution
- Set halts or watchpoints

Refer to *Section 47.6: Initialization/application information* for how the following functions provide these features.

47.5.7 Debug status

The GTMDI module provides the Debug Status via the NAR SoC level modules.

47.5.7.1 Messaging

The GTMDI block provides debug status messaging using IEEE-ISTO 5001-2002 standard-defined public messages. If the message queue is full and a new message has to be sent, this message is lost and an ERROR message is queued instead, indicating the loss of trace messages. The debug status message format is shown in *Figure 684*.

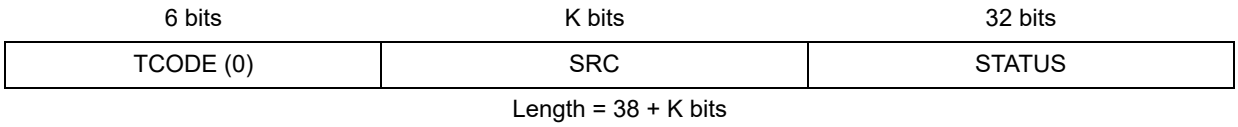

Figure 684. Debug status message format

47.5.7.2 Error messages

A debug status overrun error event is queued if a debug status event occurs while the Event Queue is full and is not able to store snapshots. The error message is stored to the event queue indicating a message was lost. The error message is sent as soon as the client is enabled for transmission. The error message format is shown in *Figure 685*.

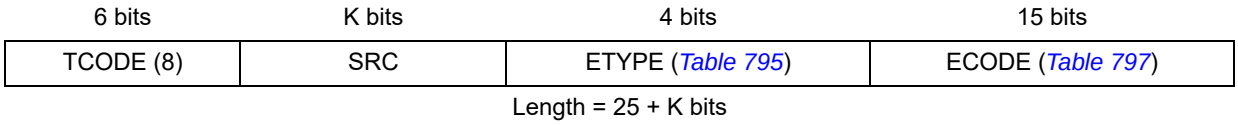

Figure 685. Debug status error message format

Note: The timestamp value in an Error Message does not contain valid information.

47.5.8 Data trace

MCS cores, ARU and DPLL perform loads and stores to RAM memory modules. The GTMDI block gathers information about these accesses and generate trace messages if enabled.

47.5.8.1 MCS data write message

The MCS data write message contains the data write value and the address of the RAM target location. The data write message format is shown in *Figure 686*.

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (56)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

Figure 686. Data write message format

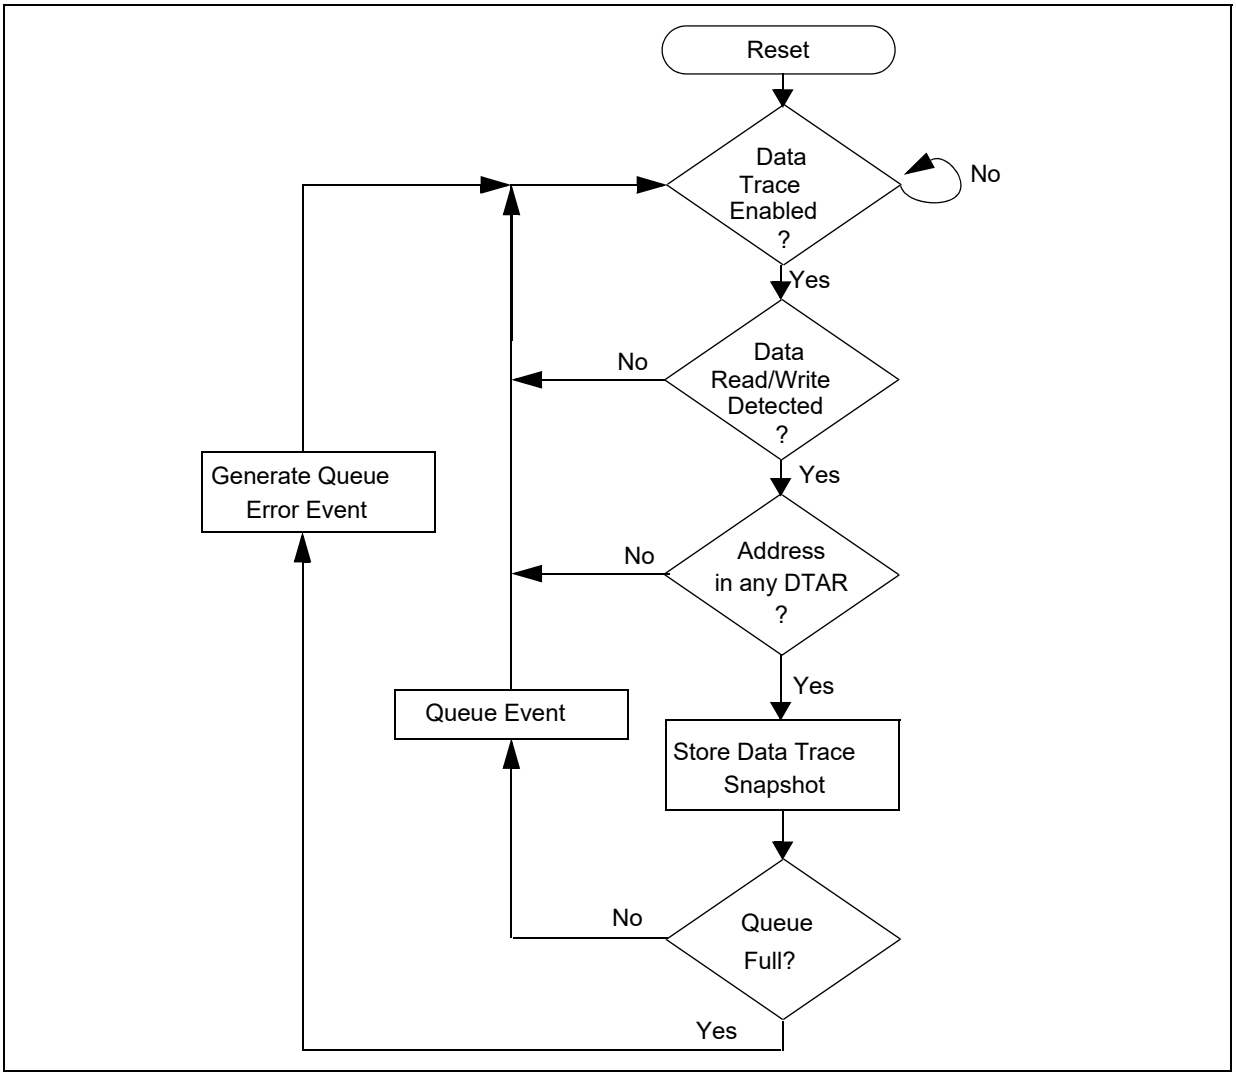
47.5.8.2 MCS data read message

The MCS data read message contains the data read value and the address of the RAM target location. The data read message format is shown in *Figure 687*.

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (57)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

Figure 687. Data read message format



47.5.8.3 MCS data trace operation

Data tracing is performed by snooping a dedicated MCS/Nexus interface for RAM read and write cycles. Data trace functions are enabled by setting the appropriate fields in the following registers:

- MCSx Development Control (GTMDI_MCSx_DC) Register
- MCSx Data Trace Control (GTMDI_MCSx_DTC) Register
- MCSx Data Trace Address Range (GTMDI_MCSx_DTAR) Register

For details on register configuration, refer to *Section 47.4.1: Register descriptions*. The MCSx data tracing have independent Data Trace Address Range registers which allows more flexibility. An Error condition may occur in case of Queue full event. Data trace flow is depicted in *Figure 688*.

Figure 688. GTMDI generic data trace flow diagram

47.5.8.3.1 MCS data trace windowing

Data trace windowing is provided so that the development tool can decrease the auxiliary port usage by limiting the accesses that are traced. Data trace windowing is achieved via the address range defined by the DTSA and the DTEA fields of the DTAR register. RAM accesses are traced if their address fall in any of these ranges and the specific range is enabled in the data trace control register. Data read and data write trace may be enabled via the Read/Write Trace Control fields in the data trace control registers.

Data trace ranges are 32-bit aligned. This alignment is done by making the two least significant bits of the DTSA and DTEA fields read only. Since the two least significant bits of DTSA and DTEA are read only and default to different values, DTSA can never be equal to DTEA. *Figure 689* shows the relationship between the DTSA and DTEA fields.

Programmed Value	Range Selected
DTSA =< DTEA	[DTSA: DTEA]
DTSA > DTEA	All addresses are out of range(1)

Figure 689. Data trace address range options

1. Since all addresses are considered to be out of range, a Data Trace Event may be recognized if the DTC register is programmed so that addresses out of range are queued.

Note: Before sending through the NAR interface, the MCS, DPLL or ARU Data Trace message is buffered. Due to bandwidth constraints in the NAR interface and in the data trace buffering, this data trace message can be lost when superseded by another data trace message from the same source. In this case an error message is sent. See Table 795 for more details about GTMDI NAR messages.

47.5.8.4 DPLL data trace

DPLL Data Trace is a straight forward implementation in which the trace is enabled using the DMC bit in the *Figure 639*. It is possible to select individual DPLL RAM modules such as RAM1a, RAM1b or RAM2 for tracing using the RAMSEL bit in the same register. Only one memory module is selected for tracing at a given time. Start/Stop inputs from the SPU module can be used to control the DPLL Data Trace messages as well as JTAG interface. This is achieved by controlling the DMC bit which can be done from SPU or JTAG interface. See *Table 756* for more details about the bits that should be used in this process.

47.5.8.5 ARU data trace

The GTM module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1, see the GTM documentation for details on how to program these channels. The data trace for these two channels is controlled by DMC1/2 bits in the GTMDI_ARU_DTC, see *Section 47.4.1.26: ARU data trace control register (GTMDI_ARU_DTC)*. Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

47.5.9 Fetch trace

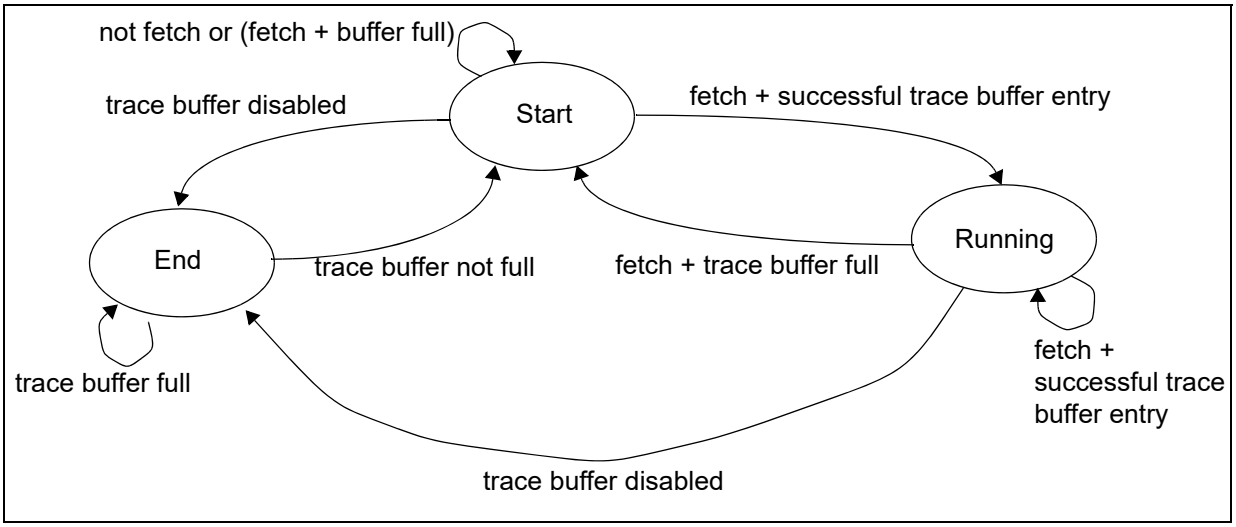
Fetch trace tries to record all instruction fetch accesses done by an MCS channel which are executed in the MCS pipeline. Fetch trace is handled independently for each MCS channel, therefore what happens to a certain channel does not affect other channels since all channels run independently. Even error conditions are handled independently for each channel.

Fetch trace can be enabled/disabled by two ways:

- By watchpoint hit, if the watchpoint is configured to do so
- Directly by register

When a fetch access hits a watchpoint and the last enables fetch trace (having it disabled before the watchpoint hit), that access is ignored by the fetch trace logic.

47.5.9.1 Enabling MCS program fetch trace



Program fetch trace for the MCS is enabled on a channel by channel basis. This selective enabling allows the debug tool to control the bandwidth for the transmitted messages. The

program fetch trace is enabled through a JTAG register, see *Figure 649*.Since the registers may be changed in the middle of a program execution, program fetch trace may be enabled or disabled during program execution as well.

47.5.9.2 Fetch trace state machine

The fetch trace state machine is composed basically by three states: *start*, *running* and *end*. When the fetch trace is enabled, fetch state machine goes to the *start* state. *Figure 690* describes the fetch trace machine state diagram.

Figure 690. Fetch trace state machine state diagram

47.5.9.2.1 Fetch trace start state

In this state, the fetch trace logic waits for a fetch access to occur. When an instruction is executed in the last stage of the MCS pipeline, it is considered as a valid fetch access. When a fetch access occurs, the fetch trace logic tries to insert (into the corresponding MCS trace buffer) a fetch trace message with FSCNT=0 and the FADDR field equal to the fetch access address. It is possible that the corresponding MCS trace message buffer is full when fetch trace logic tries to insert the message. In this case, the fetch trace logic ignores the current fetch access, does not generate any error, and tries again when another fetch access occurs.

After inserting a message into the buffer, the fetch trace state machine goes to the *running* state.

It is also possible that the fetch trace is disabled before a message is inserted into the MCS trace buffer. In this case state machine goes to the *end* state

47.5.9.2.2 Fetch trace running state

When the fetch trace state machine enters in the *running state* a counter, called CNT, is initialized to 1 and starts counting the number of sequential instruction fetch accesses.

When a fetch access with address ADDR is detected, the fetch trace logic tests if ADDR is equal to the previous fetch address, ADDR_PRV, +1 (ADDR = ADDR_PRV + 1). If so, no message is buffered for transmission and CNT increments by 1 (CNT = CNT + 1). Otherwise, if ADDR is not a sequential address, a fetch trace message is generated with the

FSCNT field equals to the CNT counter value (FSCNT = CNT) and FADDR equals to the current address ADDR. The CNT counter is then initialized to 1.

At the moment the previous message is generated, the corresponding MCS fetch trace buffer may or may not be full. If the buffer is not full, the message is inserted into the buffer and the fetch trace state machine continues in the *running* state, otherwise a fetch trace error message is generated for the corresponding MCS and the fetch trace state machine goes to the *start* state.

Note: The MCS is a multi-thread core which executes eight threads, also called channels, in fixed time-slots of one system clock for each thread. Fetch trace is a per channel resource. Thus if more than one channel is selected for trace, each one generates its corresponding fetch trace message. There is one independent fetch state machine and CNT counter for each selected channel.

47.5.9.2.3 Fetch trace end state

In this state, the fetch trace logic ignores all fetch accesses and waits for the corresponding MCS trace buffer to be not full. When this happens, a fetch trace end message is inserted into the buffer with FSCNT equal to CNT (FSCNT = CNT). The CNT value is always reset to 0 when previous state was *start* state.

If the buffer is always full, the fetch trace logic does not exit *end* state until a reset occurs.

Note: A Fetch trace end message is sent when a system reset is detected in the GTM module. There are no further indications about the GTM reset condition.

47.5.10 Watchpoint trace

The GTMDI module provides watchpoint messaging via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

47.5.10.1 Messaging

The GTMDI block provides watchpoint messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When a watchpoint occurs, a watchpoint event is sent to the Event Queue. If the watchpoint condition occurs while the Event Queue is full, an error message is generated. The watchpoint message format is shown in *Figure 691*.

6 bits	K bits	15 bits
TCODE (15)	SRC	WPHIT

Length = 21+Kbits

Figure 691. Watchpoint hit message format

The values for the WPHIT packet are described in *Table 798*, *Table 799* and *Table 800*. Notice that WPHIT is never 0 because the message is only generated when a watchpoint has occurred.

47.6 Initialization/application information

47.6.1 Accessing GTMDI tool-mapped registers

To initialize the JTAG port for register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Retrieve Device ID if needed
3. Load the Nexus TAP controller with the NEXUS-ENABLE instruction

To write control data to GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select register with a pass through the SELECT-DR-SCAN path in the JTAG state machine
2. Write the register value with a pass through the SELECT-DR-SCAN path. The prior value of this register is shifted out during the write

To read status and control data from GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear write bit to select register with a pass through SELECT-DR-SCAN path
2. Read the register value with a pass through the SELECT-DR-SCAN path. Data shifted in is ignored

See *Section 47.5.5: IEEE 1149.1 (JTAG) input port* for more detail.

48 CAN subsystem

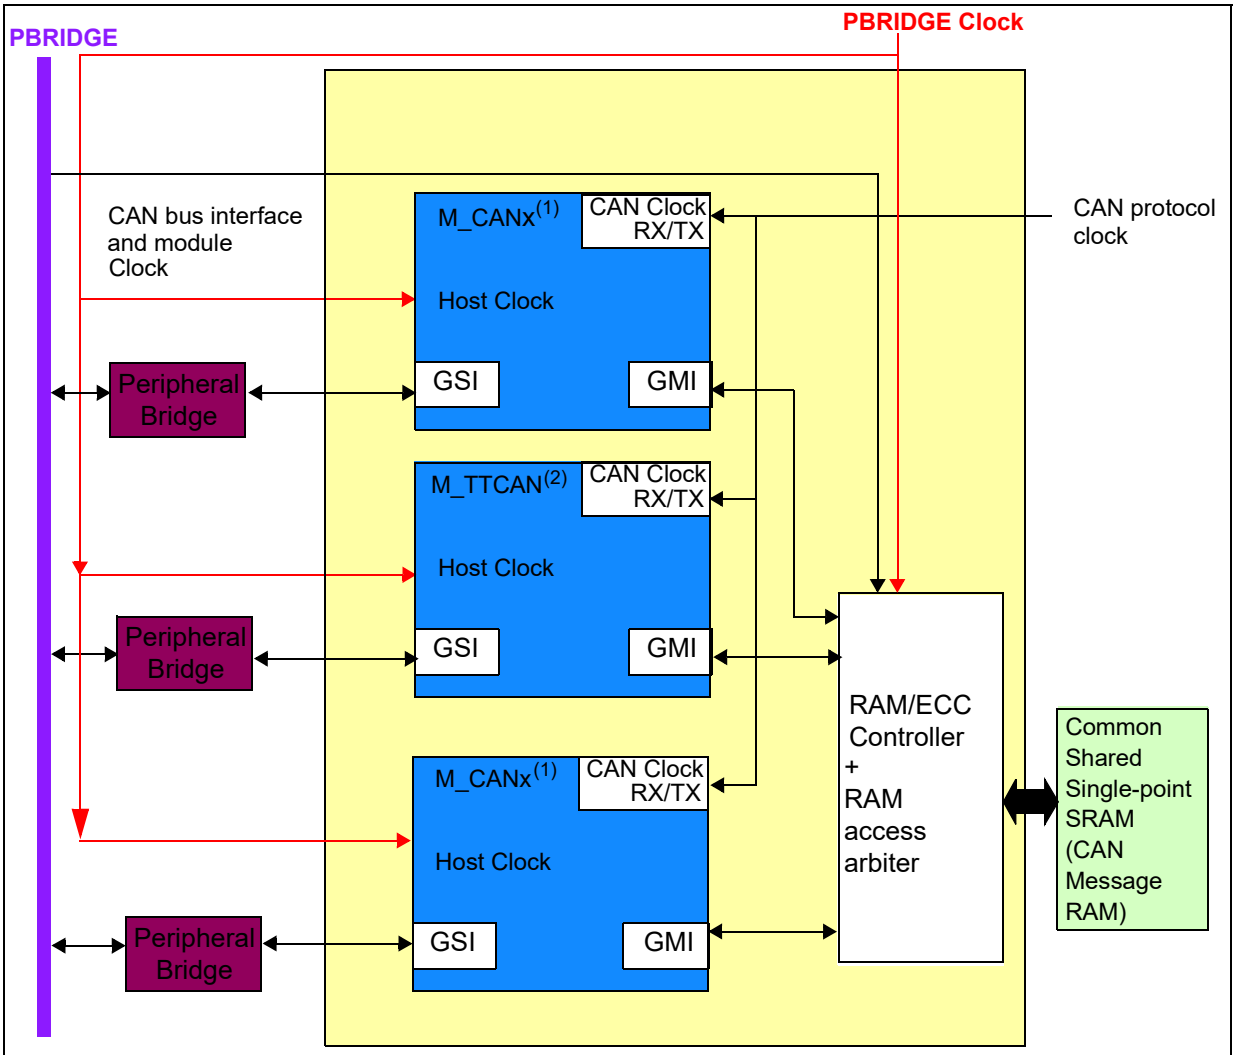
48.1 Introduction

SPC58xNx has two CAN subsystems implemented:

- CAN Subsystem 0
- CAN Subsystem 1

Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the subsystems implementation.

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules and, for at least one subsystem, Time triggered CAN (M_TTCAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection and M_TTCAN trigger memory from CPU write access. The subsystem follows the little endian format.



Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the number of CAN nodes used in the device.

Table 805. IP user manual versions

IP Name	Version
M_CAN IP	Revision 3.2.1
M_TTCAN IP	Revision 3.2.1

The general CAN subsystem implementation is shown in Section 48.2. It interfaces with the Host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.

Figure 692. CAN subsystem generic block diagram

1: Number of M_CAN nodes varies per device. x = 1 to n. Please refer to Device Configuration chapter to see the number of M_CAN nodes used in the device.
2: Please refer to Device Configuration chapter to see the number of M_TTCAN nodes used in the device.

48.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- Time triggered CAN core. The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller

48.3 Modular CAN (M_CAN) cores

M_CAN functionality conforms to CAN specification V2.0B active for each M_CAN node.The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0.Flexible assignment of Message Objects to nodes.
The bit rate can be programmed to values up to 1 Mbit/s for standard CAN frames. High bit rates are possible in CAN FD mode. Additional transceiver hardware is required for connection to the physical layer.

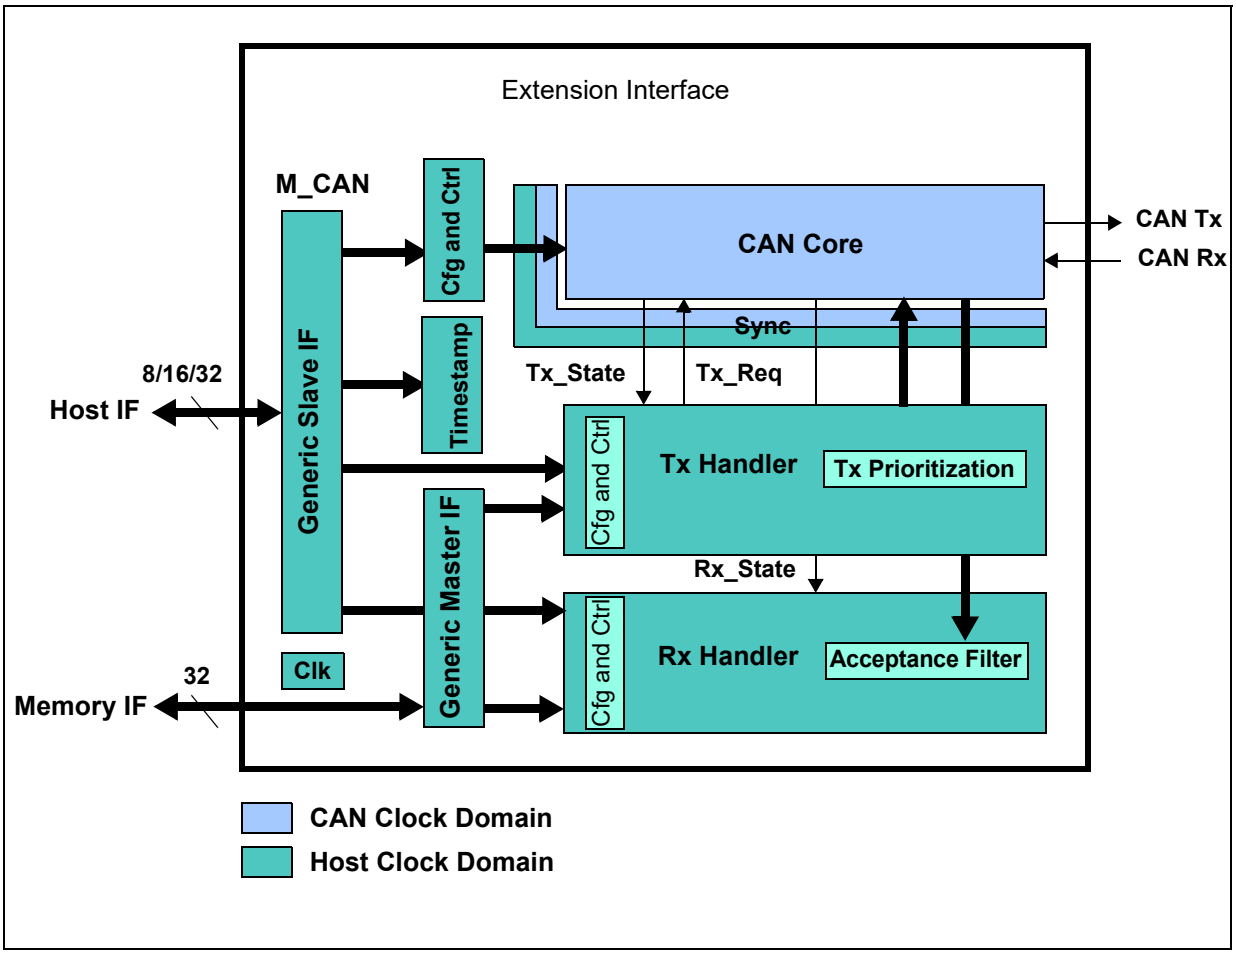
Note: Implemented CAN nodes are fully compliant to ISO CAN FD specification ISO 11898-1: 2015.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.



48.3.1 Features

The following are the features of Modular CAN cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015
- CAN Flexible data-rate (ISO CAN FD) protocol with up to 64 data bytes on M_TTCAN and 64 data bytes on M_CAN is supported
- Bit rates up to 1 Mbit/s in standard CAN mode
- Bit rates up to 8 Mbit/s in ISO CAN FD mode
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bits Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN
- Clock calibration over M_CAN is supported

48.3.2 Block diagram

Figure 693. M_CAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.
- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored

together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable of connecting to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB $\times$ 32 bits.
- Extension Interface: All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

48.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

48.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to EINT0 or to EINT1. By default all interrupts are routed to interrupt line EINT0. By programming EINT0 and EINT1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

48.3.5 Memory map and register descriptions

48.3.5.1 Hardware reset description

After hardware reset, the registers of the M_CAN hold the reset values listed in *Table 806*. Additionally the *Bus_Off* state is reset and the M_CAN Tx output is set to *recessive* (HIGH). The value 0x0001 (bit 0 [INIT] of the CCCR register = ‘1’) in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets bit 0 [INIT] of the CCCR register = ‘0’.

48.3.5.2 Register map

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR register is set to '1'.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

Caution: Any write access to reserved or not implemented registers in the 16 KB slot assigned by the peripherals bridge to the M_CAN IP will not generate any bus access error.

48.3.5.2.3 Data Bit Timing and Prescaler Register (DBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_CAN clock periods. tq = (FBRP + 1) M_CAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (programmed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning that the data for the next bit is available at the first clock edge after the sample point.

Offset: 0x000C Access: Read Protected

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	1	0	1	0	0	0	1	1	0	0	1	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 696. Data Bit Timing and Prescaler Register (DBTP)

Table 809. DBTP field descriptions

Field	Description
8 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
11:15 DBRP	Data Baud Rate Prescaler (0x00–0x1F) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
19:23 DTSEG1	Data time segment before sample point (0x0–0x1F) Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 DTSEG2	Data time segment after sample point (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 DSJW	Data (Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via DBTP must be higher than or equal to the bit rate configured for the arbitration phase via NBTP.

To achieve high bit rates in CAN FD mode for the data phase up to 8 Mbit/s the number of time quanta bits per CAN bit can be chosen down to 4 time quanta per bit time.

48.3.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting CCCR[TEST] to ‘1’. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back mode and software control of M_CAN Tx pin are hardware test modes. Programming of **TX** ≠ ‘00’ may disturb the message transfer on the CAN bus.

48.3.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR is set. The RAM Watchdog Counter is clocked by the Host clock .

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.
2. These are protected set (p) bits.

Figure 699. CC Control register (CCCR)

Table 812. CCCR field descriptions

Field	Description
16 NISO	Non ISO Operation If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame. 0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	Edge Filtering during Bus Integration 0 Edge filtering disabled 1 Two consecutive dominant tq required to detect an edge for hard synchronization
19 PXHD	Protocol Exception Handling Disable 0 Protocol exception handling enabled 1 Protocol exception handling disabled **Note:** When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
22 BRSE	Bit Rate Switch Enable 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled **Note:** When CAN FD operation is disabled FDOE = ‘0’, BRSE is not evaluated.
23 FDOE	FD Operation Enable 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping Host clock and core clock

Table 812. CCCR field descriptions (continued)

Field	Description
29 ASM	Restricted Operation Mode Bit ASM is only set by the Host when both CCE and INIT are set to '1'. The bit is reset by the Host at any time. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started **Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

48.3.5.2.7 Nominal Bit Timing and Prescaler Register (NBTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of [4…385] time quanta. The CAN time quantum may be programmed in the range of [1…512] M_CAN clock periods.

Equation 33 tq = (NBRP + 1) M_CAN clock period

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (prog rammed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Figure 700. Nominal Bit Timing and Prescaler Register (NBTP)

Table 813. NBTP field descriptions

Field	Description
0:6 NSJW	(Re) Synchronization Jump Width (0x00–0x7F) Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
7:15 NBRP	Baud Rate Prescaler (0x000–0x1FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16:23 NTSEG1	Time segment before sample point (0x01–0xFF) Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
25:31 NTSEG2	The time segment after the sample point (0x00–0x7F) Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the M_CAN for a bit rate of 500 kbit/s.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 702. Timestamp Counter Value Register (TSCV)

Table 815. TSCV field descriptions

Field	Description
16:31 TSC	Timestamp Counter The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = '01', the Timestamp Counter is incremented in multiples of CAN bit times [1 to 16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero. When TSCC.TSS = '10', TSC reflects the external Timestamp Counter value. A write access has no impact.

Note: A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

48.3.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter, refer to *Section 48.3.9*.

R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Figure 705. Error Counter Register (ECR)

Table 818. ECR field descriptions

Field	Description
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR register.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

48.3.5.2.13 Protocol Status Register (PSR)

1. Access type is RX: reset on read.
2. Access type is RS: set on read.

Figure 706. Protocol Status Register (PSR)

Table 819. PSR field descriptions

Field	Description
9:15 TDCV	Transmitter Delay Compensation Value (0x00-0x7F) Position of the secondary sample point, defined by the sum of the measured delay from CAN Tx to CAN Rx and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
17 PXE	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state

Table 819. PSR field descriptions (continued)

Field	Description
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing – node is synchronizing on CAN communication 01 Idle-node is neither receiver nor transmitter 10 Receiver-node is operating as receiver 11 Transmitter-node is operating as transmitter
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

The Bus_Off recovery sequence (refer to CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT.] If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

48.3.5.2.14 Transmitter Delay compensation Register (TDCR)

Offset: 0x0048 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 707. Transmitter Delay compensation Register (TDCR)

Table 820. TDCR field descriptions

Field	Description
17:23 TDCO	Transmitter Delay Compensation Offset (0x00-0x7F) Offset value defining the distance between the measured delay from CAN Tx to CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.
25:31 TDCF	Transmitter Delay Compensation Filter Window Length (0x00-0x7F) Defines the minimum value for the SSP position, dominant edges on CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

48.3.5.2.15 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred

Table 821. IR field descriptions (continued)

Field	Description
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (for example parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (for example ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler – has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. – was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler is not able to read a message from the Message RAM in time. In this case message transmission is aborted. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to '1'.

Figure 715. Extended ID and Mask Register (XIDAM)

Table 828. XIDAM field descriptions

Field	Description
3:31 EIDM	Extended ID Mask For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.

48.3.5.2.23 High Priority Message Status Register (HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Offset: 0x0094 Access: R

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 721. Rx FIFO 0 Acknowledge Register (RXF0A)

Table 834. RXF0A field descriptions

Field	Description
26:31 F0AI	Rx FIFO 0 Acknowledge Index After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This will set the Rx FIFO 0 Get Index RXF0S[F0GI] to F0AI + 1 and update the FIFO 0 Fill Level RXF0S[F0FL].

Figure 728. Tx FIFO/Queue Status Register (TXFQS)

Table 841. TXFQS field descriptions

Field	Description
10 TFQF	Tx FIFO/Queue Full 0 Tx FIFO/Queue not full 1 Tx FIFO/Queue full
11:15 TFQPI	Tx FIFO/Queue Put Index Tx FIFO/Queue write index pointer, range 0 to 31.
19:23 TFGI	Tx FIFO Get Index Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (TXBC[TFQM] = ‘1’).
26:31 TFFL	Tx FIFO Free Level Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 32. Read as zero when Tx Queue operation is configured (TXBC[TFQM] = ‘1’).

Note: In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get indexes indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers. Example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

48.3.5.2.36 Tx Buffer Element Size Configuration (TXESC)

It configures the number of data bytes belonging to a Tx Buffer element. Data field sizes > 8 bytes are intended for CAN FD operation only.

Offset: 0x00C8 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 730. Tx Buffer Request Pending Register (TXBRP)

Table 843. TXBRP field descriptions

Field	Description
0:31 TRP[31:0]	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (refer to *Section 48.4.7.16: Debug on CAN Support*) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – after successful transmission together with the corresponding TXBTO bit – when the transmission has not yet been started at the point of cancellation – when the transmission has been aborted due to lost arbitration – when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

48.3.5.2.38 Tx Buffer Add Request Register (TXBAR)

Offset: 0x00D0 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 731. Tx Buffer Add Request Register (TXBAR)

Table 844. TXBAR field descriptions

Field	Description
0:31 AR[31:0]	Add Request Each Tx Buffer has its own Add Request bit. Writing a ‘1’ will set the corresponding Add Request bit; writing a ‘0’ has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to TXBAR. TXBAR bits are set only for those Tx Buffers configured via TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed. 0 No transmission request added 1 Transmission requested added

Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

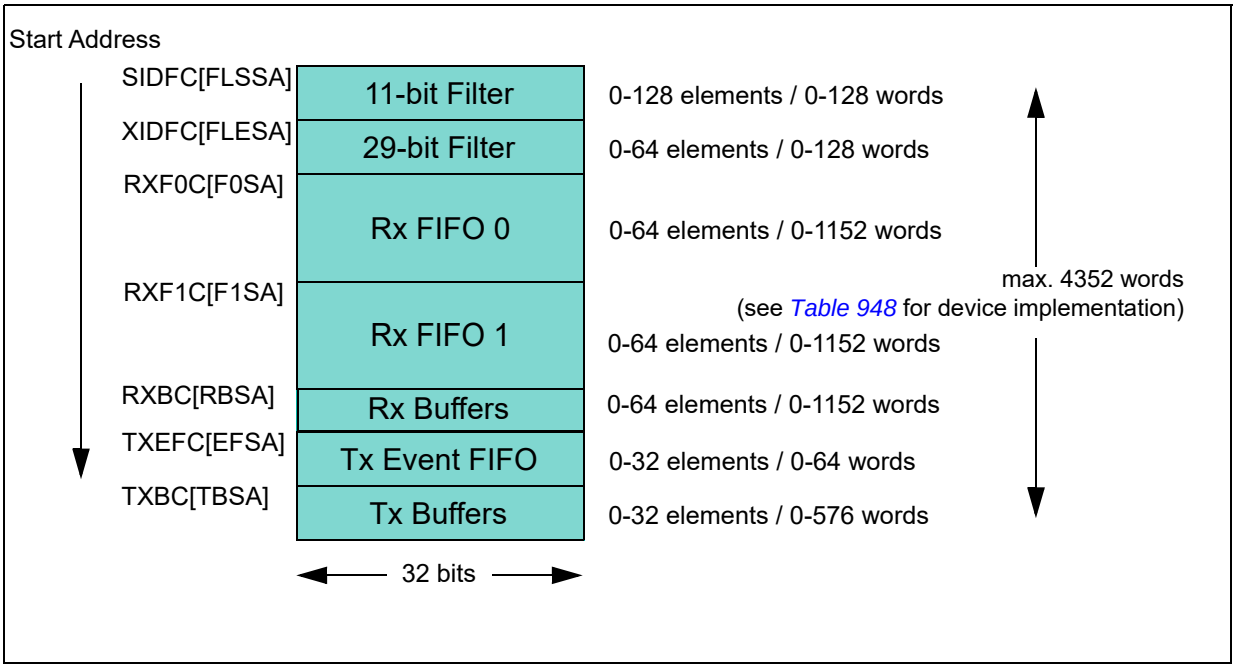
Figure 739. Tx Event FIFO Acknowledge Register (TXEFA)

Table 852. TXEFA field descriptions

Field	Description
27:31 EFAI	Event FIFO Acknowledge Index After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

48.3.6 Message RAM



For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_CAN module.

Note: Because the Message RAM is equipped with ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing, for example, 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 4352 words in the Message RAM (for the chip-specific implementation details of each module's instance, refer to device configuration chapter). It is not necessary to configure each of the sections listed in *Figure 740*, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC.F0DS, RXESC.F1DS, RXESC.RBDS, and TXESC.TBDS.

Figure 740. Message RAM Configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses such as only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Note: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

48.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

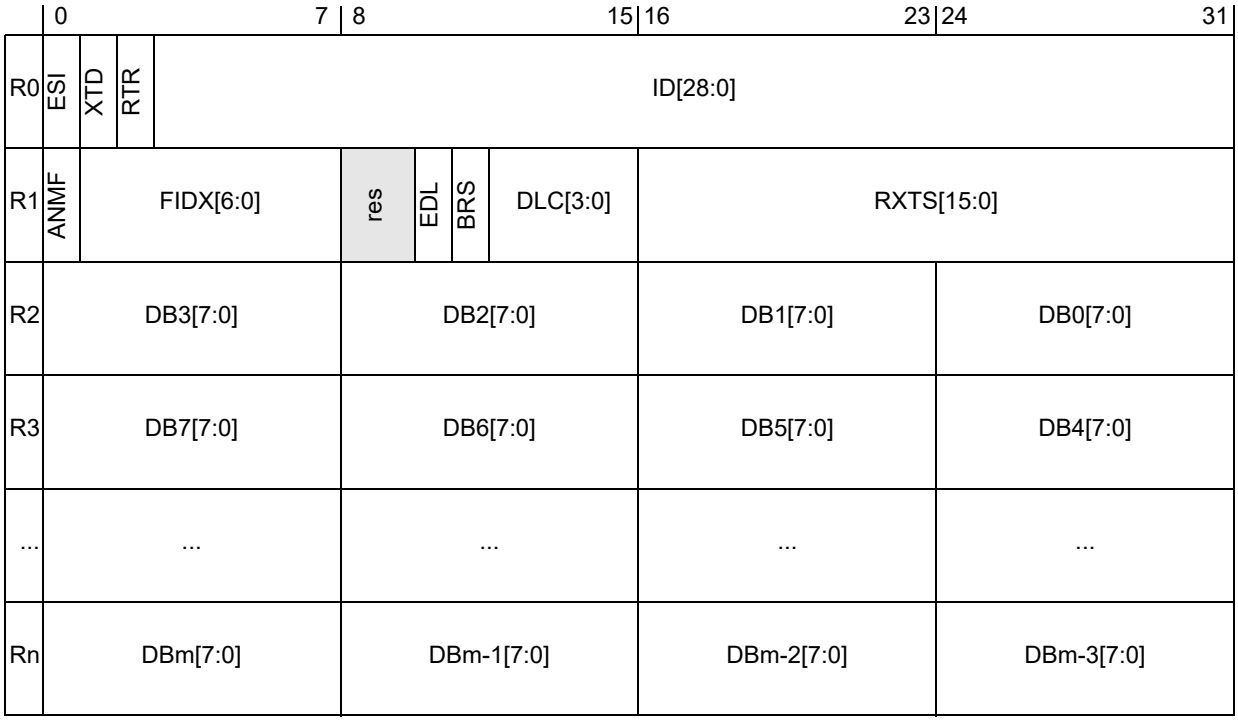


Figure 741. Rx Buffer and FIFO element

Table 853. Rx Buffer and FIFO element descriptions

Field	Description
R0 bit 0 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 bit 1 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 bit 2 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (EDL = '1'), bit RTR reflects the state of the reserved bit r1.
R0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 bit 0 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element

Table 853. Rx Buffer and FIFO element descriptions (continued)

Field	Description
R1 bits 1:7 FIDX[6:0]: Filter Index	0-127=Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 bit 10 EDL: Extended Data Length	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
R1 bit 11 BRS: Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 bits 12:15 DLC[3:0]: Data Length Code	0-8 CAN + CAN FD: Received frame has 0-8 data bytes 9-15 CAN: Received frame has 8 data bytes 9-15 CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
R1 bits 16:31 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 bits 0:7	DB3[7:0]: Data Byte 3
R2 bits 8:15	DB2[7:0]: Data Byte 2
R2 bits 16:23	DB1[7:0]: Data Byte 1
R2 bits 24:31	DB0[7:0]: Data Byte 0
R3 bits 0:7	DB7[7:0]: Data Byte 7
R3 bits 8:15	DB6[7:0]: Data Byte 6
R3 bits 16:23	DB5[7:0]: Data Byte 5
R3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Rn bits 0:7	DBm[7:0]: Data Byte m
Rn bits 8:15	DBm-1[7:0]: Data Byte m-1
Rn bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 to 17) are used for storage of a CAN message's data field.

48.3.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer

configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

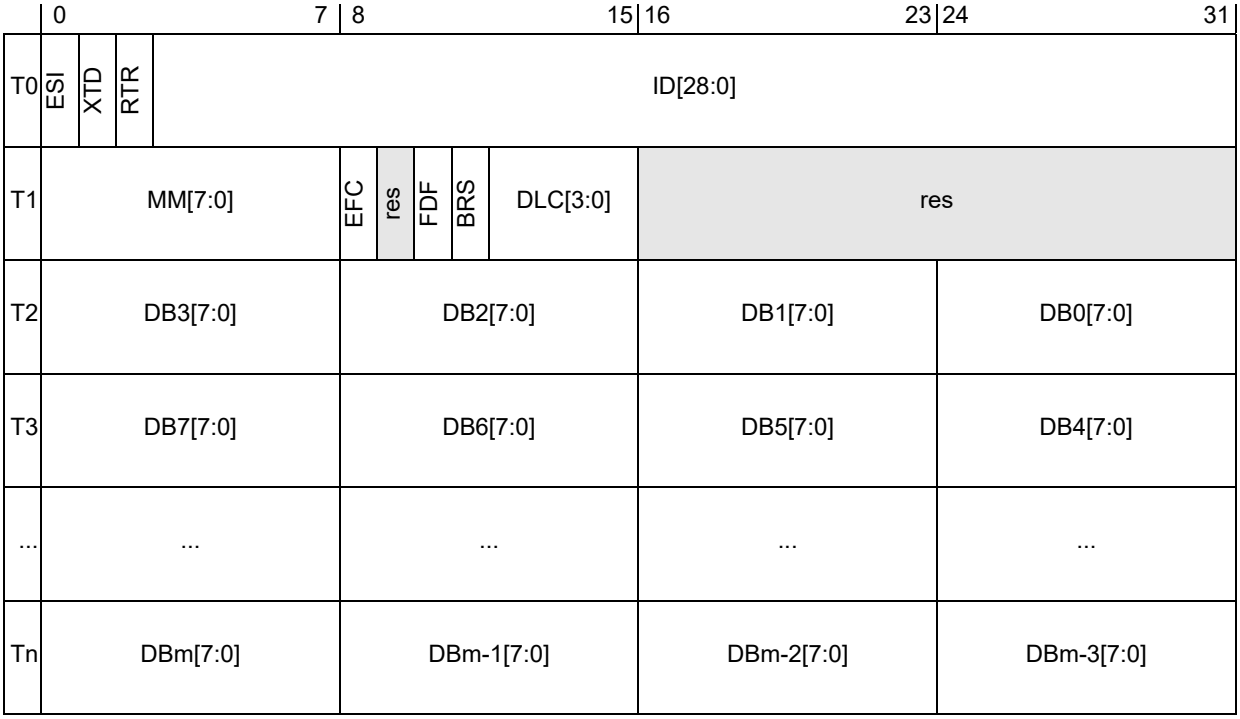

Figure 742. Tx Buffer element

Table 854. Tx Buffer element descriptions

Field	Description
T0 bit 0 ESI: Error State Indicator	0 ESI bit in CAN FD format depends only on error passive flag 1 ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive
T0 bit 1 XTD: Extended Identifier	0 11-bit standard identifier 129-bit extended identifier
T0 bit 2 RTR: Remote Transmission Request	0 Transmit data frame 1 Transmit remote frame **Note:** When RTR = 1, the M_CAN transmits a remote frame according to ISO11898-1, even if CCCR.FDOE enables the transmission in CAN FD format.
T0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
T1 bits 0:7 MM[7:0]: Message Marker	Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

Table 854. Tx Buffer element descriptions (continued)

Field	Description
T1 bit 8 EFC **Event FIFO Control**	0 Don't store Tx events 1 Store Tx events
T1 bit 10 FDF **FD Format**	0 Frame transmitted in Classic CAN format 1 Frame transmitted in CAN FD format
T1 bit 11 BRS **Bit Rat Switching**	0 CAN FD frames transmitted without bit rate switching 1 CAN FD frames transmitted with bit rate switching
T1 bits 12:15 DLC[3:0] **Data Length Code**	0-8 Transmit frame with 0-8 data bytes 9-15 Transmit frame with 8 data bytes 9-15 CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
T2 bits 0:7	DB3[7:0]: Data Byte 3
T2 bits 8:15	DB2[7:0]: Data Byte 2
T2 bits 16:23	DB1[7:0]: Data Byte 1
T2 bits 24:31	DB0[7:0]: Data Byte 0
T3 bits 0:7	DB7[7:0]: Data Byte 7
T3 bits 8:15	DB6[7:0]: Data Byte 6
T3 bits 16:23	DB5[7:0]: Data Byte 5
T3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Tn bits 0:7	DBm[7:0]: Data Byte m
Tn bits 8:15	DBm-1[7:0]: Data Byte m-1
Tn bits 16:23	DBm-2[7:0]: Data Byte m-2
Tn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.

48.3.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

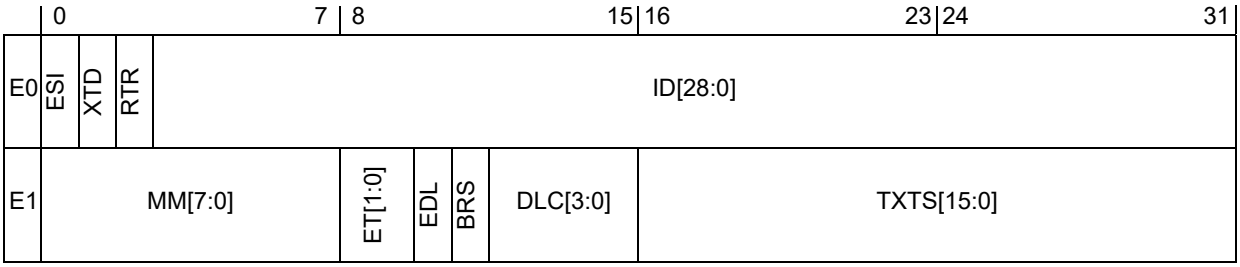

Figure 743. Tx Event FIFO element

Table 855. Tx Event FIFO element descriptions

Field	Description
E0 bit 0 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 bit 1 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.
E1 bit 8:9 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching

Table 855. Tx Event FIFO element descriptions (continued)

Field	Description
E1 bits 12:15 DLC[3:0]	Data Length Code 0-8 CAN + CAN FD: frame with 0-8 data bytes transmitted 9-15 CAN: frame with 8 data bytes transmitted 9-15 CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
E1 bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

48.3.6.4 Standard Message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0 to 127).

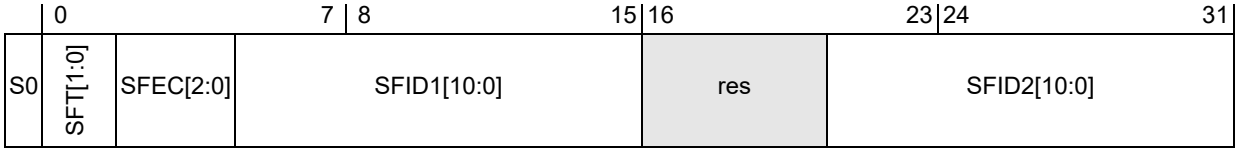

Figure 744. Standard Message ID Filter element

Table 856. Standard Message ID Filter element descriptions

Field	Description
Bits 0:1 SFT[1:0]	Standard Filter Type 00 Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 01 Dual ID filter for SFID1 or SFID2 10 Classic filter: SFID1 = filter, SFID2 = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored

Table 856. Standard Message ID Filter element descriptions (continued)

Field	Description
Bits 5:15 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31 SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: 1) SFEC = '001'...'110' Second ID of standard ID filter element 2) SFEC = '111' Filter for Rx Buffers or for debug messages
	SFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN Host clock period in case the filter matches.
	SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

48.3.6.5 Extended Message ID Filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0 to 63).

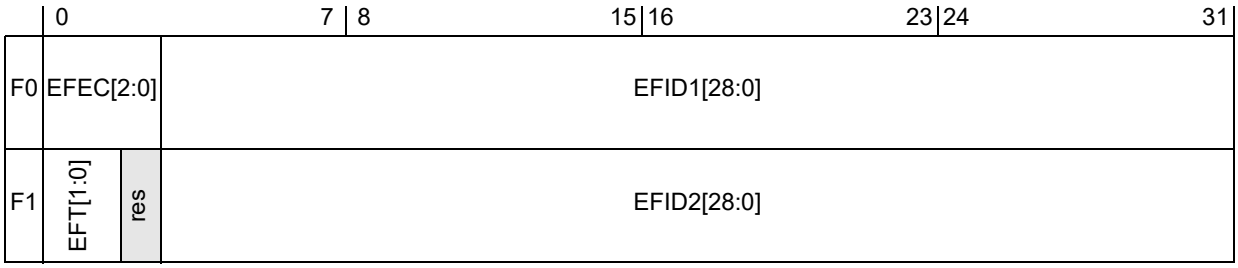

Figure 745. Extended Message ID Filter element

Table 857. Extended Message ID Filter element description

Field	Description
F0 bits 0:2 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 bits 3:31 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (refer to *Section 48.3.10.1.5*) is used.
F1 bits 0:1 EFT[1:0]	Extended Filter Type 00 Range filter from EFID1 to EFID1 (EFID2 ≥ EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
F1 bits 3:31 EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = '001'...'110' Second ID of extended ID filter element 2) EFEC = '111' Filter for Rx Buffers or for debug messages EFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6] is used to control the filter event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

48.3.7 M_CAN functional description

48.3.7.1 Operating modes

48.3.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = ‘1’. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS–High Priority Message Status
- RXF0S–Rx FIFO 0 Status
- RXF1S–Rx FIFO 1 Status
- TXFQS–Tx FIFO/Queue Status
- TXBRP–Tx Buffer Request Pending
- TXBTO–Tx Buffer Transmission Occurred
- TXBCF–Tx Buffer Cancellation Finished
- TXEFS–Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writable while CCCR[CCE] = ‘0’

- TXBAR–Tx Buffer Add Request
- TXBCR–Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

The following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
     while (read_data != 0x003){
        write(M_CAN0,0xF,driver.regs.can0_cccr.addr,0x003);
           read_data = read(M_CAN0,0xF,driver.regs.can0_cccr.addr);
     };
```

```
-- Configuring the time stamp and timeout registers
     write(M_CAN0,0xF,driver.regs.can0_tscc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_tocc.addr,0x000);

-- Configuring the interrupt registers
     write(M_CAN0,0xF,driver.regs.can0_ie.addr,0xFFFFFFFF);
     write(M_CAN0,0xF,driver.regs.can0_ils.addr,0x00000002);
     write(M_CAN0,0xF,driver.regs.can0_ile.addr,0x00000003);

     write(M_CAN0,0xF,driver.regs.can0_gfc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_xidam.addr,0x00FFFFFF);

-- Writing the start addresses of all the M_CAN Buffers
     generate and drive M_CAN0 can0_rxf0c keeping {
                                          .f0sa == 0x100;
                                          .f0s  == 0x03;
                                          .f0wm == 0x01;
                                       };
     generate and drive M_CAN0 can0_rxf1c keeping {

```

48.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, the received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers or a Tx FIFO, or both, or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

48.3.7.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = *recessive* signifies a CAN FD frame, FDF = *dominant* signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = *dominant* and BRS = *recessive*. The coding of res = *recessive* is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = *recessive* and res = *recessive*, it will signal a Protocol Exception Event by setting bit PSR.PXE. When Protocol Exception Handling is enabled (CCCR.PXHD = ‘0’), this causes the operation state to change from Receiver (PSR.ACT = “10”) to Integrating (PSR.ACT = “00”) at the next sample point. In case Protocol Exception Handling is disabled (CCCR.PXHD = ‘1’), the M_CAN will treat a *recessive* res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = ‘1’, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = ‘0’, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = ‘0’, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘0’, only bit FDF of a Tx Buffer element is evaluated. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘1’, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to *Table 858*.

Table 858. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is *recessive*. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing and Prescaler Register NBTP. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing and Prescaler Register DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (CAN clock). Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit ESI (Error Status Indicator) is determined by the transmitter’s error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted *recessive*, else it is transmitted *dominant*.

48.3.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via CAN Tx output pin the M_CAN the transmitted data from its local CAN transceiver via CAN Rx input pin. The received data is delayed by the transmitter delay. In case this delay is greater than NTSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is

introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

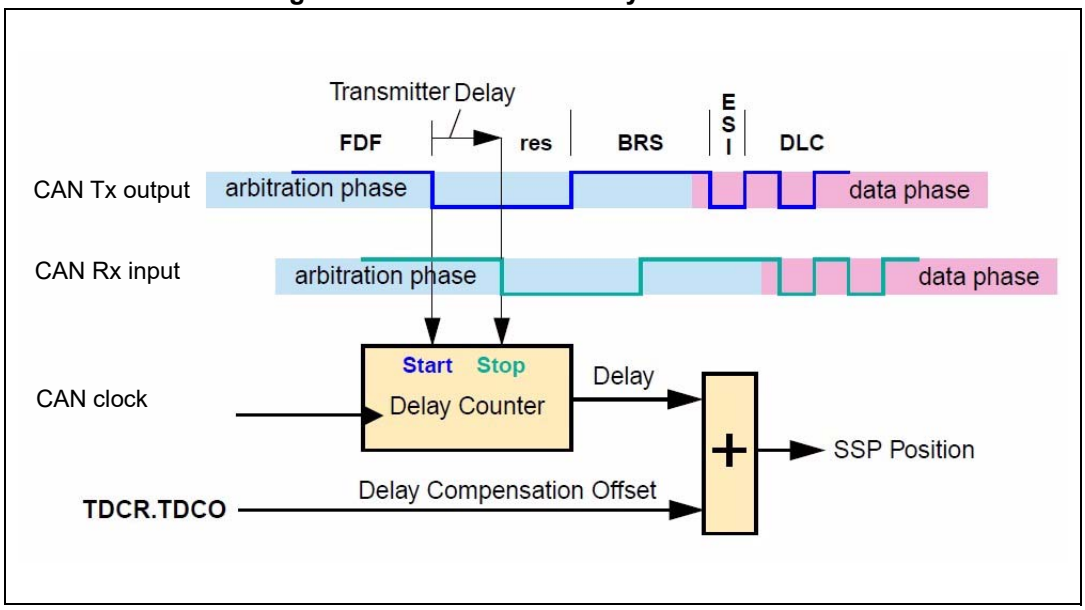
48.3.7.4.1 Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration the transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_CAN's Tx output through the transceiver to the CAN Rx input plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.



The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than 6 bit times in the data phase
- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

Figure 746 below describes how the Transceiver Delay Compensation measurement.

If transmitter delay compensation is enabled by programming DBTP.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input CAN Rx input of the transmitter. The resolution of this measurement is one mtq.

Figure 746. Transceiver Delay measurement

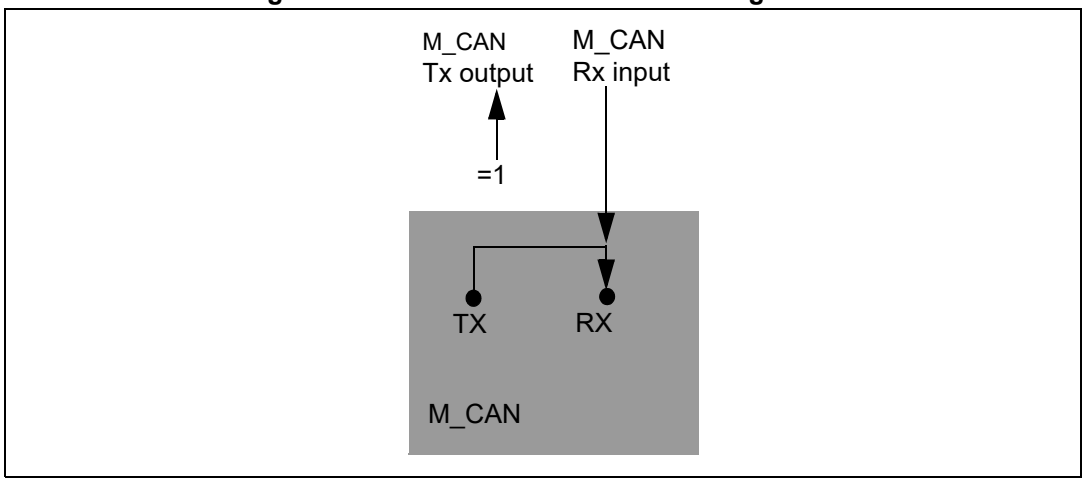
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on CAN Rx input, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF AND CAN Rx input is low.

48.3.7.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCR.ASM. The bit can only be set by the Host when both CCCR.CCE and CCCR.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.



If the M_CAN is connected to a Clock Calibration on CAN Unit, CCCR.ASM is controlled by “calibration OK” input. In case “calibration OK” switches to ‘0’, bit CCCR.ASM is set. When “calibration OK” switches back to ‘1’, bit CCCR.ASM returns to the previously written value. The state of CCCR.ASM is the written value while “calibration OK” input is at ‘1’. The input is hardwired to ‘1’ when there is no Clock Calibration on CAN Unit connected.

48.3.7.6 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (refer to ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

Figure 747 shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

Figure 747. Pin control in Bus Monitoring mode

48.3.7.7 Disabled automatic retransmission

According to the CAN Specification (refer to ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

48.3.7.7.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful

transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = ‘10’ (transmission in spite of cancellation).

48.3.7.8 Power down (Sleep mode)

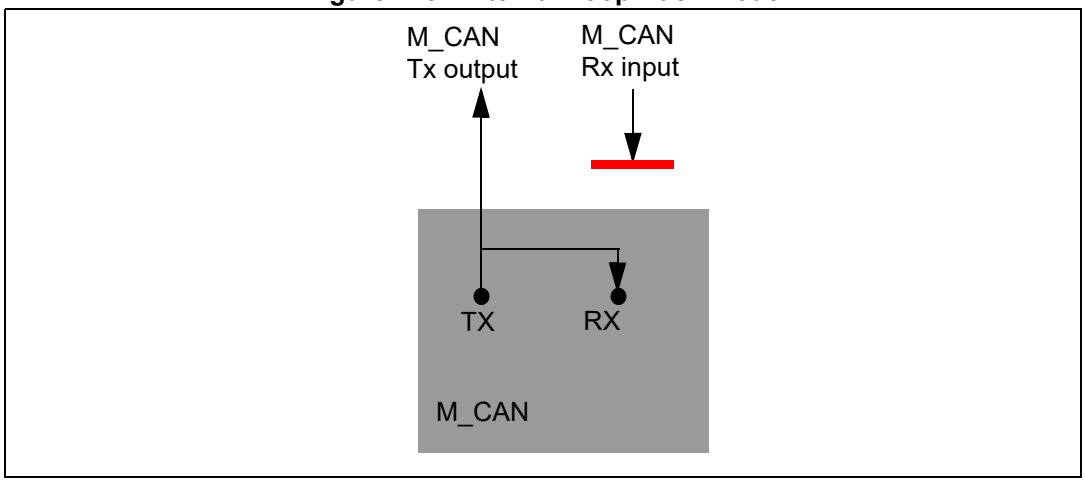
The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and Host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

48.3.7.9 Test modes

To enable write access to register TEST (refer to *Section 48.3.5.2.4: Test Register (TEST)*), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN Tx output pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN’s bit timing and it can drive constant dominant or recessive values. The actual value at M_CAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].



Note: Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

48.3.7.9.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. *Figure 748* shows the connection of Tx and Rx signals to the M_CAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the CAN Tx output pin.

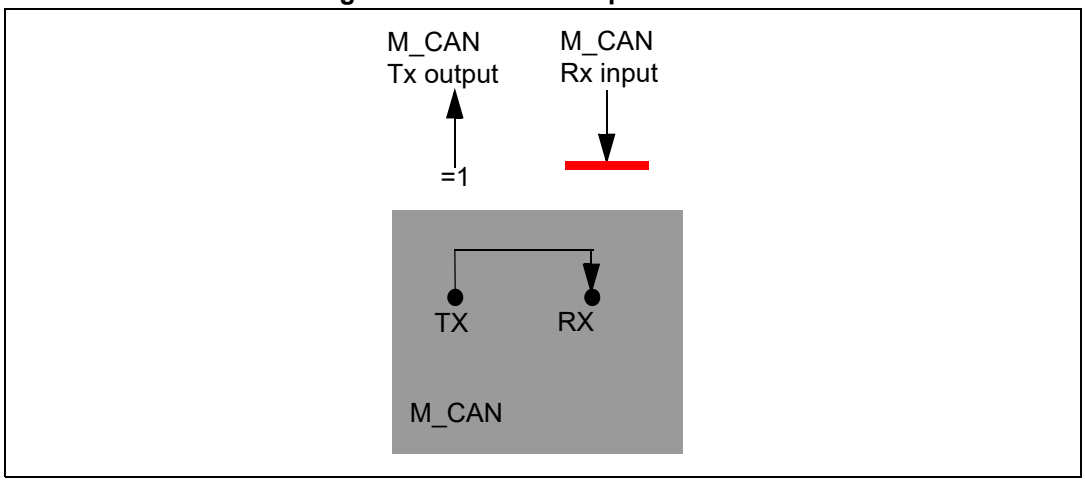


Figure 748. External Loop Back mode

48.3.7.9.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the CAN Tx output and Rx input pins. In this mode M_CAN Tx pin is disconnected from the M_CAN and M_CAN Tx pin is held recessive. *Figure 749* shows the connection of M_CAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

Figure 749. Internal loop back mode

48.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer /Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

48.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = ‘0’. It is stopped when CCCR[INIT] = ‘1’, for example when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core’s sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

48.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indexes.

48.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (such as CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC.

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Section 48.3.10.2.2: Rx FIFO Overwrite Mode* have to be considered.

Note: When an accepted message is written to one of the two Rx FIFOs, or into a Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process strongly depends on the sequence of configured filter elements.

48.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SFID1/SFID2 resp. EFID1/EFID2. There are two possibilities when range filtering is used together with extended frames:

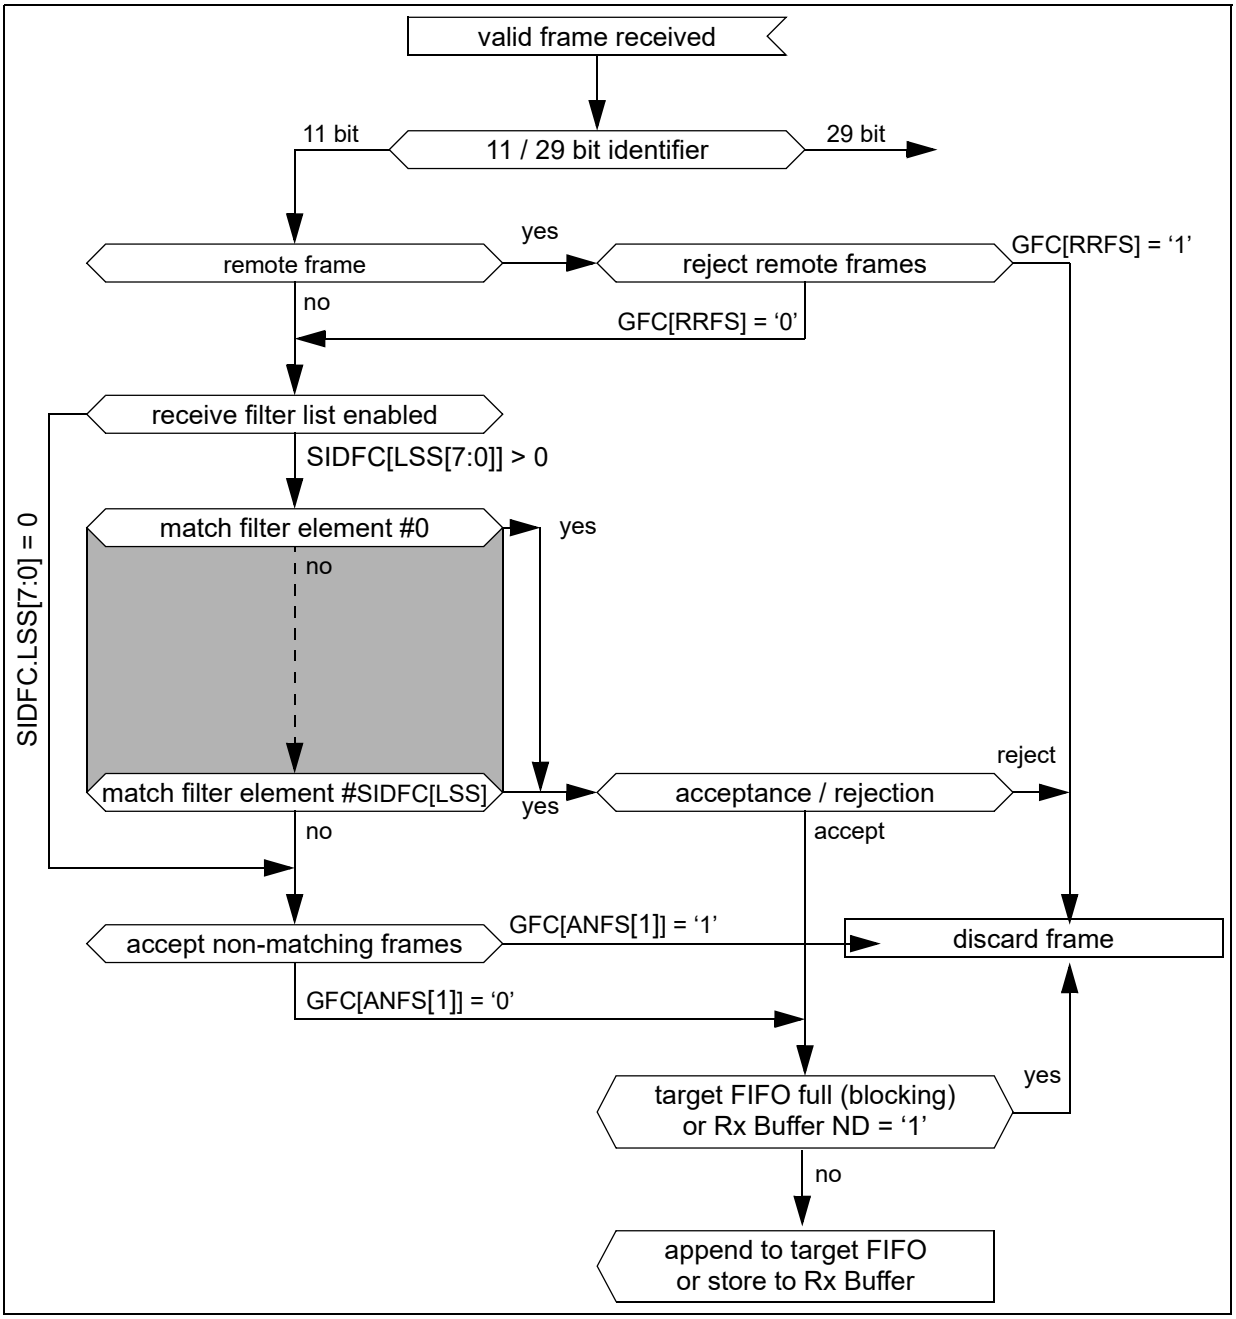
- EFT = '00': The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = '11': The Extended ID AND Mask (XIDAM) is not used for range filtering

48.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1 = SFID2 resp. EFID1 =EFID2.

48.3.10.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1/EFID2 is used as Message ID filter, while SFID2/EFID2 is used as filter mask.



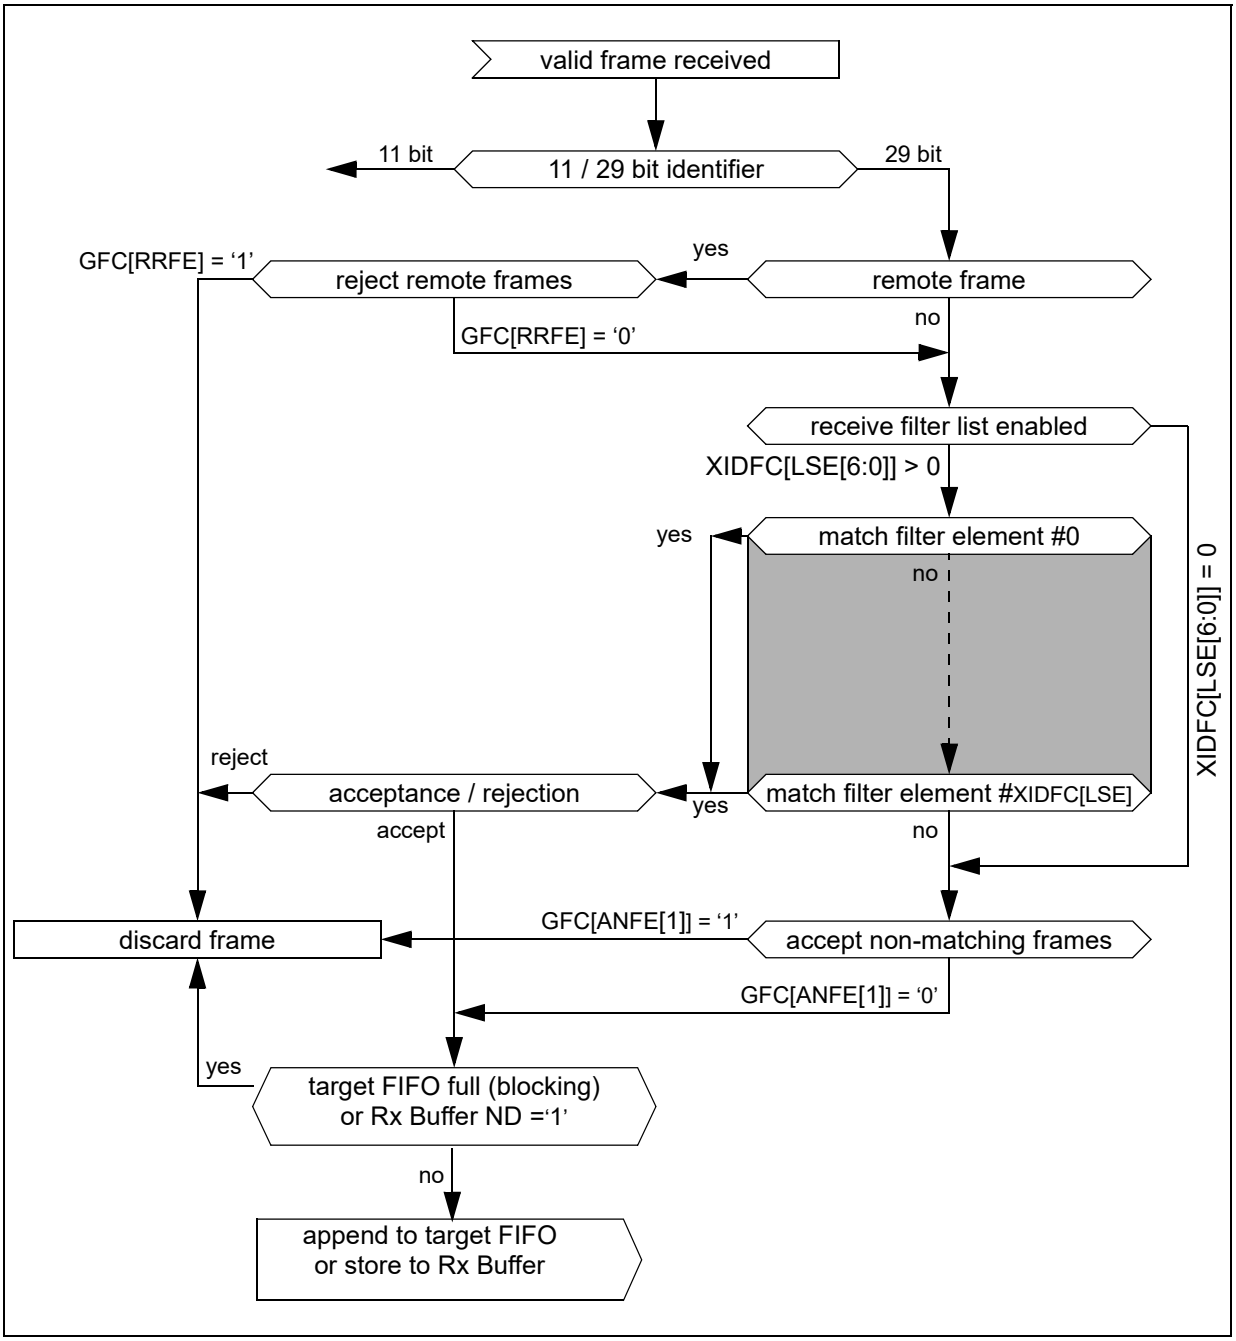
A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

48.3.10.1.4 Standard message ID filtering

Figure 744 shows the flow for standard message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in *Section 48.4.6.4: Standard Message ID Filter element*.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 750. Standard Message ID Filter Path



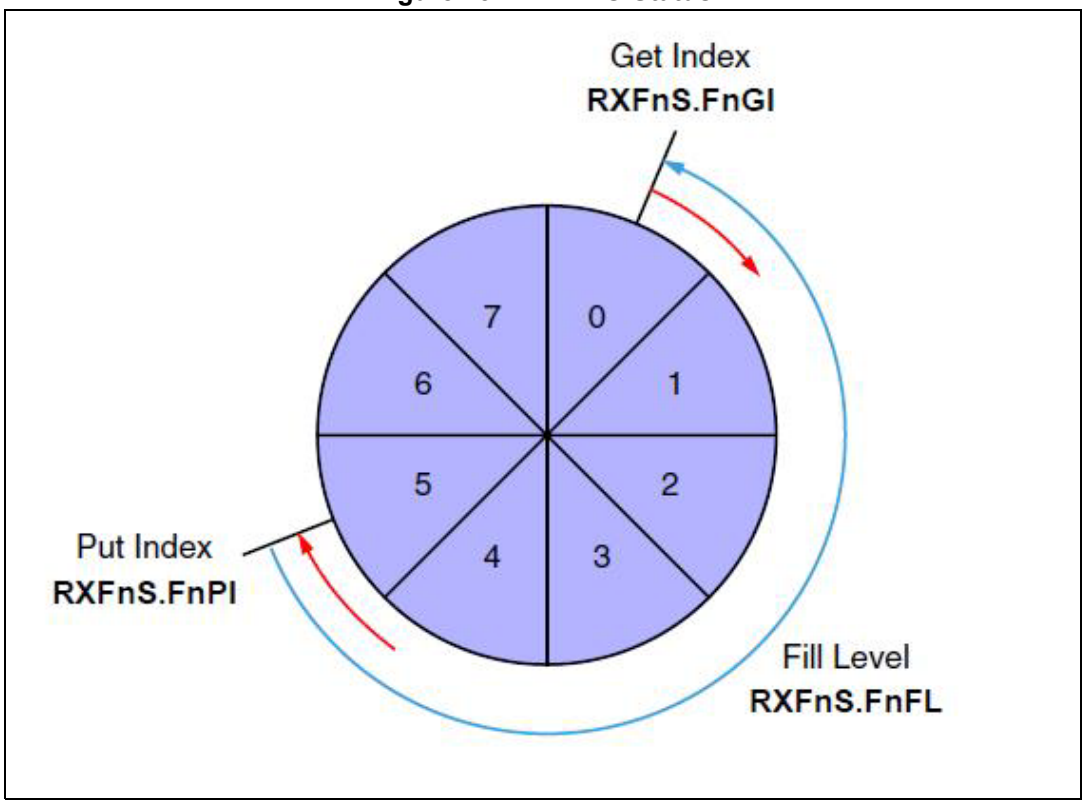
48.3.10.1.5 Extended message ID filtering

Figure 751 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in *Section 48.3.5.2.21: Extended ID Filter Configuration Register (XIDFC)*.

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the

Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 751. Extended Message ID Filter Path



48.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 refer to *Section 48.3.10.1: Acceptance filtering*. The Rx FIFO element is described in *Section 48.3.6.1: Rx Buffer and FIFO element*.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IR.RFnW is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag IR.RFnF is set.

Figure 752. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI × FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 859. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10

Table 859. Rx Buffer / FIFO Element Size (continued)

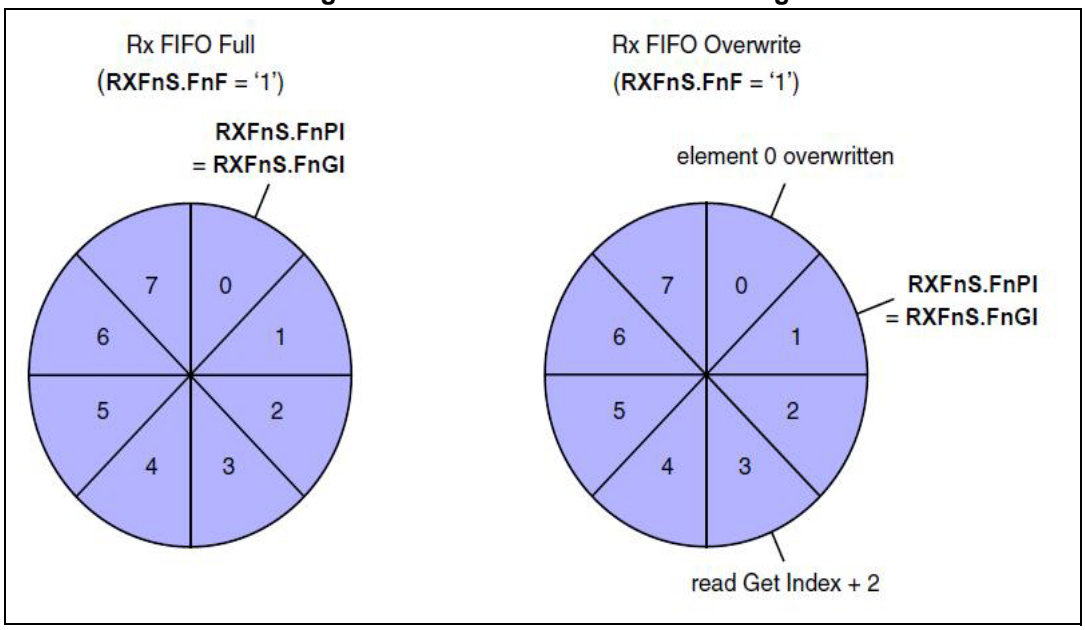
RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
110	48	14
111	64	18

48.3.10.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IR.RFnL is set.



48.3.10.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. *Figure 753* shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 753. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = '0').

48.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (refer to *Section 48.3.6.4: Standard Message ID Filter element* and *Section 48.3.6.5: Extended Message ID Filter element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 860. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set,

the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a ‘1’ to the respective bit position.

While an Rx Buffer’s New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

48.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

48.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (for example #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (refer to *Section 48.3.6.1: Rx Buffer and FIFO element*).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = ‘111’ have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while DMA request output is activated. The behavior is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets the DMA acknowledge input . This resets the DMA request output. Now the M_CAN is prepared to receive the next set of debug messages.

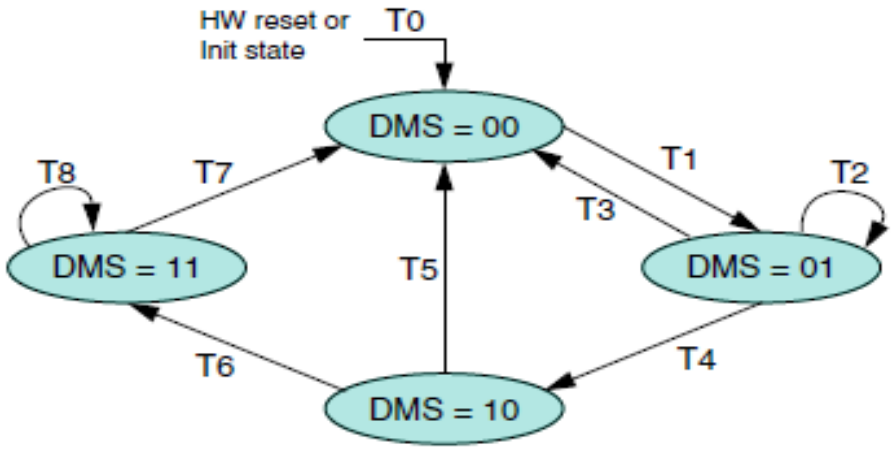
Note: To use full ‘Debug on CAN Support’ feature on a M_(TT)CAN instance, a DMA channel is required. Refer to device DMA map, to see which M_(TT)CAN instances has got an assigned DMA channel.

48.3.12.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to ‘111’. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 /EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 861. Example Filter Configuration for debug messages



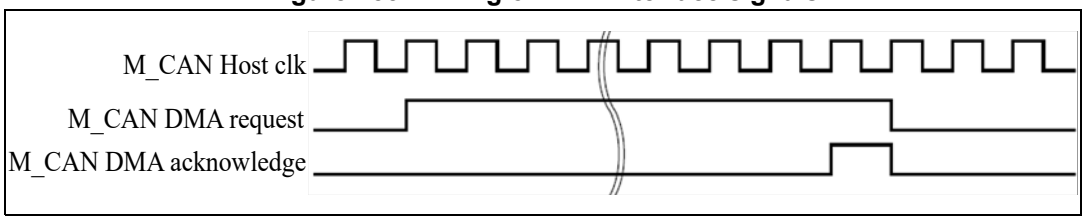
Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

48.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S.DMS.

Figure 754. Debug Message Handling State Machine



T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C
T1: reception of debug message A
T2: reception of debug message A
T3: reception of debug message C
T4: reception of debug message B
T5: reception of debug messages A, B
T6: reception of debug message C
T7: DMA transfer completed
T8: reception of debug message A,B,C (message rejected)

48.3.12.3 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message handling state machine enters idle state (DMS = ‘00’) and waits for reception of the next debug messages.

Figure 755. Timing of DMA interface signals

Note: If the DMA unit activates input M_CAN DMA acknowledge signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

48.3.13 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indexes, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in the *Note: on page 1535*.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

48.3.13.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU’s CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If for example CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR.TXP = ‘0’).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

48.3.13.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 862*). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

Table 862. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

48.3.13.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to ‘0’. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = ‘1’) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

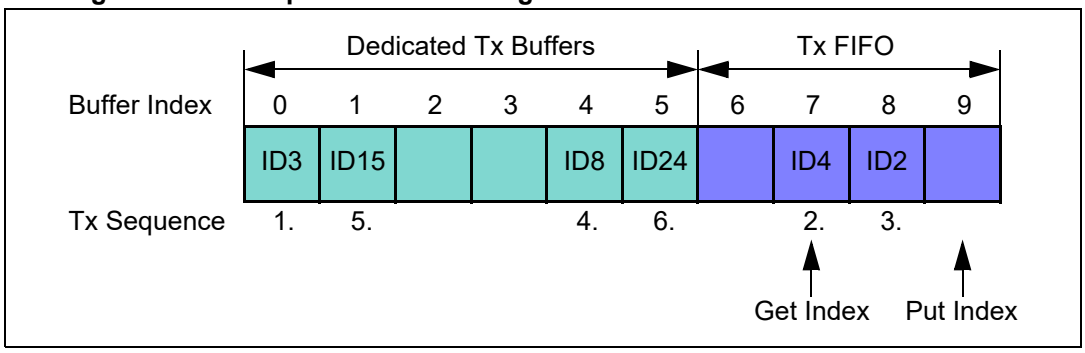
When a single message is added to the Tx FIFO, the transmission is requested by writing a ‘1’ to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (refer to *Table 862*). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

48.3.13.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to ‘1’. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = ‘1’), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.



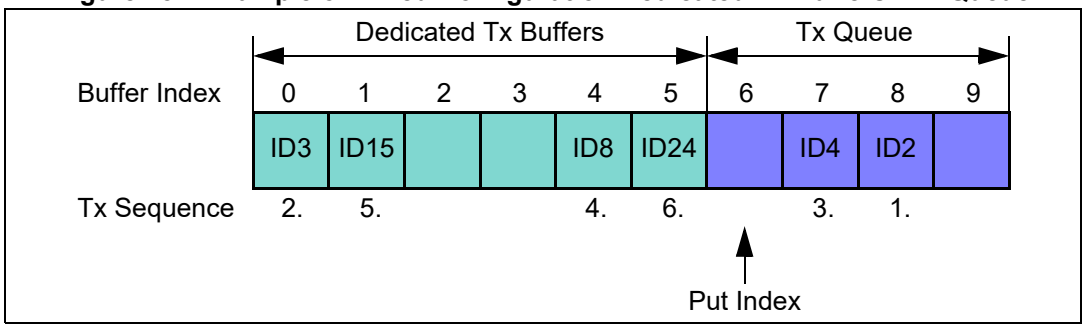
The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 862*). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

48.3.13.5 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 756. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO



Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.13.6 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 757. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.13.7 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a ‘1’ to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to ‘1’.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits

are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

48.3.13.8 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in the Note *Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.*. When a Tx Event FIFO full condition is signaled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

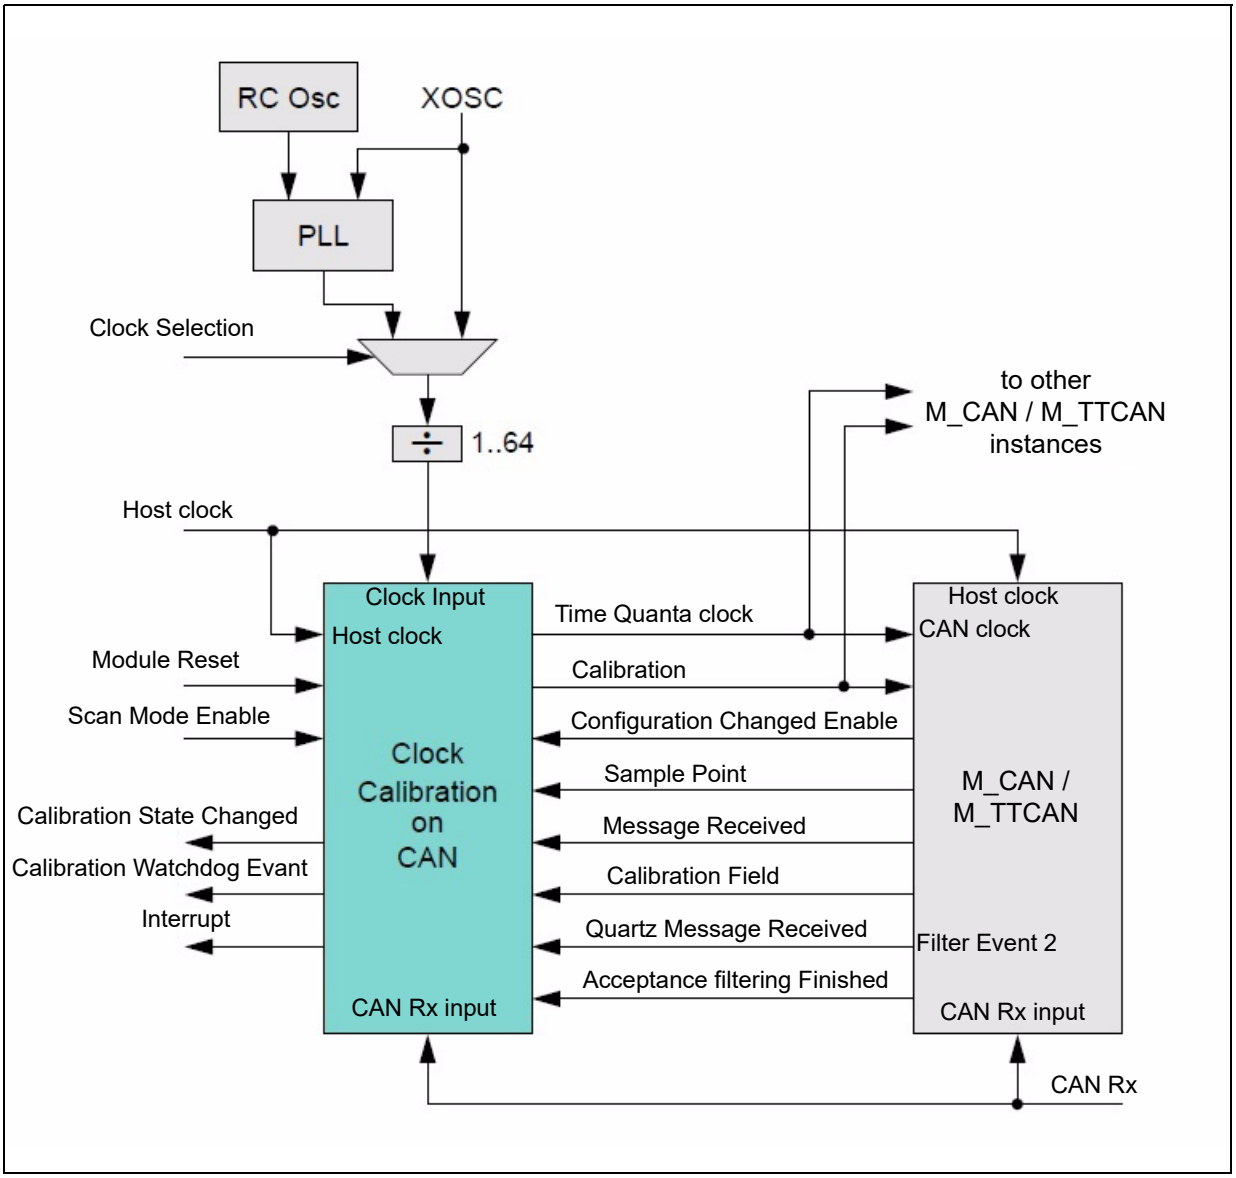
48.3.14 FIFO acknowledge handling

The Get Indexes of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (refer to *Section 48.3.5.2.28: Rx FIFO 0 Acknowledge Register (RXF0A)* and *Section 48.3.5.2.46: Tx Event FIFO Acknowledge Register (TXEFA)*). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.



48.3.15 Clock Calibration on CAN Unit (CCCU)

This section describes an add-on for the M_CAN modules that generates a calibrated CAN Time Quanta Clock from an on-chip RC-oscillator clock by evaluating CAN messages received by the attached M_CAN. Calibration on CAN is only possible when the M_CAN is operated in standard CAN mode.

Note: If calibration unit is intended to generate the protocol clock, then it is mandatory to configure calibration unit and MCAN1 before use the other CAN controller like MCAN2 and MCAN3, because the calibrated clock is generated through MCAN1.

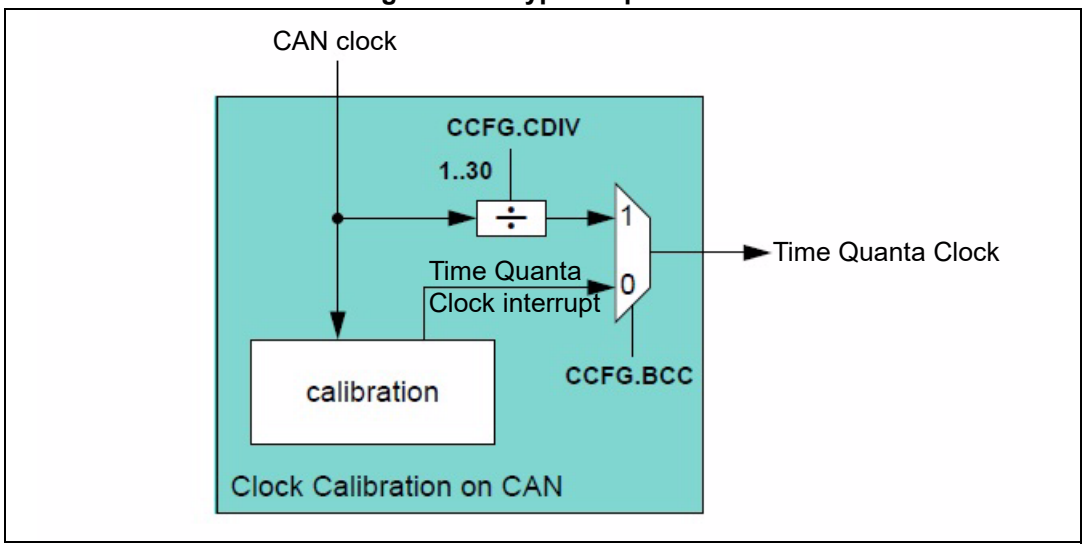


Figure 758 shows the interface of the Clock Calibration on CAN Unit. The clock multiplexer controlled by clock input from Clock Select multiplexer controls whether the clock from the PLL or XOSC is routed to Clock Select multiplexer input. The calibrated Time Quanta Clock is routed to all CAN instances. In case of a successful calibration this is signaled via Calibration.

Figure 758. Connection of Clock Calibration on CAN Unit to M_CAN

CPU accesses to the Clock Calibration on CAN Unit use the Host clock connected to Host clock input from Clock Select Multiplexer. Clock calibration is bypassed when CCFG.BCC = ‘1’. In this case, the clock from Clock Select multiplexer is routed through a clock divider to Time Quanta Clock output (refer to *Figure 759*).

Figure 759. Bypass operation

48.3.15.1 Operating Conditions

The Clock Calibration on CAN Unit is designed to operate under the following conditions:

- Clock input from PLL (clock input from Clock Select multiplexer) between 80 MHz and 500 MHz
- M_CAN bit rates between 125 kbit/s and 1 Mbit/s
- Clock for Host accesses (Host clock) is 40/50 MHz

The Clock Calibration on CAN Unit generates a calibrated Time Quanta clock in the range from 0.5 MHz to 25 MHz.

Note: The M_CAN requires that the CAN clock is always below or equal to the Host clock (CAN clock ≤ Host clock). This has to be considered when the Clock Calibration on CAN Unit is bypassed (CCFG.BCC = '1').

48.3.15.2 Calibration Accuracy

The calibration accuracy in state Precision_Calibrated depends on:

- The dynamic clock tolerance at the clock input from clock select multiplexer
- The measurement error. For each bit sequence used for calibration measurement, there is a maximum error of one clock input from Clock Select multiplexer period. The number of bits used for measurement of the bit time is 32 or 64-bit, depending on configuration of CCFG.CFL.
- Tolerable error in calibration mechanism

The distance between two calibration messages has to be chosen to fit the clock tolerance requirements of the attached M_CANs.

Note: Dynamic clock tolerance is the clock frequency variation between two calibration messages, such as, caused by change of temperature or operating voltage.

48.3.15.3 Memory map and register description

48.3.15.3.1 Hardware Reset Description

After hardware reset, the registers of the Clock Calibration on CAN Unit hold the reset values listed in *Table 863*.

The Clock Calibration on CAN Unit allocates an address space of 16 bytes. All registers are organized as 32-bit registers. The Clock Calibration on CAN Unit is accessible by the Host CPU using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access). Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when Configuration Change Enable input = ‘1’. Configuration Change Enable signal is activated when the M_CAN control bits CCCR.CCE = ’1’ AND CCCR.INIT = ‘1’.

1. Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when Configuration Change Enable input = ‘1’. Configuration Change Enable signal is activated when the M_CAN control bits CCCR.CCE = ‘1’ AND CCCR.INIT = ‘1’.

Figure 761. Calibration Configuration Register (CCFG)

Table 866. CCFG field descriptions

Field	Description
0 SWR	Software Reset Writing a ‘1’ to this bit will reset the calibration FSM to state Not_Calibrated (CSTAT.CALS = ‘00’). The Calibration Watchdog value CWD.WDV is also reset. Registers CCFG, CSTAT and the Calibration Watchdog configuration CWD.WDC are unchanged. The bit remains set until reset has completed.
12:15 CDIV	Clock Divider The clock divider has to be configured when the clock calibration is bypassed (BCC = ‘1’) to assure that the M_CAN requirement CAN clock <= Host clock is fulfilled. 0000 Divide by 1 0001 Divide by 2 0010 Divide by 4 0011 Divide by 6 0100 Divide by 8 0101 Divide by 10 0110 Divide by 12 0111 Divide by 14 1000 Divide by 16 1001 Divide by 18 1010 Divide by 20 1011 Divide by 22 1100 Divide by 24 1101 Divide by 26 1110 Divide by 28 1111 Divide by 30
16:23 OCPM	Oscillator Clock Periods Minimum (0x00–0xFF) Configures the minimum number of clock input from Clock Select multiplexer periods in two CAN bit times. OCPM is used in Basic Calibration to avoid false measurements in case of glitches on the bus line. The configured number of clock input from Clock Select multiplexer periods is OCPM × 32. The configuration depends on the clock input from Clock Select multiplexer frequency (80 MHz to 500 MHz) and the bit rate configured in the attached M_CANs (125 kbit/s to 1 Mbit/s). It is recommended to configure a value slightly below two CAN bit times. The reset value is 1.6 bit times at 80 MHz clock input from Clock Select multiplexer and 1 Mbit/s CAN bit rate.
24 CFL	Calibration Field Length 0 Calibragation field length is 32 bits. 1 Calibragation field length is 64 bits.

Table 866. CCFG field descriptions (continued)

Field	Description
25 BCC	Bypass Clock Calibration If this bit is set, the clock input clock input from Clock Select multiplexer is routed to the Time Quanta clock output through a clock divider configurable via CDIV, Calibration is always ‘1’. In this case the baud rate prescaler of the connected M_CANs has to be configured to generate the M_CAN internal time quanta clock. 0 Clock calibration unit generates Time Quanta clock 1 Clock calibration unit bypassed **Note:** As long as clock input from Clock Select multiplexer is equal or above 80 MHz the Clock Calibration on CAN Unit is functional, even when BCC = ‘1’. The calibration state can be read from register CSTAT.
27:31 TQBT	Time Quanta per Bit Time (0x04–0x19) Configures the number of time quanta per bit time. Same value as configured in the attached M_CANs. The range of the resulting Time Quanta clock is from 0,5 MHz (bit rate of 125 kbit/s with 4 tq per bit time) to 25 MHz (bit rate of 1 Mbit/s with 25 tq per bit time). Valid values are 4 to 25. Configured values below 4 are interpreted as 4, values above 25 are interpreted as 25.

14:31 OCPC	Oscillator Clock Period Counter (0x00000–0x3FFFF) Captured number of oscillator clock periods in calibration field (32 or 64 bits). Only valid when the clock calibration unit is in state Precision_Calibrated.

48.3.15.3.5 Calibration Watchdog Register (CWD)

The calibration watchdog is started after the first falling edge when the calibration FSM is in state Not_Calibrated (CSTAT.CALS = ‘00’). In this state the calibration watchdog monitors the Message Received input. In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM stays in state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When in state Basic_Calibrated (CSTAT.CALS = ‘01’), the calibration watchdog is restarted with each Message Received = ‘1’). In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM returns to state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When a quartz message was received, state Precision_Calibrated (CSTAT.CALS = ‘10’) is entered and the calibration watchdog is restarted. In this state the calibration watchdog monitors the Quartz Message Received input. In case no message from a quartz controlled node was received by the attached M_CAN until the calibration watchdog has counted down to zero, the calibration FSM transits back to state Basic_Calibrated (CSTAT.CALS = ‘01’).

The Calibration Watchdog Counter is clocked by the Sample Point input. The duration of a cu_spt pulse is one Time Quanta clock period. The signal is active when the CAN protocol engine on the attached M_CAN is started, that is when the INIT bit is reset.

A calibration watchdog event is signaled by Calibration Watchdog Event output. The duration of aCalibration Watchdog Event pulse is one Host clock period.

A calibration watchdog event also sets interrupt flag **CUIR.CWE**. If enabled by **CUIE.CWEE**, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag **CUIR.CWE** is reset.

48.3.15.3.6 CU Interrupt Register (CUIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ’0’ has no effect. A hard reset will clear the register. The configuration of CUIE controls whether an interrupt is generated.

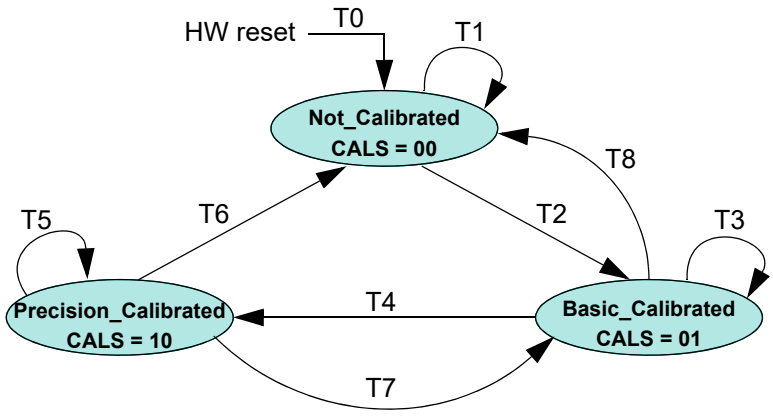
48.3.15.4 Functional Description



Calibration of the Time Quanta clock via CAN messages is performed by adapting a clock divider that generates the CAN protocol time quantum tq from the clock input from Clock Select multiplexer .

- First step: Basic Calibration–The minimum distance between two edges from recessive to dominant is measured, this time to be assumed two CAN bit times, counted in PLL clock periods. The clock divider is updated each time a new measurement finds a smaller distance between edges. Basic calibration is achieved when the CAN protocol

controller detects a valid CAN message. This is signaled to the Calibration on CAN unit by Message Received input signal.

- Second step: Precision Calibration – The calibration state machine measures the length of a longer bit sequence inside a CAN frame by counting the number of clock input from Clock Select multiplexer periods. The length of this bit sequence can be configured to 32 or 64 bits via CCFG.CLF. For a calibration field length of 32/64 bit a calibration message with at least 2/6 byte data field is required. The counter is controlled by Calibration Field and Sample Point input signals. The counter is enabled when Calibration Field is set and stops after the configured number of bits has been received. Received bits are signaled by the M_CAN by Sample Point signal. Precision calibration is based on the new clock divider value calculated from the measurement of the longer bit sequence.

Figure 766. Calibration FSM

T0: HW reset

T1: check for minimum

T2: Message Received = ‘1’

T3: evaluate messages

T4: Quartz Message Received = ‘1’

T5: evaluate quartz messages

T6: Configuration Change Enabled = ‘1’

T7: watchdog event: no quartz message received

T8: watchdog event: no message received
or Configuration Change Enabled = ‘1’

A change in the calibration state is signaled via by Calibration State Changed output. The duration of a Calibration State Changed output pulse is one Host clock period.

A change in the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

Until precision calibration is achieved (Calibration=‘1’), the attached M_CANs operate in a restricted mode (no frame transmission, no error or overload flag transmission, no error counting). In case calibration of the PLL is done by software by evaluating the calibration status from register CSTAT, the attached M_CANs have to be set to restricted operation

mode (CCCR.ASM = ‘1’) until the Calibration on CAN unit is in state Precision_Calibrated (refer to *Section 48.3.15.4.3: Software Calibration*).

Precision calibration may be performed only on valid CAN frames transmitted by a node with a stable, quartz-controlled clock. Calibration frames are detected by the M_CAN’s acceptance filtering and are signaled to the Clock Calibration on CAN Unit by Quartz Message Received, to be connected to one of the M_CAN’s Filter Event outputs, signal. A filter element and an Rx Buffer have to be configured in the attached M_CAN to identify and store calibration messages. After reception of a calibration message the Rx Buffer’s new data flag has to be reset to enable signaling of the next calibration message.

In case there is only one CAN transmitter with a quartz clock in the network, this node has to transmit its first message after startup with at least one ‘1010’ sequence in the data field or in the identifier. This assures that the non-quartz nodes can enter state Basic_Calibrated and then acknowledge the quartz node’s messages.

Precision calibration must be repeated in predefined maximum intervals supervised by the calibration watchdog.

Note: When the Clock Calibration on CAN Unit transits from state Precision_Calibrated back to Basic_Calibrated, the calibration OK signal is deasserted, the attached M_CANs complete ongoing transmissions, and then enter restricted operation (no frame transmission, no error or overload flag transmission, no error counting).

48.3.15.4.1 Configuration

The Clock Calibration on CAN Unit is configured via register CCFG. The register is only writeable while Configuration Change Enable = ‘1’, that is when the attached M_CAN has CCCR.CCE and CCCR.INIT set.

For basic calibration the minimum number of oscillator periods between two consecutive falling edges at CAN receive input pin is measured. The number of clock periods depends on the clock frequency applied at clock input from clock select multiplexer. In case the measured number of clock periods is below the minimum configured by CCFG.OCPM, for example due to a glitch on CAN receive input, the value is discarded and measurement continues.

It is recommended to configure CCFG.OCPM slightly below two CAN bit times:

CCFG.OCPM < ((2 x CAN bit time) / Clock input from Clock Select multiplexer period) / 32

The length of the bit field used for precision calibration can be configured to 32 or 64 bits via CCFG.CFL. The number of bits used for precision calibration has an impact on calibration accuracy and the maximum distance between two calibration messages. The reception of the bits is signaled by the attached M_CAN by Sample Point input.

The number of time quanta per bit time configured by CCFG.TQBT is used together with the measured number of oscillator clock periods CSTAT.OCPC to define the number of oscillator clocks per bit time.

When the clock calibration is bypassed by configuring CCFG.BCC = ‘1’, the internal clock divider has to be configured via CCFG.CDIV to fulfill the condition CAN clock $\leq$ Host clock.

Note: When clock calibration on CAN is active (CCFG.BCC = ‘0’), the baud rate prescaler of the attached M_CANs has to be configured to inactive.

48.3.15.4.2 Status signaling

The status of the Clock Calibration on CAN Unit can be monitored by reading register CSTAT. When in state Precision_Calibrated the oscillator clock period counter CSTAT.OCPC signals the number of oscillator clock periods in the calibration field while CSTAT.TQC signals the number of time quanta in the calibration field.

The calibration state is monitored by CSTAT.CALS. A change in the calibration state is signalled at the module interface by Calibration State Changed. The duration of a Calibration State Changed pulse is one Host clock period. A change in the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

A calibration watchdog event is signalled by Calibration Watchdog Event output. The duration of a Calibration Watchdog Event output pulse is one Host clock period. A calibration watchdog event also sets interrupt flag CUIR.CWE. If enabled by CUIE.CWEE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CWE is reset

48.3.15.4.3 Software Calibration

The Clock Calibration on CAN Unit also supports software calibration of the clock generated from an adjustable PLL, connected to the clock input, from Clock Select multiplexer. For this purpose the clock from Clock Select multiplexer has to be routed to Time Quanta clock output by programming CCFG.BCC = ‘1’. The Clock Calibration on CAN Unit’s internal clock divider has to be configured via CCFG.CDIV to meet the clock requirements of the attached M_CANs. All other configuration parameters have to be set via CCFG as if the Clock Calibration on CAN Unit is generating Time Quanta clock.

For startup the M_CANs attached to the Clock Calibration on CAN Unit have to be configured for Restricted Operation (CCCR.ASM = ‘1’). The PLL clock has to be adjusted until the Clock Calibration on CAN Unit has reached state Precision_Calibrated. Now the software has to reset CCCR.ASM and the M_CANs can start normal operation.

During operation the software has to check regularly whether the Clock Calibration on CAN Unit is still in state Precision_Calibrated. In case the Clock Calibration on CAN Unit has left state Precision_Calibrated due to drift of the PLL clock, the attached M_CANs have to be set into Restricted Operation Mode by programming CCCR.INIT, CCCR.CCE, and CCCR.ASM to ‘1’.

After the PLL clock has been adjusted successfully (Clock Calibration on CAN Unit is in state Precision_Calibrated), the M_CANs can be set to normal operation again.

48.4 Time Triggered Modular CAN (M_TTCAN) core

The M_TTCAN performs communication according to ISO 11898-1 (identical to Bosch CAN protocol specification 2.0 part A,B) and according to ISO 11898-4 (time-triggered communication on CAN). The M_TTCAN provides all features of time-triggered communication specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation.

In addition the M_TTCAN supports communication according to CAN FD protocol specification 1.0. The CAN FD option can be used together with event-triggered and time-triggered CAN communication.

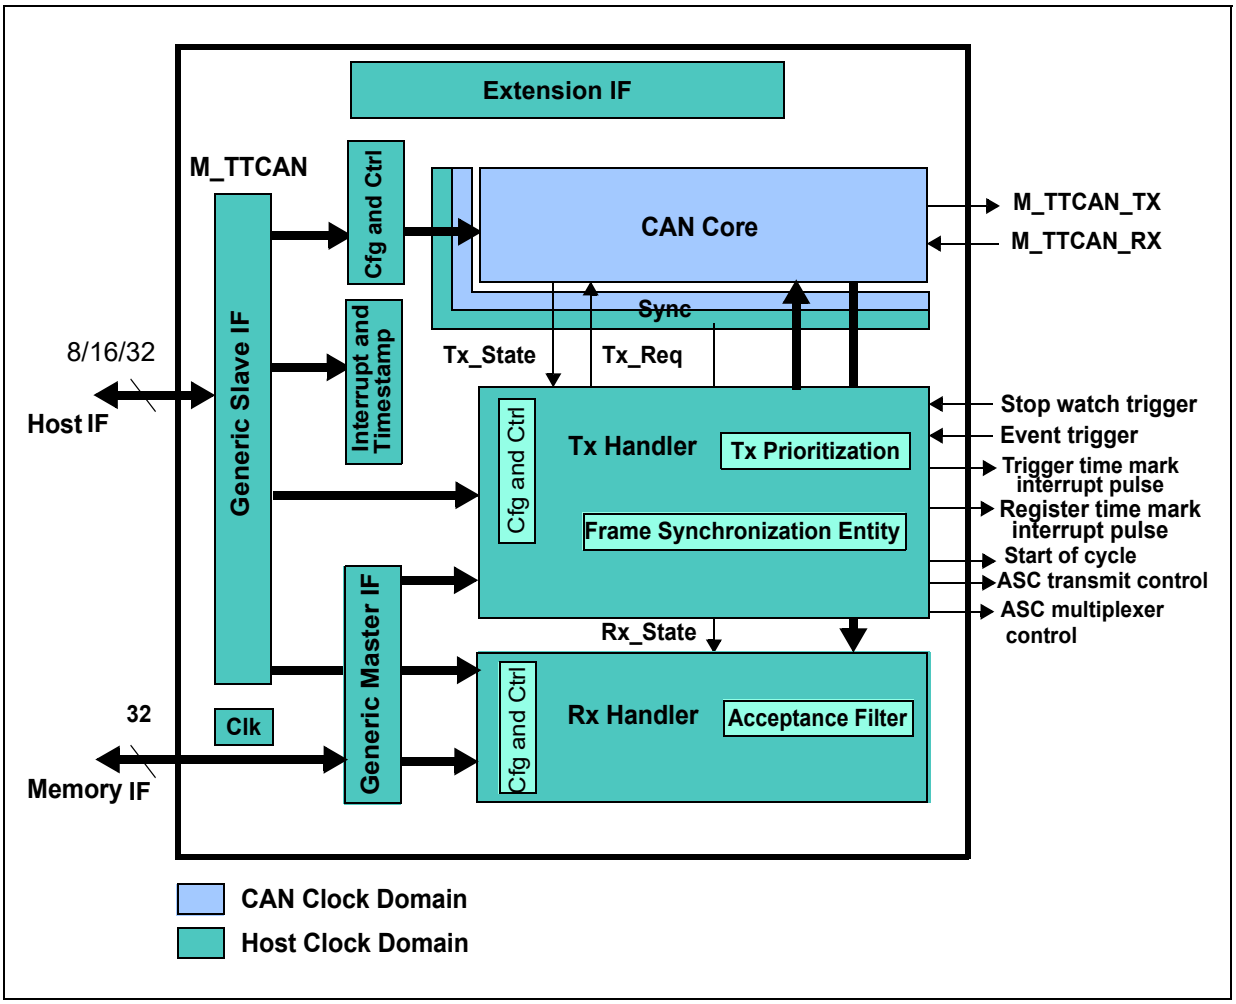
Note: Implemented TTCAN nodes are fully compliant to ISO CAN FD specification ISO 11898-1: 2015.

The message storage is intended to be a single-ported or dual-ported Message RAM outside of the module. It is connected to the M_TTCAN via the Generic Master Interface. Depending on the chosen ASIC integration, multiple M_TTCAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information. It implements all functions concerning the time schedule and the global system time.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_TTCAN can be connected to a wide range of Host CPUs via its 8/16/32-bit Generic Slave Interface. The M_TTCAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.



48.4.1 Features

The following are the features of M_TTCAN:

- M_TTCAN protocol level 1 and level 2 completely in hardware
- AUTOSAR optimized
- SAE J1939 optimized
- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1, -4
- ISO CAN FD with max. 64 data bytes supported
- TTCAN protocol level 1 and level 2 completely in hardware
- Event synchronized time-triggered communication supported
- CAN Error Logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 Transmit Buffers
- Configurable Transmit FIFO / Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_(TT)CAN share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32 bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug on CAN support

48.4.2 Block Diagram

Figure 767. M_TTCAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported. The Tx Handler also implements the Frame Synchronization Entity FSE which controls time-triggered communication according to ISO11898-4. It synchronizes itself to the reference messages on the CAN bus, controls cycle time and global time,

and handles transmissions according to the predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the Message RAM. Stop Watch Trigger, Event Trigger, and Time Mark Interrupt are synchronization interfaces.

- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs
- Generic Slave Interface: Connects the M_TTCAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_TTCAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB $\times$ 32 bit.
- Extension Interface: All flags from the Interrupt Register IR and TT Interrupt Register TTIR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_TTCAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

48.4.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as M_TTCAN clock. The CAN core should be programmed to have at least 8 clocks per bit time, this is, for example, 1 Mbaud at M_TTCAN clock $\geq$ 8 MHz. Even in case of a very high Host clock frequency, the clock frequency of the CAN core needs not to be higher than 8 MHz.

Within the M_TTCAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_TTCAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

48.4.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to TTCAN interrupt 0 or TTCAN interrupt 1. By default all interrupts are routed to interrupt line TTCAN interrupt 0. By programming ILE.EINT0 and ILE.EINT1 the interrupt lines can be enabled or disabled separately.

48.4.5 Memory map and registers description

48.4.5.1 Hardware reset description

After hardware reset, the registers of the M_TTCAN hold the reset values listed in *Table 871*. Additionally the Bus_Off state is reset and the TTCAN Tx output is set to recessive (HIGH). The value 0x0001 (CCCR[INIT] = '1') in the CC Control Register enables software initialization. The M_TTCAN does not influence the CAN bus until the CPU resets CCCR[INIT] to '0'.

48.4.5.2 Register map

The M_TTCAN module allocates an address space of 512 bytes. All registers are organized as 32-bit registers. The M_TTCAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access). Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only with CCCR[CCE]= '1' AND CCCR[INIT]= '1'. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

48.4.5.2.3 Data Bit Timing and Prescaler register (DBTP)

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_TTCAN clock periods.

Equation 34 tq = (DBRP + 1) M_TTCAN clock period

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 770. Data Bit Timing and Prescaler Register (DBTP)

Table 874. DBTP field descriptions

Field	Description
8 TDC	Transmitter Delay Compensation 0 Transmitter Delay Compensation disabled 1 Transmitter Delay Compensation enabled
11:15 DBRP	Data Bit Rate Prescaler (0x00–0x1F) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Bit Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
19:23 DTSEG1	Data time segment before sample point (0x1–0xF) Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 DTSEG2	Data time segment after sample point (0x0–0xF) Valid values are 0 to 7. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 DSJW	Data (Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a M_TTCAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_TTCAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via DBTP must be superior or equal to the bit rate configured for the arbitration phase via NBTP.

48.4.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting bit CCCR[TEST] to ‘1’. All Test Register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back mode and software control of TTCAN Tx pin are hardware test modes. Programming of TX ≠ ‘00’ may disturb the message transfer on the CAN bus.

48.4.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM .A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the RWD[WDC] bits. The counter is reloaded with RWD[WDC] bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag IR[WDI] bit is set. The RAM Watchdog Counter is clocked by the Host clock.

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 773. CC Control Register (CCCR)

Table 877. CCCR field descriptions

Field	Description
16 NISO	Non ISO Operation If this bit is set, the M_TTCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	TXP Transmit Pause If this bit is set, the M_TTCAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame (refer to *Section 48.4.7.19: Transmit Pause*). 0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	CAN FD Bit Rate Switching 0 This node transmits no frames with bit rate switching 1 This node transmits all frames (excluding remote frames) with bit rate switching
19 PXHD	CAN FD Operation 0 This node transmits all frames in CAN format according to ISO11898-1 1 This node transmits all frames (excluding remote frames) in CAN FD format **Note:** When protocol exception handling is disabled, the M_TTCAN will transmit an error frame when it detects a protocol exception condition.
22 BRSE	Bit Rate Switch Enable 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled **Note:** When CAN FD operation is disabled FDOE = ‘0’, BRSE is not evaluated.

Table 877. CCCR field descriptions (continued)

Field	Description
23 FDOE	FD Operation Enable 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_TTCAN may be set in power down by stopping Host clock and Core CAN clock
29 ASM	ASM Restricted Operation Mode The Restricted Operation Mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame. In the optional Restricted Operation Mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. If the M_TTCAN is connected to a Clock Calibration on CAN Unit, ASM is controlled by calibration input signal. In case calibration ” switches to ‘0’, bit ASM is set. When calibration ” switches back to ‘1’, bit ASM returns to the previously written value. The state of ASM is the written value while input calibration” is at ‘1’. The input is hardwired to ‘1’ when there is no Clock Calibration on CAN Unit connected. 0 Normal CAN operation 1 Restricted Operation Mode active

Table 877. CCCR field descriptions (continued)

Field	Description
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started

Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

48.4.5.2.7 Nominal Bit Timing and Prescaler Register (NBTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programed in the range of 4 to 385 time quanta (tq). The CAN time quantum may be programmed in the range of 1 to 512 core CAN clock periods.

Equation 35 tq = (NBRP + 1) core CAN clock period

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 776. Timestamp Counter Value Register (TSCV)

Table 880. TSCV field descriptions

Field	Description
16:31 TSC	Timestamp Counter The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = ‘01’, the Timestamp Counter is incremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC[TCP]. A wrap around sets interrupt flag IR[TSW]. Write access resets the counter to *zero*. When TSCC.TSS = “10”, TSC reflects the external Timestamp Counter value. A write access has no impact.

Note: A “wrap around” is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

48.4.5.2.10 Timeout Counter Configuration Register (TOCC)

R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Figure 779. Error Counter Register (ECR)

Table 883. ECR field descriptions

Field	Description
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[ELO].
16 RP	Receive Error Passive 0 The Receive Error Counter is below the *error passive* level of 128 1 The Receive Error Counter has reached the *error passive* level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

Note: When CCCR[ASM] is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented. This enables monitoring of collisions between CAN frames and ASC frames.

48.4.5.2.13 Protocol Status Register (PSR)

1. Access type is RX: reset on read.
2. Access type is RS: set on read.

Figure 780. Protocol Status Register (PSR)

Table 884. PSR field descriptions

Field	Description
9:15 TDCV	Transmitter Delay Compensation Value (0x00-0x7F) Position of the secondary sample point, defined by the sum of the measured delay from TTCAN Tx output to TTCAN Rx input and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point Valid values are 0 to 127 mtq.
17 PXE	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with EDL flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 DLEC	Data phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_TTCAN is not Bus_Off 1 The M_TTCAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_TTCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_TTCAN is in the Error_Passive state

Table 884. PSR field descriptions (continued)

Field	Description
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing: node is synchronizing on CAN communication 01 Idle: node is neither receiver nor transmitter 10 Receiver: node is operating as receiver 11 Transmitter: node is operating as transmitter **Note:** ACT is set to "00" by a Protocol Exception Event.
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_TTCAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error

The Bus_Off recovery sequence (refer to CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 $\times$ 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

48.4.5.2.14 Transmitter Delay Compensation Register (TDCR)

Offset: 0x0048 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	TDCO(1)							0	TDCF(1)						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. These are protected write (P) bits which means that write access by the bit is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 781. Transmitter Delay Compensation Register (TDCR)

Table 885. TDCR field descriptions

Field	Description
17:23 TDCO	Transmitter Delay Compensation Offset (0x00-0x7F) Offset value defining the distance between the measured delay from TTCAN Tx output to M_TTCAN Rx input and the secondary sample point. Valid values are 0 to 127 mtq.
25:31 TDCF	Transmitter Delay Compensation Filter Window Length (0x00-0x7F) Defines the minimum value for the SSP position, dominant edges on TTCAN Rx input that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

48.4.5.2.15 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. A hard reset will clear the register. The configuration of **IE** controls whether an interrupt is generated. The configuration of **ILS** controls on which interrupt line an interrupt is signaled.

Figure 782. Interrupt Register (IR)

Table 886. IR field descriptions

Field	Description
2 ARA	Access to Reserved Address 0 No access to reserved address occurred 1 Access to reserved address occurred
3 PED	Protocol Error in Data phase (Data Bit Time is used) 0 No protocol error in data phase 1 Protocol error in data phase detected (PSR.DLEC ≠ 0,7)
4 PEA	Protocol Error in Arbitration Phase (Nominal Bit Time is used) 0= No protocol error in arbitration phase 1= Protocol error in arbitration phase detected (PSR.LEC ≠ 0,7)
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status 0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to ‘1’. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (for example parity logic)

Table 886. IR field descriptions (continued)

Field	Description
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (for example ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler – has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. – was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the M_TTCAN is switched into Restricted Operation Mode. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Element Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full 0 Tx Event FIFO not full 1 Tx Event FIFO full
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark

Table 886. IR field descriptions (continued)

Field	Description
19 TEFN	Tx Event FIFO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element

Figure 802. Tx FIFO/Queue Status Register (TXFQS)

Table 906. TXFQS field descriptions

Field	Description
10 TFQF	Tx FIFO/Queue Full 0 Tx FIFO/Queue not full 1 Tx FIFO/Queue full
11:15 TFQPI	Tx FIFO/Queue Put Index Tx FIFO/Queue write index pointer, range 0 to 31
19:23 TFGI	Tx FIFO Get Index Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (TXBC.TFQM = ‘1’).
26:31 TFFL	Tx FIFO Free Level Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 32. Read as zero when Tx Queue operation is configured (TXBC[TFQM] = ‘1’).

Note: In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Index indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

For example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

48.4.5.2.36 Tx buffer element size configuration (TXESC)

Offset: 0x0C8 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 804. Tx Buffer Request Pending Register (TXBRP)

Table 908. TXBRP field descriptions

Field	Description
0:31 TRP[31:0]	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (refer to *Section 48.4.7.16: Debug on CAN Support*) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – after successful transmission together with the corresponding TXBTO bit – when the transmission has not yet been started at the point of cancellation – when the transmission has been aborted due to lost arbitration – when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

48.4.5.2.38 Tx Buffer Add Request Register (TXBAR)

20:23 TXEW	Tx Enable Window (0x0–0xF) Length of Tx enable window, 1-16 NTU cycles.
24:25 CSS	Cycle Start Synchronization Enables sync pulse output at Start of Cycle pin. 00 No sync pulse 01 Sync pulse at start of basic cycle 10 Sync pulse at start of matrix cycle 11 Reserved
26:31 CCM	Cycle Count Max 0x00: 1 Basic Cycle per Matrix Cycle 0x01: 2 Basic Cycles per Matrix Cycle 0x03: 4 Basic Cycles per Matrix Cycle 0x07: 8 Basic Cycles per Matrix Cycle 0x0F: 16 Basic Cycles per Matrix Cycle 0x1F: 32 Basic Cycles per Matrix Cycle 0x3F: 64 Basic Cycles per Matrix Cycle Others reserved.

Note: ISO 11898-4, Section 5.2.1 requires, that only the listed cycle count values are configured. Other values are possible but may lead to inconsistent matrix cycles.

48.4.5.2.51 TUR Configuration Register (TURCF)

The length of the NTU is given by: NTU = CAN Clock Period x NC/DC

NC is an 18-bit value. Its high part, NCH[17:16] is hard wired to 0b01. Therefore the range of NC is 0x10000…0x1FFFF. The value configured by NCL is the initial value for TURNA[NAV[15:0]]. DC is set to 0x1000 by hardware reset and it may not be written to 0x0000.

Level 1: NC >= 4 × DC and NTU = CAN bit time

Level 0, 2: NC >= 8 × DC

The actual value of TUR may be changed by the clock drift compensation function of M_TTCAN Level 0 and Level 2 in order to adjust the node's local view of the NTU to the time master's view of the NTU. DC will not be changed by the automatic drift compensation, TURNA[NAV] may be adjusted around NC in the range of the Synchronization Deviation Limit given by TTOCF[LDSDL]. NC and DC should be programmed to the largest suitable values in order to allow the best computational accuracy for the drift compensation process.

Offset: 0x110 Access: RP

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 818. TUR Configuration Register (TURCF)

Table 922. TURCF field descriptions

Field	Description
0 ELT	Enable Local Time 0 Local time is stopped, default 1 Local time is enabled **Note:** The local time is started by setting ELT. It remains active until ELT is reset or until the next hardware reset. TURCF[DC] is locked when TURCF[ELT] = ‘1’. If ELT is written to ‘0’, the readable value will stay at ‘1’ until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register remains locked.
2:15 DC	Denominator Configuration 0x0000: Illegal value (0x0001–0x3FFF) Denominator Configuration
16:31 NCL	Numerator Configuration Low Write access to the TUR Numerator Configuration Low is only possible during configuration with TURCF[ELT] = ‘0’ or if TTOCF[EECS] (external clock synchronization enabled) is set. When a new value for NCL is written outside TT Configuration Mode, the new value takes effect when TTOST.WECS is cleared to ‘0’. NCL is locked TTOST[WECS] is ‘1’. (0x0000–0xFFFF) Numerator Configuration Low

Note: If NC < 7 × DC in M_TTCAN Level 1, then it is required that subsequent Time Marks in the Trigger Memory must differ by at least two NTU.

Figure 819. TT Operation Control Register (TTOCN)

Table 923. TTOCN field descriptions

Field	Description
16 LCKC	TT Operation Control Register Locked Set by a write access to register TTOCN. Reset when the updated configuration has been synchronized into the CAN clock domain. 0 Write access to TTOCN enabled 1 Write access to TTOCN locked
18 ESCN	External Synchronization Control If enabled the M_TTCAN synchronizes its cycle time phase to an external event signaled by a rising edge at Event Trigger pin(*Section 48.4.19: Synchronization to external time schedule*). 0 External synchronization disabled 1 External synchronization enabled
19 NIG	Next is Gap This bit can only be set when the M_TTCAN is the actual Time Master and when it is configured for external event-synchronized time-triggered operation (TTOCF[GEN] = ‘1’). 0 No action, reset by reception of any Reference message 1 Transmit next Reference Message with Next_is_Gap = ‘1’
20 TMG	Time Mark Gap 0 Reset by each Reference message 1 Next Reference message started when Register Time Mark interrupt TTIR[RTMI] is activated
21 FGP	Finish Gap Set by the CPU, reset by each reference message 0 No reference message requested 1 Application requested start of reference message
22 GCS	Gap Control Select 0 Gap control independent from Event trigger 1 Gap control by input Event trigger pin

Table 923. TTOCN field descriptions (continued)

Field	Description
23 TTIE	Trigger Time Mark Interrupt Pulse Enable External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the M_TTCAN is in synchronization state In_Schedule or In_Gap. 0 Trigger Time Mark Interrupt output disabled 1 Trigger Time Mark Interrupt output enabled
24:25 TMC	Register Time Mark Compare 00 No Register Time Mark Interrupt generated 01 Register Time Mark Interrupt if Time Mark = cycle time 10 Register Time Mark Interrupt if Time Mark = local time 11 Register Time Mark Interrupt if Time Mark = global time **Note:** When changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = ‘00’, then reconfigure TTTMK, and finally set TMC to the intended time reference.
26 RTIE	Register Time Mark Interrupt Pulse Enable Register time mark interrupts are configured by register **TTTMK**. A register time mark interrupt pulse with the length of one CAN clock period is generated when time referenced by TTOCN[TMC] (cycle, local, or global) equals TTTMK[TM], independent of the synchronization state. 0 Register Time Mark Interrupt output disabled 1 Register Time Mark Interrupt output enabled
27:28 SWS	Stop Watch Source 00 Stop Watch disabled 01 Actual value of cycle time is copied to TTCPT[SWV] 10 Actual value of local time is copied to TTCPT[SWV] 11 Actual value of global time is copied to TTCPT[SWV]
29 SWP	Stop Watch Polarity 0 Rising edge trigger 1 Falling edge trigger
30 ECS	External Clock Synchronization Writing a ‘1’ to **ECS** sets TTOST[WECS] if the node is the actual Time Master. ECS is reset after one Host clock period. The external clock synchronization takes effect at the start of the next basic cycle.
31 SGT	Set Global time Writing a ‘1’ to SGT sets TTOST[WGDT] if the node is the actual Time Master. SGT is reset after one Host clock period. The global time preset takes effect when the node transmits the next Reference message with the Master_Ref_Mark modified by the preset value written to TTGTP.

48.4.5.2.53 TT Global Time Preset Register (TTGTP)

If TTOST.WGDT is set, the next Reference message will be transmitted with the Master_Ref_Mark modified by the preset value and with Disc_Bit = ‘1’, presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a Reference message with Disc_Bit = ‘1’ becomes valid or if the node is not the current Time Master. TP is locked while TTOST[WGTD] = ‘1’ after

setting TTOCN[SGT] until the Reference message with Disc_Bit = ‘1’ becomes valid or until the node is no longer the current Time Master.

Figure 825. TT Operation Status Register (TTOST)

Table 929. TTOST field descriptions

Field	Description
0 SPL	Schedule Phase Lock The bit is valid only when external synchronization is enabled (TTOCN[ESCN] = ‘1’). In this case it signals that the difference between cycle time configured by TTGTP[CTP] and the cycle time at the rising edge at Event Trigger pin is less than or equal to 9 NTU (refer to *Section 48.4.19*). 0 Phase outside range 1 Phase inside range
1 WECS	Wait for External Clock Synchronization 0 No external clock synchronization pending 1 Node waits for external clock synchronization to take effect. The bit is reset at the start of the next basic cycle.
2 AWE	Application Watchdog Event The application watchdog is served by reading TTOST. When the watchdog is not served in time, bit AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode. 0 Application Watchdog served in time 1 Failed to serve Application Watchdog in time
3 WFE	Wait for Event 0 No Gap announced, reset by a Reference Message with Next_is_Gap = ‘0’ 1 Reference Message with Next_is_Gap = ‘1’ received
4 GSI	Gap Started Indicator 0 No Gap in schedule, reset by each reference message and for all time slaves 1 Gap time after Basic Cycle has started
5:7 TMP	Time Master Priority (0x0-0x7) Priority of actual Time Master

Table 929. TTOST field descriptions (continued)

Field	Description
8 GFI	Gap Finished Indicator Set when the CPU writes TTOCN[FGP], or by a Time Mark Interrupt if TMG = '1', or via input Event Trigger pin if TTOCN[GCS] = '1'. Not set by Ref_Trigger_Gap or when Gap is finished by another node sending a reference message. 0 Reset at the end of each reference message 1 Gap finished by M_TTCAN
9 WGTD	Wait for Global Time Discontinuity 0 No global time preset pending 1 Node waits for the global time preset to take effect. The bit is reset when the node has transmitted a Reference message with **Disc_Bit** = '1' or after it received a Reference message.
16:23 RTO	Reference Trigger Offset The Reference Trigger Offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F). There is no notification when the lower limit of-127 is reached. In case the M_TTCAN becomes Time Master (MS[1:0] = '11'), the reset of RTO is delayed due to synchronization between Host and CAN clock domain. For time slaves the value configured by TTOCF[IRTO] is read. (0x00-0xFF) Actual Reference Trigger offset value
24 QCS	Quality of Clock Speed Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '1'. 0 Local clock speed not synchronized to Time Master clock speed 1 Synchronization Deviation ≤ **SDL**
25 QGTP	Quality of Global Time Phase Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '0'. 0 Global time not valid 1 Global time in phase with Time Master
26:27 SYS	Synchronization State 00 Out of Synchronization 01 Synchronizing to M_TTCAN communication 10 Schedule suspended by Gap (In_Gap) 11 Synchronized to schedule (In_Schedule)
28:29 MS	Master State 00 Master_Off, no master properties relevant 01 Operating as Time Slave 10 Operating as Backup Time Master 11 Operating as current Time Master
30:31 EL	Error Level 00 Severity 0: No Error 01 Severity 1: Warning 10 Severity 2: Error 11 Severity 3: Severe Error

48.4.5.2.59 TUR Numerator Actual Register (TURNA)

There is no drift compensation in M_TTCAN Level 1 (NAV = NC). In M_TTCAN Level 0 and Level 2, the drift between the node's local clock and the time master's local clock is calculated.

The drift is compensated when the Synchronization Deviation (difference between NC and the calculated NAV) is not more than $2^{(TTOCF[LDSDL] + 5)}$. With TTOCF[LDSDL] <= 7, this results in a maximum range for NAV of (NC - 0x1000) <= NAV <= (NC + 0x1000).

Field	Description
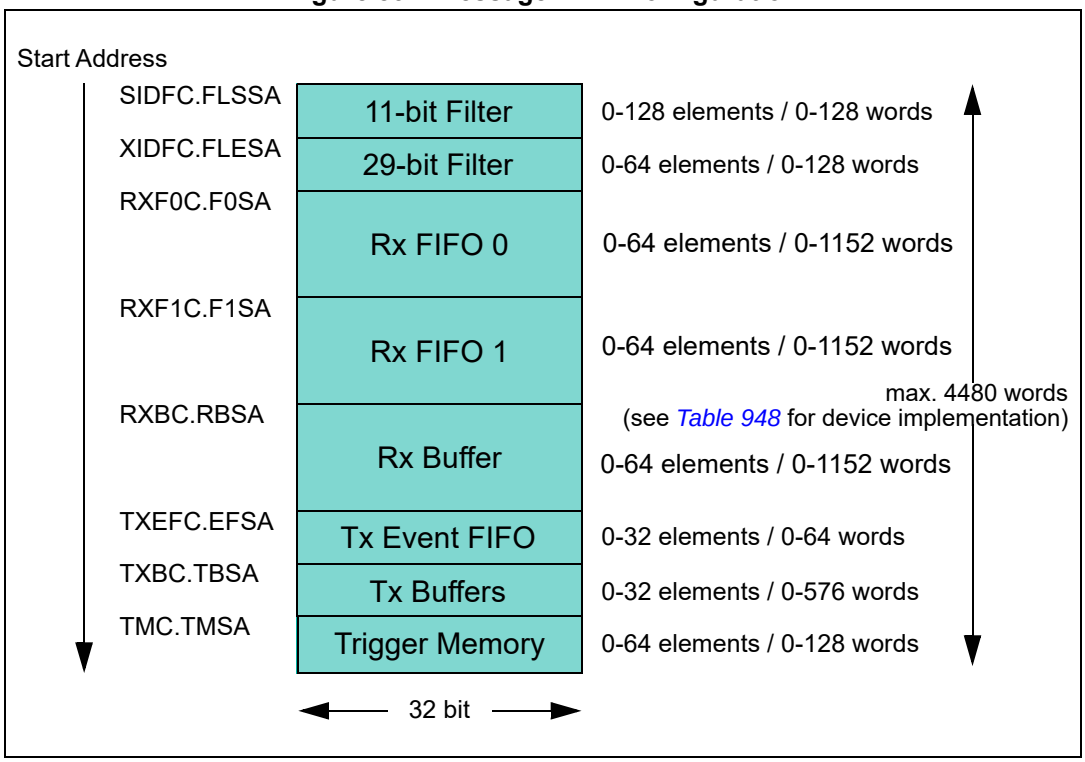
16:31 CSM	Cycle Sync Mark The Cycle Sync Mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid. (0x0000–0xFFFF) Captured cycle time



48.4.6 Message RAM

For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_TTCAN module.

The Message RAM has a width of 32 bits plus ECC checking bit. The M_TTCAN module can be configured to allocate up to 4480 words in the Message RAM (for the chip-specific implementation details of each module's instance, refer to device configuration chapter). It is not necessary to configure each of the sections listed in *Figure 831*, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC.F0DS, RXESC.F1DS, RXESC.RBDS, and TXESC.TBDS.

Figure 831. Message RAM Configuration

When the M_TTCAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configured start addresses are 32-bit word addresses that is only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Note: The M_TTCAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

48.4.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages.The structure of a Rx Buffer/ FIFO element is shown below.

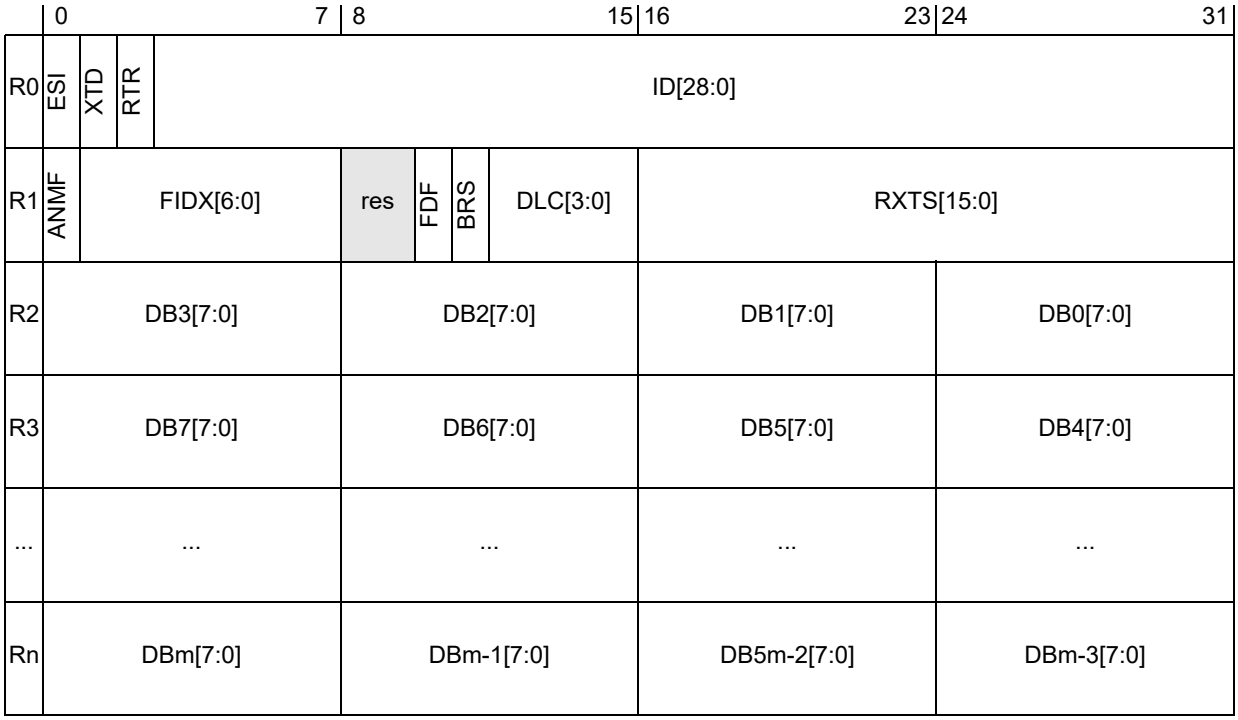


Figure 832. Rx Buffer and FIFO element

Table 935. Rx Buffer and FIFO element descriptions

Field	Description
R0 bit 0 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 bit 1 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 bit 2 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame

Table 935. Rx Buffer and FIFO element descriptions (continued)

Field	Description
R0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 bit 0 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element
R1 bits 1:7 FIDX[6:0]: Filter Index	0-127 = Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 bit 10 FDF: FD Format	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
R1 bit 11 BRS: Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 bits 12:15 DLC[3:0]: Data Length Code	0-8 Received frame has 0-8 data bytes 9-1 Received frame has 8 data bytes
R1 bits 16:31 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 bits 0:7	DB3[7:0]: Data Byte 3
R2 bits 8:15	DB2[7:0]: Data Byte 2
R2 bits 16:23	DB1[7:0]: Data Byte 1
R2 bits 24:31	DB0[7:0]: Data Byte 0
R3 bits 0:7	DB7[7:0]: Data Byte 7
R3 bits 8:15	DB6[7:0]: Data Byte 6
R3 bits 16:23	DB5[7:0]: Data Byte 5
R3 bits 24:31	DB4[7:0]: Data Byte 4
Rn bits 0:7	DBm[7:0]: Data Byte m
Rn bits 8:15	DBm-1[7:0]: Data Byte m-1
Rn bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3...17) are used for storage of a CAN message's data field.

48.4.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC[TFQS] and TXBC[NDTB].

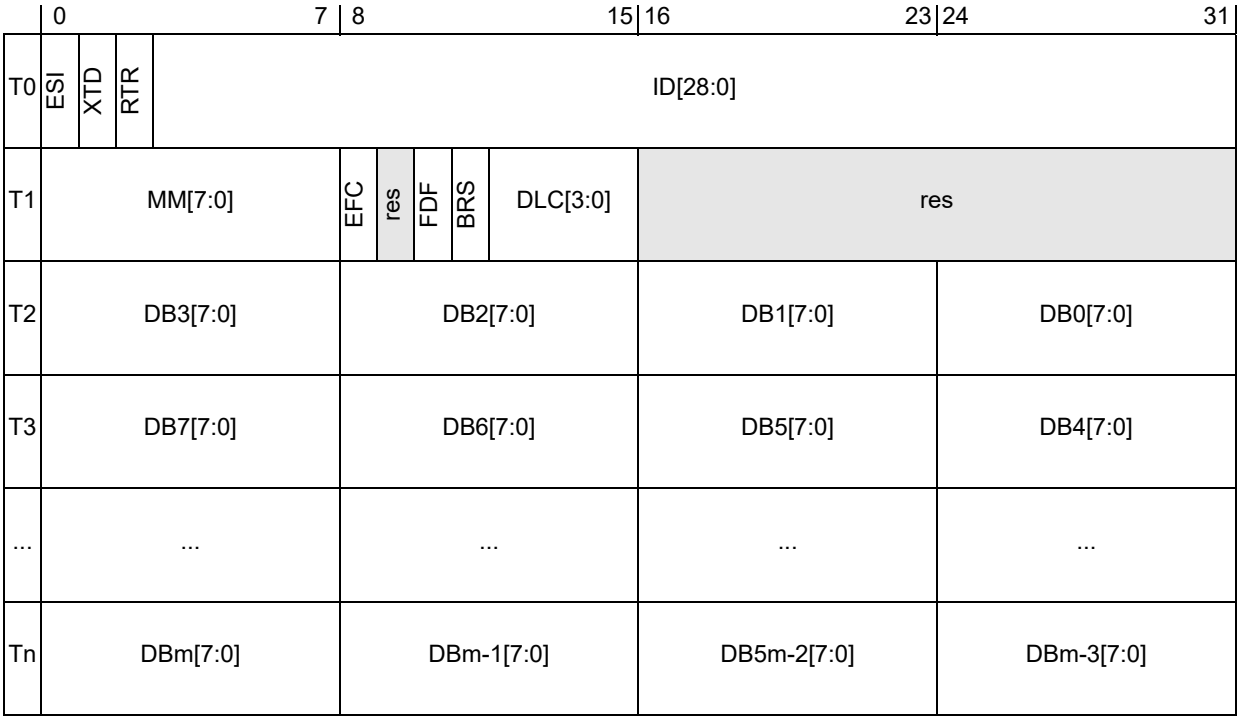

Figure 833. Tx Buffer element

Table 936. Tx Buffer element descriptions

Field	Description
T0 bit 0 ESI: Error State Indicator	0 ESI bit in CAN FD format depends only on error passive flag 1 ESI bit in CAN FD format transmitted recessive
T0 bit 1 XTD: Extended Identifier	0 11-bit standard identifier 1 29-bit extended identifier
T0 bit 2 RTR: Remote Transmission Request	0 Transmit data frame 1 Transmit remote frame
T0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
T1 bits 0:7 MM[7:0]: Message Marker	Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

Table 936. Tx Buffer element descriptions (continued)

Field	Description
T1 bit 8 EFC **Event FIFO Control**	0 Don't store Tx events 1 Store Tx events
T1 bit 10 FDF **FD Format**	0 Frame transmitted in Classic CAN format 1 Frame transmitted in CAN FD format
T1 bit 11 BRS **Bit Rat Switching**	0 CAN FD frames transmitted without bit rate switching 1 CAN FD frames transmitted with bit rate switching
T1 bits 12:15 DLC[3:0]	Data Length Code 0-8 Transmit frame with 0-8 data bytes 9-15 Transmit frame with 8 data bytes
T2 bits 0:7	DB3[7:0]: Data Byte 3
T2 bits 8:15	DB2[7:0]: Data Byte 2
T2 bits 16:23	DB1[7:0]: Data Byte 1
T2 bits 24:31	DB0[7:0]: Data Byte 0
T3 bits 0:7	DB7[7:0]: Data Byte 7
T3 bits 8:15	DB6[7:0]: Data Byte 6
T3 bits 16:23	DB5[7:0]: Data Byte 5
T3 bits 24:31	DB4[7:0]: Data Byte 4
Tn bits 0:7	DBm[7:0]: Data Byte m
Tn bits 8:15	DBm-1[7:0]: Data Byte m-1
Tn bits 16:23	DBm-2[7:0]: Data Byte m-2
Tn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage of a CAN message's data field.

48.4.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

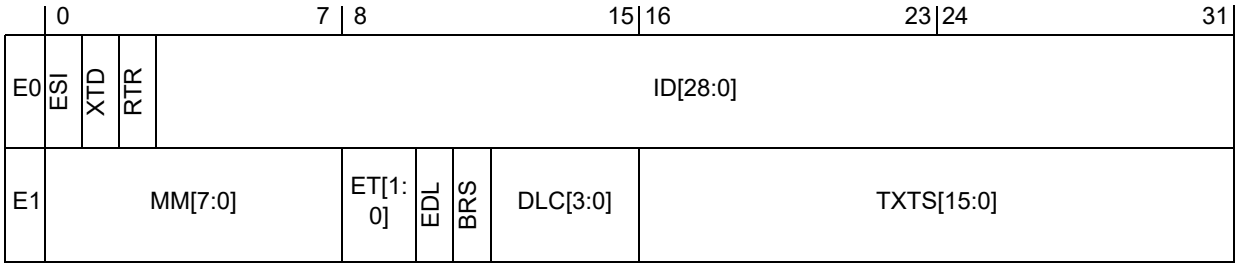

Figure 834. Tx Event FIFO element

Table 937. Tx Event FIFO element

Field	Description
E0 bit 0 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 bit 1 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.
E1 bit 8:9 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching
E1 bits 12:15 DLC[3:0]	Data Length Code 0-8 Frame with 0-8 data bytes transmitted 9-1 Frame with 8 data bytes transmitted
E1 bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

48.4.6.4 Standard Message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC.FLSSA plus the index of the filter element (0…127).

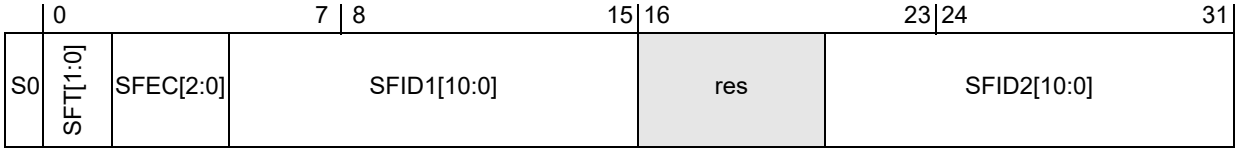

Figure 835. Standard Message ID Filter element

Table 938. Standard Message ID Filter element description

Field	Description
Bits 0:1 SFT[1:0]	Standard Filter Type 00 Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 01 Dual ID filter for SFID1 or SFID2 10 Classic filter: SFID1 = filter, SFID2 = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of SFT[1:0] ignored
Bits 5:15 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.

Table 938. Standard Message ID Filter element description (continued)

Field		Description
Bits 21:31	**SFID2[10:0]**	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: – SFEC = '001'...'110' Second ID of standard ID filter element – SFEC = '111' Filter for Rx Buffers or for debug messages
	SFID2[10:9]	Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6]	Is used to control the Filter Event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches.
	SFID2[5:0]	Defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

Note: In case a reserved value is configured, the filter element is considered disabled.

48.4.6.5 Extended Message ID Filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0…63).

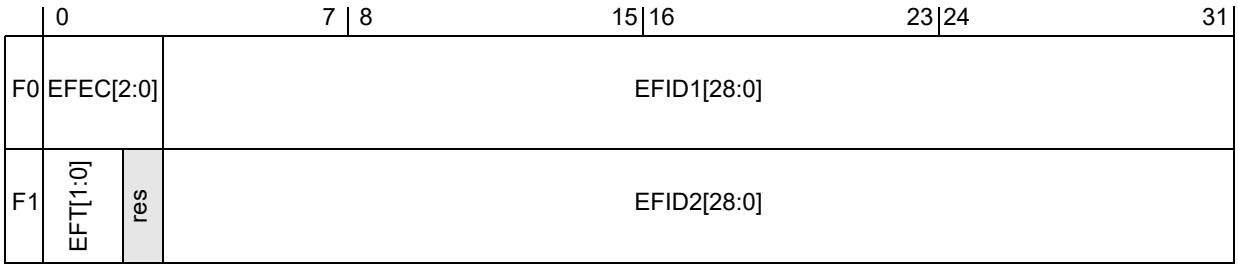

Figure 836. Extended Message ID Filter element

Table 939. Extended Message ID Filter element description

Field		Description
F0 bits 0:2 EFEC[2:0]		Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of EFT[1:0] ignored
F0 bits 3:31 EFID1[28:0]		Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (refer to *Section 48.4.7.13.5*) is used.
F1 bits 0:1 EFT[1:0]		Extended Filter Type 00 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
F1 bits 3:31	**EFID2[28:0]**	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: – EFEC = '001'...'110' Second ID of extended ID filter element – EFEC = '111' Filter for Rx Buffers or for debug messages
	EFID2[10:9]	Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	EFID2[8:6]	Is used to control the Filter Event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches.
	EFID2[5:0]	Defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

48.4.6.6 Trigger Memory element

Up to 64 trigger memory elements can be configured. When accessing a Trigger Memory element, its address is the Trigger Memory Start Address TTTMC[TMSA] plus the index of the trigger memory element (0…63).

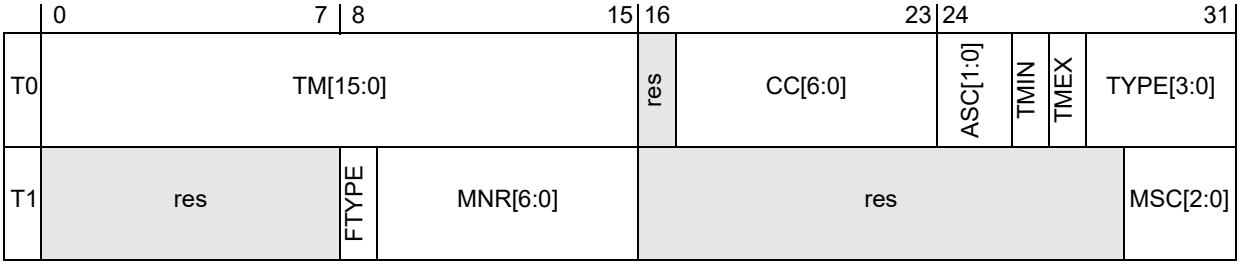

Figure 837. Trigger Memory element

Table 940. Trigger Memory element descriptions

Field	Description
T0 bit 0:15 TM[15:0]	Time Mark Cycle time for which the trigger becomes active.
T0 bit 17:23 CC[6:0]	Cycle Code Cycle count for which the trigger is valid. Ignored for trigger types Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, End_of_List. 0b000000x valid for all cycles 0b000001c valid every 2nd cycle at cycle count mod2 = c 0b00001cc valid every 4th cycle at cycle count mod4 = cc 0b0001ccc valid every 8th cycle at cycle count mod8 = ccc 0b001cccc valid every 16th cycle at cycle count mod16 = cccc 0b01ccccc valid every 32nd cycle at cycle count mod32 = ccccc 0b1cccccc valid every 64th cycle at cycle count mod64 = cccccc
T0 bit 24:25 ASC[1:0]	Asynchronous Serial Communication 00 No ASC operation 01 Reserved, do not use 10 Node is ASC receiver 11 Node is ASC transmitter
T0 bit 26 TMIN	Time Mark Event Internal 0 No action 1 TTIR.TTMI is set when trigger memory element becomes active
T0 bit 27 TMEX	Time Mark Event External 0 No action 1 Pulse at Trigger Time Mark Interrupt Pulse output with the length of one CAN clock period is generated when the time mark of the trigger memory element becomes active and TTOCN.TTMIE = ‘1’

Table 940. Trigger Memory element descriptions (continued)

Field	Description
T0 bit 28:31 TYPE[3:0]	Trigger Type 0000 Tx_Ref_Trigger - valid when not in Gap 0001 Tx_Ref_Trigger_Gap - valid when in Gap 0010 Tx_Trigger_Single - starts a single transmission in an exclusive time window 0011 Tx_Trigger_Continuous - starts continuous transmission in an exclusive time window 0100 Tx_Trigger_Arbitration - starts a transmission in an arbitrating time window 0101 Tx_Trigger_Merged - starts a merged arbitration window 0110 Watch_Trigger - valid when not in Gap 0111 Watch_Trigger_Gap - valid when in Gap 1000 Rx_Trigger - check for reception 1001 Time_Base_Trigger - only control TMIN, TMEX, and ASC 1010…1111 = End_of_List - illegal type, causes configuration error **Note:** For ASC operation (ASC = '10', '11') only trigger types Rx_Trigger and Time_Base_Trigger should be used.
T1 bit 8 FTYPE	Filter Type 0 11-bit standard message ID 1 29-bit extended message ID
T1 bit 9:15 MNR[6:0]	Message Number Transmission: Trigger is valid for configured Tx Buffer number. Valid values are 0 to 31. Reception: Trigger is valid for standard / extended message ID filter element number. Valid values are 0 to 63 resp. 0 to 127.
T1 bits 29:31 MSC[2:0]	Message Status Count Counts scheduling errors for periodic messages in exclusive time windows. It has no function for arbitrating messages and in event-driven CAN communication (ISO11898-1). 0-7= Actual status **Note:** The trigger memory elements have to be written when the M_TTCAN is in INIT state.Write access to the trigger memory elements outside INIT state is not allowed.There is an exception for TMIN and TMEX when they are defined as part of a trigger memory element of TYPE Tx_Ref_Trigger. In this case they become active at the time mark modified by the actual Reference Trigger Offset (TTOST[RTO]).

48.4.7 M_TTCAN functional description

48.4.7.1 Operating modes

48.4.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any

configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (=Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_TTCAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = ‘1’. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set:

- HPMS - High Priority Message Status
- RXF0S - Rx FIFO 0 Status
- RXF1S - Rx FIFO 1 Status
- TXFQS - Tx FIFO/Queue Status
- TXBRP - Tx Buffer Request Pending
- TXBTO - Tx Buffer Transmission Occurred
- TXBCF - Tx Buffer Cancellation Finished
- TXEFS - Tx Event FIFO Status
- TTOST - TT Operation Status
- TTLGT - TT Local and Global Time, only Global Time TTLGT[GT] is reset
- TTCTC - TT Cycle Time and Count
- TTCSM - TT Cycle Sync Mark

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writeable while CCCR[CCE] = ‘0’

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

CCCR[TEST] and CCCR[MON] can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] =‘1’. Both bits may be reset at any time. CCCR[DAR] can only be set/reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

Note: In case the Message RAM is equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing such as 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

48.4.7.2 Normal operation

The M_TTCAN’s default operating mode after hardware reset is event-driven CAN communication without time triggers (TTOCF[OM] = ‘00’). It is required that both CCCR[INIT] and CCCR[CCE] are set before the TT Operation Mode can be changed.

Once the M_TTCAN is initialized and CCCR[INIT] is reset to zero, the M_TTCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into the Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers or a Tx FIFO, or both, or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

48.4.7.3 CAN FD Operation

There are two variants in the CAN FD frame format, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = recessive signifies a CAN FD frame, FDF = dominant signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. The coding of res = recessive is reserved for future expansion of the protocol. In case the M_TTCAN receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting bit PSR.PXE. When Protocol Exception Handling is enabled (CCCR.PXHD = ‘0’), this causes the operation state to change from Receiver (PSR.ACT = “10”) to Integrating (PSR.ACT = “00”) at the next sample point. In case Protocol Exception Handling is disabled (CCCR.PXHD = ‘1’), the M_TTCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = ‘1’, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = ‘0’, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = ‘0’, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘0’, only bit FDF of a Tx Buffer element is evaluated. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘1’, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.It is not necessary to change the CAN operation mode after system startup.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to *Table 941*:

Table 941. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing and Prescaler Register NBTP. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing and Prescaler Register DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency. For example, with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

48.4.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via M_TTCAN Tx output pin the TTCAN receives the transmitted data from its local CAN transceiver via M_TTCAN Rx input pin. The received data is delayed by the transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay. The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

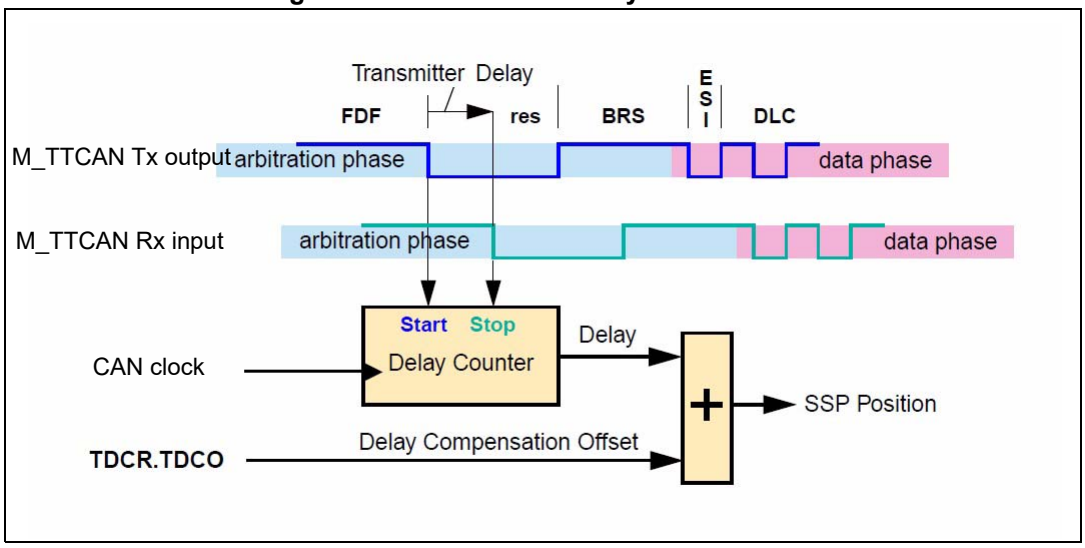
The M_TTCAN's protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_TTCAN Tx output through the transceiver to the M_TTCAN Rx input plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (such as half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.



The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_TTCAN:

- The sum of the measured delay from the M_TTCAN Tx to the M_TTCAN Rx and the configured transmitter delay compensation offset TDCR.TDCO has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the M_TTCAN Tx output to the M_TTCAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

If transmitter delay compensation is enabled by programming DBTP.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the M_TTCAN Rx input of the transmitter. The resolution of this measurement is one mtq.

Figure 838 describes how the Transmitter Delay Compensation is measured.

Figure 838. Transceiver Delay measurement

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a to early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on M_TTCAN Rx input, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF AND M_TTCAN Rx input is low.

48.4.7.5 Restricted Operation Mode

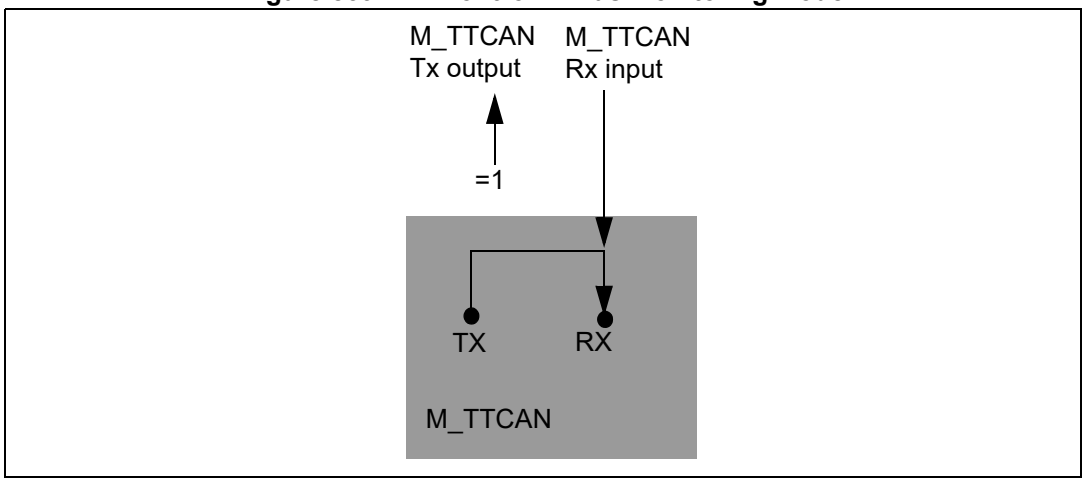
In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (ECR.REC, ECR.TEC) are frozen while Error Logging (ECR.CEL) is active. The Host can set the M_TTCAN into Restricted Operation mode by setting bit CCCR.ASM. The bit can only be set by the Host when both CCCR.CCE and CCCR.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

When the M_TTCAN is configured for Asynchronous Serial Communication, the Host has to set CCCR.ASM during initialization to start with an ASC window. The bit is reset at the end of the first ASC window after the M_TTCAN has finished initializing. During time-triggered operation CCCR.ASM is set by the M_TTCAN at the beginning of an ASC window (trigger memory element with T0.ASC = “10”, “11”). It is reset by each trigger memory element with T0.ASC = “00”.

If the M_TTCAN is connected to a Clock Calibration on CAN Unit, CCCR.ASM is controlled by calibration input. In case calibration input switches to ‘0’, bit CCCR.ASM is set. When m_ttcan_cok switches back to ‘1’, bit CCCR.ASM returns to the previously written value. When there is no Clock Calibration on CAN unit connected calibration input is hardwired to ‘1’.



Note: The Restricted Operation Mode must not be combined with the Loop Back Mode (internal or external).

48.4.7.6 Bus Monitoring mode

The M_TTCAN is set in Bus Monitoring Mode by programming CCCR.MON to one or when error level S3 (TTOST[EL] = ‘11’) is entered. In Bus Monitoring Mode (refer to ISO11898-1, 10.12 Bus monitoring), the M_TTCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the M_TTCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_TTCAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode register TXBRP is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. *Figure 839* shows the connection of signals M_TTCAN Tx output and M_TTCAN Rx output to the M_TTCAN in Bus Monitoring Mode.

Figure 839. Pin Control in Bus Monitoring Mode

48.4.7.7 Disabled automatic retransmission

According to the CAN Specification (refer to ISO11898-1, 6.3.3 Recovery Management), the M_TTCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

48.4.7.8 Frame transmission in DAR mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer’s Tx Request Pending bit TXBRP.TRPx is reset after successful

transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = ‘10’ (transmission in spite of cancellation).

48.4.7.9 Power down (Sleep mode)

The M_TTCAN can be set into power down mode controlled by clock stop request input signal or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one.

When all pending transmission requests have completed, the M_TTCAN waits until bus idle state is detected. Then the M_TTCAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_TTCAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs M_TTCAN Host clock and CAN clock may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting clock stop request signal respectively CC Control Register flag CCCR.CSR. The M_TTCAN will acknowledge this by resetting output clock stop acknowledge signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

48.4.7.10 Test modes

To enable write access to register TEST (refer to *Section 48.4.5.2.4: Test Register (TEST)*), bit CCCR.TEST has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the M_TTCAN Tx output pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_TTCAN’s bit timing and it can drive constant dominant or recessive values. The actual value at M_TTCAN Rx input pin can be read from TEST.RX. Both functions can be used to check the CAN bus’ physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST.TX until the new configuration is visible at M_TTCAN Tx output pin. This applies also when reading M_TTCAN Rx input pin via TEST.RX.

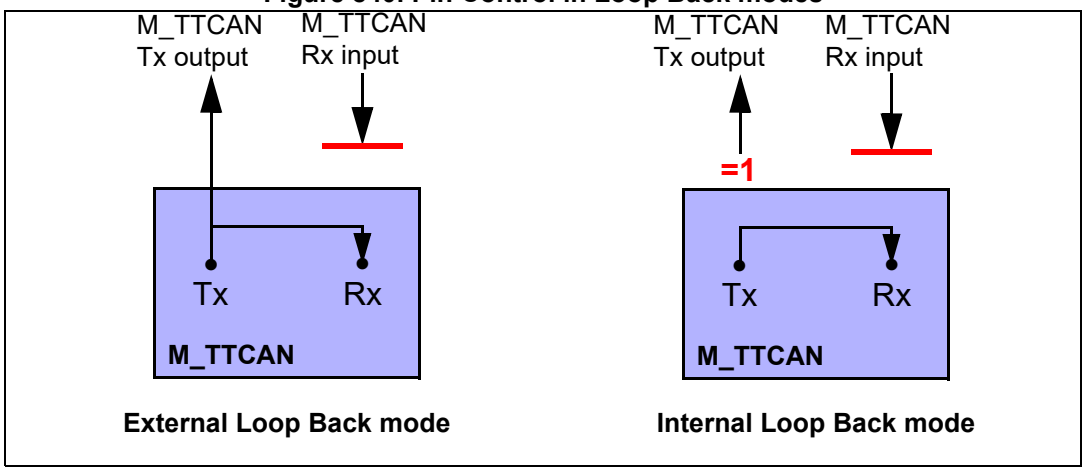
Note: Test modes should be used for production tests or self test only. The software control for M_TTCAN Tx output pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

48.4.7.10.1 Application Watchdog

The application watchdog is served by reading register TTOST. When the application watchdog is not served in time, bit TTOST.AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode.

The TT Application Watchdog can be disabled by programming the Application Watchdog Limit TTOCF[AWL] to 0x00. The TT Application Watchdog should not be disabled in a M_TTCAN application program.

48.4.7.10.2 External Loop Back mode



The M_TTCAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_TTCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. *Figure 840* shows the connection of transmit and receive signals to the M_TTCAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_TTCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/ remote frame) in Loop Back mode. In this mode the M_TTCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the M_TTCAN Rx input pin is disregarded by the M_TTCAN. The transmitted messages can be monitored at the M_TTCAN Tx output pin.

48.4.7.10.3 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST.LBCK and CCCR.MON to one. This mode can be used for a “Hot Selftest”, meaning the M_TTCAN can be tested without affecting a running CAN system connected to the M_TTCAN Tx output and Rx input pins. In this mode M_TTCAN Rx input pin is disconnected from the M_TTCAN and the M_TTCAN Tx output pin is held recessive. *Figure 840* shows the connection of the M_TTCAN Tx output and Rx input to the M_TTCAN in case of Internal Loop Back Mode.

Figure 840. Pin Control in Loop Back modes

48.4.7.11 Timestamp generation

For timestamp generation the M_TTCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TCV]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of a Rx Buffer/ Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

48.4.7.12 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_TTCAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC].

The Timeout Counter can only be started while CCCR[INIT] = ‘0’. It is stopped when CCCR[INIT] = ‘1’, for example when the M_TTCAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

48.4.7.13 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indexes.

48.4.7.13.1 Acceptance filtering

The M_TTCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx buffer, Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Note: When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process strongly depends on the sequence of configured filter elements.

48.4.7.13.2 Range filter

The filter matches for all received frames with Message IDs in the range defined by SFID1/SFID2 resp. EFID1/EFID2.

There are two possibilities when range filtering is used together with extended frames:

- EFT = ‘00’: The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = ‘11’: The Extended ID AND Mask (XIDAM) is not used for range filtering

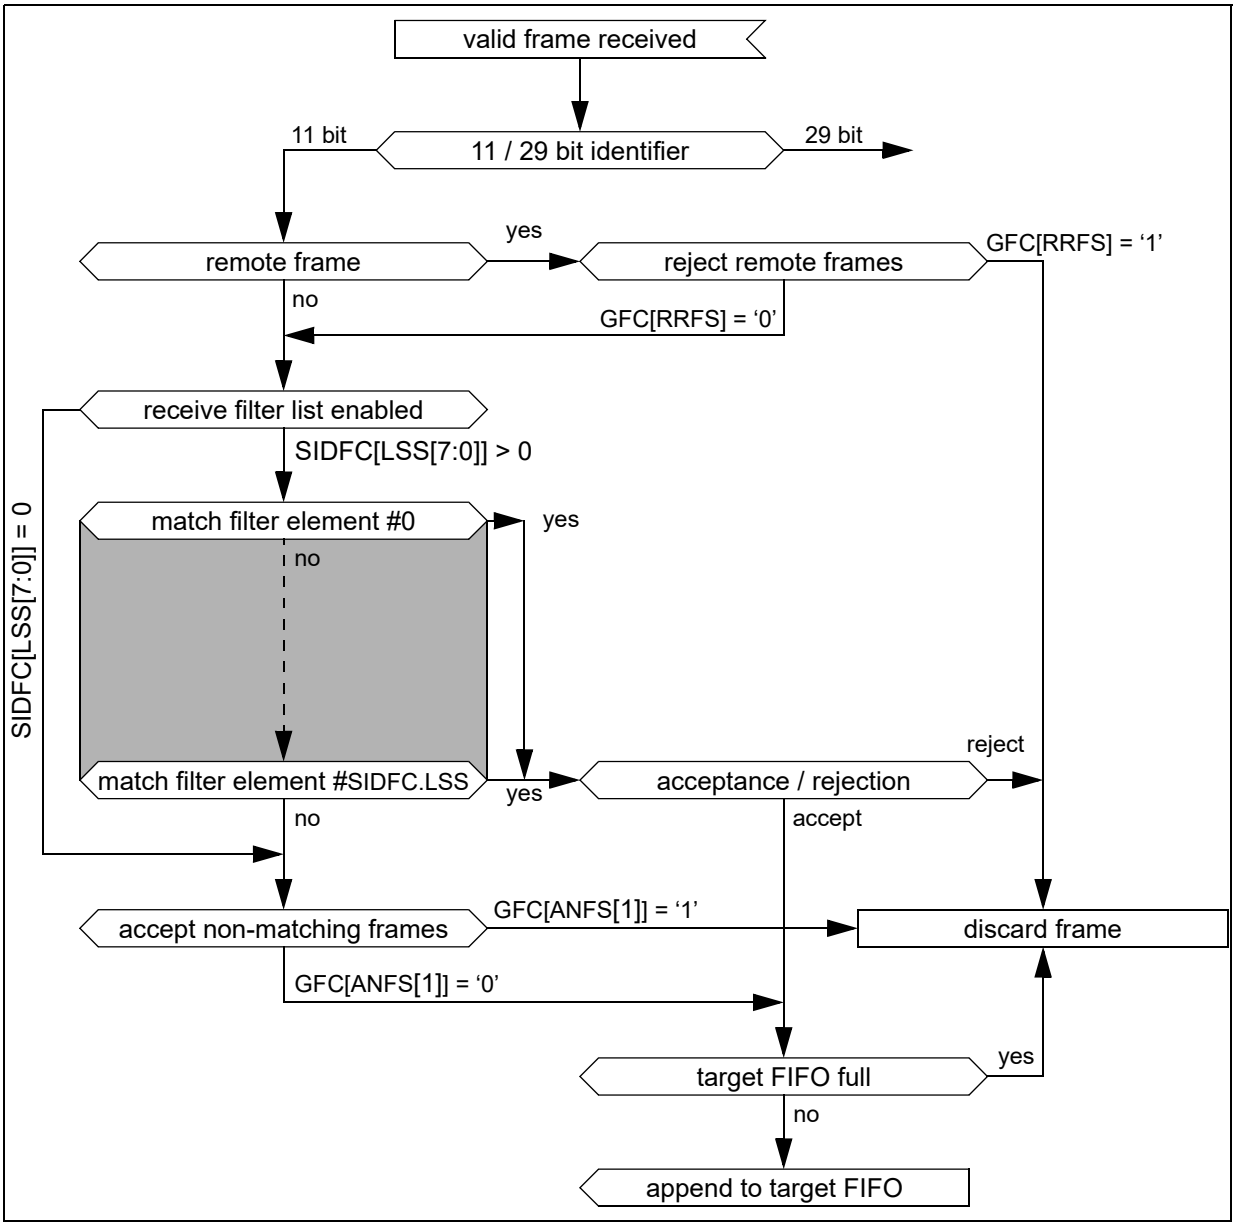
48.4.7.13.3 Filter for dedicated IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1=SFID2 resp. EFID1=EFID2.

48.4.7.13.4 Classic bit mask filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1 /EFID1 is used as Message ID filter, while SFID2/EFID2 is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.



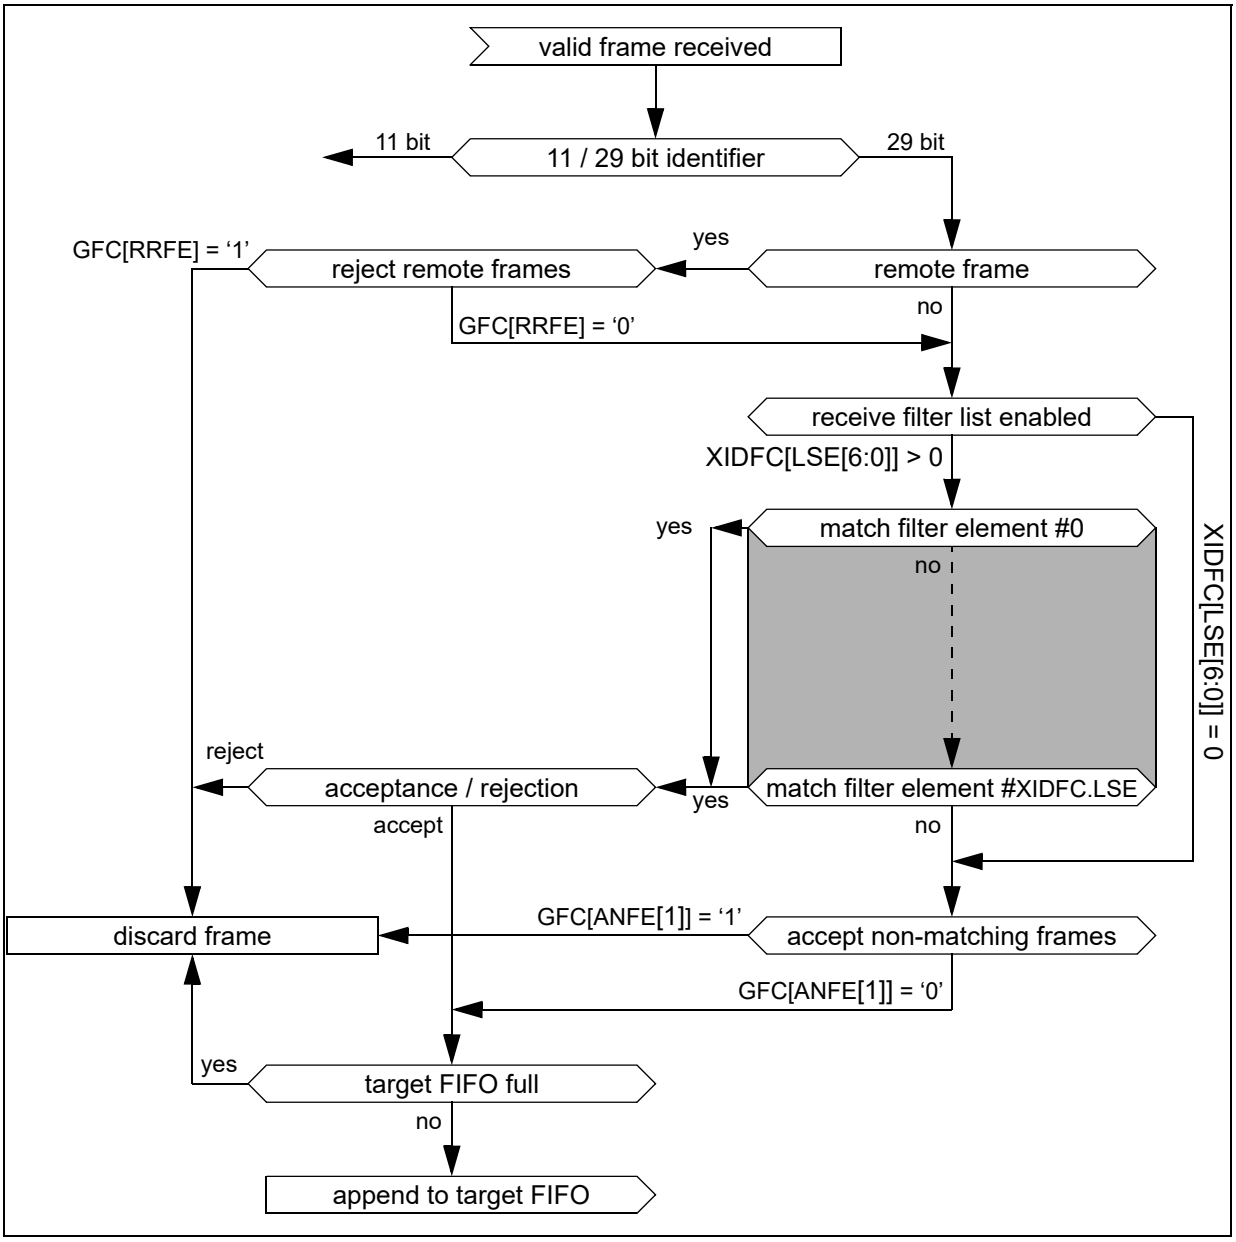
In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

48.4.7.13.5 Standard message ID filtering

Figure 841 below shows the ow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in *Section 48.4.6.4: Standard Message ID Filter element*.

Controlled by the Global Filter Configuration (GFC) and the Standard ID Filter Configuration (SIDFC) Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 841. Standard Message ID Filter Path



48.4.7.13.6 Extended message ID filtering

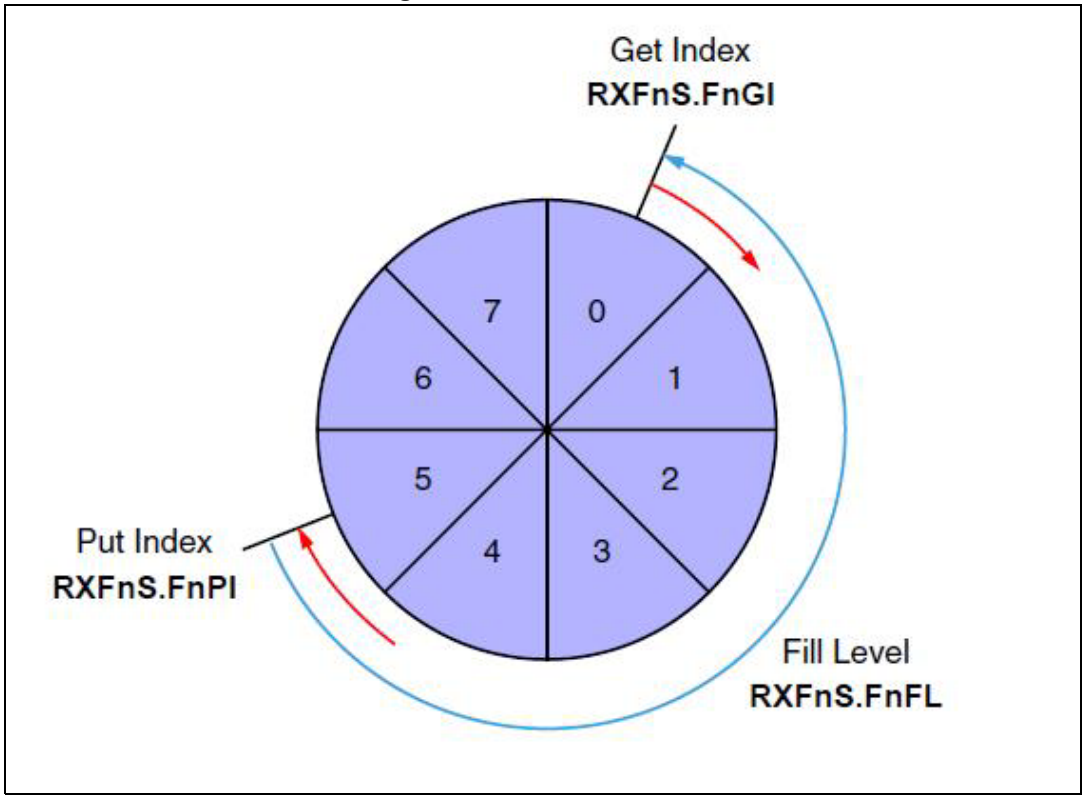
Figure 842 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in *Section 48.4.6.5: Extended Message ID Filter element*.

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 842. Extended Message ID Filter Path

48.4.7.14 Rx FIFOs



Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, refer to *Section 48.4.7.13.1: Acceptance filtering*. The Rx buffer and FIFO element is described in *Section 48.4.6.1: Rx Buffer and FIFO element*.

To avoid an Rx FIFO over ow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IR.RFnW

is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag IR.RFnF is set.

Figure 843. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI × FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 942. Rx Buffer / FIFO Element Size

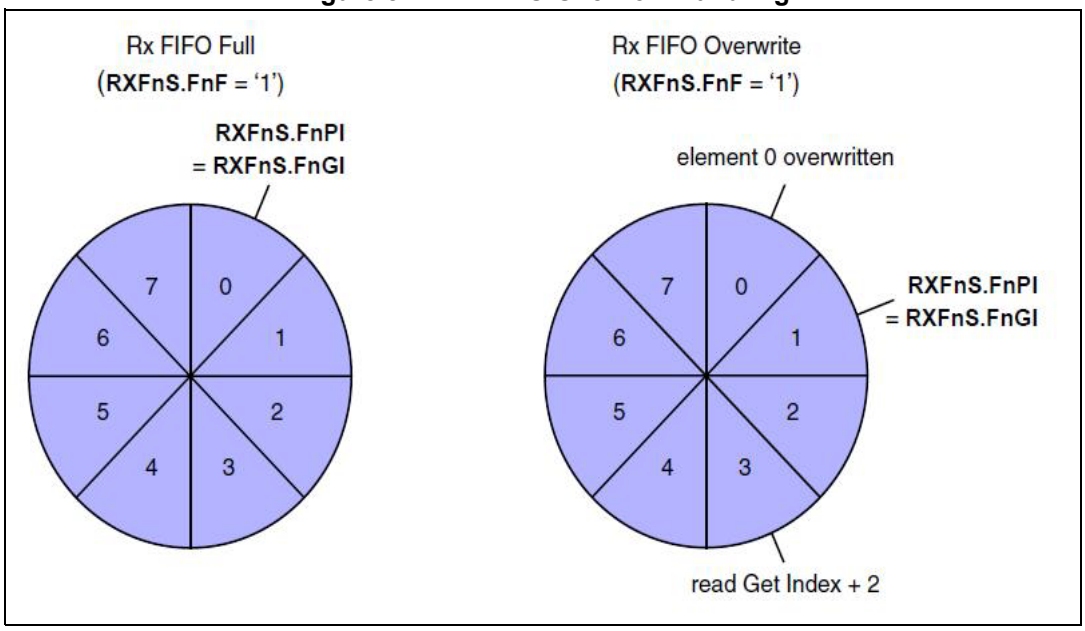
RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

48.4.7.14.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IR.RFnL is set.



48.4.7.14.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. Figure 9 shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 844. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = ‘0’).

48.4.7.15 Dedicated Rx Buffers

The M_TTCAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (refer to *Section 48.4.6.4: Standard Message ID Filter element* and *Section 48.4.6.5: Extended Message ID Filter element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 943. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. The following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

48.4.7.15.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

48.4.7.16 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (for example, #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (refer to *Section 48.4.6.1*).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = ‘111’ have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_TTCAN while DMA request output is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets DMA acknowledge input . This resets DMA request output. Now the M_TTCAN is prepared to receive the next set of debug messages.

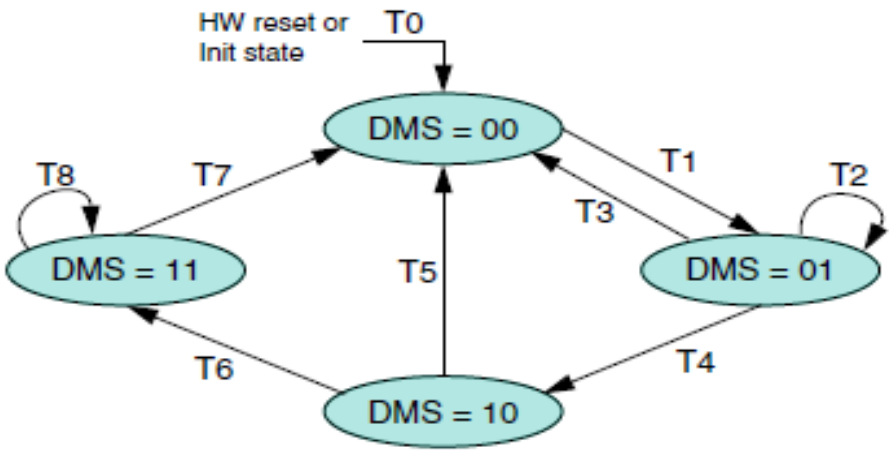
Note: To use full ‘Debug on CAN Support’ feature on a M_(TT)CAN instance a DMA channel is required. Please refer to device DMA map to see which M_(TT)CAN instances has got an assigned DMA channel.

48.4.7.16.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to ‘111’. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning (refer to *Section 48.4.6.4: Standard Message ID Filter element* and *Section 48.4.6.5: Extended Message ID Filter element*). While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 944. Example Filter Configuration for Debug Messages



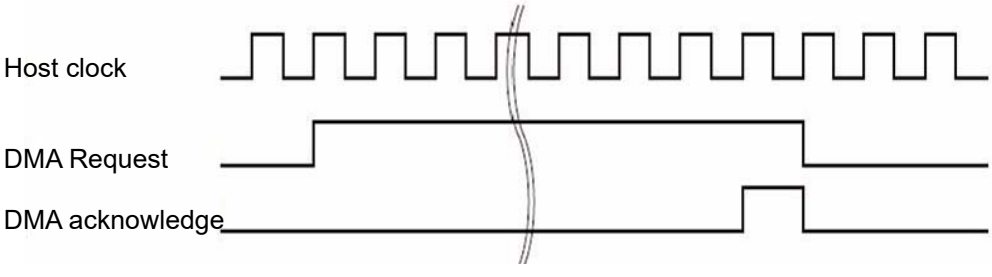
Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

48.4.7.16.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signalled via RXF1S.DMS.

Figure 845. Debug Message Handling State Machine



T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C
T1: reception of debug message A
T2: reception of debug message A
T3: reception of debug message C
T4: reception of debug message B
T5: reception of debug messages A, B
T6: reception of debug message C
T7: DMA transfer completed
T8: reception of debug message A,B,C (message rejected)

48.4.7.17 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_TTCAN DMA request output signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_TTCAN while M_TTCAN DMA request output is active.

After the transfer of the received messages has completed the DMA unit activates DMA acknowledge input signal. This resets M_TTCAN DMA request output. The debug message handling state machine enters idle state (DMS = “00”) and waits for reception of the next debug messages.

Figure 846. Timing of DMA Interface Signals

Note: If the DMA unit activates TT_CAN DMA acknowledge input signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

48.4.7.18 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indexes, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in the *Note:: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 to 17) are used for storage of a CAN message's data field. on page 1535*

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

48.4.7.19 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, for example, CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit **CCCR.TXP**. If the bit is set, the M_TTCAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (**CCCR.TXP** = '0').

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

48.4.7.20 Dedicated Tx buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional

Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding four times the transmit buffer index (0…31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.21 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to ‘0’. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_TTCAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF]= ‘1’) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a ‘1’ to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

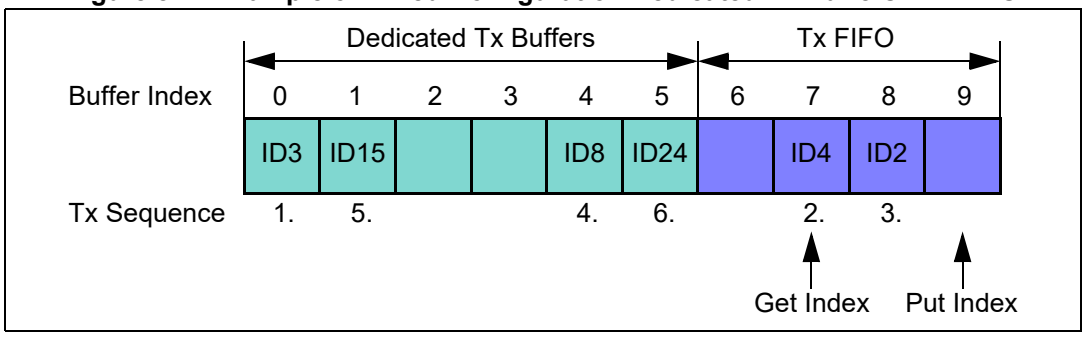
When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0 to 31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.22 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to ‘1’. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF]= ‘1’), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.



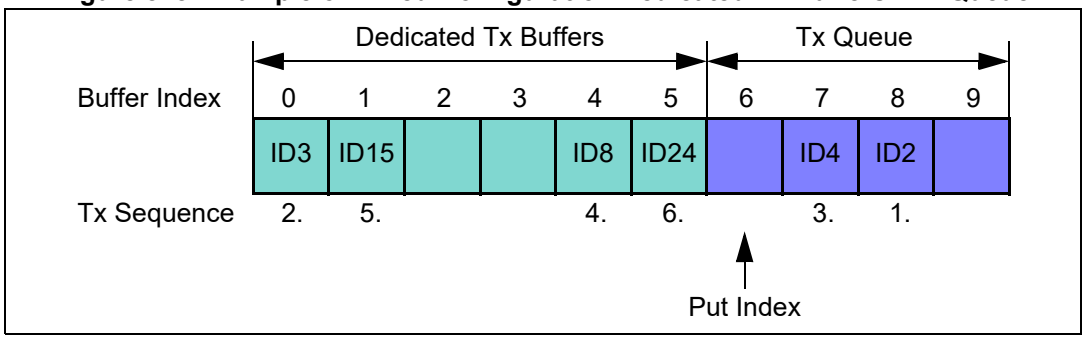
The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding four times the Tx Queue Put Index TXFQS[TFQPI] (0 to 31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.23 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case, TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 847. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO



Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer
- Buffer with lowest Message ID gets highest priority and is transmitted next

48.4.7.24 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only dedicated Tx Buffers are used.

Figure 848. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

48.4.7.25 Transmit cancellation

The M_TTCAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a ‘1’ to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to ‘1’.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is star ed even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

48.4.7.26 Tx Event handling

To support Tx event handling the M_TTCAN has implemented a Tx Event FIFO. After the M_TTCAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in the Note *Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message’s data field.*

When a Tx Event FIFO full condition is signaled by IR[TEFF], no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

To avoid a Tx Event FIFO over ow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR[TEFW] is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

48.4.8 FIFO acknowledge handling

The Get Indexes of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (refer to *Section 48.4.5.2.28: Rx FIFO 0 Acknowledge Register (RXF0A)*, *Section 48.4.5.2.33: Rx Buffer / FIFO element size configuration (RXESC)*, and *Section 48.4.5.2.44: Tx Event FIFO Configuration Register (TXEFC)*). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.

When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_TTCAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

48.4.9 M_TTCAN operations

48.4.9.1 Reference message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the Time Master (sender of the reference message).

For Level 1 the data length must be at least one; for Level 0, 2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to eight potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference message is configured via register TTRMC.

The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted Master_Ref_Mark is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (Next_is_Gap bit) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters.

The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

48.4.9.2 Level 1

Level 1 operation is configured via TTOCF[OM] = ‘01’ and TTOCF[GEN]. External clock synchronization is not available in Level 1. The information related to the reference message is stored in the first data byte as shown below. Cycle_Count is optional.

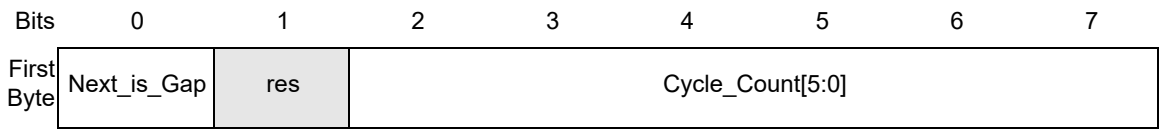


Figure 849. First byte of Level 1 reference message

48.4.9.3 Level 2

Level 2 operation is configured via TTOCF[OM] = ‘10’ and TTOCF[GEN].The information related to the reference message is stored in the first four data bytes as shown below. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

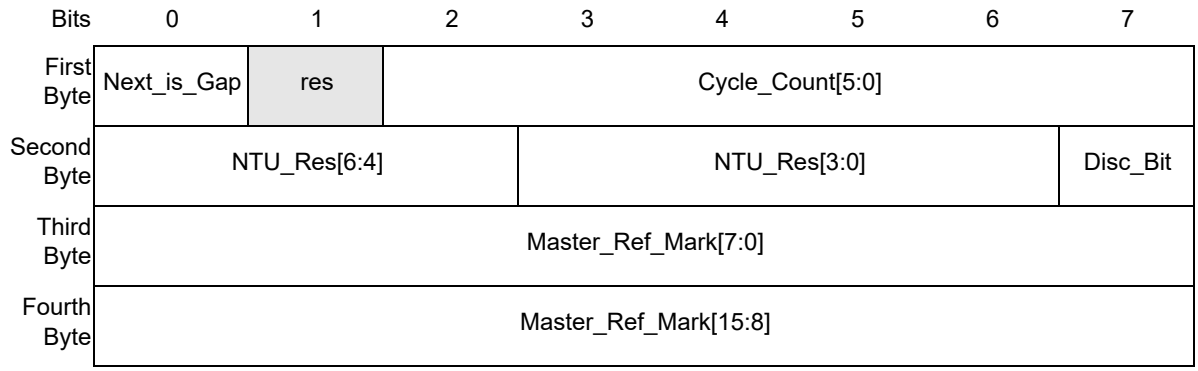

Figure 850. First four bytes of Level 2 reference message

48.4.9.4 Level 0

Level 0 operation is configured via TTOCF[OM] = ‘11’. External event-synchronized time-triggered operation is not available in Level 0. The information related to the reference message is stored in the first four data bytes as shown in the table below. In Level 0 Next_is_Gap is always zero. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

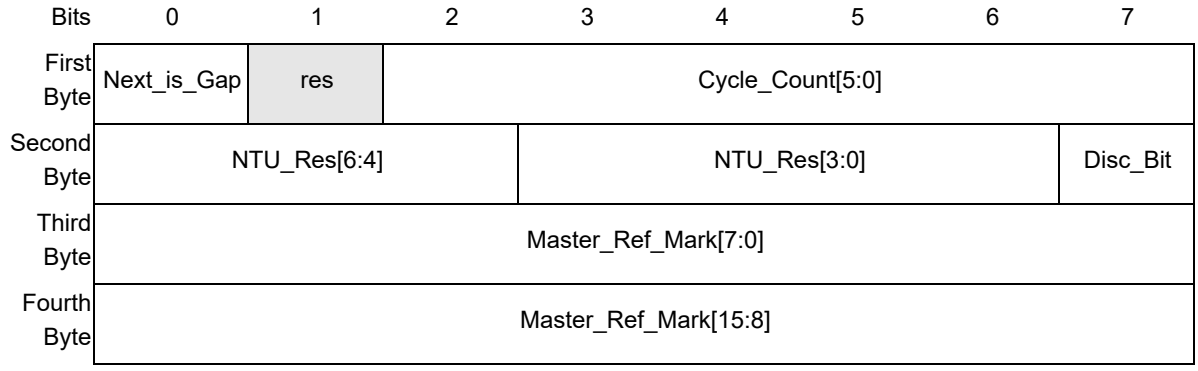

Figure 851. First four bytes of Level 0 reference message

48.4.10 M_TTCAN configuration

48.4.10.1 M_TTCAN timing

The Network Time Unit NTU is the unit in which all times are measured. The NTU is a constant of the whole network and is defined a priority by the network system designer. In M_TTCAN Level 1 the NTU is the nominal CAN bit time. In M_TTCAN Level 0 and Level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable.

In M_TTCAN Level 0 and Level 2 the length of the NTU is defined by the Time Unit Ratio TUR. The TUR is in general a non-integer number, given by the formula TUR = TURNA[NAV]/TURCF[DC]. The length of the NTU is given by the formula NTU = CAN Clock Period $\times$ TUR.

The TUR Numerator Configuration NC is an 18-bit number, TURCF[NCL[15:0]] can be programmed in the range 0x0000–0xFFFF. TURCF[NCH[17:16]] is hard wired to 0b01. When the number 0xnnnn is written to TURCF[NCL[15:0]], TURNA[NAV] starts with the value 0x10000 + 0x0nnnn = 0x1nnnn. The TUR Denominator Configuration TURCF[DC] is a 14-bit number. TURCF[DC] may be programmed in the range 0x0001 - 0x3FFF, 0x0000 is an illegal value.

In Level 1, NC must be $\geq 4 \times$ TURCF**[**DC]. In Level 0, 2 NC must be $\geq 8 \times$ TURCF**[**DC] to allow the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets TURCF[DC] to 0x1000 and TURCF[NCL] to 0x10000, resulting in an NTU consisting of 16 CAN clock periods. Local time and application watchdog are not started before either the CCCR[INIT] is reset, or TURCF[ELT is set. TURCF[ELT] may not be set before the NTU is configured. Setting TURCF[ELT] to e1f also locks the write access to register TURCF.

At startup TURNA[NAV] is updated from NC (= TURCF[NCL] + 0x10000) when TURCF[ELT] is set. In M_TTCAN Level 1 there is no drift compensation. TURNA.NAV does not change during operation, it always equals NC.

In M_TTCAN Level 0 and Level 2 there are two possibilities for TURNA[NAV] to change. When operating as time slave or backup time master, and when TTOCF[ECC] is set, TURNA[NAV] is updated automatically to the value calculated from the monitored global time speed, as long as the M_TTCAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization it returns to NC. When operating as the actual time master, and when TTOCF[EECS] is set, the Host may update TURCF[NCL]. When the Host sets TTOCN[ECS], TURNA[NAV] will be updated from the new value of NC at the next reference message. The status flag TTOST[WECS] as is set when TTOCN[ECS] is set and is cleared when TURNA[NAV] is updated. TURCF[NCL] is write locked while TTOST[WECS] is set.

In M_TTCAN Level 0 and Level 2 the clock calibration process adapts TURNA[NAV] in the range of the Synchronization Deviation Limit SDL of NC+/- $2^{(TTOCF[LDSDL]+5)}$. TURCF[NCL] should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of TURNA[NAV].

The synchronization deviation SD is the difference between NC and TURNA[NAV] (SD = |NC - TURNA[NAV]|). It is limited by the Synchronization Deviation Limit SDL, which is configured by its dual logarithm TTOCF[LDSDL] (SDL = $2^{(TTOCF[LDSDL]+5)}$) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new Basic Cycle. When the calculated TURNA[NAV] deviates by more than SDL from NC, or if the Disc_Bit in the Reference Message is set, the drift compensation is suspended and TTIR[GTE] is set and TTOSC[QCS] is reset, or in case of the Disc_Bit = ‘1’, TTIR[GTD] is set.

Figure 852. TUR configuration examples

TUR	8	10	24	50	510	125000	32.5	100/12	529/17
NC	0x1FFF8	0x1FFFE	0x1FFF8	0x1FFEA	0x1FFFE	0x1E848	0x1FFE0	0x19000	0x10880
TURCF.DC	0x3FFF	0x3333	0x1555	0x0A3D	0x0101	0x0001	0x0FC0	0x3000	0x0880

TTOCN[ECS] schedules NC for activation by the next reference message. TTOCN[SGT] schedules TTGTP[TP] for activation by the next reference message. Setting of TTOCN[ECS] and TTOCN[SGT] requires TTOCF[EECS] to be set (external clock synchronization enabled) while the M_TTCAN is actual time master.

The M_TTCAN module provides an application watchdog to verity the function of the application program. The Host has to serve this watchdog regularly, else all CAN bus activity is stopped. The Application Watchdog Limit TTOCF[AWL] specifies the number of NTUs between two times the watchdog has to be served. The maximum number of NTUs is 256. The Application Watchdog is served by reading register TTOST. TTOST[AWE] indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag TTIR[AW] is set. For software development, the application watchdog may be disabled by programming TTOCF[AWL] to 0x00 (refer to *Section 48.4.7.10.1: Application Watchdog*).

48.4.10.2 Timing of interface signals

The timing events which cause a pulse at output M_TTCAN trigger time mark interrupt pulse and M_TTCAN register time mark interrupt pulse are generated in the CAN clock domain. There is a clock domain crossing delay to be considered before the same event is visible in the Host clock domain (TTIR[TTMI] resp. TTIR[RTMI] set). The signals can be connected for example to the timing input(s) of another M_TTCAN node, in order to automatically synchronize two M_TTCAN networks.

Output M_TTCAN start of cycle gets active whenever a reference message is completed (either transmitted or received). The output is controlled in the Host clock domain.

48.4.11 Message scheduling

TTOCF[TM**]** controls whether the M_TTCAN operates as a potential time master or as a time slave. If it is a potential time master, the three LSBs of the reference message's identifier TTRMC[RID] define the master priority, 0 giving the highest and 7 giving the lowest priority. There may not be two nodes in the network using the same master priority. TTRMC[RID] is used for recognition of reference messages. TTRMC[RMPS] is not relevant for time slaves.

The Initial Reference Trigger Offset TTOCF[IRTO] is a 7-bit-value that defines (in NTUs) how long a backup time master waits before it starts the transmission of a reference message when a reference message is expected but the bus remains idle. The recommended value for TTOCF[IRTO] is the master priority multiplied with a factor depending on the expected clock drift between the potential time masters in the network. The sequential order of the backup time masters, when one of them starts the reference message in case the current time master fails, should correspond to their master priority, even with maximum clock drift.

TTOCF[OM] decides whether the node operates in M_TTCAN Level 0, Level 1, or Level 2. In one network, all potential time masters have to operate on the same level. Time slaves

may operate on Level 1 in a Level 2 network, but not vice versa. The configuration of the M_TTCAN operation mode via TTOCF[OM] is the last step in the setup. With TTOCF[OM] = ‘00’ (event-driven CAN communication), the M_TTCAN operates according to ISO 11898-1, without time triggers.With TTOCF[OM] = ‘01’ (Level 1), the M_TTCAN operates according to ISO 11898-4, but without the possibility to synchronize the basic cycles to external events, the Next_is_Gap bit in the reference message is ignored. With TTOCF[OM] = ‘10’ (Level 2), the M_TTCAN operates according to ISO 11898-4, including the event-synchronized start of a basic cycle. With TTOCF[OM] = ‘11’ (Level 0), the M_TTCAN operates as event-driven CAN but maintains a calibrated global time base as in Level 2.

TTOCF[EECS] enables the external clock synchronization, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in Level 0,2 only) the global clock phase to an external reference.

TTMLM[ENTT] in the TT Matrix Limits register specifies the number of expected Tx_Triggers in the system matrix. This is the sum of Tx_Triggers for exclusive, single arbitrating and merged arbitrating windows, excluding the Tx_Ref_Triggers. Note that this is usually not the number of Tx_Trigger memory elements; the number of basic cycles in the system matrix and the trigger’s repeat factors have to be taken into account. An inaccurate configuration of TTMLM[ENTT] will result in either a TxCount Underflow (TTIR[TXU] = ‘1’ and TTOST[EL] = ‘01’, severity 1) or in a Tx Count Overflow (TTIR[TXO] = ‘1’ and TTOST[EL] = ‘10’, severity 2).

Note: In case the first Reference Message seen by a node does not have Cycle_Count zero, this node may finish its first matrix cycle with its Tx count resulting in a Tx Count Underflow condition. As long as a node is in state Synchronizing its Tx_Triggers will not lead to transmissions.

TTMLM[CCM] specifies the number of the last basic cycle in the system matrix. The counting of basic cycles starts at 0. In a system matrix consisting of 8 basic cycles TTMLM[CCM] would be 7. TTMLM[CCM] is ignored by time slaves, a receiver of a reference message considers the received cycle count as the valid cycle count for the actual basic cycle.

TTMLM[TXEW] specifies the length of the Tx enable window in NTUs. The Tx enable window is that period of time at the beginning of a time window where a transmission may be started. If a transmission of a message cannot be started inside the Tx enable window because of for example, a slight overlap from the previous time window’s message, the transmission cannot be started in that time window at all. TTMLM[TXEW] has to be chosen with respect to the network’s synchronization quality and with respect to the relation between the length of the time windows and the length of the messages.

48.4.11.1 Trigger memory

The trigger memory is part of the external Message RAM to which the M_TTCAN is connected via its Generic Master Interface (refer to *Figure 740*). It stores up to 64 trigger elements. A trigger memory element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, Filter Type FTYPE, Message Number MNR, Message Status Count MSC, Time Mark Event Internal TMIN, Time Mark Event External TMEX, and Asynchronous Serial Communication ASC (refer to *Section 48.4.6.6: Trigger Memory element*).

The time mark defines at which cycle time a trigger becomes active. The triggers in the trigger memory have to be sorted by their time marks. The trigger element with the lowest time mark is written to the first trigger memory word. Message number and cycle code are

ignored for triggers of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, and End_of_List.

When the cycle time reaches the time mark of the actual trigger, the FSE switches to the next trigger and starts to read the following trigger from the trigger memory. In case of a transmit trigger, the Tx Handler starts to read the message from the Message RAM as soon as the FSE switches to its trigger. The RAM access speed defines the minimum time step between a transmit trigger and its preceding trigger, the Tx Handler has to be able to prepare the transmission before the transmit trigger's time mark is reached. The RAM access speed also limits the number of non-matching (with regard to their cycle code) triggers between two matching triggers, the next matching trigger must be read before its time mark is reached. If the reference message is n NTU long, a trigger with a time mark< n will never become active and will be treated as a configuration error.

Starting point of the cycle time is the sample point of the reference message's start of frame bit. The next reference message is requested when cycle time reaches the Tx_Ref_Trigger's time mark. The M_TTCAN reacts on the transmission request at the next sample point. A new Sync_Mark is captured at the start of frame bit, but the cycle time is incremented until the reference message is successfully transmitted (or received) and the Sync_Mark is taken as the new Ref_Mark. At that point in time, cycle time is restarted. As a consequence, cycle time can never (with the exception of initialization) be seen at a value< n, with n being the length of the reference message measured in NTU.

Length of a basic cycle: Tx_Ref_Trigger's time mark+1 NTU+1 CAN bit time.

The trigger list will be different for all nodes in the M_TTCAN network. Each node knows only the Tx_Triggers for its own transmit messages, the Rx_Triggers for those receive messages that are processed by this node, and the triggers concerning the reference messages.

48.4.11.1.1 Trigger types

Tx_Ref_Trigger (TYPE = '0000') and Tx_Ref_Trigger_Gap (TYPE = '0001') cause the transmission of a reference message by a time master. A configuration error (TTOST[EL] = '11', severity 3) is detected when a time slave encounters a Tx_Ref_Trigger(_Gap) in its trigger memory. Tx_Ref_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, Tx_Ref_Trigger is ignored when the M_TTCAN synchronization state is In_Gap (TTOST[SY]S = '10').

Tx_Trigger_Single (TYPE = '0010'), Tx_Trigger_Continuous (TYPE = '0011'), Tx_Trigger_Arbitration (TYPE = '0100'), and Tx_Trigger_Merged (TYPE = '0101') cause the start of a transmission. They define the start of a time window.

Tx_Trigger_Single starts a single transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit is reset.

Tx_Trigger_Continuous starts a transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit remains set, and the message buffer is transmitted again in the next matching time window.

Tx_Trigger_Arbitration starts an arbitrating time window, Tx_Trigger_Merged a merged arbitrating time window. The last Tx_Trigger of a merged arbitrating time window must be of type Tx_Trigger_Arbitration. A Configuration Error (TTOST[EL] = '11', severity 3) is detected when a trigger of type Tx_Trigger_Merged is followed by any other Tx_Trigger than one of type Tx_Trigger_Merged or Tx_Trigger_Arbitration. Several Tx_Triggers may be defined for

the same Tx message buffer. Depending on their cycle code, they may be ignored in some basic cycles. The cycle code has to be considered when the expected number of Tx_Triggers (TTMLM[ENTT]) is calculated.

Watch_Trigger (TYPE = ‘0110’) and Watch_Trigger_Gap (TYPE = ‘0111’) check for missing reference messages. They are used by both time masters and time slaves. Watch_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, a Watch_Trigger is ignored when the M_TTCAN synchronization state is In_Gap (TTOST[SYS] = ‘10’).

Rx_Trigger (TYPE = ‘1000’) is used to check for the reception of periodic messages in exclusive time windows. Rx_Triggers are not active until state In_Schedule or In_Gap is reached. The time mark of an Rx_Trigger shall be placed after the end of that message’s transmission, independent of time window boundaries. Depending on their cycle code, Rx_Triggers may be ignored in some basic cycles. At the time mark of the Rx_Trigger, it is checked whether the last received message before this time mark and after start of cycle or previous Rx_Trigger had matched the acceptance filter element referenced by MNR. Accepted messages are stored in one of the two receive FIFOs, according to the acceptance filtering, independent of the Rx_Trigger. Acceptance filter elements which are referenced by Rx_Triggers should be placed at the beginning of the filter list to ensure that the filtering is finished before the Rx_Trigger’s time mark is reached.

Time_Base_Trigger (TYPE = ‘1001’) are used to generate internal/external events depending on the configuration of ASC, TMIN, and TMEX.

End_of_List (TYPE = ‘1010…1111’) is an illegal trigger type, a configuration error (TTOST[EL] = ‘11’, severity 3) is detected when an End_of_List trigger is encountered in the trigger memory before the Watch_Trigger and Watch_Trigger_Gap.

48.4.11.1.2 Restrictions for the node’s trigger list

There may not be two triggers that are active at the same cycle time and cycle count, but triggers that are active in different basic cycles (different cycle code) may share the same time mark.

Rx_Triggers and Time_Base_Triggers may not be placed inside the Tx enable windows of Tx_Trigger_Single/Continuous/Arbitration, but they may be placed after Tx_Trigger_Merged.

Triggers that are placed after the Watch_Trigger (or the Watch_Trigger_Gap when TTOST[SYS] = ‘10’) will never become active. The watch triggers themselves will not become active when the reference messages are transmitted on time.

All unused trigger memory words (after the Watch_Trigger or after the Watch_Trigger_Gap when TTOST[SYS] = ‘10’) must be set to trigger type End_of_List.

A typical trigger list for a potential time master will begin with a number of Tx_Triggers and Rx_Triggers followed by the Tx_Ref_Trigger and the Watch_Trigger. For networks with external event- synchronized time-triggered communication, this is followed by the Tx_Ref_Trigger_Gap and the Watch_Trigger_Gap. The trigger list for a time slave will be the same but without the Tx_Ref_Trigger and the Tx_Ref_Trigger_Gap.

At the beginning of each basic cycle, that is at each reception or transmission of a reference message, the trigger list is processed starting with the first trigger memory element. The FSE looks for the first trigger with a cycle code that matches the current cycle count. The FSE waits until cycle time reaches the trigger’s time mark and activates the trigger.

Afterwards the FSE looks for the next trigger in the list with a cycle code that matches the current cycle count.

Special consideration is needed for the time around Tx_Ref_Trigger and Tx_Ref_Trigger_Gap. In a time master competing for master ship, the effective time mark of a Tx_Ref_Trigger may be decremented in order to be the first node to start a reference message. In backup time masters the effective time mark of a Tx_Ref_Trigger or Tx_Ref_Trigger_Gap is the sum of its configured time mark and the Reference Trigger Offset TTOCF[IRTO]. In case error level 2 is reached (TTOST[EL] = '10'), the effective time mark is the sum of its time mark and 0x127. No other trigger elements should be placed in this range otherwise it may happen, that the time marks appear out of order and are flagged as a configuration error. Trigger elements which are coming after Tx_Ref_Trigger may never become active as long as the reference messages come in time.

There are interdependencies between the following parameters:

- Host clock frequency
- Speed and waiting time for Trigger RAM accesses
- Length of the acceptance filter list
- Number of trigger elements
- Complexity of cycle code filtering in the trigger elements
- Offset between time marks of the trigger elements

48.4.11.1.3 Example for trigger handling

The example below shows how the trigger list is derived from a node's system matrix. Assumed node A is first time master and has knowledge of the section of the system matrix shown below.

Table 945. System Matrix Node A

Cycle Count	Time Mark1	Time Mark2	Time Mark3	Time Mark4	Time Mark5	Time Mark6	Time Mark7
0	Tx7					TxRef	Error
1	Rx3		Tx2, Tx4			TxRef	Error
2						TxRef	Error
3	Tx7		Rx5			TxRef	Error
4	Tx7			Rx6		TxRef	Error

The cycle count starts with 0 and runs until 0, 1, 3, 7, 15, 31, 63 (the number of basic cycles in the system matrix is 1, 2, 4, 8, 16, 32, 64). The maximum cycle count is configured by TTMLM.CCM. The Cycle Code CC is composed of repeat factor (= value of most significant '1') and the number of the first basic cycle in the system matrix (= bit field after most significant '1').

Example: with a cycle code of 0b0010011 (repeat factor: 16, first basic cycle: 3) and a maximum cycle count of TTMLM.CCM = '0x3F' matches occur at cycle counts 3, 19, 35, 51.

A trigger element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, and Message Number MNR. For transmission MNR references the Tx Buffer number (0...31). For reception MNR references the number of the filter element (0 to 127) that matched

during acceptance filtering. Depending on the configuration of the Filter Type FTYPE, the 11-bit or 29-bit message ID filter list is referenced.

In addition a trigger element can be configured for Asynchronous Serial Communication ASC, generation of Time Mark Event Internal TMIN, and Time Mark Event External TMEX. The Message Status Count MSC holds the counter value (0...7) for scheduling errors for periodic messages in exclusive time windows at the point in time when the time mark of the trigger element became active.

Table 946. Trigger List Node A

Trigger	Time Mark TM[15:0]	Cycle Code CC [6:0]	Trigger Type TYPE [3:0]	Mess No. MNR [6:0]
0	Mark 1	0b0000100	Tx_Trigger_Single	7
1	Mark 1	0b1000000	Rx_Trigger	3
2	Mark 1	0b1000011	Tx_Trigger_Single	7
3	Mark 3	0b1000001	Tx_Trigger_Merged	2
4	Mark 3	0b1000011	Rx_Trigger	5
5	Mark 4	0b1000001	Tx_Trigger_Arbitration	4
6	Mark 4	0b1000100	Rx_Trigger	6
7	Mark 6	n.a.	Tx_Ref_Trigger	0 (Ref)
8	Mark 7	n.a.	Watch_Trigger	n.a.
9	n.a.	n.a.	End_of_List	n.a.

Tx_Trigger_Single, Tx_Trigger_Continuous, Tx_Trigger_Merged, Tx_Trigger_Arbitration, Rx_Trigger, and Time_Base_Trigger are only valid for the specified cycle code. For all other trigger types the cycle code is ignored.

The FSE starts the basic cycle with scanning the trigger list starting from zero until a trigger with time mark > cycle time and with its Cycle Code CC matching the actual cycle count is reached, or a trigger of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, or Watch_Trigger_Gap is encountered.

When the cycle time reached the Time Mark TM, the action defined by Trigger Type TYPE and Message Number MNR is started. There is an error in the configuration when End_of_List is reached.

At Mark6 the reference message (always TxRef) is transmitted. After transmission of the reference message the FSE returns to the beginning of the trigger list. When the Watch Trigger at Mark7 is reached, the node was not able to transmit the reference message; error treatment is started.

48.4.11.1.4 Detection of configuration errors

A configuration error is signaled via TTOST[EL] = ‘11’ (severity 3) when:

- The FSE comes to a trigger in the list with a cycle code that matches the current cycle count but with a time mark that is less than the cycle time.
- The previous active trigger was a Tx_Trigger_Merged and the FSE comes to a trigger in the list with a cycle code that matches the current cycle count but that is neither a

Tx_Trigger_Merged nor a Tx_Trigger_Arbitration nor a Time_Base_Trigger nor an Rx_Trigger.

- The FSE of a node with TTOCF[TM]=‘0’ (time slave) encounters a Tx_Ref_Trigger or a Tx_Ref_Trigger_Gap.
- Any time mark placed inside the Tx enable window (defined by TTMLM[TXEW]) of a Tx_Trigger with a matching cycle code.
- A time mark is placed near the time mark of a Tx_Ref_Trigger and the Reference Trigger Offset TTOST[RTO] causes a reversal of their sequential order measured in cycle time.

48.4.11.2 M_TTCAN schedule initialization

The synchronization to the M_TTCAN’s message schedule starts when CCCR[INIT] is reset. The M_TTCAN can operate strictly time-triggered (TTOCF[GEN] = ‘0’) or external event-synchronized time-triggered (TTOCF[GEN] = ‘1’). All nodes start with cycle time zero at the beginning of their trigger list with TTOST[SYS] = ‘00’ (out of synchronization), no transmission is enabled with the exception of the reference message. Nodes in external event-synchronized time-triggered operation mode will ignore Tx_Ref_Trigger and Watch_Trigger and will use instead Tx_Ref_Trigger_Gap and Watch_Trigger_Gap until the first reference message decides whether a Gap is active.

48.4.11.2.1 Time slaves

After configuration, a time slave will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message before reaching the Watch_Triggers. When it reaches Init_Watch_Trigger, interrupt flag TTIR[IWT] is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). The first received reference message will restart the FSE and the cycle time.

Note: Init_Watch_Trigger is not part of the trigger list. It is implemented as an internal counter which counts up to 0xFFFF = maximum cycle time.

When a time slave has received any message but the reference message before reaching the Watch_Triggers, it will assume a fatal error (TTOST[EL] = ‘11’, severity 3), set interrupt flag TTIR[WT], switch off its CAN bus output, and enter the bus monitoring mode (CCCR[MON] set to ‘1’). In the bus monitoring mode it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

Note: To leave the fatal error state, the Host has to set CCCR[INIT] = ‘1’. After reset of CCCR[INIT], the node restarts M_TTCAN communication.

When no error is encountered during synchronization, the first reference message sets TTOST[SYS] = ‘01’ (Synchronizing), the second sets the M_TTCAN synchronization state (depending on its Next_is_Gap bit) to TTOST[SYS] = ‘11’ (In_Schedule) or TTOST[SYS] = ‘10’ (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

48.4.11.2.2 Potential time masters

After configuration, a potential time master will start the transmission of a reference message when it reaches its Tx_Ref_Trigger (or its Tx_Ref_Trigger_Gap when in external event-synchronized time-triggered operation). It will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message or transmit the reference message successfully before reaching the Watch_Triggers (assumed reason: all other

nodes still in reset or configuration, giving no acknowledge). When it reaches Init_Watch_Trigger, the attempted transmission is aborted, interrupt flag TTIR[IWT] is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). Resetting TTIR[IWT] will re-enable the transmission of reference messages until next time the Init_Watch_Trigger condition is met, or another CAN message is received. The FSE will not be restarted by the reception of a reference message.

When a potential time master reaches the Watch_Triggers after it has received any message but the reference message, it will assume a fatal error (TTOST[EL] = ‘11’, severity 3), set interrupt flag TTIR[WT], switch off its CAN bus output, and enter the bus monitoring mode (CCCR[MON] set to ‘1’). In bus monitoring mode, it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

When no error is detected during initialization, the first reference message sets TTOST[SYS] = ‘01’ (synchronizing), the second sets the M_TTCAN synchronization state (depending on its Next_is_Gap bit) to TTOST[SYS] = ‘11’ (In_Schedule) or TTOST[SYS] = ‘10’ (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

A potential time master is current time master (TTOST[MS] = ‘11’) when it was the transmitter of the last reference message, else it is backup time master (TTOST[MS] = ‘10’).

When all potential time masters have finished configuration, the node with the highest time master priority in the network will become the current time master.

48.4.12 M_TTCAN gap control

All functions related to Gap control apply only when the M_TTCAN is operated in external event synchronized time-triggered mode (TTOCF[GEN] = ‘1’). In this operation mode the M_TTCAN message schedule may be interrupted by inserting Gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a Gap, all transmissions are stopped and the CAN bus remains idle. A Gap is finished when the next reference message starts a new basic cycle. A Gap starts at the end of a basic cycle that itself was started by a reference message with bit Next_is_Gap = ‘1’ , for example, Gaps are initiated by the current time master.

The current time master has two options to initiate a Gap. A Gap can be initiated under software control when the application program writes TTOCN[NIG] = ‘1’. The Next_is_Gap bit will be transmitted as ‘1’ with the next reference message. A Gap can also be initiated under hardware control when the application program enables the M_TTCAN event trigger input pin by writing TTOCN[GCS] = ‘1’. When a reference message is started and TTOCN[GCS] is set, a HIGH level at M_TTCAN event trigger pin will set Next_is_Gap = ‘1’.

As soon as that reference message is completed, the TTOST[WFE] bit will announce the Gap to the time master as well as to the time slaves. The current basic cycle will continue until its last time window. The time after the last time window is the Gap time.

For the actual time master and the potential time masters, TTOST[GSI] will be set when the last basic cycle has finished and the Gap time starts. In nodes that are time slaves, bit TTOST[GSI] will remain at ‘0’.

When a potential time master is in synchronization state In_Gap (TTOST[SYS] = ‘10’), it has four options to intentionally finish a Gap:

Under software control by writing TTOCN[FGP] = ‘1’.

Under hardware control (TTOCN[GCS] = ‘1’) an edge from HIGH to LOW at the M_TTCAN event-trigger input pin sets TTOCN[FGP] and restarts the schedule.

The third option is a time-triggered restart. When TTOCN[TMG] = ‘1’, the next register time mark interrupt (TTIR[RTMI] = ‘1’) will set TTOCN[FGP] and start the reference message.

Finally any potential time master will finish a Gap when it reaches its Tx_Ref_Trigger_Gap, assuming that the event to synchronize on did not occur in time.

Neither of these options can cause a basic cycle to be interrupted with a reference message.

Setting of TTOCN[FGP] after the Gap time has started will start the transmission of a reference message immediately and will thereby synchronize the message schedule. When TTOCN[FGP] is set before the Gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger – there will be no Gap time in the message schedule.

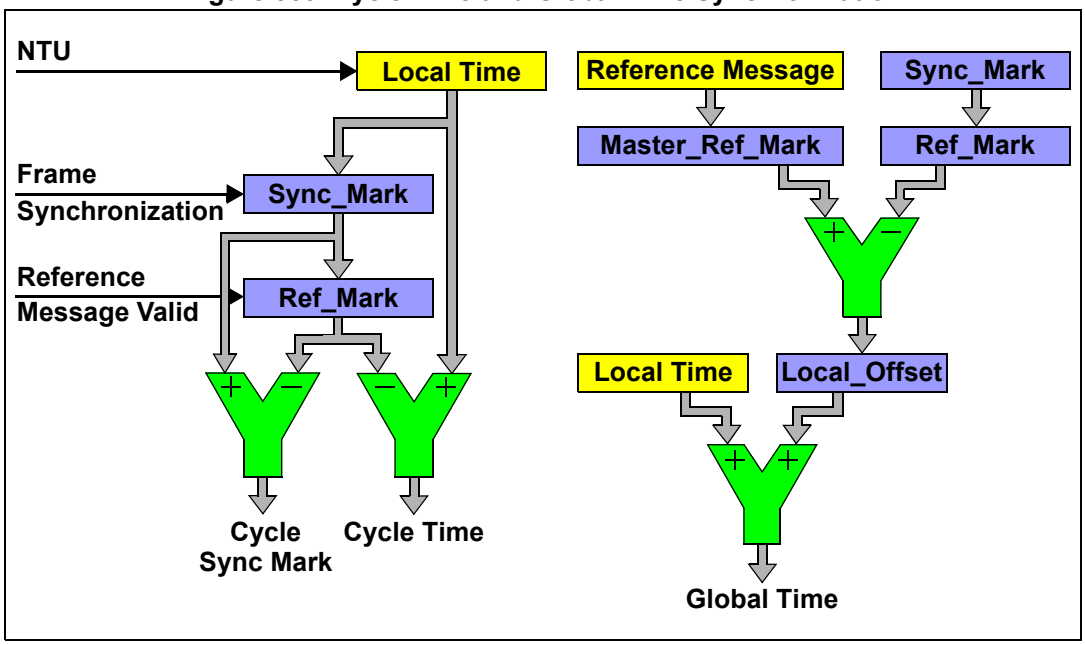
In strictly time-triggered operation, bit Next_is_Gap = ‘1’ in the reference message will be ignored, as well as the M_TTCAN event-trigger input pin and the bits TTOCN[NIG], TTOCN[FGP], and TTOCN[TMG].

48.4.13 Stop watch

The stop watch function enables capturing of M_TTCAN internal time values (local time, cycle time, or global time) triggered by an external event.

To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via TTOCN[SWS].When TTOCN[SWS] is ≠ ‘00’ and TT Interrupt Register flag TTIR[SWE] is ‘0’, the actual value of the time selected by TTTOCN[SWS] will be copied into TTCPT[SWV] on the next rising/falling edge (as configured via TTOCN[SWP]) on M_TTCAN stop watch trigger pin. This will set interrupt flag TTIR[SWE]. After the application program has read TTCPT[SWV], it may enable the next stop watch event by resetting TTIR[SWE] to ‘0’.

48.4.14 Local time, cycle time, global time, and external clock synchronization



There are two possible levels in time-triggered CAN: Level 1 and Level 2. Level 1 only provides time-triggered operation using cycle time. Level 2 additionally provides increased synchronization quality, global time and external clock synchronization. In both levels, all timing features are based on a local time base - the local time.

The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented 8 times each NTU. If the length of the NTU is shorter than 8 CAN clock periods (as may be configured in Level 1, or as a result of clock calibration in Level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only 4 times each NTU.

Figure 853 describes the synchronization of the cycle time and global time, performed in the same manner by all M_TTCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message is frame synchronization event. This frame synchronization event occurs at the sample point of each Start of Frame (SoF) bit and causes the local time to be stored as Sync_Mark. Sync_Marks and Ref_Marks are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the Cycle Sync Mark (Cycle Sync Mark = Sync_Mark - Ref_Mark) stored in register **TTCSM**. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (Cycle Time = Local Time - Ref_Mark).

Figure 853. Cycle Time and Global Time Synchronization

The cycle time that can be read from TTCTC[CT] is the difference of the node's local time and Ref_Mark, both synchronized into the Host clock domain and truncated to 16 bit.

The global time exists for M_TTCAN Level 0 and Level 2 only, in Level 1 it is invalid. The node's view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master will use its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3,4). The global time that can be read from TTLGT[GT] is the sum of the node's local time and its local offset, both synchronized into the Host clock domain and truncated to 16 bit. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark. The node's view of the global time is local time + local offset. In a potential time master that has never received another time master's reference message, Local_Offset will be zero. When a node becomes the current time master after first having received other reference messages, Local_Offset will be frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signaled by Disc_Bit in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register TTLGT is smoothed by a low-pass filtering to have a continuous monotonic value.

Figure 854. M_TTCAN Level 0 and Level 2 Drift Compensation

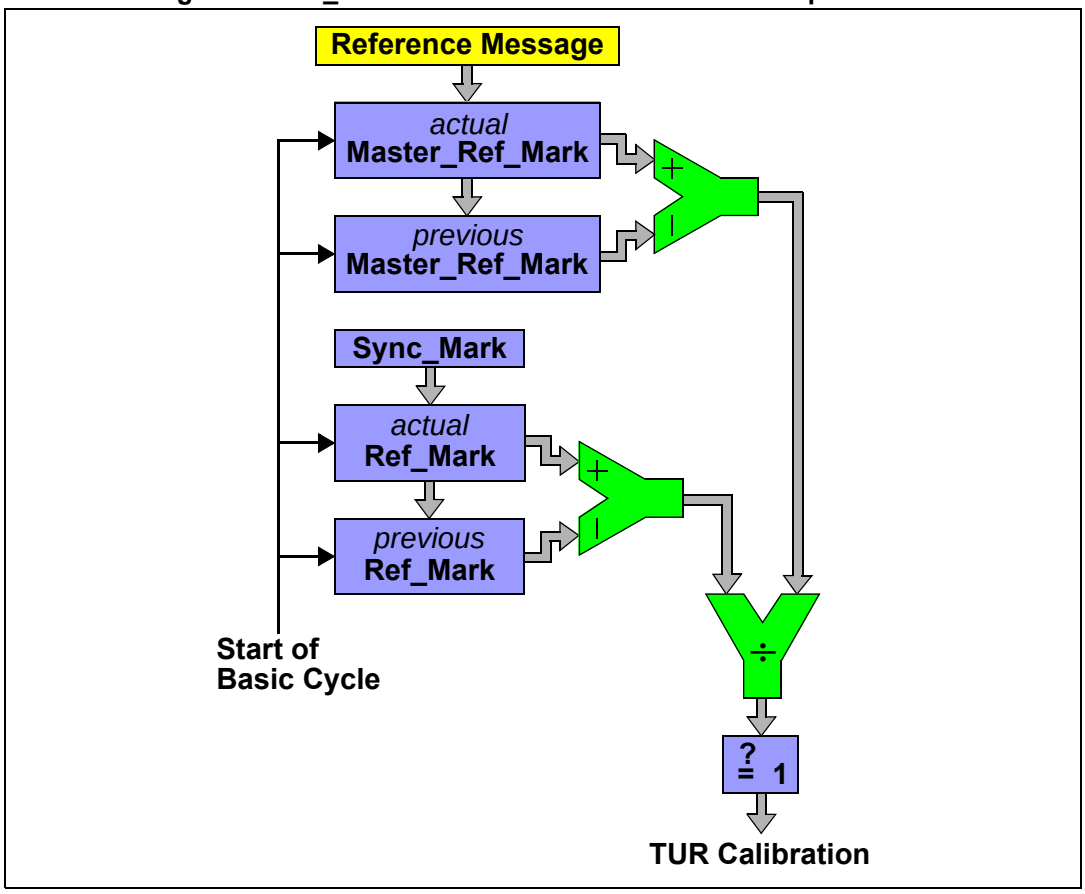


Figure 854 describes how in M_TTCAN Level 0,2 each time receiving node compensates the drift between its own local clock and the time master's clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the Disc_Bit in the reference message is not set, a new value for TURNA[NAV] is calculated. If the Synchronization Deviation SD = |NC - TURNA[NAV]| ≤ SDL (Synchronization Deviation Limit), the new value for TURNA[NAV] takes effect. Else the automatic drift compensation is suspended.

In M_TTCAN Level 0 and Level 2, TTOST[QCS] indicates whether the automatic drift compensation is active or suspended. In M_TTCAN Level 1, TTOST[QCS] is always '1'.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit TTOCF[EECS].

The stop watch function (refer to *Section 48.4.13*) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated Numerator Configuration Low to TURCF[NCL] (TURCF[DC] cannot be updated during operation). The new value takes effect by writing TTOCN[ECS] to '1'.

The global time phase is adjusted by first writing the phase offset into the TT Global Time Preset register TTGTP. The new value takes effect by writing TTOCN[SGT] to '1'. The first reference message transmitted after the global time phase adjustment will have the Disc_Bit set to '1'.

TTOST[QGTP] shows whether the node's global time is in phase with the time master's global time. TTOST[QGTP] is permanently '0' in M_TTCAN Level 1 and when the Synchronization Deviation Limit is exceeded in M_TTCAN Level 0,2 (TTOST[QCS] = '0'). It is temporarily '0' while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a Disc_Bit = '1' or when TTOST[QCS]='0'.

48.4.15 M_TTCAN error level

The ISO 11898-4 specifies four levels of error severity:

- S0: No Error
- S1: Warning.
  Only notification of application, reaction application-specific.
- S2: Error.
  Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (that is no data or remote frames may be started). Potential time masters still transmit reference messages with the Reference Trigger Offset TTOST[RTO] set to the maximum value of 127.
- S3: Severe Error.
  Notification of application. All CAN bus operations are stopped, that is transmission of dominant bits is not allowed, and CCCR[MON] is set. The S3 error condition remains active until the application updates the configuration (set CCCR[CCE]).

If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by TTIR[ELC]. The error level is monitored by TTOST[EL].

The M_TTCAN signals the following error conditions as required by ISO 11898-4:

- Config_Error (S3):
  Sets Error Level TTOST[EL] to '11' when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.
- Watch_Trigger_Reached (S3):
  Sets Error Level TTOST[EL] to '11' when a watch trigger was reached because the reference message is missing.
- Application_Watchdog (S3):
  Sets Error Level TTOST[EL] to '11' when the application failed to serve the application watchdog.The application watchdog is configured via TTOCF[AWL]. It is served by reading register TTOST.When the watchdog is not served in time, bit TTOST[AWE] and interrupt flag TTIR[AW] are set, all M_TTCAN communication is stopped, and the M_TTCAN is set into bus monitoring mode (CCCR[MON]set to '1').
- CAN_Bus_Off (S3):
  Entering CAN_Bus_Off state sets error level TTOST[EL] to '11'. CAN_Bus_Off state is signaled by PSR[BO] = '1' and CCCR[INIT] = '1'.
- Scheduling_Error_2 (S2):
  Sets Error Level TTOST[EL] to '10' if the MSC of one Tx_Trigger has reached 7. In addition interrupt flag TTIR[SE2] is set. The Error Level TTOST[EL] is reset to '00' at the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.
- Tx_Overflow (S2):
  Sets Error Level TTOST[EL] to '10' when the Tx count is equal or superior to the

expected number of Tx_T riggers TTMLM[ENTT] and a Tx_Trigger event occurs. In addition interrupt flag TTIR[TXO] is set. The Error Level TTOST[EL] is reset to '00' when the Tx count is no more than TTMLM[ENTT] at the start of a new matrix cycle.

- Scheduling_Error_1 (S1):
  Sets Error Level TTOST[EL] to '01' if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than 2, or if one of the MSCs of an exclusive Rx_Trigger has reached 7. In addition interrupt flag TTIR[SE1] is set. If within one matrix cycle none of these conditions is valid, the Error Level TTOST[EL] is reset to '00'.
- Tx_Underflow (S1):
  Sets Error Level TTOST[EL] to '01' when the Tx count is less than the expected number of Tx_Triggers TTMLM[ENTT] at the start of a new matrix cycle. In addition interrupt flag TTIR[TXU] is set. The Error Level TTOST[EL] is reset to '00' when the Tx count is at least TTMLM[ENTT] at the start of a new matrix cycle.

48.4.16 M_TTCAN message handling

48.4.16.1 Reference message

For potential time masters the identifier of the reference message is configured via TTRMC[RID]. No dedicated Tx Buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte (M_TTCAN Level 1) resp. the first four data bytes (M_TTCANM_TTCAN Level 0 and Level 2) will be provided by the FSE.

In case the Reference Message Payload Select TTRMC[RMPS] is set, the rest of the reference message's payload (Level 1: bytes 2-8, Level 0,2: bytes 5-6) is taken from Tx Buffer 0. In this case the data length DLC code from message buffer 0 is used.

Table 947. Number of Data Bytes transmitted with a Reference Messages

TTRMC.RMPS	TXBRP.TRP0	Level 0	Level 1	Level 2
0	0	4	1	4
0	1	4	1	4
1	0	4	1	4
1	1	4+MBO	1+MBO	4+MBO

To send additional payload with the reference message in Level 1 a DLC > 1 has to be configured, for Level 0, 2 a DLC > 4 is required. In addition the transmission request pending bit TXBRP[TRP0] of message buffer 0 must be set (refer to *Table 947*). In case bit TXBRP[TRP0] is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the Reference Identifier TTRMC[RID] is used.

48.4.16.2 Message reception

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (refer to *Section 48.3.10*).

The Message Status Count MSC is part of the corresponding trigger memory element and has to be initialized to zero during configuration. It is updated while the M_TTCAN is in

synchronization states In_Gap or In_Schedule. The update happens at the message's Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

48.4.16.3 Message transmission

For time-triggered message transmission the M_TTCAN supplies 32 dedicated Tx buffers (refer to *Section 48.4.7.20: Dedicated Tx buffers*). A Tx FIFO or Tx queue is not available when the M_TTCAN is configured for time-triggered operation (TTOCF[OM] = '01' or '10').

Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle.

The application program has to update the data regularly and on time, synchronized to the cycle time. The Host CPU is responsible that no partially updated messages are transmitted. To assure this the Host has to proceed in the following way:

Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration

- Check whether the previous transmission has completed by reading TXBTO
- Update the Tx buffer's configuration or payload, or both
- Issue an Add Request to set the Tx Buffer Request Pending bit

Tx_Trigger_Continous

- Issue a Cancellation Request to reset the Tx Buffer Request Pending bit
- Check whether the cancellation has finished by reading TXBCF
- Update Tx buffer's configuration or payload, or both
- Issue an Add Request to set the Tx Buffer Request Pending bit

The message's MSC stored with the corresponding Tx_Trigger provides information on the success of the transmission.

The MSC is incremented by one when the transmission could not be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and could not be completed successfully. The MSC is decremented by one when the message was transmitted successfully or when the message could have been started within its transmit enable window but was not started because transmission was disabled (M_TTCAN in Error Level S2 or Host has disabled this particular message).

The Tx buffers may be managed dynamically, that is several messages with different identifiers may share the same Tx buffer element. In this case the Host has to assure that no transmission request is pending for the Tx buffer element to be reconfigured by checking TXBRP.

If a Tx buffer with pending transmission request should be updated, the Host first has to issue a cancellation request and check whether the cancellation has completed by reading TXBCF before it starts updating.

The Tx Handler will transfer a message from the Message RAM to its intermediate output buffer at the trigger element which becomes active immediately before the Tx_Trigger element which defines the beginning of the transmit window. During and after the transfer time the transmit message may not be updated and its TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be example of a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger has to be large enough to guarantee that the Tx Handler can read four words from the Message RAM even at high RAM access load from other modules.

48.4.16.3.1 Transmission in exclusive time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continuous. There is no arbitration on the bus with messages from other nodes. The MSC is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx Buffer Request Pending bit is reset. After successful transmission started by a Tx_Trigger_Continuous the respective Tx Buffer Request Pending remains set. When the transmission was not successful due to disturbances, it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

48.4.16.3.2 Transmission in arbitrating time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The MSC is not updated. When the transmission was not successful (lost arbitration or disturbance), it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

48.4.16.3.3 Transmission in merged arbitrating time windows

The purpose of a merged arbitrating time window is to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a single node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission will not be started if the corresponding Transmission Request Pending flag was reset by a successful Tx cancellation.

In single transmit windows, the Tx Handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmissions will be attempted in the sequence defined by the trigger list. If the time mark of a fourth message is reached before the first is transmitted (or canceled by the Host), the four the request will be ignored.

The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window will be started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if their is compelling bus traffic. This has to be considered for the configuration of the trigger list. Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx Buffer needs to be updated.

48.4.17 M_TTCAN interrupt and error handling

The TT Interrupt Register TTIR consists off our segments. Each interrupt can be enabled separately by the corresponding bit in the TT Interrupt Enable register TTIE. The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position.

The first segment consists of flags CER, AW, WT, and IWT. Each flag indicates a fatal error condition where the CAN communication is stopped. With the exception of IWT, these error conditions require a re-configuration of the M_TTCAN module before the communication can be restarted.

The second segment consists of flags ELC, SE1, SE2, TXO, TXU, and GTE. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, for example by disturbances on the CAN bus, they will be handled by the M_TTCAN protocol’s failure handling and do not require intervention by the application program.

The third segment consists of flags GTD, GTW, SWE, TTMI, and RTMI. The first two flags are controlled by global time events (Level 0,2 only) that require a reaction by the application program. With a Stop Watch Event triggered by a rising edge on stop watch trigger pin internal time values are captured. The Trigger Time Mark Interrupt notifies the application that a specific Time_Base_Trigger is reached. The Register Time Mark Interrupt signals that the time referenced by TTOCN[TMC] (Cycle, Local, or Global) equals time mark TTTMK[TM]. It can also be used to finish a Gap.

The fourth segment consists of flags SOG, CSM, SMC, and SBC. These flags provide a means to synchronize the application program to the communication schedule.

48.4.18 Level 0

M_TTCAN Level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in M_TTCAN Level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1.

Level 0 operation is configured via TTOCF[OM] = ‘11’. In this mode the M_TTCAN operates in event driven CAN communication, there is no fixed schedule, the configuration of TTOCF[GEN] is ignored. External event-synchronized operation is not available in Level 0. A synchronized time base is maintained by transmission of reference messages.

In Level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (TTIR[TTMI]) is set when the cycle time has reached TTOCF[IRTO] $\times$ 0x200, it reminds the Host to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (TTIR[WT]) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks.

Register time mark interrupts (TTIR[RTMI]) are also possible.

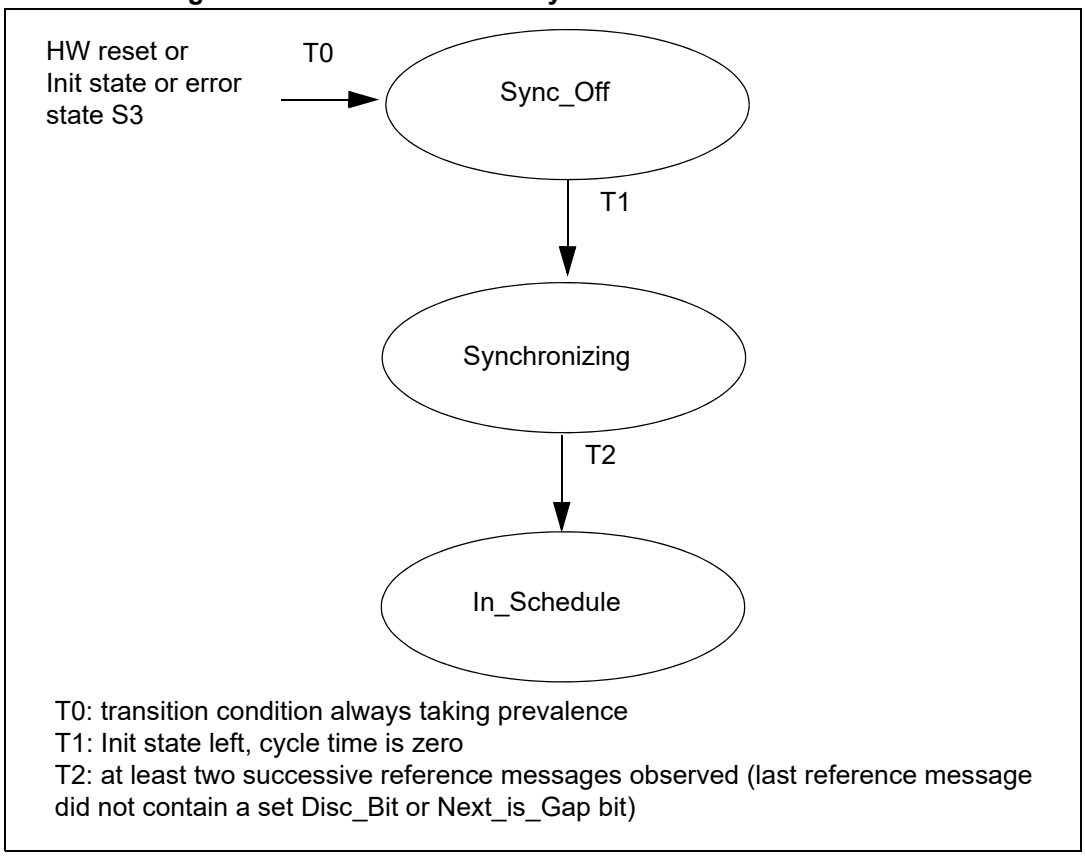
The reference message is configured as for Level 2 operation. Received reference messages are recognized by the identifier configured in register TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the Host sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:

- TTRMC
- TTOCF except EVTP, AWL, GEN
- TTMLM except ENTT, TXEW
- TURCF

Level 0 operation is controlled via:

- TTOCN except NIG, TMG, FGP, GCS, TTMIE
- TTGTP
- TTTMK
- TTIR excluding bits CER, AW, IWT SE2, SE1, TXO, TXU, SOG (no function)
- TTIR the following bits have changed function
  - TTMI not defined by trigger memory: activated at cycle time TTOCF[IRTO] $\times$ 0x200
  - WT not defined by trigger memory: activated at cycle time 0xFF00



Level 0 operation is signaled via:

- TTOST excluding bits AWE, WFE, GSI, GFI, RTO (no function)

48.4.18.1 Synchronizing

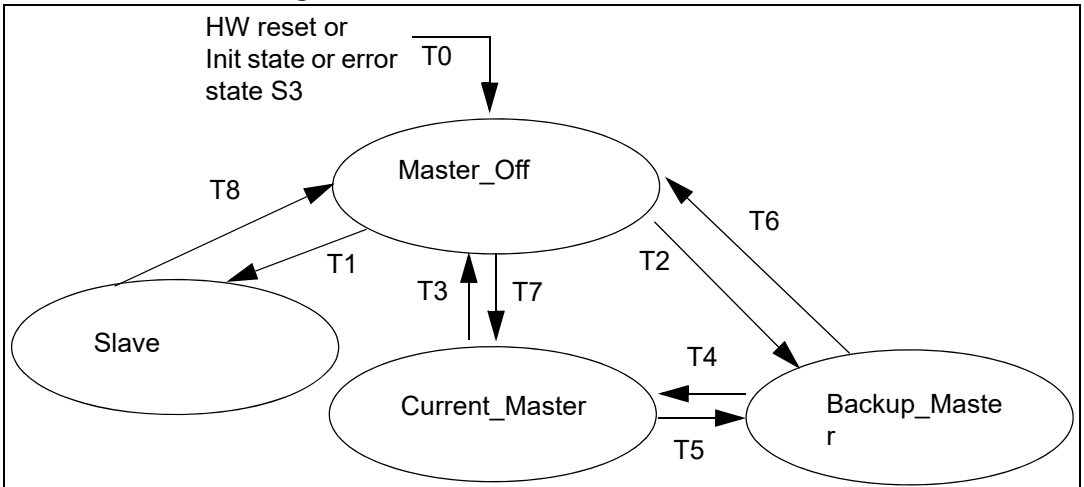
Figure 855 describes the states and state transitions in M_TTCAN Level 0 operation. Level 0 has no In_Gap state.

Figure 855. Level 0 schedule synchronization state machine

48.4.18.2 Handling of error levels

During Level 0 operation only the following error conditions may occur:

- Watch_Trigger_Reached (S3), reached cycle time 0xFF00
- CAN_Bus_Off (S3)



Since no S1 and S2 error are possible, the error level can only switch between S0 (No Error) and S3 (Severe Error). In M_TTCAN Level 0 an S3 error is handled differently. When error level S3 is reached, both TTOST[SYS] and TTOST[MS] are reset, and interrupt flags TTIR[GTE] and TTIR[GTD] are set.

When error level S3 (TTOST[EL] = ‘11’) is entered, bus monitoring mode is, contrary to M_TTCAN Level 1 and Level 2, not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.

48.4.18.3 Master slave relation

Figure 856 below describes the master slave relation in M_TTCAN Level 0. In case of an S3 error the M_TTCAN returns to state Master_Off.

Figure 856. Level 0 master to slave relation

T0: transition condition always taking prevalence
T1: reference message observed when not potential time master
T2: reference message observed with master priority ≠ own master priority, error state ≠ S3
T3: reference message observed with master priority = own master priority, error state ≠ S3
T4: reference message observed with own master priority

48.4.19 Synchronization to external time schedule

This feature can be used to synchronize the phase of the M_TTCAN's schedule to an external schedule (such as that of a second M_TTCAN network or FlexRay network). It is applicable only when the M_TTCAN is current time master (TTOST[MS] = '11').

External synchronization is controlled by event trigger input pin. If bit TTOCN[ESCN] is set, a rising edge at the event trigger pin the M_TTCAN compares its actual cycle time with the target phase value configured by TTGTP[CTP].

Before setting TTOCN[ESCN] the Host has to adapt the phases of the two time schedules such as by using the M_TTCAN gap control (refer to *Section 48.4.12*). When the Host sets TTOCN[ESCN], TTOST[SPL] is set.

If the difference between the cycle time and the target phase value TTGTP[CTP] at the rising edge at M_TTCAN event trigger pin is greater than 9 NTU, the phase lock bit TTOST[SPL] is reset, and interrupt flag TTIR[CSM] is set. TTOST[SPL] is also reset (and TTIR[CSM] is set), when another node becomes time master.

If both TTOST[SPL] and TTOCN[ESCN] are set, and if the difference between the cycle time and the target phase value TTGTP[CTP] at the rising edge at event trigger pin is less or equal 9 NTU, the phase lock bit TTOST[SPL] remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

Note: The rising edge detection at event trigger pin is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with TTGTP[CTP]. All further edges until the beginning of the next basic cycle are ignored.

48.5 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes in one CAN subsystem and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note: From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

48.5.1 Features

- Active low asynchronous reset
- 1–CPU + up to 5–CAN arbiter
- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth
- Time slot is defined as one peripheral clock cycle

48.5.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
  - CPU obtains every 2nd slot
  - CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
  - CPU obtains no time slots
  - CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains every 2nd time slot
  - Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains no time slots
  - Active CAN 1/2 obtains every 2nd time slot

48.6 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are detailed in *Section 48.11: Shared memory map*.

48.6.1 ECC controller

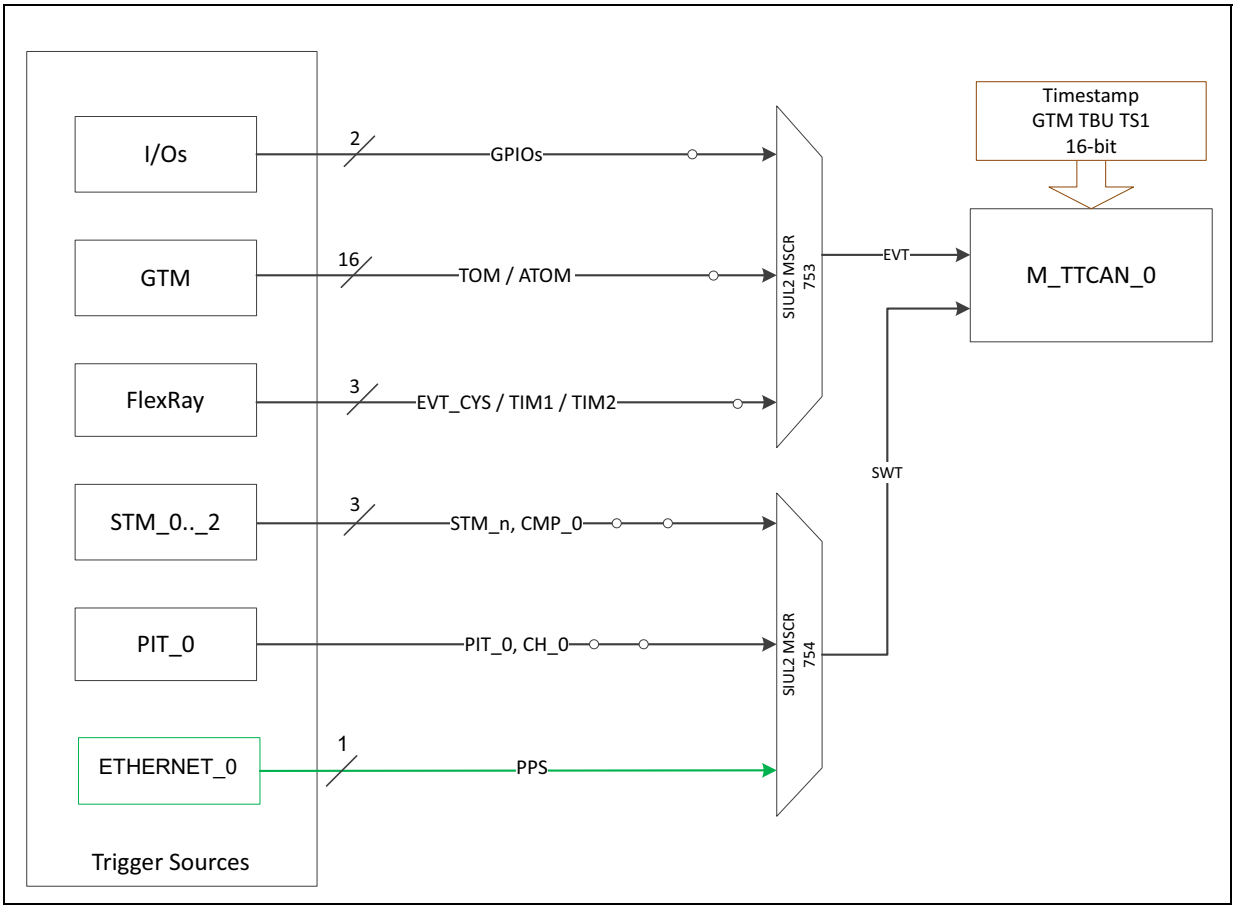
The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access. The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2 bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors displays the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

48.6.1.1 Features



The ECC module supports the following:

- ecc_error = ‘00’ No error is detected in the read data from memory
- ecc_error = ‘01’ This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.
- ecc_error = ‘10’ This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- ecc_error = ‘11’ This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

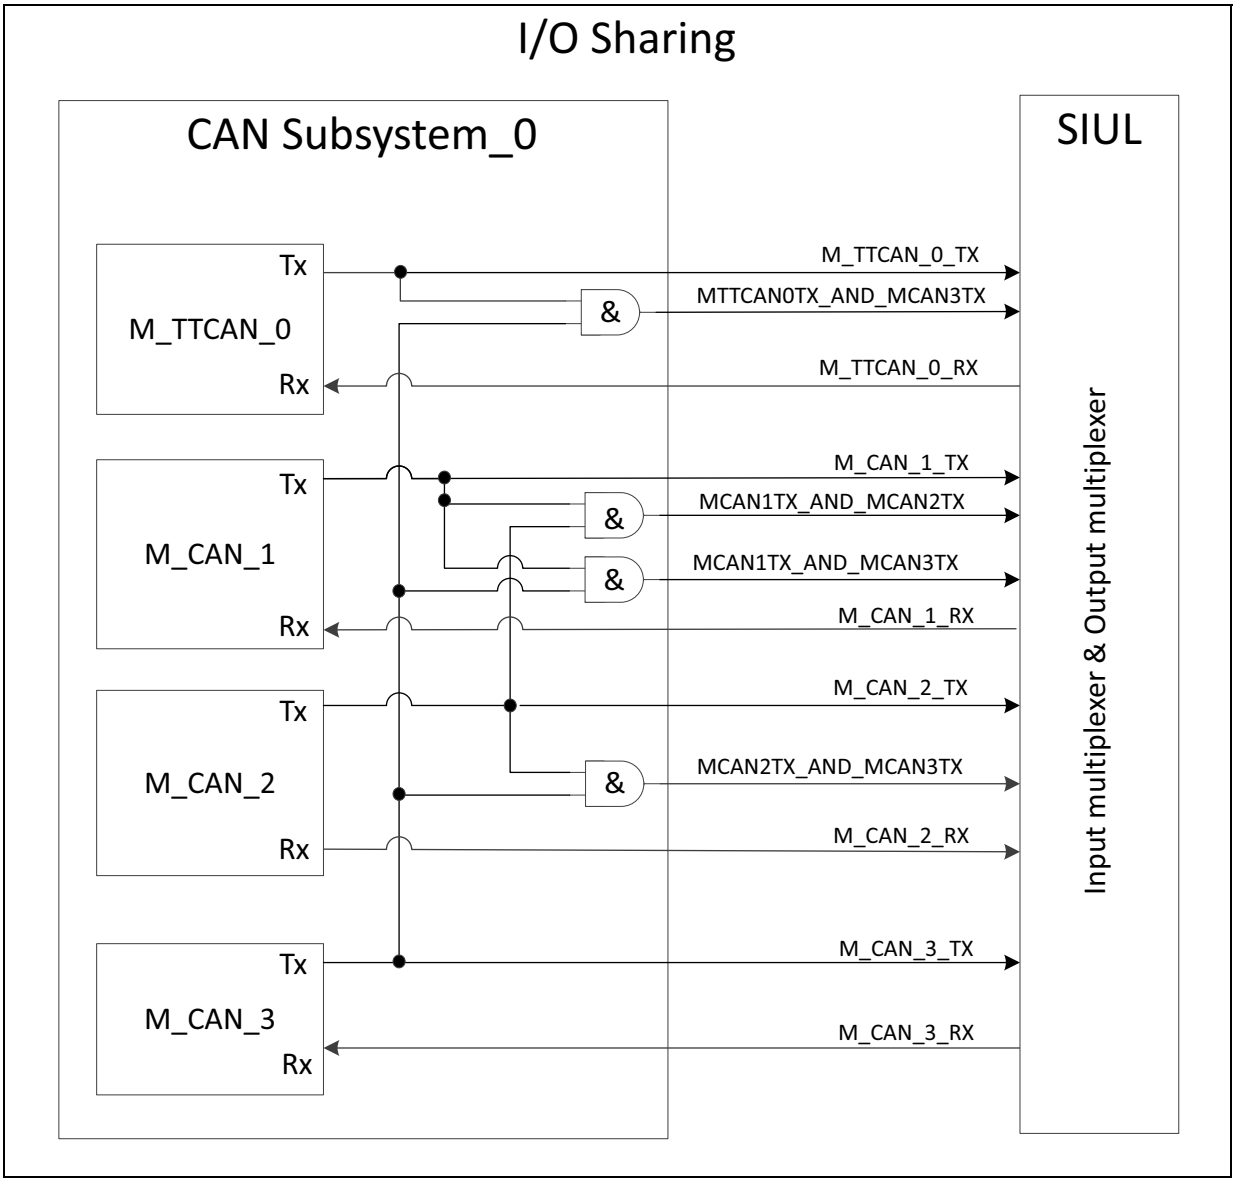
48.7 Time Triggered CAN matrix and basic cycles management

Figure 857 shows hardware control for M_TTCAN cycles management.

Figure 857. Hardware control for M_TTCAN cycles management

48.8 CAN nodes I/Os sharing

In standard applications each M_CAN node has got several multiplexing options in SIUL2 module to map its Tx/Rx signals on GPIO pairs different to those GPIO pairs used by other M_CAN nodes.



In addition there are special applications which require to share the same GPIO pair between two M_CAN nodes. Such use cases are, for example, applications where more than the maximum supported 128 message ID filters are required on one CAN bus node. For this purpose, two M_CAN modules can be operated in parallel on the same GPIO pairs in order to have message filter capability of both M_CAN modules available on the same physical interface.

To support this special use case the CAN Subsystem_0 provides some logic gates to connect two M_CAN Tx signals at the same time to one GPIO pin used as common CAN Tx. On the M_CAN Rx pin no further logic is required because both M_CAN nodes can select the same GPIO as Rx input at the same time without any interference.

Thanks to this implementation the standard arbitration mechanism between different nodes on the CAN bus is also working between these two connected M_CAN nodes on the same silicon without having any physical interface between.

The selection of the AND-connected Tx functionality is available as multiplexing option for several GPIO pins in the SIUL2 module. The implementation of the CAN nodes I/Os sharing is shown in *Figure 858*.

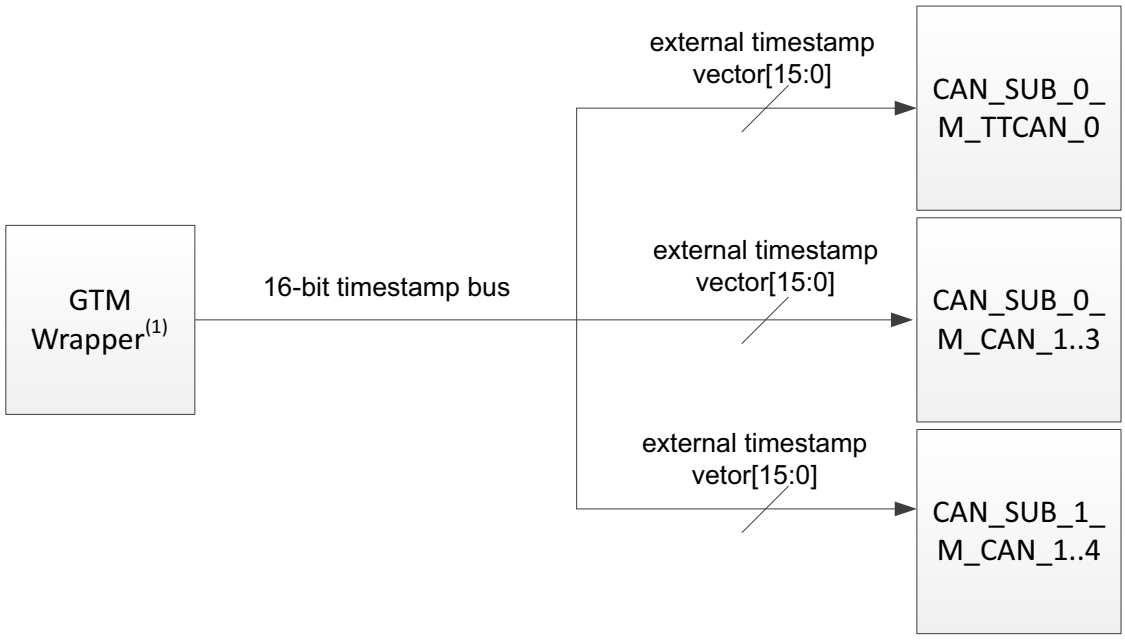


Figure 858. I/O sharing in CAN Subsystem_0

48.9 External Time Stamp

The external 16-bit time stamp bus of all M_CAN and M_TTCAN nodes is connected to the 16-bit of the GTM Wrapper time base unit as shown in *Figure 859*.

Figure 859. CAN external time base

1. For details see *Chapter 45: GTM344 Integration (GTMINT) Module*.

48.10 External signal description

The CAN subsystem has the following external pins.

- M_CAN_x_RX: M_CAN x receive input
- M_CAN_x_TX: M_CAN x transmit output
- M_TTCAN_x_RX: M_TTCAN x receive input
- M_TTCAN_x_TX: M_TTCAN x transmit output
- M_CAN_x_RXFD: M_CAN_x Receive Fast Data control signal
- M_CAN_x_TXFD: M_CAN_x Transmit Fast Data control signal

48.11 Shared memory map

Table 948 shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 948. Shared memory map versus CAN transmit, receive and filters elements

Start Address Offset (byte)	End Address Offset (byte)	CAN block/sub block		Comment
CAN Subsystem_0 - PBRIDGE_2				
0x0000	0x7BFF	CAN_SUB_0_M_TTCAN_0 CAN_SUB_0_M_CAN_1 CAN_SUB_0_M_CAN_2 CAN_SUB_0_M_CAN_3	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 1	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			M_TTCAN triggers	
CAN Subsystem_1 - PBRIDGE_1				
0x0000	0x3DFF	CAN_SUB_1_M_CAN_1 CAN_SUB_1_M_CAN_2 CAN_SUB_1_M_CAN_3 CAN_SUB_1_M_CAN_4	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 2	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			Reserved	

Note: There is no write access protection from a CAN module to the message memory space.

The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters, the Tx/Rx buffers and the triggers used, it is mandatory for the user to configure the start address registers, specified in Table 949, in order to fit the memory mapping specified in Table 948.

The CPU uses the peripheral interface to access the memory locations. It must be noted that there is no transfer error reported to the CPU in case of access to reserved memory locations.

Table 949. Detailed mapping in CAN sub-blocks

CAN sub-block	Element name	Comment
Standard Filters	Standard Message ID filter 0 ... Standard Message ID filter 127	address configured in SIDFC [FLSSA]
Extended Filters	Extended Message ID filter 0 ... Extended Message ID filter 63	address configured in XIDFC [FLESA]
Rx FIFO0	Rx FIFO0 element 0 ... Rx FIFO0 element 63	address configured in RXF0C[F0SA]
Rx FIFO1	Rx FIFO1 element 0 ... Rx FIFO1 element 63	address configured in RXF1C[F1SA]

M_TTCAN triggers (on M_TTCAN0 only)	Trigger element 0 --- Trigger element 63	address configured in TMC[TMSA]

49 Serial Interprocessor Interface (SIPI)

49.1 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol that runs on top of the LFAST module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

49.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multi-master, multi-channel memory interface between two devices using few interconnecting signals.

Main scalable features:

- Number of concurrent channels:
  - Full Implementation = 4
  - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum Implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

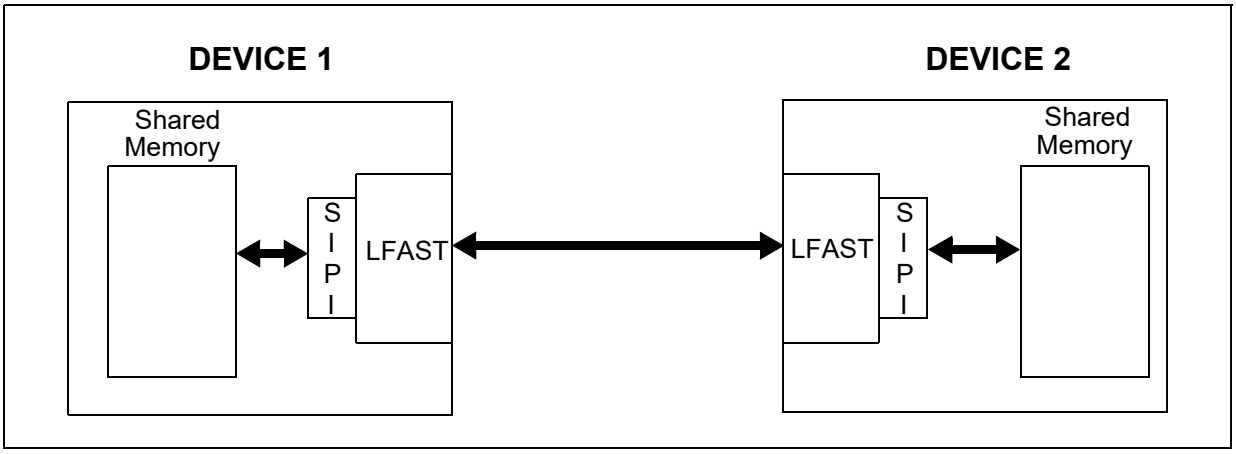
The rest of this section describes a full implementation of SIPI, which includes:

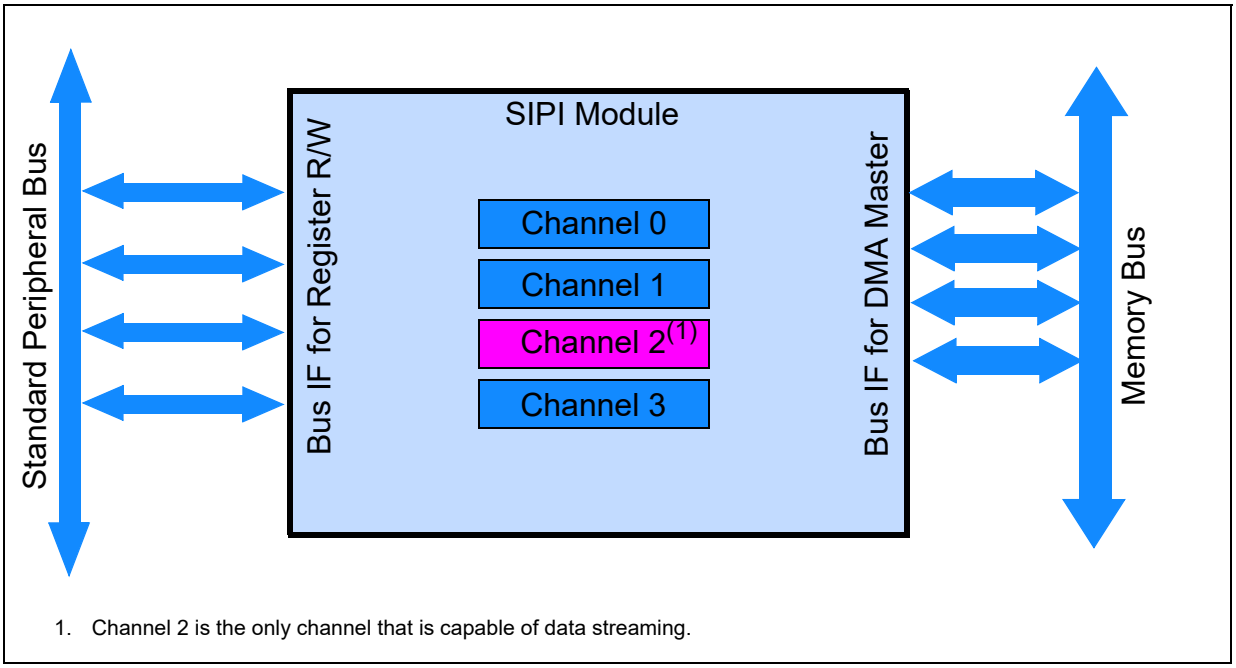
- Advanced High-Performance Bus (AHB-Lite) master interface
- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

49.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

Figure 860. Interprocessor communication diagram





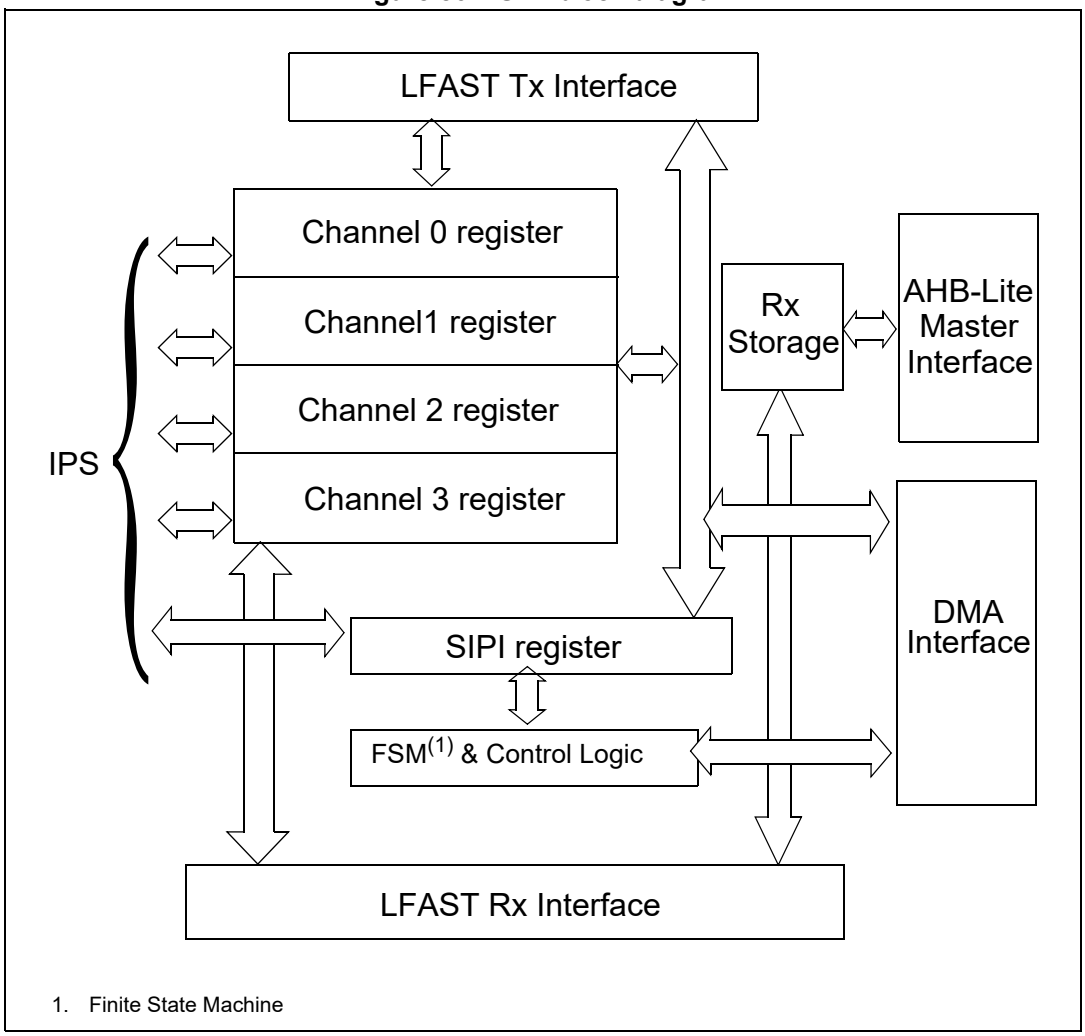


Figure 861. SIPI module

1. Channel 2 is the only channel that is capable of data streaming.

49.3 SIPI block diagram

Figure 862. SIPI block diagram

1. Finite State Machine

49.4 Feature description

This section describes the features of the SIPI module.

49.4.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface that is used by target node to access shared memory
- Up to two outstanding requests are supported at initiator

49.4.2 Standard features

- IPS bus interface
- SPP DMA2x bus interface
- AHB master interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

49.5 SIPI operation from reset

When the SIPI module exits reset, it is operational when SIPI_MCR[MOEN] = 1 and target mode SIPI_MCR[TEN]=1, without the need to configure more control registers.

49.6 Functional description

49.6.1 External signals

The SIPI has no chip external signals.

49.6.2 Frame format

All frames have the same general format:

- 16-bit header
- Address, address and data, or nothing
- 16-bit CRC

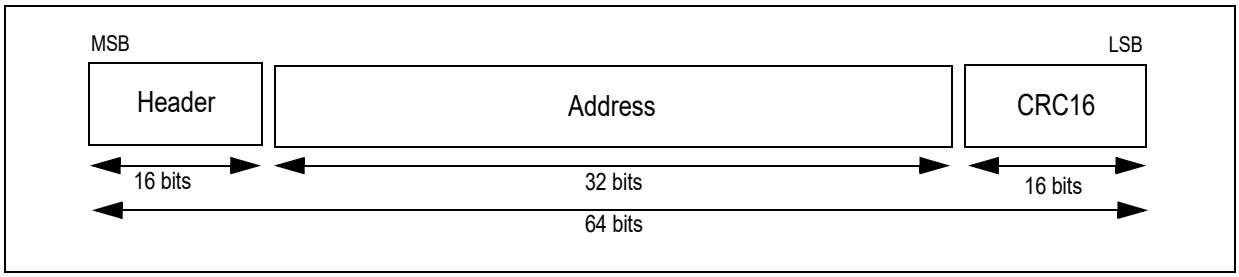
There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

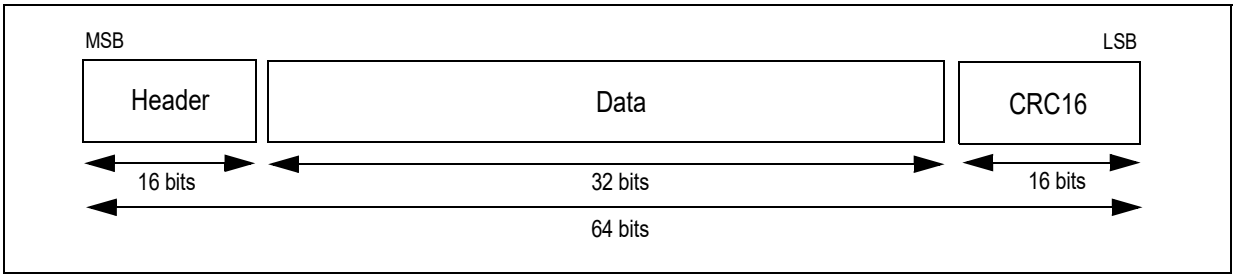
There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID.



The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

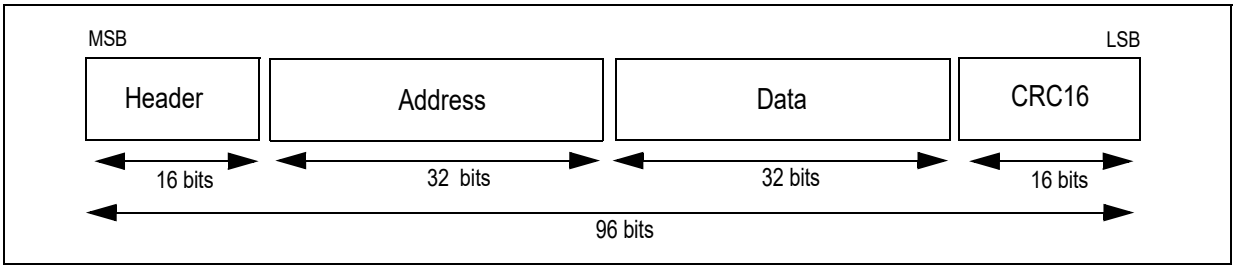
The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

Note: SIPI module architecture is always big endian but the storage in host memory depends on endianness architecture of host memory.



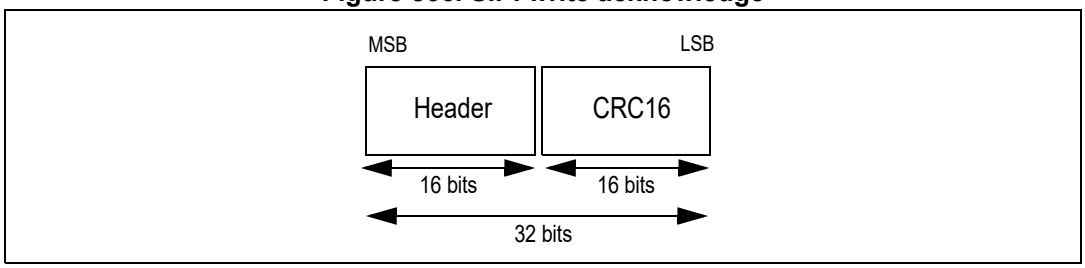
49.6.2.1 Register read request

Figure 863. SIPI register read request



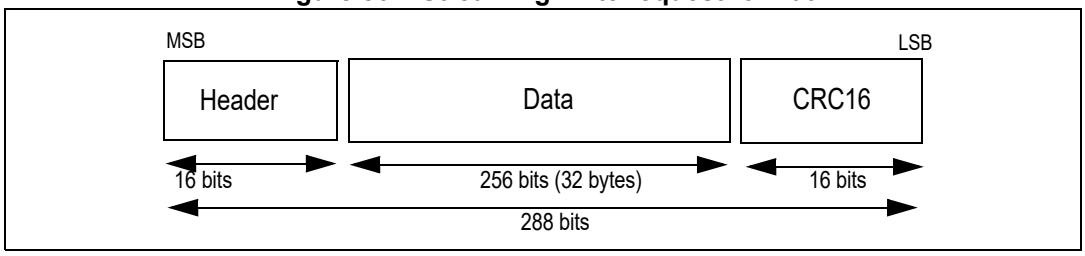
49.6.2.2 Register read response, ID request response

Figure 864. SIPI read response



49.6.2.3 Register write request

Figure 865. SIPI register write request



49.6.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

Figure 866. SIPI write acknowledge

49.6.2.5 Streaming write request

Figure 867. Streaming write request format

Note: Direct write operations (IPS) are used to set the streaming address (refer to Figure 875: Streaming transfer with data in Section 49.7.3.2.1: Streaming write transfer with address).

Streaming data write is performed using the format shown in Figure 867.

49.6.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

49.6.2.6.1 SIPI header coding

Figure 868, *Table 950*, *Figure 869*, and *Table 951* show how the SIPI header bits are coded.

Figure 868. SIPI header coding

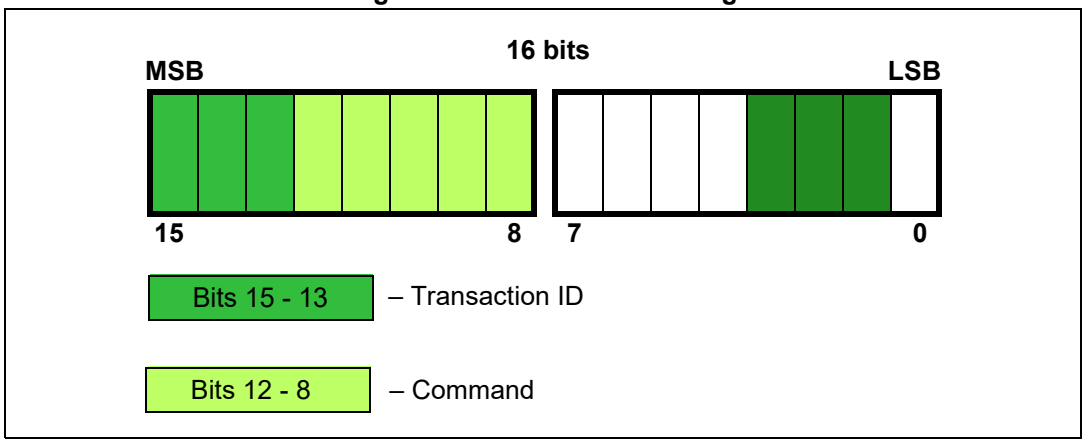


Table 950 shows the command coding for the bits[12:8] of the header.

Table 950. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
0x00	Read 8 bits	64
0x01	Read 16 bits	64
0x02	Read 32 Bits	64
0x03	Reserved	—
0x04	Write 8 bits with ACK	96
0x05	Write 16 bits with ACK	96
0x06	Write 32 bits with ACK	96
0x07	Reserved	—
0x08	ACK – OK	32
0x09	ACK – Fault	32
0x0A	Read Answer – OK	64
0x0B	Reserved	—
0x0C	Trigger comm with ACK	32
0x0D	Reserved	—
…	…	…
0x11	Reserved	—
0x12	ID Register Read Request	32
0x13	Reserved	—
…	…	…
0x16	Reserved	—
0x17	Stream Data with ACK (32 bytes)	288
0x18	Reserved	—

Table 950. SIPI header command coding (continued)

b[12:8] (hex)	Command	Payload Size
…	…	...
0x1F	Reserved	—

Figure 869 shows the content of bits[7:0] in the SIPI header.

Figure 869. SIPI header channel field

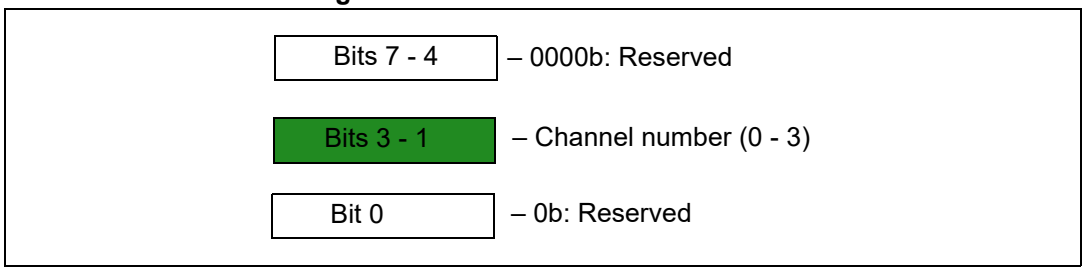

Table 951 shows the channel number coding.

Table 951. SIPI Header Channel Number Coding

SIPI channel name	Channel number coding in header(s)		Comment
	SIPI channel coding select bit		
	Code table I (1)	Code table II (0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

49.6.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

49.6.2.8 Payload field

Table 952 shows the payload sizes of LFAST frames.

Table 952. Payload size of LFAST channel frame

LFAST code for payload size	SIPI Code	LFAST payload size (bits)(1)	LFAST payload size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16
101b	101b	256	32
111b	111b	288	36

1. Only 32, 64, 96 and 288 bits sizes are used for SIPI.

Table 953 shows the coding of LFAST channel for a given SIPI channel code.

Table 953. Converted coding of LFAST channel code for SIPI headers

LFAST channel code	SIPI channel code	Data channel(1)
0100b	100b	Data channel A
0101b	101b	Data channel B
0110b	110b	Data channel C
0111b	111b	Data channel D
1000b	000b	Data channel E (not used by SIPI)
1001b	001b	Data channel F (not used by SIPI)
1010b	010b	Data channel G (not used by SIPI)
1011b	011b	Data channel H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

49.6.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). The data stream is transmitted with the MSB sent first.

49.6.2.9.1 CRC examples

Example 1 – 32-bit write on channel 1 with ID1

- Header = 0x260A
- Address = 0x1122_3344
- Data = 0xCCDD_EEFF
- CRC = 0xBF7D

Example 2 – 32-bit read on channel 2 with ID2

- Header = 0x420C
- Address = 0x89AB_CDEF
- CRC = 0x6B80

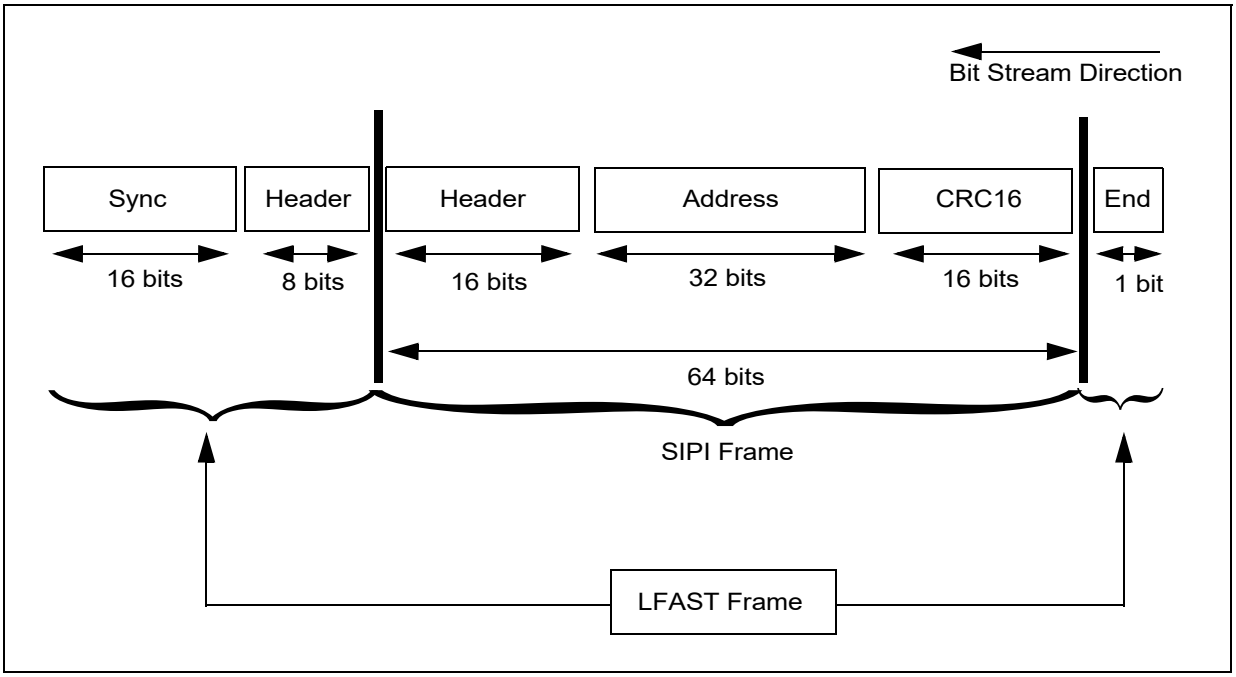
Example 3 – Event command on channel 3 with ID3

- Header = 0x6C0E
- CRC = 0xB286

49.7 Transfer types

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

49.7.1 Read transfer



A Read transfer can be of two types:

- Read request transfer (at initiator node)
- Read response transfer (at target node)

49.7.1.1 Register read request transfer

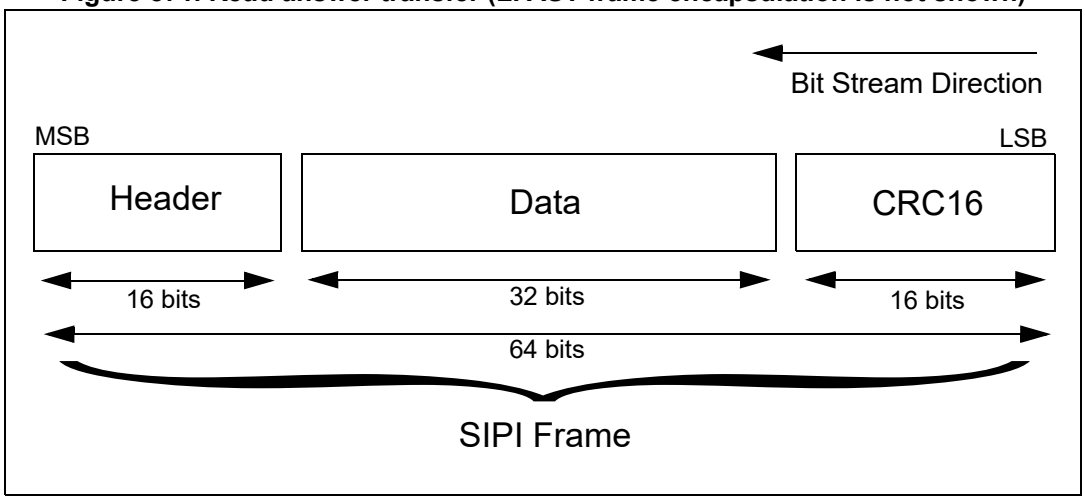
If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in *Figure 870*.

Figure 870. Read request transfer (showing LFAST frame encapsulation)

49.7.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (refer to *Figure 871*). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (refer to *Figure 872*).

Figure 871. Read answer transfer (LFAST frame encapsulation is not shown)



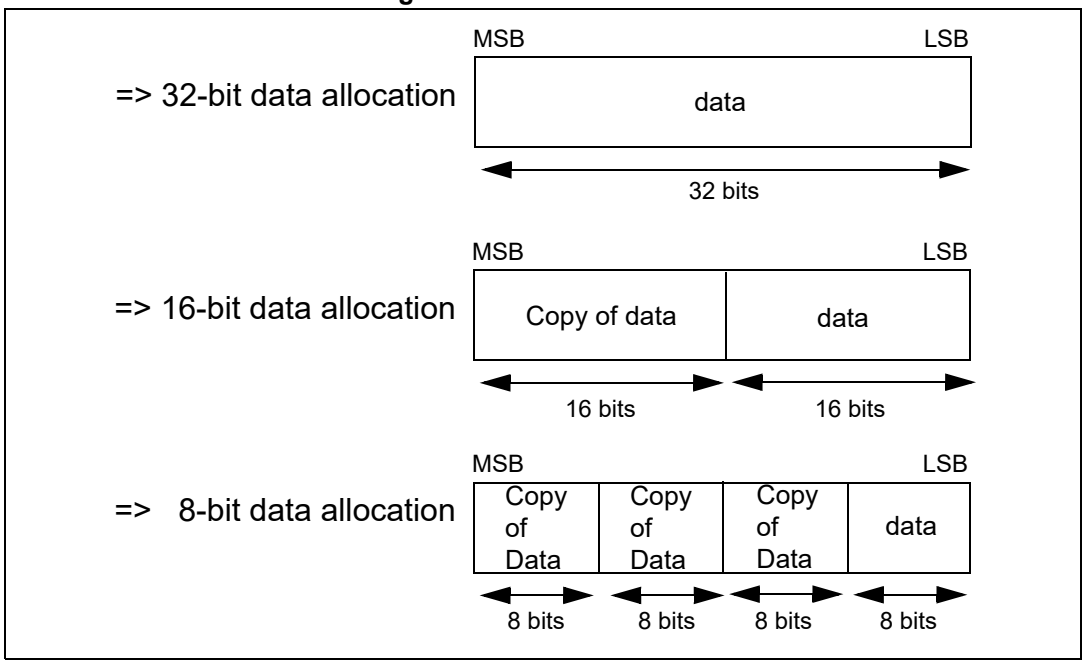


Figure 872. Data allocation

Note: For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables (big endian):

Bits[1:0]:

- *00: Byte 3 enabled (MSB)*
- *01: Byte 2 enabled*
- *10: Byte 1 enabled*
- *11: Byte 0 enabled (LSB)*

For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable (big endian).

Bit[0]:

- *0: Half-word 1 enabled (MSB)*
- *1: Half-word 0 enabled (LSB)*

Note: Byte Ordering depends from address written in CAR and transfer width:
Example:

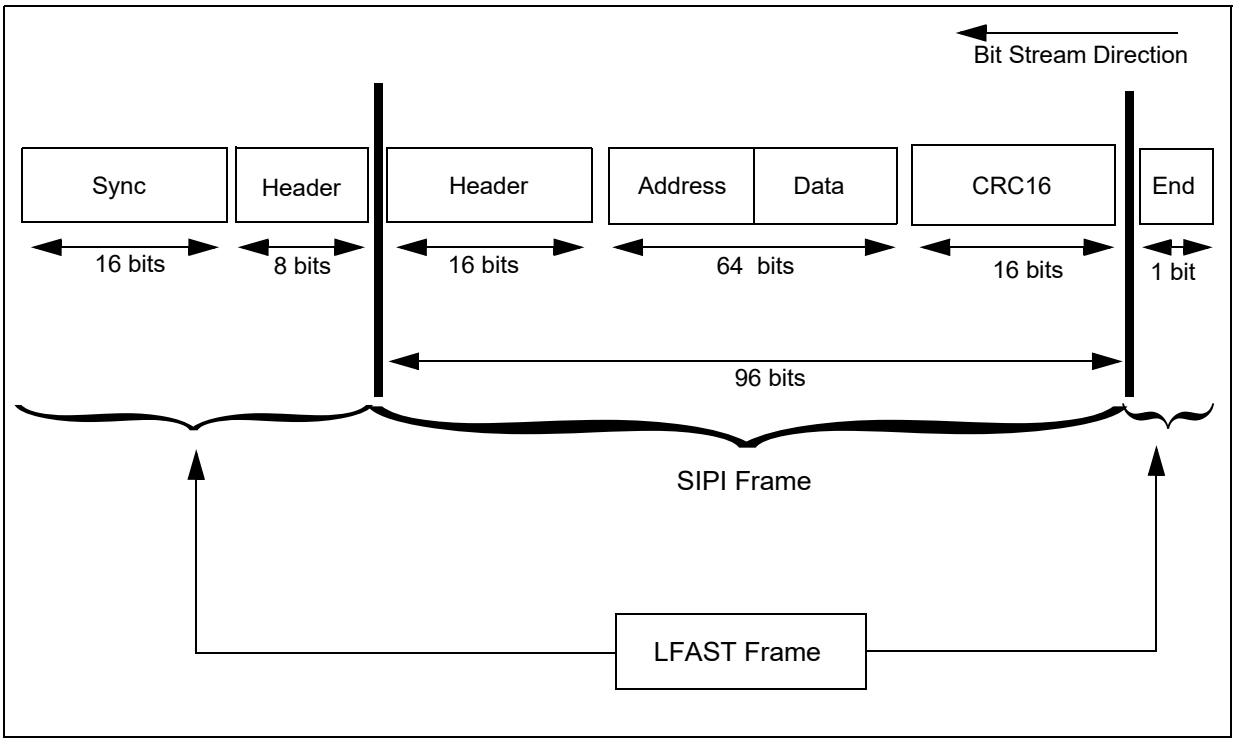
- *CDR content: 0x12345678*
- *CAR content: see table columns*

Table 954. Target Memory content dependent from CAR content

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
32-bit transfer	0x02040	12	12	12	12
	0x02041	34	34	34	34
	0x02042	56	56	56	56
	0x02043	78	78	78	78

Table 954. Target Memory content dependent from CAR content (continued)

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
16-bit transfer	0x02040	12	56	xx	xx
	0x02041	34	78	xx	xx
	0x02042	xx	xx	12	56
	0x02043	xx	xx	34	78
8-bit transfer	0x02040	12	xx	xx	xx
	0x02041	xx	34	xx	xx
	0x02042	xx	xx	56	xx
	0x02043	xx	xx	xx	78



49.7.3 Register write transfer

Register write transfer can be of two types:

- Normal write transfer – channels 0, 1, 2 and 3
- Streaming Data transfer – channel 2 only

A Register write transfer can be done through Normal write transfer - channels 0, 1, 2 and 3 (refer to *Section 49.7.3.1: Normal write transfer*) as shown in *Figure 873*.

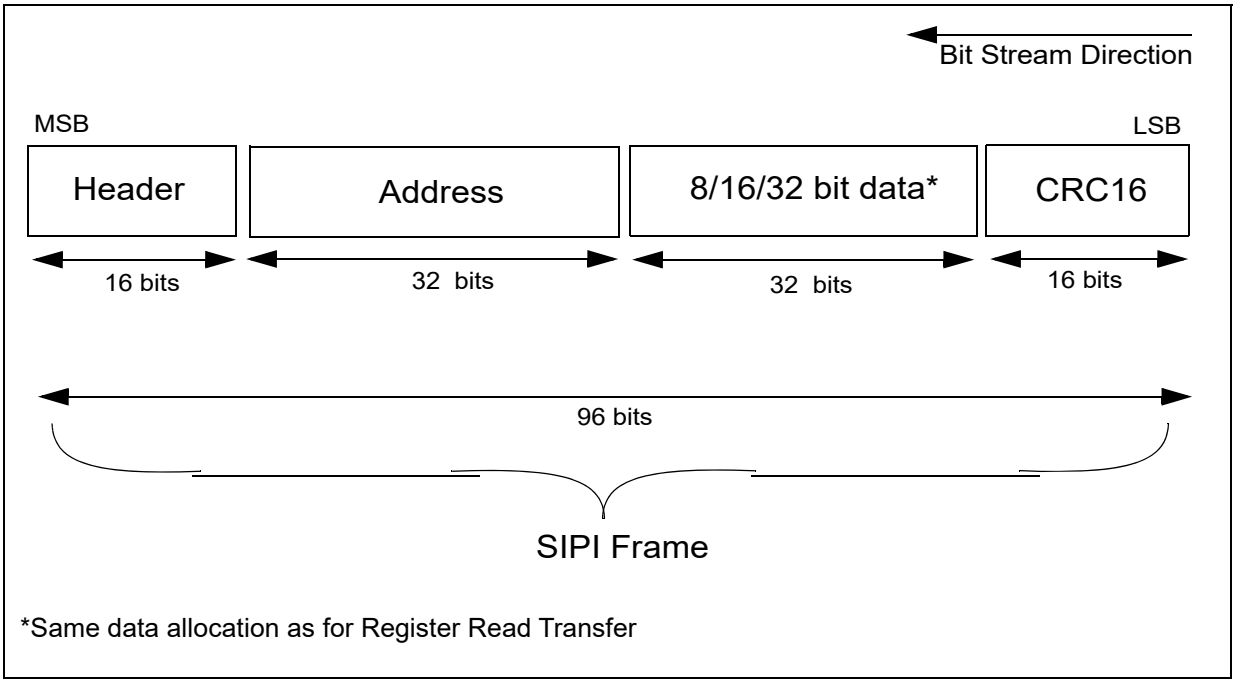


Figure 873. Register write transfer (showing LFAST frame encapsulation)

49.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and 16-bit CRC as shown in *Figure 874*.

Figure 874. Write transfer (LFAST frame encapsulation is not shown)

Note: In the case of an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as a byte enable:

Bits[1:0]:

- *00 – byte 3 enabled (MSB)*
- *01 – byte 2 enabled*
- *10 – byte 1 enabled*
- *11 – byte 0 enabled (LSB)*

In the case of a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as a half-word enable:

Bit[0]:

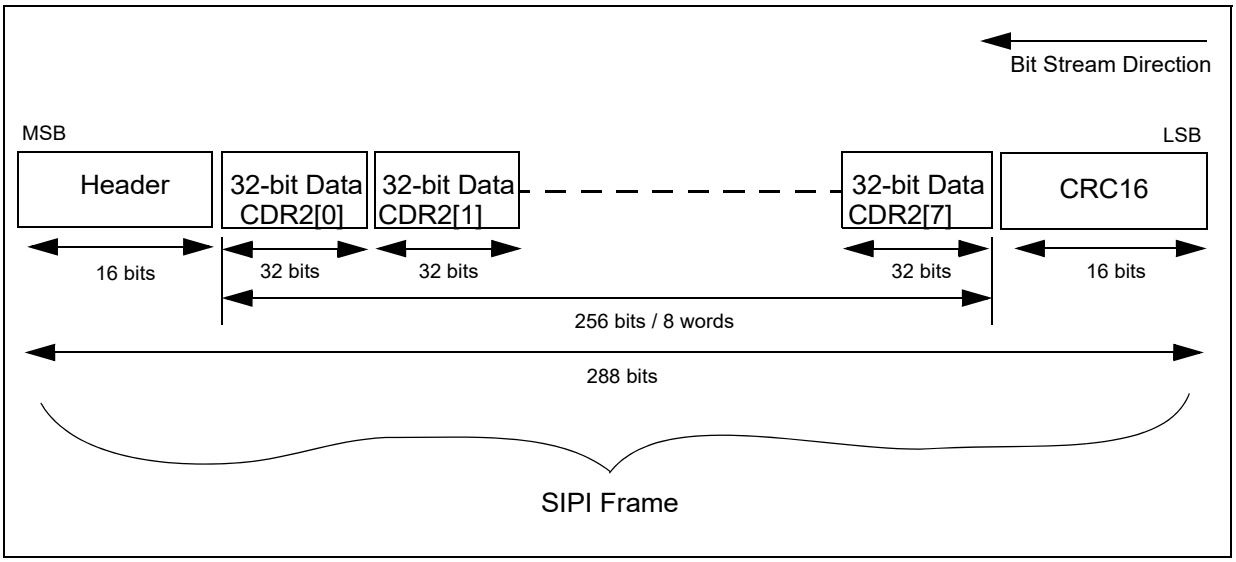
- *0 – half-word 1 enabled (MSB)*
- *1 – half-word 0 enabled (LSB)*

49.7.3.2 Streaming write transfer

Streaming write transfers have 256 bits of payload.

49.7.3.2.1 Streaming write transfer with address

The related registers need to be set on target side using direct register write (32-bit).



Setting the address is performed using a direct register write. SIPI_MAXCR and SIPI_ARR are written before the SIPI_ACR. This is to ensure that the unwanted behavior of the SIPI

trying to access non-shared memory is avoided. This is only true for the very first streaming command, subsequent streaming command(s) may not have the need to write SIPI_MAXCR and SIPI_ARR (refer to *Section 49.15.1.10: SIPI Max Count Register (SIPI_MAXCR)*, *Section 49.15.1.12: SIPI Address Count Register (SIPI_ACR)*, and *Section 49.15.1.11: SIPI Address Reload Register (SIPI_ARR)*.

49.7.3.2.2 Streaming transfer with data

Figure 875 shows the packet structure of streaming transfers that contain data.

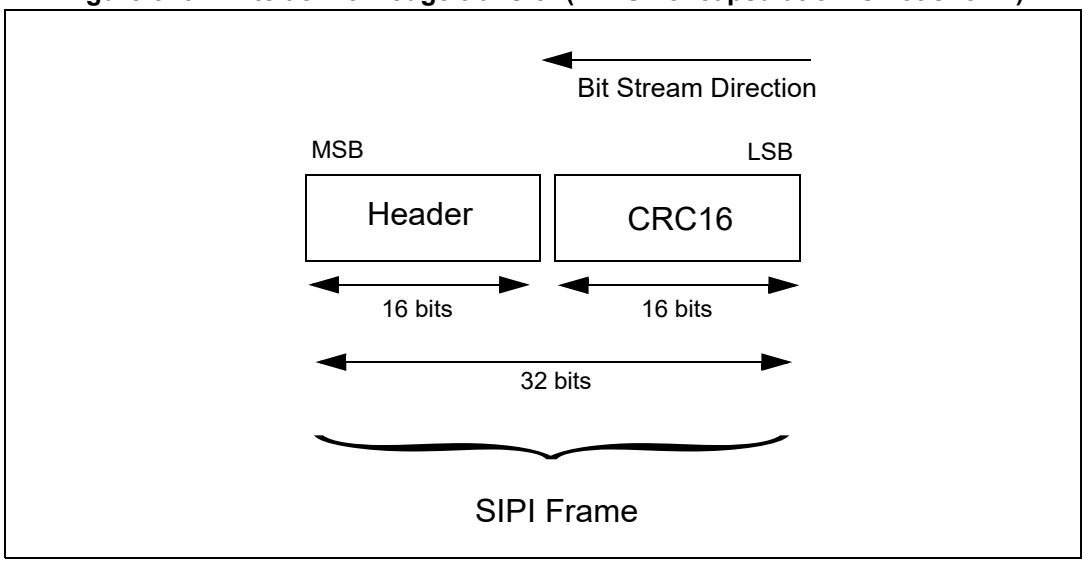


Figure 875. Streaming transfer with data

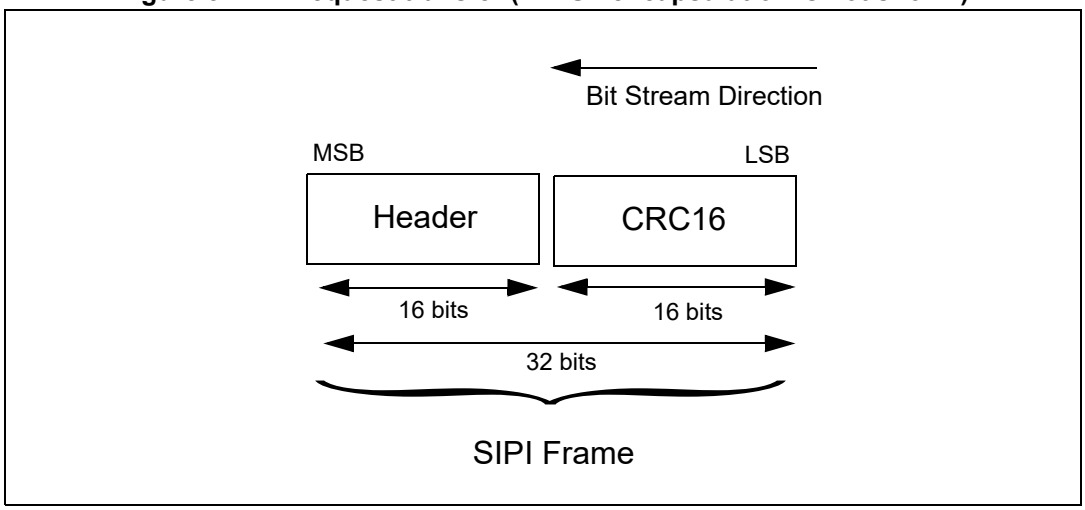
49.7.4 Write acknowledge transfer

A write acknowledge transfer contains only header and CRC bits (refer to *Figure 876*). The CRC bits are calculated on the header field.

Figure 876. Write acknowledge transfer (LFAST encapsulation is not shown)



49.7.5 ID request response

49.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in *Figure 877*.

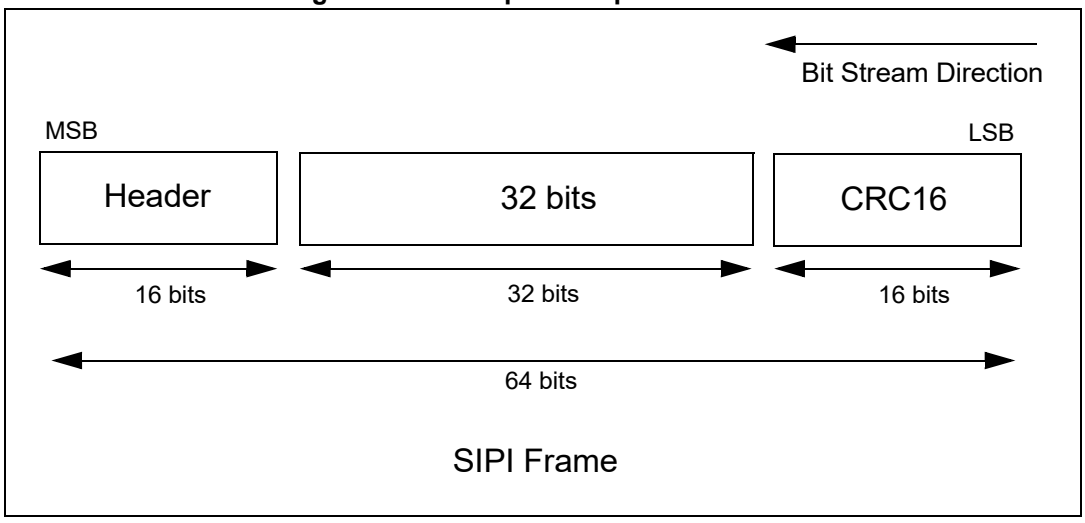


Figure 877. ID request transfer (LFAST encapsulation is not shown)

49.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in *Figure 878*.

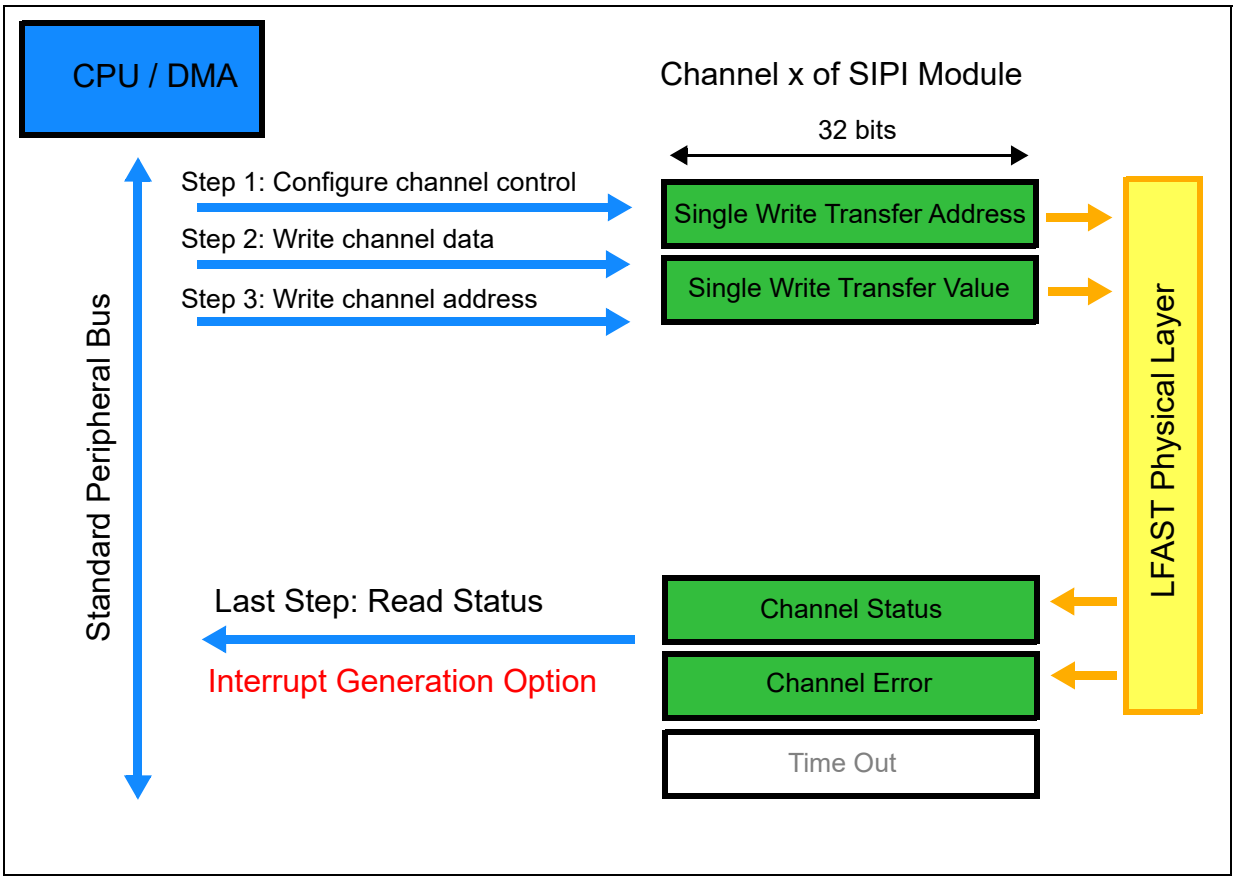

Figure 878. ID request response transfer

Note: The ID request response contains the value of the CHIP ID in place of data.

49.8 Transfer API and flow charts

Figure 879. SIPI single register write API

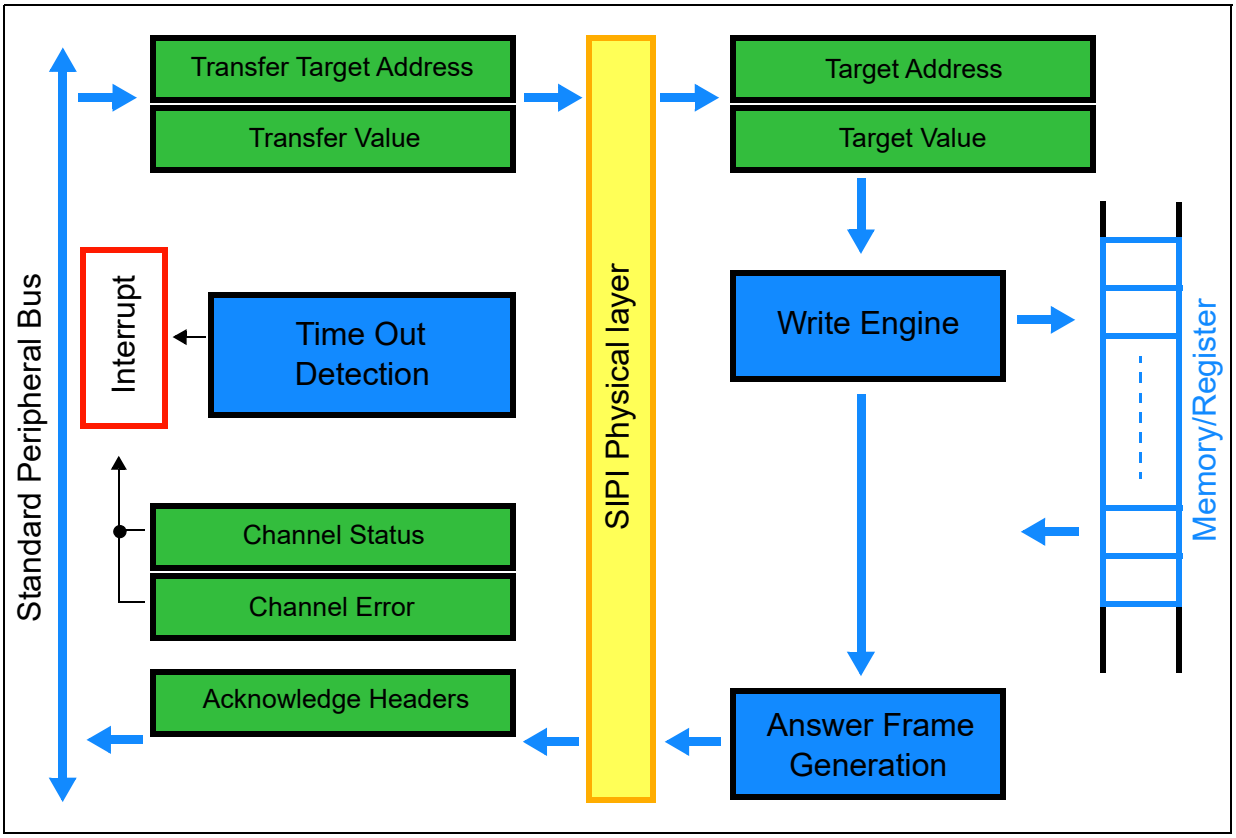
For a single write transfer request generation (refer to *Figure 879*):

1. Configure SIPI_CCR*n* at the initiator node.
2. Write data in SIPI_CDR*n* at the initiator node.
3. Configure SIPI_CAR*n* at the initiator node.
   As soon as the channel address register (SIPI_CAR*n*) is written and if SIPI_CCR*n*[CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.
4. Software polls the status register bits (CSR*n*) to determine when the request completes, SIPI_CSR*n*[ACKR] = 1. An interrupt will be generated if the corresponding SIPI_CIR*n*[ACKIE] = 1.

On a single write transfer request reception (refer to *Figure 880*):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process in completed, the target node will generate an acknowledge frame and send it back to the LFAST.

Figure 880. SIPI single register write API – Flow chart



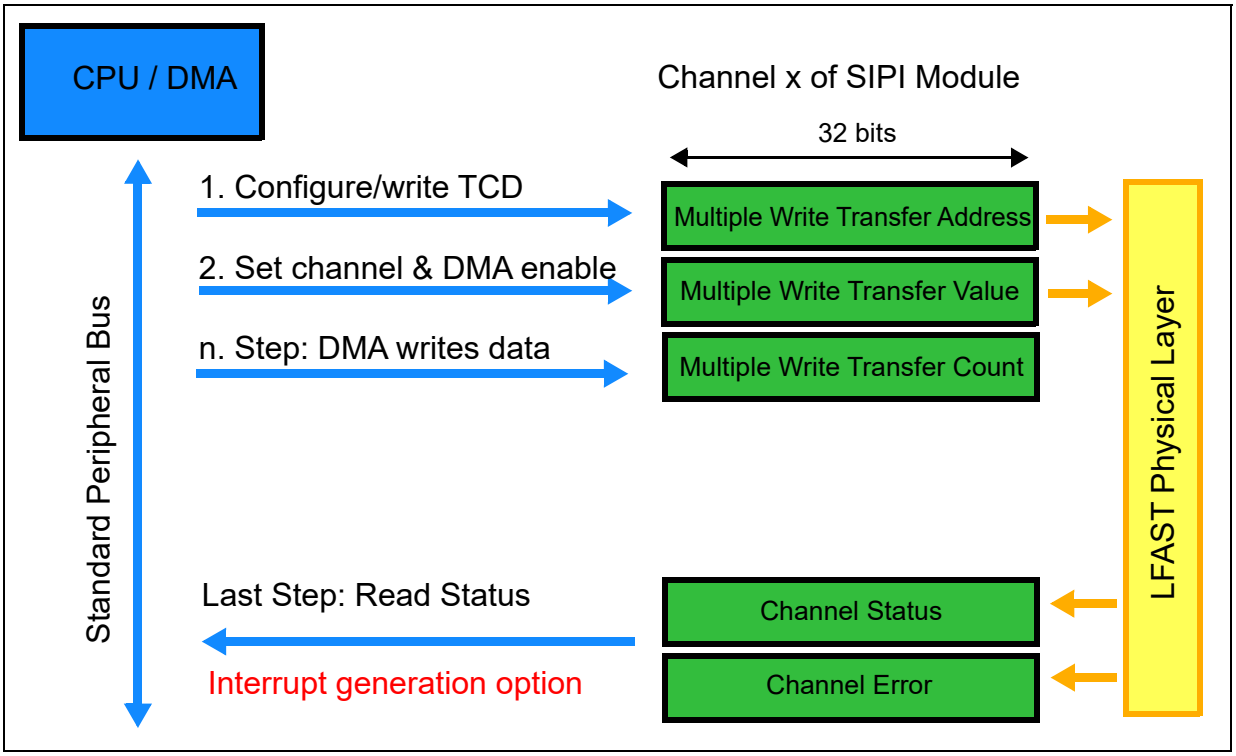


Figure 881. SIPI multiple register write API

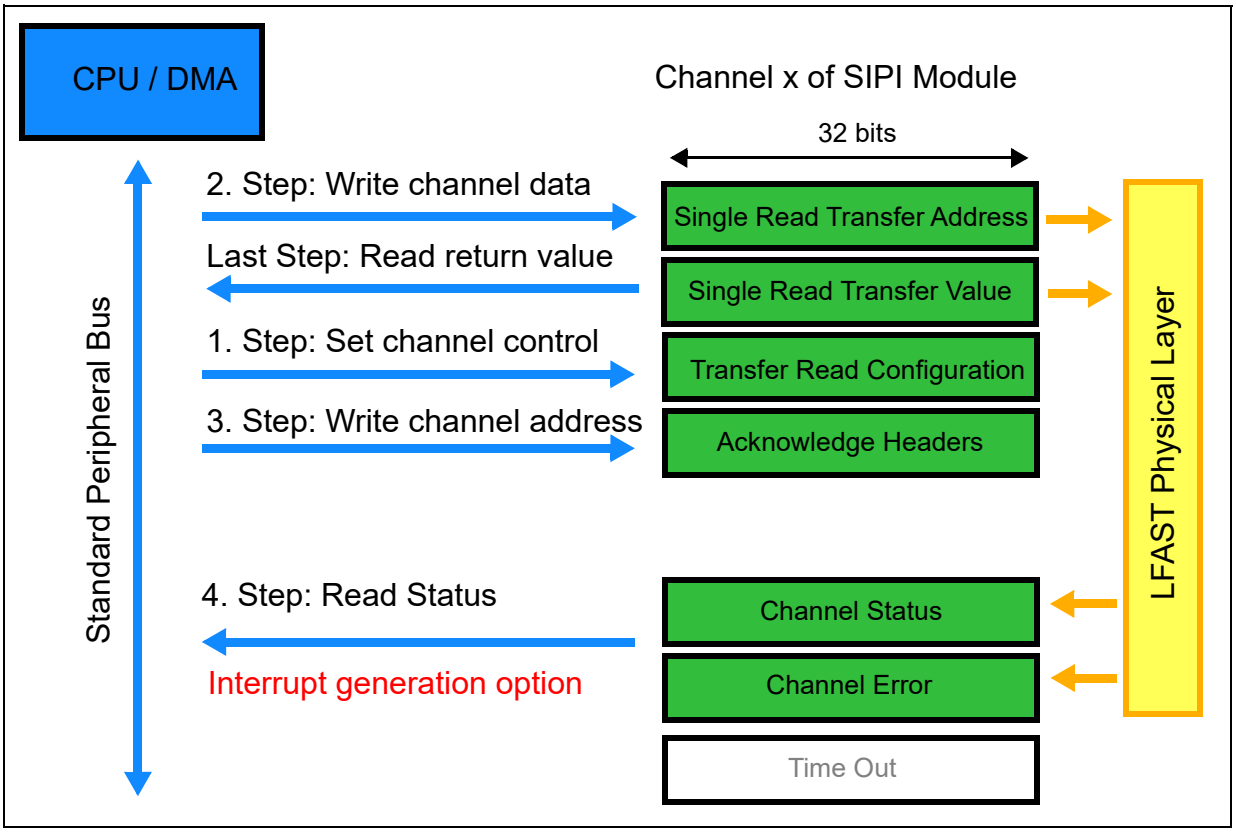


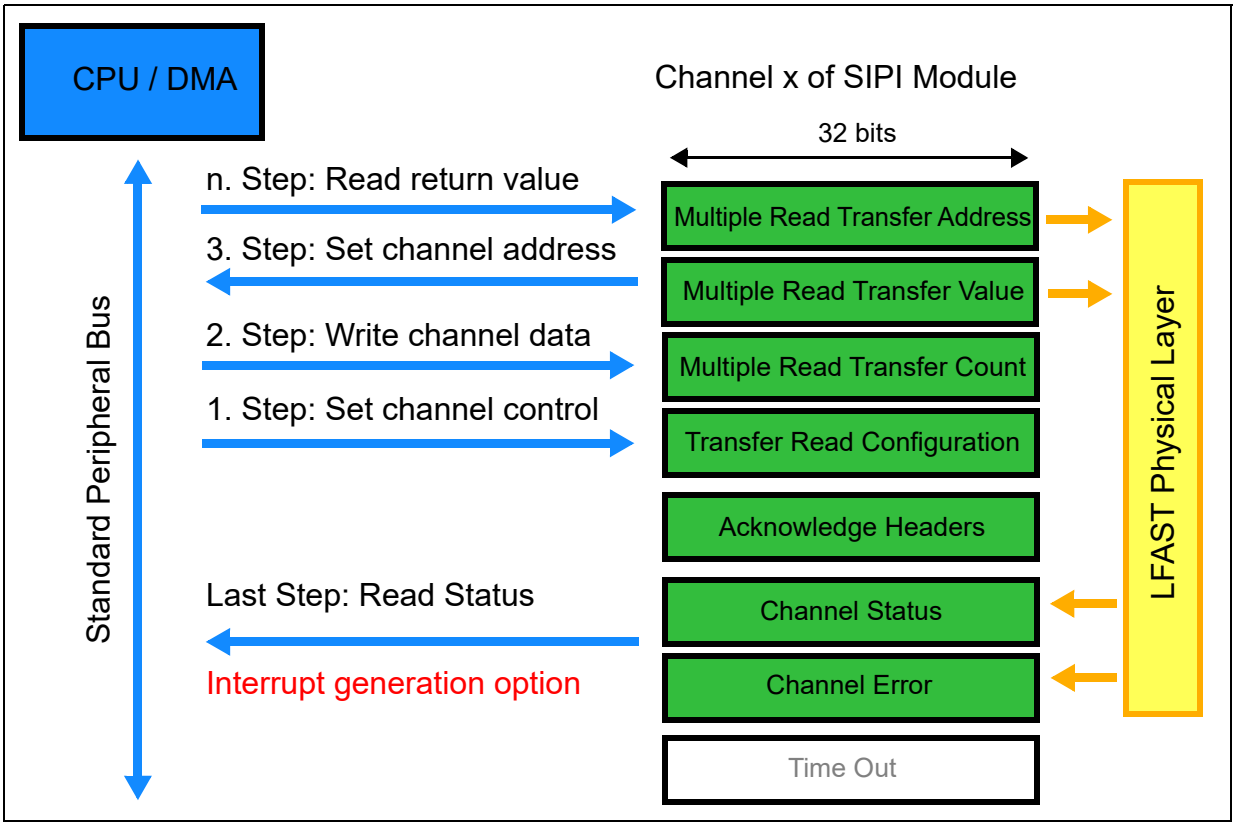
For multiple write transfer request (including streaming) generation (refer to *Figure 881*):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write SIPI_CCR*n*[CHEN] = 1 and SIPI_CCR*n*[DEN] = 1.
3. SIPI will generate request (DMA Request) and send it to the DMA controller.
4. SIPI will start copying data into the SIPI_CDR*n* through its DMA interface, depending on the transfer count and data registers size.
5. When the copying process is completed, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST after SIPI_CARx (SIPI_CAR2 is valid for streaming mode only) is written.
6. Software should poll the SIPI_CSR*n* status register bits to determine if the request has completed. If SIPI_CSR*n*[ACKR] = 1, an interrupt will be generated (if the corresponding SIPI_CIR*n*[ACKIE] = 1).
7. If SIPI_CCR*n*[DEN] = 1, the SIPI request will generate a request and send it to the DMA controller. If not, the request will not be sent and the state machine will enter idle mode.
8. Steps 4 to 7 will be repeated.

On multiple write transfer request reception (refer to *Figure 881*):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process is completed, target node will generate an acknowledge frame and send it back to the LFAST.

Figure 882. SIPI single register read API



For single read transfer request generation (refer to *Figure 882*):

1. Software/DMA will configure SIPI_CCR*n,* with the last step by writing SIPI_CAR*n*.
2. As soon as SIPI_CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll SIPI_CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1, and interrupt will be generated (if SIPI_CIR*n*[RAIE] = 1). If SIPI_CSR*n*[RAR] does not set then SIPI_ERR[TOE*n*] = 1, which indicates a timeout has occurred.
4. If SIPI_CSR*n*[RAR] = 1, then software can read the data register, or can take other necessary action if SIPI_CSR*n*[RAR] = 0.

On single read transfer request reception (refer to *Figure 882*):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process in completed, target node will send read response back to LFAST.

Figure 883. SIPI multiple register read API

For multiple read transfer request generation (refer to *Figure 883*):

1. Software/DMA will configure SIPI_CCR*n,* with the last step by writing SIPI_CAR*n*.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then start transmitting data to the LFAST.
3. Software should poll SIPI_CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1 and SIPI_CIR*n*[RAIE] = 1, an interrupt will be generated. If SIPI_CSR*n*[RAR] does not set, then SIPI_ERR[TOE*n*] = 1, which indicates a timeout.
4. Steps 2 to 3 will be repeated for multiple requests.

On multiple read transfer request reception (refer to *Figure 883*):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

Figure 884, *Figure 885*, *Figure 886* and *Figure 887* show the SIPI data streaming of data.

Figure 884. SIPI data stream model

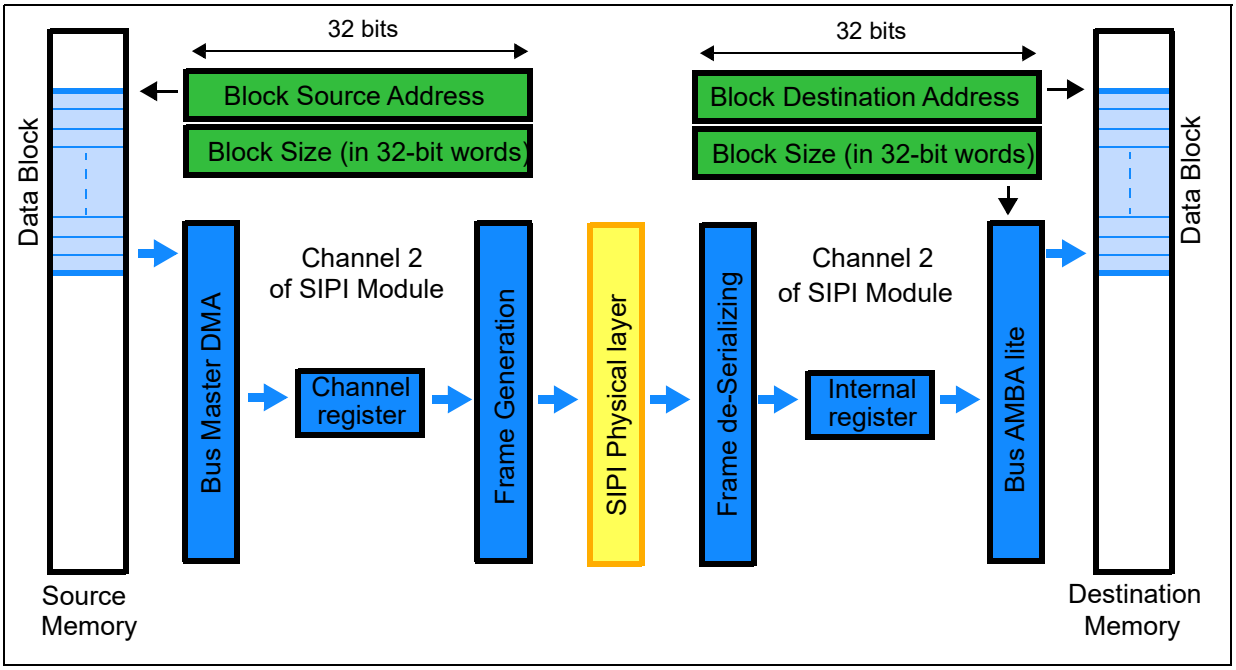


Figure 885. SIPI data stream model - Initiator

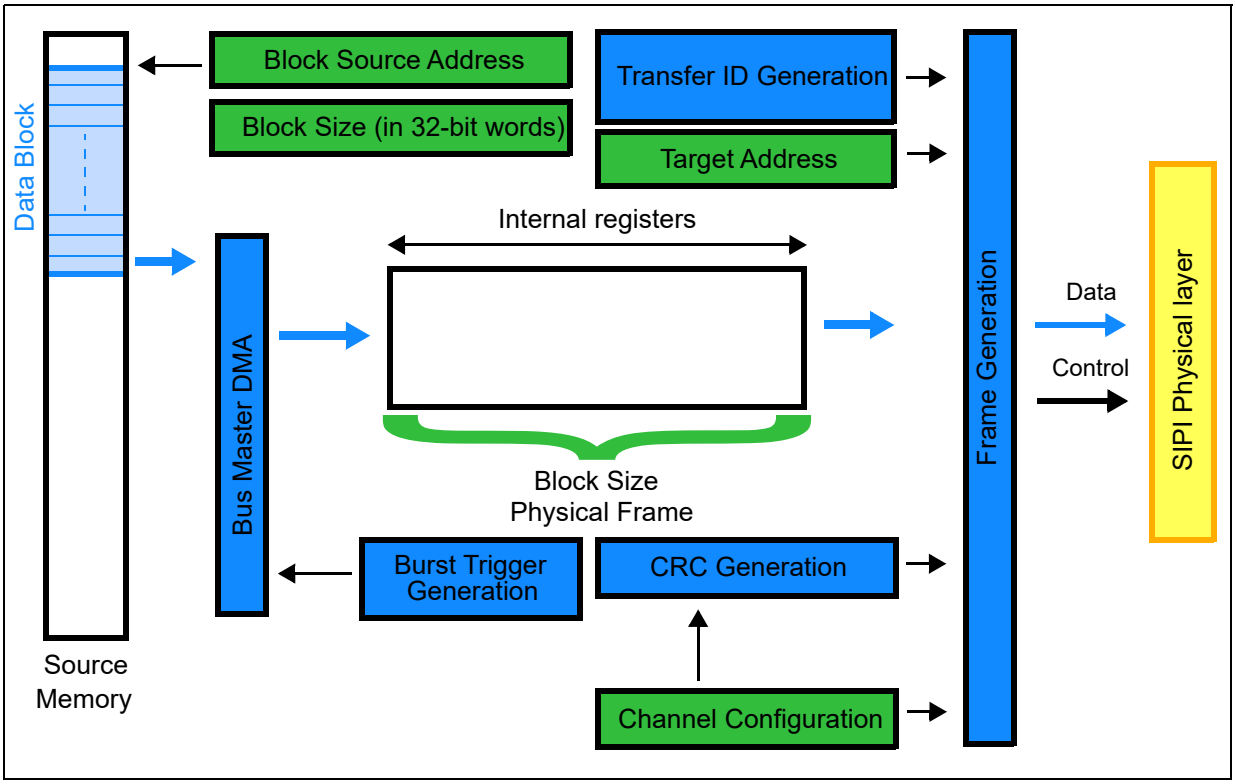

Figure 886. SIPI data stream model - Target

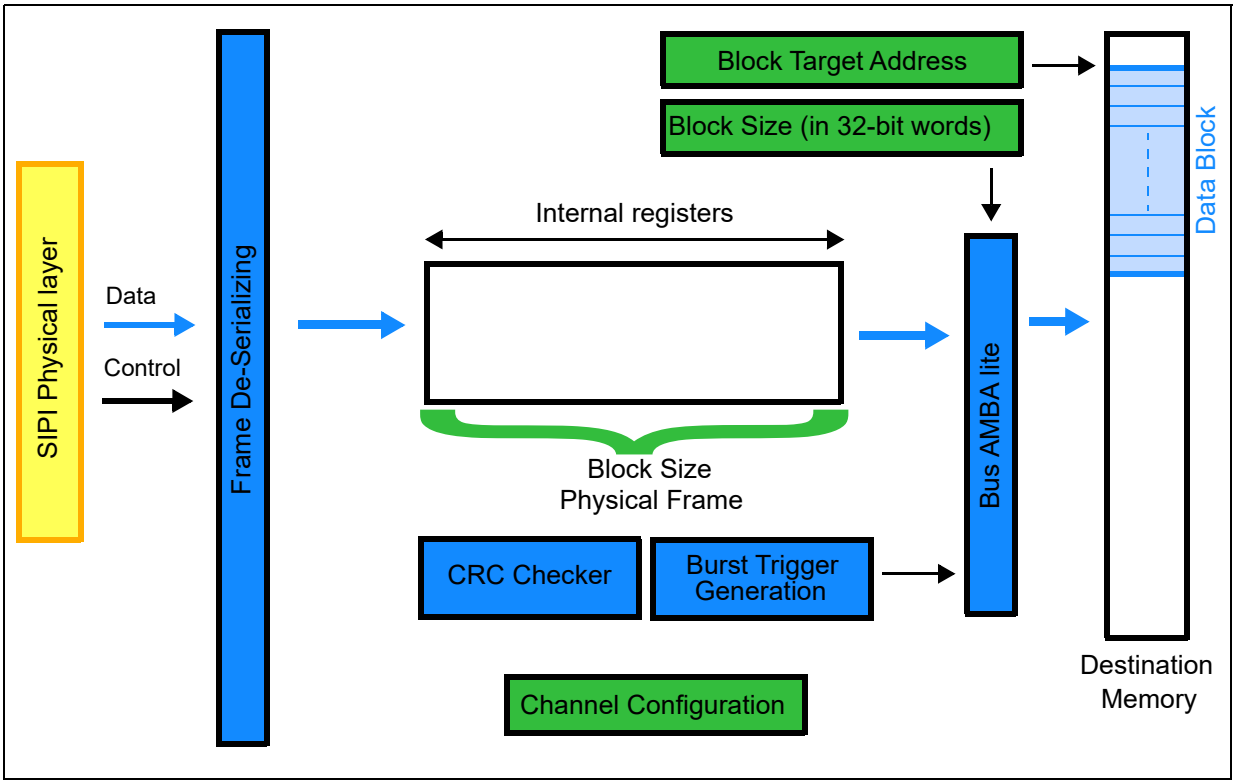

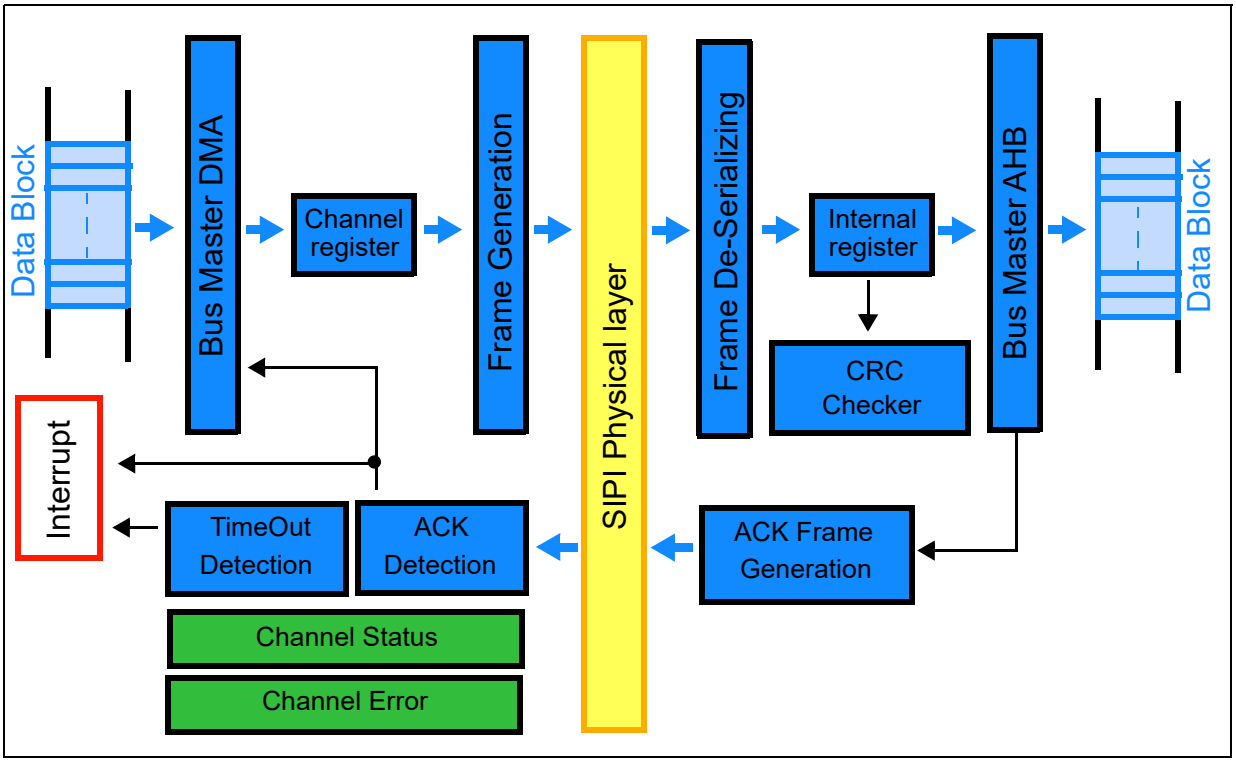

Figure 887. SIPI data stream with acknowledge trigger

49.9 DMA handling in transfer initiator mode

DMA handling of transfer initiator: the initiator of the SIPI transfer (SIPI master) uses the external DMA module on system level to exchange the data between System RAM and SIPI registers via the Peripheral Bridge Interface.

DMA handling of transfer target: the target of the SIPI transfer (SIPI slave) uses its built-in DMA capabilities to write received data into System RAM or to read requested data from System RAM via its data master port on the device interconnect.

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. If SIPI has received a read response, and error flags are not set on the LFAST Rx port, SIPI will assert a request. In case of an error, move to Step 8.
6. As soon as the request is asserted, DMA transfer starts between the SIPI registers and RAM.
7. If DMA transfer minor loop/major loop is complete, the request is negated.
8. If an error occurs:
   a) The SIPI generates an interrupt.
   b) Software takes control of the SIPI.
9. Steps 5 to 8 are repeated until the transfer is finished.

49.10 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in Module Disable mode, which helps reduce power consumption (refer to *Section 49.10.3*).

49.10.1 Initialization mode (INIT)

To enter Initialization mode software writes SIPI_MCR[INIT] = 1 (SIPI_MCR[MOEN] = 1 must be written before attempting to write SIPI_MCR[INIT]). To exit Initialization mode software writes SIPI_MCR[INIT] = 0 (refer to *Section 49.15.1.8: SIPI Module Configuration Register (SIPI_MCR)*). SIPI_MCR[PRSCLR], SIPI_MCR[AID], SIPI_CCRn[DEN], SIPI_CCRn[CHEN], SIPI_CTORn[TOR], SIPI_CCRn[TC] fields can only be written in INIT mode.A channel already enabled will not be disabled on entry to INIT mode unless the SIPI_CCRn[CHEN] field is written a value 0.

Note: It is recommended that software checks the SIPI state (SIPI_MCR[MOEN]) before setting SIPI_MCR[INIT].

49.10.2 Normal Mode (NM)

Once software has completed initialization of SIPI (SIPI_MCR[INIT] = 1), it can enter Normal mode by writing SIPI_MCR[INIT] = 0.

Note: SIPI must be enabled before attempting to write to SIPI_MCR[INIT] (for example, SIPI_MCR[MOEN] = 1).

49.10.3 Module Disable (MD)

Module Disable mode in the SIPI is used to help reduce power consumption. By default, SIPI is in disable mode, SIPI_MCR[MOEN] = 0, and is exited by writing SIPI_MCR[MOEN] = 1 (refer to *Section 49.15.1.8: SIPI Module Configuration Register (SIPI_MCR)*). Future SIPI Tx transfers are disabled in Module Disable mode. To disable Rx functionality, the Target Enable (TEN) bit field has to be deasserted, then the internal Rx state machine resets to initial state.

49.11 Errors

This section describes the potential errors that can occur during SIPI operation.

49.11.1 Timeout error

This error is generated at the initiator node when the acknowledge/response is not received within the configured time in the corresponding SIPI_CTOR*n*[TOR] field setting (refer to *Section 49.15.1.4: SIPI Channel Timeout Register (SIPI_CTORn)*). SIPI_ERR[TOE*n*] = 1 indicates that a channel timeout error has occurred (refer to *Section 49.15.1.13: SIPI Channel Error Register (SIPI_ERR)*).

Note: Upon detecting timeout, the application can check the DEN bit in order to ascertain if the missing acknowledge comes from the last packet or an intermediate one:

- *DEN = 0: ack missing for last packet*
- *DEN = 1: ack missing for intermediate packet.*

Then, in order to recover functionality, the application can:

- *write the soft reset bit SIPI_MCR[SR] for the last streaming frame case; in this case, DEN bit access is gained back immediately after writing SR*
- *for non-last streaming frame, clear the timeout to automatically resume data transfer.*

49.11.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match with the calculated CRC. When a CRC error is detected the SIPI_SR[GCRCE] is set (refer to *Section 49.15.1.9: SIPI Status Register (SIPI_SR)*) and an interrupt will be generated if SIPI_MCR[CRCIE] = 1 (refer to *Section 49.15.1.8: SIPI Module Configuration Register (SIPI_MCR)*).

Note: In the case of a CRC error, the target node will not send an acknowledge to the initiator node. Then an interrupt will be generated on the target side if the corresponding interrupt enable bit is set. The initiator node will detect a time-out and take necessary action.

49.11.3 Maximum count reached error

This error is always generated at the target node only. The maximum count reached error is generated when the value of the SIPI_ACR equals SIPI_MAXCR (refer to *Section 49.15.1.12: SIPI Address Count Register (SIPI_ACR)* and *Section 49.15.1.10: SIPI Max Count Register (SIPI_MAXCR)* for more details). The SIPI_SR[MCR] will be set (refer to *Section 49.15.1.9: SIPI Status Register (SIPI_SR)*), and an interrupt will be generated if SIPI_MCR[MCRIE] = 1 (refer to *Section 49.15.1.8: SIPI Module Configuration Register (SIPI_MCR)*).

49.11.4 Transaction ID error

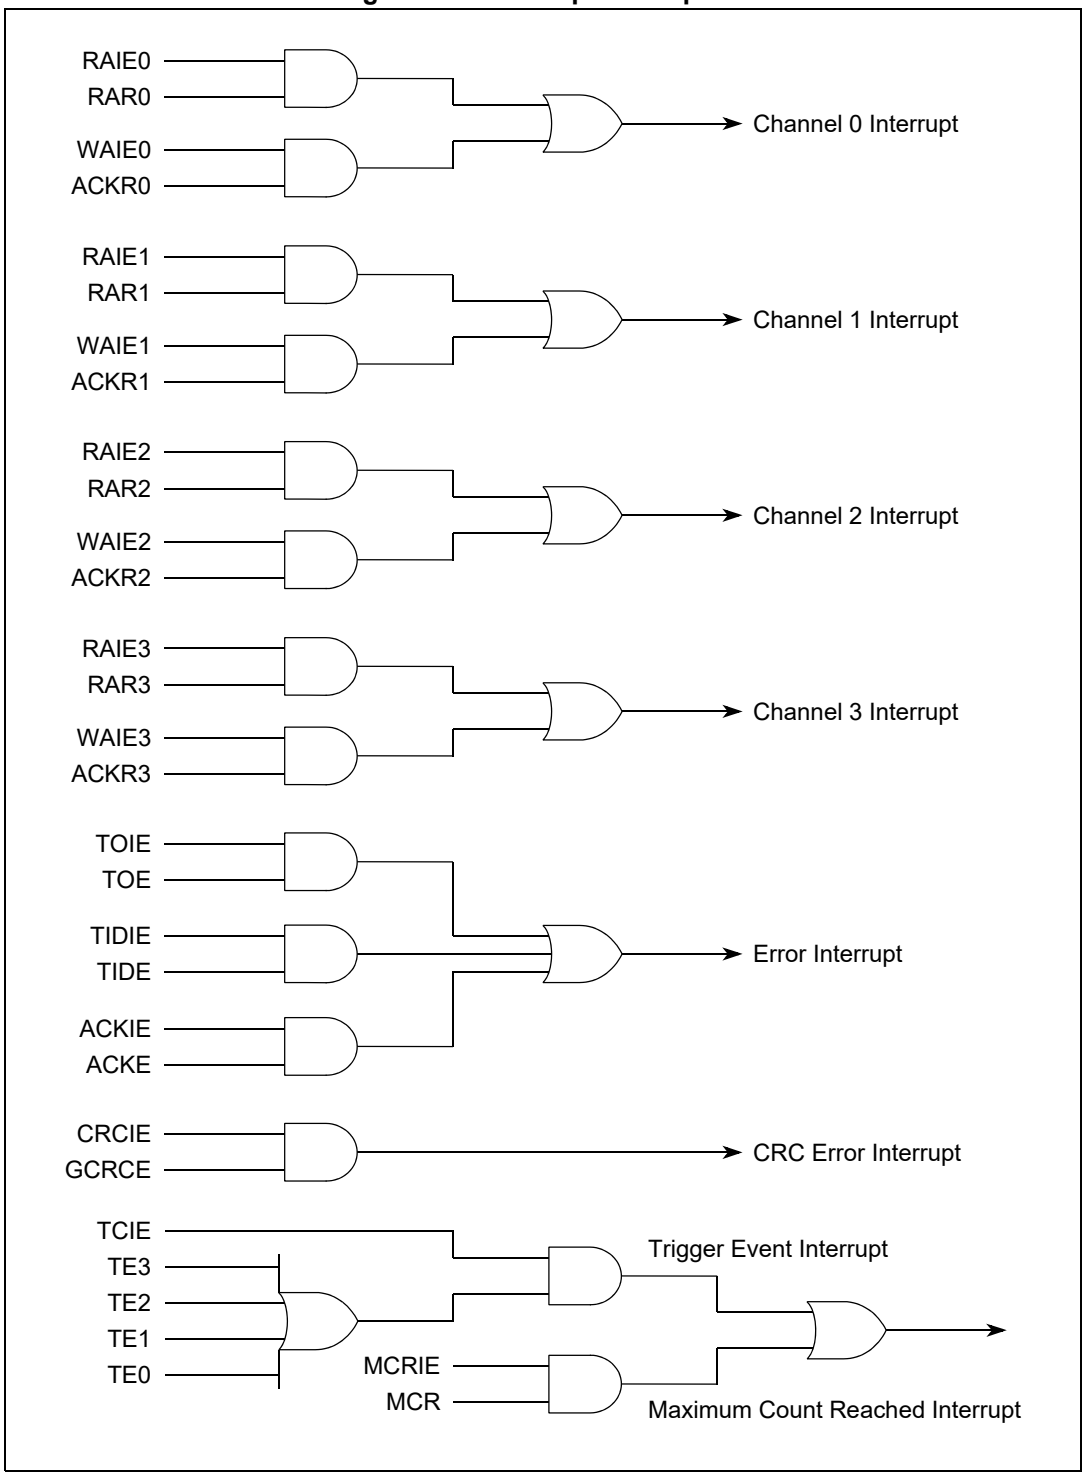
This error is always generated at the initiator node only. It is generated when header bits 15:13 do not match SIPI_CSR*n*[TID] (for transaction ID bits, refer to *Section 49.15.1.2: SIPI Channel Status Register (SIPI_CSRn)*). The SIPI_CSR*n*[TIDE] bit will be set when a TID error is detected, and an interrupt will be generated if SIPI_CIR*n*[TIDIE] = 1 (refer to *Section 49.15.1.3: SIPI Channel Interrupt Register (SIPI_CIRn)*).

49.11.5 Acknowledge error

When an incorrect Acknowledge is received the SIPI_ERR[ACKR*n*] will be set (refer to *Section 49.15.1.13: SIPI Channel Error Register (SIPI_ERR)*), at the initiator node only, and an interrupt will be generated if SIPI_CIR*n*[WAIE] = 1 (refer to *Section 49.15.1.3: SIPI Channel Interrupt Register (SIPI_CIRn)*).

49.12 CRC calculation

Example 1



If header is 0xAABB, address is 0x1122_3344 and data is 0xCCDD_EEFF. Then CRC calculation will take place as follows:

1. The CRC seed is initialized by 0xFFFF_FFFF.
2. All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
3. So the header will be sent as 0xDD55_0000, byte_enable = 0xC.
4. Address will be sent as 0x22CC_4488, byte_enable = 0xF.
5. Data will be sent as 0xFF77_BB33, byte enable = 0xF.

49.13 Interrupt logic

A description of the interrupt logic can be found in *Figure 888*.

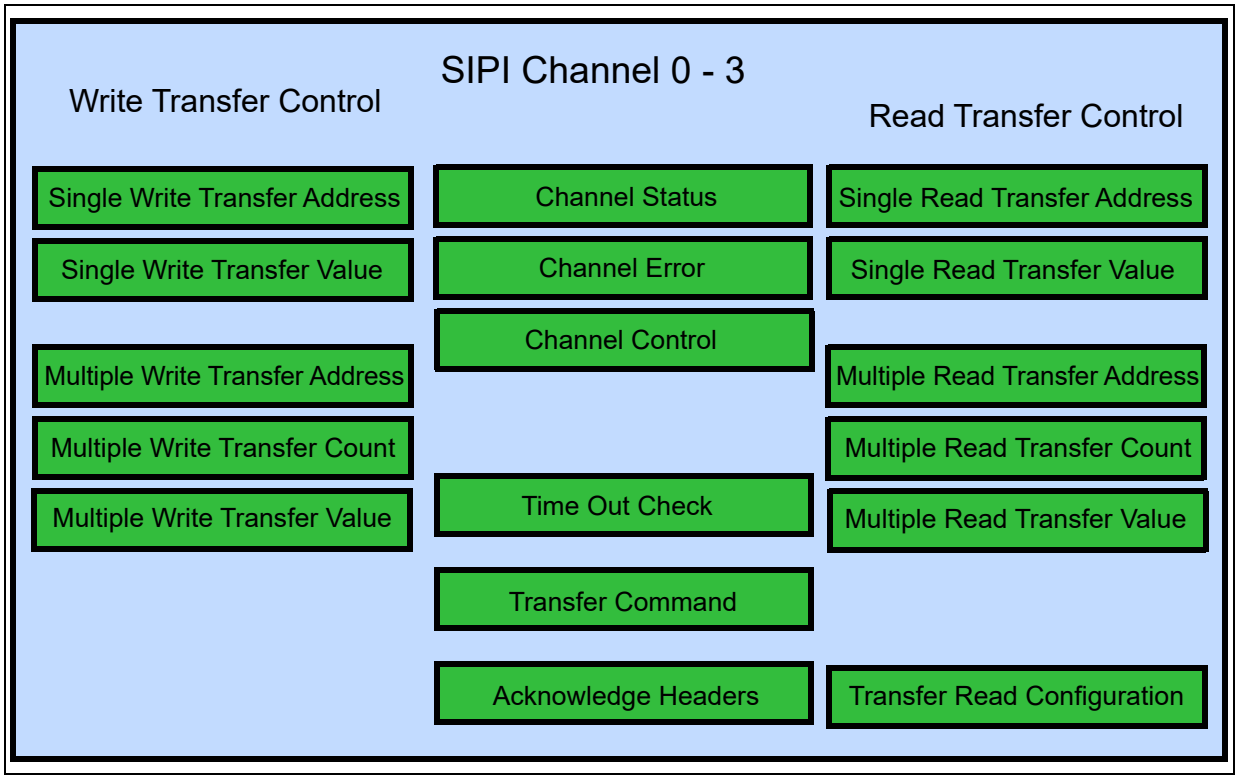


Figure 888. Interrupt description

49.14 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

Figure 889. SIPI control and status overview – Register transfer

49.15.1 Register descriptions

49.15.1.1 SIPI Channel Control Register (SIPI_CCR*n*)

Note: Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSRn[CB] = 1, is configured for 1 channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSRn[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CARn is written first will have access first, irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Priority scheduling occurs when the LFAST is unable to receive data, and no channel is pending transmission. The reason for the scheduling is that a common CRC module is shared by all channels.

Note: This register can only be written during Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSRn[CB] = 1, Section 49.15.1.2: SIPI Channel Status Register (SIPI_CSRn)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine system clock cycles (streaming command is 9 words long). The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CARn (Section 49.15.1.6: SIPI Channel Address Register (SIPI_CARn).

Offset: 0x0000 (SIPI_CCR0)
0x0020 (SIPI_CCR1)
0x0040 (SIPI_CCR2)
0x007C (SIPI_CCR3)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	TC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	WL		CHEN	ST	IDT(1)	RRT(1)	WRT(1)	DEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The order of priority for writing to IDT, WRT and RRT must be in this order: 1) IDT, 2) RRT, 3) WRT.

Figure 890. SIPI Channel Control Register (SIPI_CCR*n*)

Table 956. SIPI_CCR*n* field descriptions

Field	Description
15 TC	Trigger Command A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in the SIPI_CAR, this bit can not be set if SIPI_CSRn[CB] = 1. SW must read back to check the value and SW has to set it back to 0. 0 Trigger command not sent 1 Trigger command sent
24:25 WL	Word Length Transfer For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable If all the channel enables are pending simultaneously, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled. 1 Channel is enabled.
27 ST	Streaming Transfer This bit is hard-coded to 0 for channels 0, 1 and 3. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when SIPI_CCR*n*[WRT] = 1. 0 Streaming transfer is disabled. 1 Streaming transfer is enabled.
28 IDT	ID Read Request Transfer This request returns the value of the CHIP ID. 0 ID read request not sent. 1 ID read request sent.
29 RRT	Read Request Transfer 0 Read request will not be sent 1 Read request transfer by the initiator. This bit cannot be written if SIPI_CCR*n*[IDT] = 1.
30 WRT	Write Request Transfer 0 No write request will be sent. 1 Write request transfer by the initiator. This bit cannot be written if SIPI_CCR*n*[IDT] = 1 or SIPI_CCR*n*[RRT] = 1.
31 DEN	DMA Enable When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed (for streaming mode and multiple data transfer it is advised to assert DEN). 0 Channel will be used for bus interface access. 1 Channel will be used for DMA request to the host.

49.15.1.2 SIPI Channel Status Register (SIPI_CSR*n*)

The SIPI_CSR*n* contains the status bits for the current transfer.

Offset: 0x0004 (SIPI_CSR0)
0x0024 (SIPI_CSR1)
0x0044 (SIPI_CSR2)
0x0080 (SIPI_CSR3)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Can be written in initialization mode only (SIPI_MCR[INIT] = 1).
2. Can only be written when SIPI_MCR[MOEN] = 1.
3. Can be written only once after reset.

Figure 898. SIPI Module Configuration Register (SIPI_MCR)

Table 965. SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. 0 No Freeze mode request. 1 Enters Freeze mode if FRZ bit is asserted.

Table 965. SIPI_MCR field descriptions (continued)

Field	Description
5:15 PRSCLR	These bits should be programmed by software in initialization mode, SIPI_MCR[INIT] = 1, writes during other times are ignored. The timeout counter runs on the prescaled system clock. Default value is 64 (0x040). The allowed programmable values are: 0x040: 64 0x080: 128 0x100: 256 0x200: 512 0x400: 1024
16:17 AID	Address Increment/Decrement (for streaming mode) These bits define the type of address change at the target node for the next word write, in streaming mode. This field can be written only in INIT mode that is SIPI_MCR[INIT] = 1. This field dictates how it's memory is written when it receives a streaming command from outside world. 00 No change. address stays same 01 Address increments by 4 10 Address decrements by 4. 11 Reserved
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable 0 Interrupt is disabled. 1 Interrupt is enabled.
27 CHNSB	Channel coding select bit 0, 1 Channel number select as per *Table 951: SIPI Header Channel Number Coding*.
28 TEN	Target Enable Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in “streaming without ACK” mode. This bit has to be enabled for transmission operations as well.
29 INIT	Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits cannot be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete. Statical configuration, data and address registers remain unchanged.

49.15.1.9 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Offset: 0x00A0 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FRZACK	LPMACK	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

W						w1c	w1c		w1c							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 899. SIPI Status Register (SIPI_SR)

Table 966. SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI not in any low power modes 1 SIPI is in Disable mode
21 GCRCE	Global CRC Error Bit 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached This bit will be set whenever SIPI_ACR[ADCNT] = SIPI_MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPI_MCR[MCRIE] = 1. This bit should be cleared by software.

Table 966. SIPI_SR field descriptions (continued)

Field	Description
24:27 TE	Trigger Event on Respective Channels This field enables interrupts for target nodes. TE3 = 1 - Channel 3 trigger command received TE2 = 1 - Channel 2 trigger command received TE1 = 1 - Channel 1 trigger command received TE0 = 1 - Channel 0 trigger command received
28:31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. These bits reflect what is being transmitted that is STATE = HEADER_AND_ADDRESS_FIELD means that HEADER and ADDRESS were transmitted. Boundary of transmission is word and with the command formats, half address sent in one clock and other half in the next. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

49.15.1.10 SIPI Max Count Register (SIPI_MAXCR)

The SIPI_MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

Offset: 0x00A4 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MXCNT

R W	ADCNT														0	0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 902. SIPI Address Count Register (SIPI_ACR)

Table 969. SIPI_ACR field descriptions

Field	Description
0:29 ADCNT	Reflects the value of address at target node. It should be configured by direct write from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPI_ACR will auto update to the next address to be written.

Note: SIPI_ARR, SIPI_ACR and SIPI_MAXCR will be configured by direct write operation by the initiator.
When a streaming write command is received, the target will start the write operation from the address present in SIPI_ACR.
After each 32-bit write has completed, SIPI_ACR[ADCNT] is compared against SIPI_MAXCR[MXCNT]. If they are equal, SIPI_ACR[ADCNT] is loaded with the value stored in SIPI_ARR[ADRLD]. If they are not equal, the SIPI_ACR[ADCNT] will increment by 4, decrement by 4, or remain the same (depending on AID field). In either case, the SIPI_ACR[ADCNT] will contain the address at which the next streaming write will occur.

49.15.1.13 SIPI Channel Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate communication errors.

50 Zipwire

50.1 Overview

The SIPI and LFAST modules work together as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

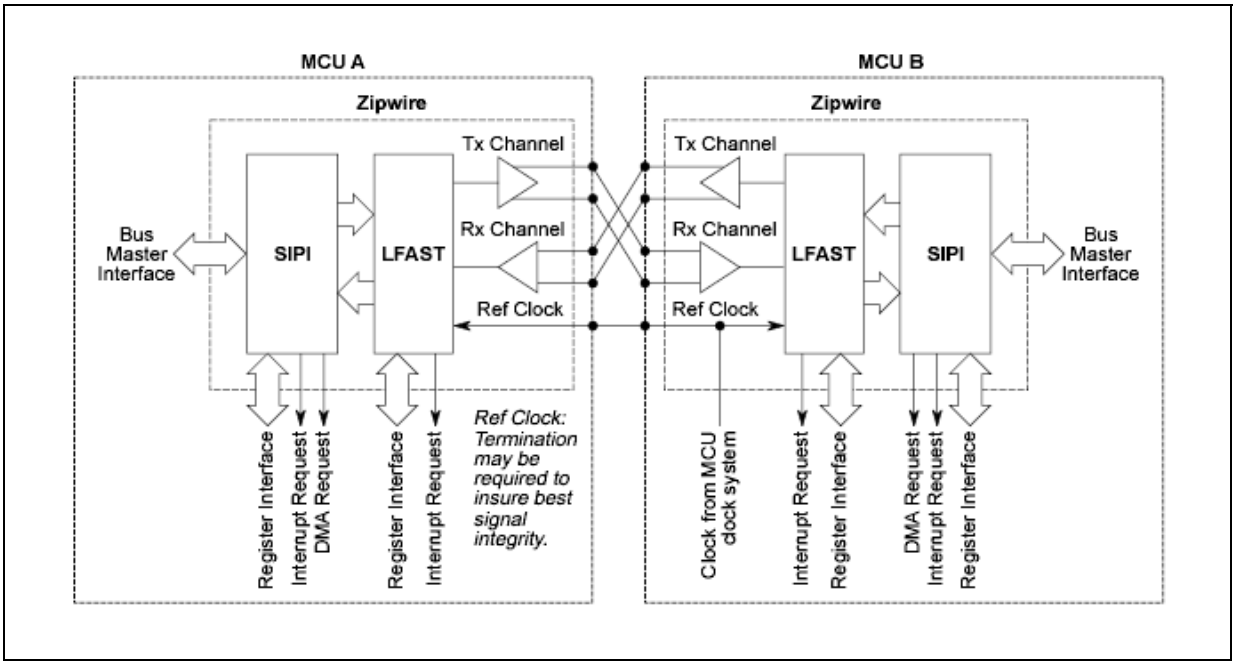
The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

50.2 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals or memories of another MCU (or both) or smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the initiator or target node. Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and supports multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.Zipwire also supports a streaming mode for the transfer of large blocks of data.



In streaming mode Zipwire has a high transfer rate. For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

50.3 Zipwire block diagram

Figure 904 shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target Mode transactions.The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST Reference clock coming from the MCU B clock system. The Ref_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

Figure 904. Zipwire connection diagram

50.4 Architecture

Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200 mV swing.The LVDS pads are shared with other I/O and GPIO.

The transport layer is a protocol called LFAST. LFAST is an asynchronous protocol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). SIPI runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload in Zipwire:

- 32-bit
- 64-bit
- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated by one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently

of each other and can run simultaneously. The SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the initiating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Initiator MCU and executed by DMA and SIPI without CPU intervention at either Initiator or Target MCU.

50.5 LFAST clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data. The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to as the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

- XOSC
- Output of PLL0 (PLL0:PHI)
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator (XOSC) from one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.

50.6 Zipwire interconnections

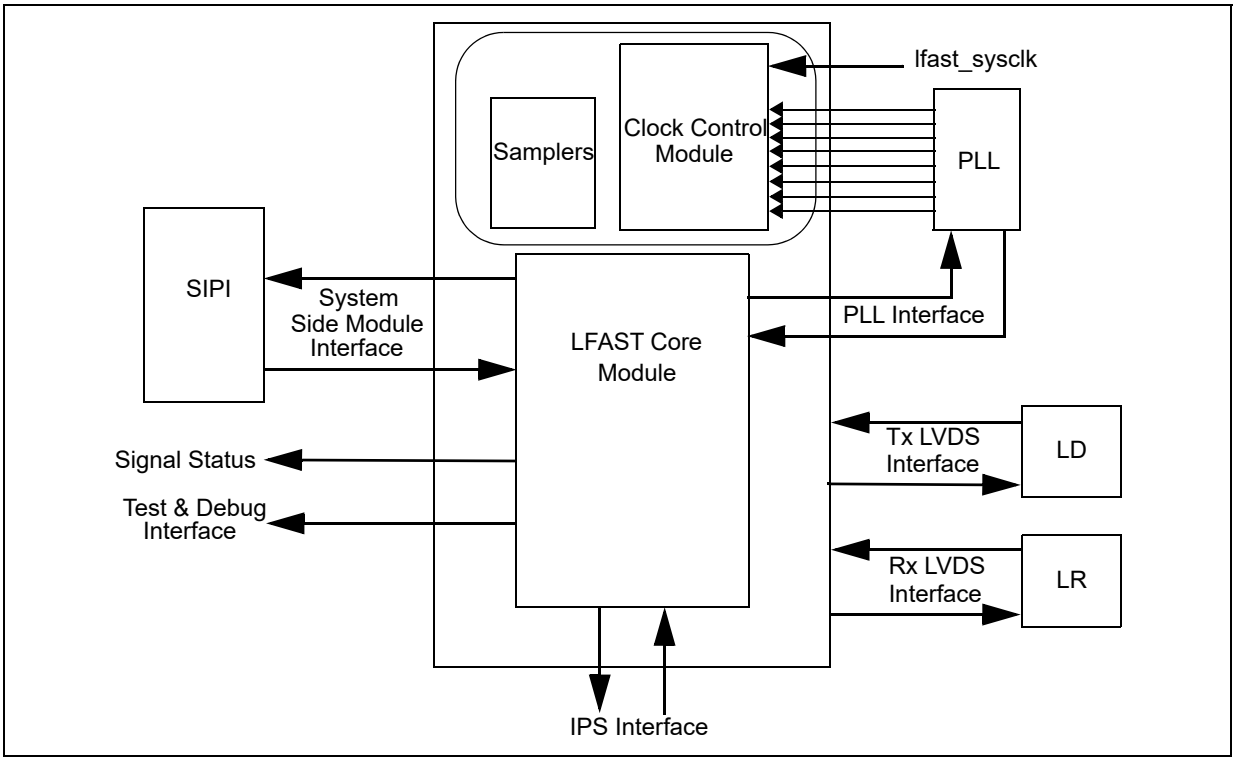
LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers
- Peripheral Bridge interface (PBRIDGE): allows software to read and write configuration registers
- Tx Data Port/Rx Data Port: directly connected to the SIPI module. Allows received data to be efficiently transferred to SIPI and transmit data to be transferred from SIPI.
- Interrupt Request connections: Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE): allows software to read and write configuration registers and SIPI Interface Registers.
- DMA connections: allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port: allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port: directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.
- Interrupt Request connections: allows the module to flag to the CPU when it requires servicing.

51 LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications



51.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

51.2 Block diagram

Figure 905 depicts LFAST interaction with other modules on the device.

Figure 905. LFAST block diagram

51.3 External signals

LFAST is a five pin interface with the following signals:

- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

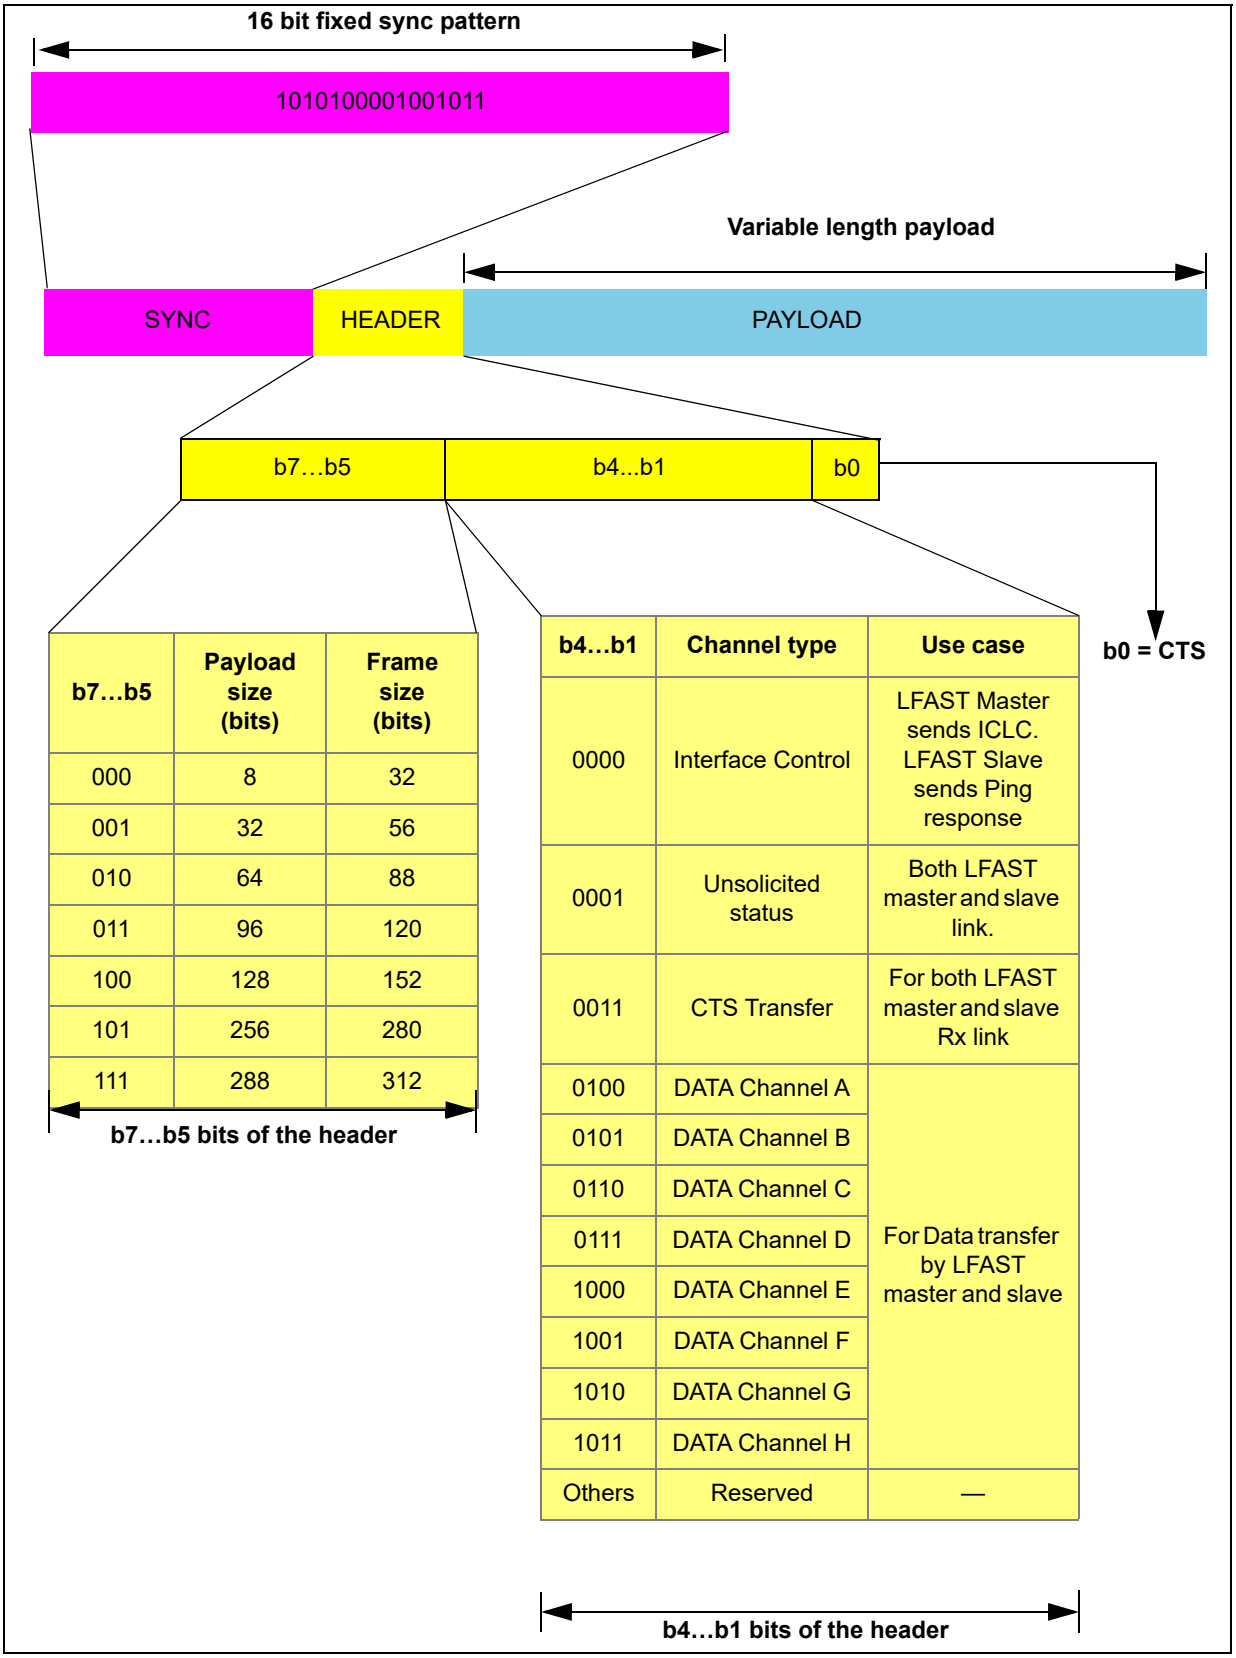
LFAST interface is an asynchronous high speed LVDS interface.

51.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

51.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.



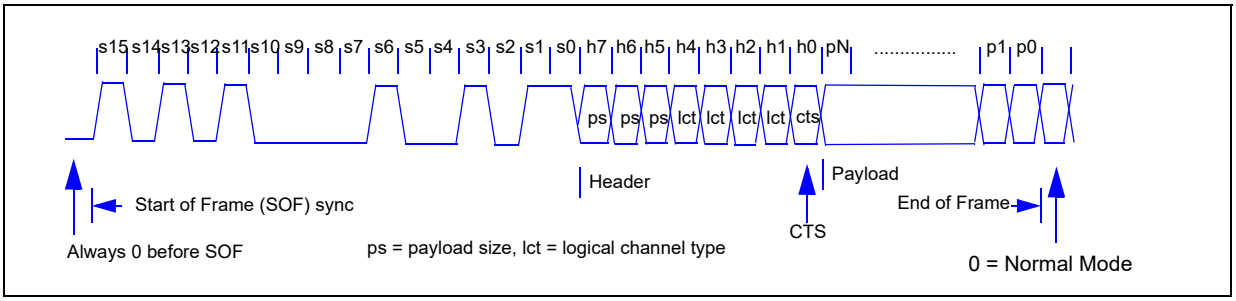
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See *Figure 906* for details of the LFAST frame.

Figure 906. LFAST frame structure



b7…b5	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	288	312

b4…b1	Channel type	Use case
0000	Interface Control	LFAST Master sends ICLC. LFAST Slave sends Ping response
0001	Unsolicited status	Both LFAST master and slave link.
0011	CTS Transfer	For both LFAST master and slave Rx link
0100	DATA Channel A	For Data transfer by LFAST master and slave
0101	DATA Channel B	
0110	DATA Channel C	
0111	DATA Channel D	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	—

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 907. Serial frame structure

The frame structure is shown in *Figure 907* and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto-correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to *Table 971*.

Table 971. Header payload sizes

b7-b5 (bin)	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

51.5 Features

- Supports dual mode (register configurable Master/Slave)
- Supports asynchronous data transfer rates up to the maximum data rated shown in the product Datasheet
- Transmits and receives data, CTS, ICLC and unsolicited frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled
- Supports flow control using sliding window protocol
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits
- Supports PLL configuration (such as feedback loop divider) through registers
- Supports LVDS configuration through registers
- Supports multiple loopback modes for checking the physical interface
- Supports automatic ping response generation in slave mode
- Supports for detection of unsupported channel number and unsupported payload size

51.6 Memory map and register definition

All registers are 32-bit wide.

51.6.1 Memory map

Table 972. LFAST memory map

1. Writable only once after the asynchronous reset.
2. Only writable when MCR[DRFEN] = 0.
3. Set by user software and cleared by system hardware.

Figure 908. Mode Configuration Register (MCR)

Table 973. MCR field descriptions

Field	Description
0 MSEN	LFAST Master or Slave mode Enable This bit selects either the LFAST master or slave functionality. This bit can be written only once after the asynchronous reset. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
7 IPGDBG	Control bit to enable support for IPG Debug mode This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode Refer to *Section 51.10.2: Slow speed clock* for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave hardware on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Transmitter is Enabled.
27 TXARBD	Tx Arbiter Disable This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.

Table 973. MCR field descriptions (continued)

Field	Description
28 CTSEN	CTS Enable This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit does not represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
30 DRFRST	LFAST Soft Reset This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

51.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Offset: 0x0004 Access: User read/write

1. Only writable when MCR[DRFEN] = 0.

Figure 909. Speed Control Register (SCR)

Table 974. SCR field descriptions

Field	Description
15 DRMD	Data Rate Controller mode Defines the mode set for LFAST slave device by the software or the LFAST master. 0 The software controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no effect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
23 RDR	Receiver Data Rate This bit defines the receiver data rate. For LFAST Master: – The software should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: – When SCR[DRMD] = 1, the hardware programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. – The software can program this bit when SCR[DRMD] = 0. – This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is high speed.
31 TDR	Transmit Data Rate This bit defines the transmitter data rate. For LFAST Master: – The software should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: – When SCR[DRMD] = 1, the hardware writes this bit on receipt of an ICLC frame changing the speed mode of the slaves Tx interface. – The software can program this bit when SCR[DRMD] = 0. – This bit is cleared onMCR[DRFEN] = 0. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is high speed.

51.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

1. Writable only when TMCR[LPON] = 0.

Figure 911. Test Mode Control Register (TMCR)

Table 976. TMCR field descriptions

Field	Description
6 CLKTST	Clock Test mode The software can define when the clock test mode is enabled. This bit can also be set and cleared by LFAST slave hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable The software can define when the loopback logic is enabled. This bit can also be written by LFAST slave hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled. 0 Loopback mode is disabled.
13:15 LPMOD	Loopback mode Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by the software)
16:31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Check 1 frame have correct sync, header and payload. … 0xFFFE: Check 65534 frames have correct sync, header and payload. 0xFFFF: Check 65535 frames have correct sync, header and payload.

51.6.2.5 Auto Loopback Control Register (ALCR)

1. Writable only when TMCR[LPON] = 0.

Figure 912. Auto Loopback Control Register (ALCR)

Table 977. ALCR field descriptions

Field	Description
15 LPCNTEN	Auto Loopback Frame Transmission Count Enable Enables fixed number of auto predefined loopback frame transmission. 0 Infinite predefined loopback frame transmission enabled 1 Fixed count of predefined loopback frame transmission enabled
16:31 LPFMCNT	Auto Loopback Frame Transmission Count Defines the number of predefined auto loopback frames to be sent. The predefined loopback frame has payload CBh, header 13h and valid sync. This mode is valid if TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Send 1 frame with correct sync, header and payload. ... 0xFFFE: Send 65534 frames with correct sync, header and payload. 0xFFFF: Send 65535 frames with correct sync, header and payload.

Figure 914. Wakeup Delay Control Register (SLCR)

Table 979. SLCR field descriptions

Field	Description
0:7 HSCNT	High Speed Sleep mode Exit Time Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. 0x00: cycle 0x01: 1 cycle … 0x12: 18 cycles (200 ns + 8 cycles of High speed clock) … 0xFE: 254 cycles 0xFF: 255 cycles
12:15 LSCNT	Low Speed Sleep mode Exit Time Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. 0x0: 0 cycle 0x1: 1 cycle (200ns + 1 cycle of Low speed clock) … 0xE: 14 cycles 0xF: 15 cycles
16:23 HWKCNT	Wake Up time for the LD Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. 0x00: 0 cycles 0x01: 1 cycle … 0x5F: 95 cycles (1.18 us) … 0xFF: 255 cycles Maximum
28:31 LWKCNT	Wake Up time for the LD Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. 0x0: 0 cycle 0x1: 1 cycle 0x2: 2 cycles (1.18 us) … 0xE: 14 cycles 0xF: 15 cycles

1. Set by user software and cleared by system hardware.
2. Writable only when ICR[SNDICLC] = 0.

Figure 915. ICLC Control Register (ICR)

Table 980. ICR field descriptions

Field	Description
14 ICLCSEQ	ICLC enabled This bit should be set whenever the software is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frame requests are ignored. 1 The software is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0. 0 Single ICLC frame transfer
15 SNDICLC	ICLC frame request This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. 1 Valid ICLC frame for transfer. 0 No Valid ICLC frame for transfer.
24:31 ICLCPLD	ICLC Payload This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. Refer to *Table 1005* for supported ICLC payloads.

51.6.2.9 Ping Control Register (PICR)

1. Set by user software and cleared by system hardware.
2. Only writable when MCR[DRFEN] = 0.

Figure 916. Ping Control Register (PICR)

Table 981. PICR field descriptions

Field	Description
15 PNGREQ	Ping Response Frame Request This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. This field can only be written when MCR[DRFEN] = 1. 1 Ping response frame transmission request is queued. 0 No pending Ping response frame transmission request.
16 PNGAUTO	Ping Response Enable Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
24:31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

51.6.2.10 Rx FIFO CTS Control Register (RFCR)

Figure 922. LVDS Control Register (LCR)

Table 987. LCR field description

Field	Description
8 SWWKLD	Software signal to take LVDS LD out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep).
9 SWSLPLD	Software signal to put LVDS LD into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep.
10 SWWKLR	Software signal to take LVDS LR out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep).
11 SWSLPLR	Software signal to put LVDS LR into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up).
12 SWOFFLD	Software signal to turn OFF the LVDS LD This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be turned OFF (provided no other source is trying to turn the LD ON).
13 SWONLD	Software signal to turn ON the LVDS LD This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be turned ON.
14 SWOFFLR	Software signal to turn OFF the LVDS LR This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be turned OFF (provided no other source is trying to turn the LR ON).
15 SWONLR	Software signal to turn ON the LVDS LR This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be turned ON.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode.
17 LVTXOE	LVDS LD output buffer enable 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled

Table 987. LCR field description (continued)

Field	Description
18 TXCMUX	Tx and Clock Mux The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad.
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only). 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only). 0 Use for LFAST receiver baud rates less than maximum baud rate 1 Required for LFAST receiver maximum baud rate
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 Normal clock used to sample the LVDS data 1 Adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

Figure 933. Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Table 998. UNSRDR8–UNSRDR0 field descriptions

Field	Description
0:31 UNRXD	Unsolicited Receive Data This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288-bit payload.

51.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements (Refer to the “Functional safety” chapter for register classification details. All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

51.7 Functional description

51.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

51.7.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDCR are programmed according to the LVDS parameters (refer to the default reset values of the related registers).
2. The PLLCR is programmed with configuration parameters for the PLL.
3. The LCR is programmed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. ICR[ICLCSEQ] = 1.
9. Write ICR[SNDICLC] = 1.
10. Write MCR[TXARBD] = 0.
11. The ICLC transmission is confirmed by verifying one of the following:
    – ICR[SNDICLC] = 0.
    – TISR[TXICLCF] = 1.
12. Write ICR[ICLCPLD] = 0x00 to check the LFAST slaves status.
13. Write ICR[SNDICLC] = 1.
14. The LFAST slave status is confirmed by occurrence of one of the following:
    – If RIISR[ICPSF] = 1 and RIISR[ICPFF] = 0 LFAST slave is enabled. Proceed to step *15.*.
    – If RIISR[ICPSF] = 0 and RIISR[ICPFF] = 1 LFAST slave is enabled but acknowledges with a wrong payload, application may proceed to step *15.* on assumption of awareness this mismatch.
    – If RIISR[ICPSF] = 0 and RIISR[ICPFF] = 0 LFAST slave is disabled. The LFAST master must wait and restart from step *7.*.

Note: RIISR[ICPSF] = 1 and RIISR[ICPFF] = 1 cannot occur

Note: Assume RIISR flags need to be cleared before submission of a new ICLC frame.

Speed mode change:

15. Write LCR[SWPON] = 1 to enable the LFAST masters PLL.
16. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
17. Write ICR[SNDICLC] = 1.
18. The ICLC transmission is confirmed by occurrence of one of the following:
    – ICR[SNDICLC] = 0.
    – TISR[TXICLCF] = 1.

19. Both of the following operations are performed to change the LFAST masters Rx interface speed:
(**Note:** The slaves Tx interface speed mode should be changed first)
   – Write ICR[ICLCPLD] = 0x80 to select Rx data fast frame.
   – Write ICR[SNDICLC] = 1.
20. To change LFAST masters Tx interface speed both of the following operations are performed:
(**Note:** The slaves Rx interface speed should be changed first.)
   – Write ICR[ICLCPLD] = 0x10 for Tx data fast frame.
   – Write ICR[SNDICLC] = 1.
21. The ICLC transmission is confirmed by the occurrence of one of the following:
   – ICR[SNDICLC] = 0
   – TISR[TXICLCF] = 1.
22. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.
23. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.
24. Write ICR[ICLCSEQ] = 0 to enable speed change for next ICLC frame.
25. Write ICR[ICLCPLD] = 0x00 to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.
26. Write ICR[SNDICLC] = 1
27. Write MCR[TXARBD] = 1, after some delay to ensure step *25.* ICLC frame is send but no other frame is sent to arbitration.
28. The LFAST slaves speed mode is confirmed by the occurrence of the following:
   – If RIISR[ICPSF] = 1 and RIISR[ICPFF] = 0 the LFAST slave is in mode matching to High speed mode of the LFAST master mode.
   – If RIISR[ICPSF] = 0 and RIISR[ICPFF] = 1 the LFAST slave responds on correct High speed mode frequency but with wrong payload.
   – If RIISR[ICPSF] = 0 and RIISR[ICPFF] = 0 the LFAST slave is not providing answer matching with High speed mode of the LFAST master. The LFAST slave is most likely still in SLOW speed mode.

Note: RIISR[ICPSF] = 1 and RIISR[ICPFF] = 1 cannot occur

Note: Assume RIISR flags needs to be cleared before submission of a new ICLC frame.

29. If the High speed frequency (based on the results of step *27.*) is set, then all frame arbitration is enabled by the following operation: Write MCR[TXARBD] = 0.
30. If the High speed frequency (based on the results of step *27.*) is not set, modifying the LFAST slaves speed needs to be repeated by:
   – Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
   – Write SCR[RDR] = 0 to return the Rx interface to Low Speed mode.
   – Write MCR[TXARBD] = 0, to enable frame transmission.
   – The operations from step *15.* need to be executed again.

51.7.1.2 LFAST slave interface startup procedure

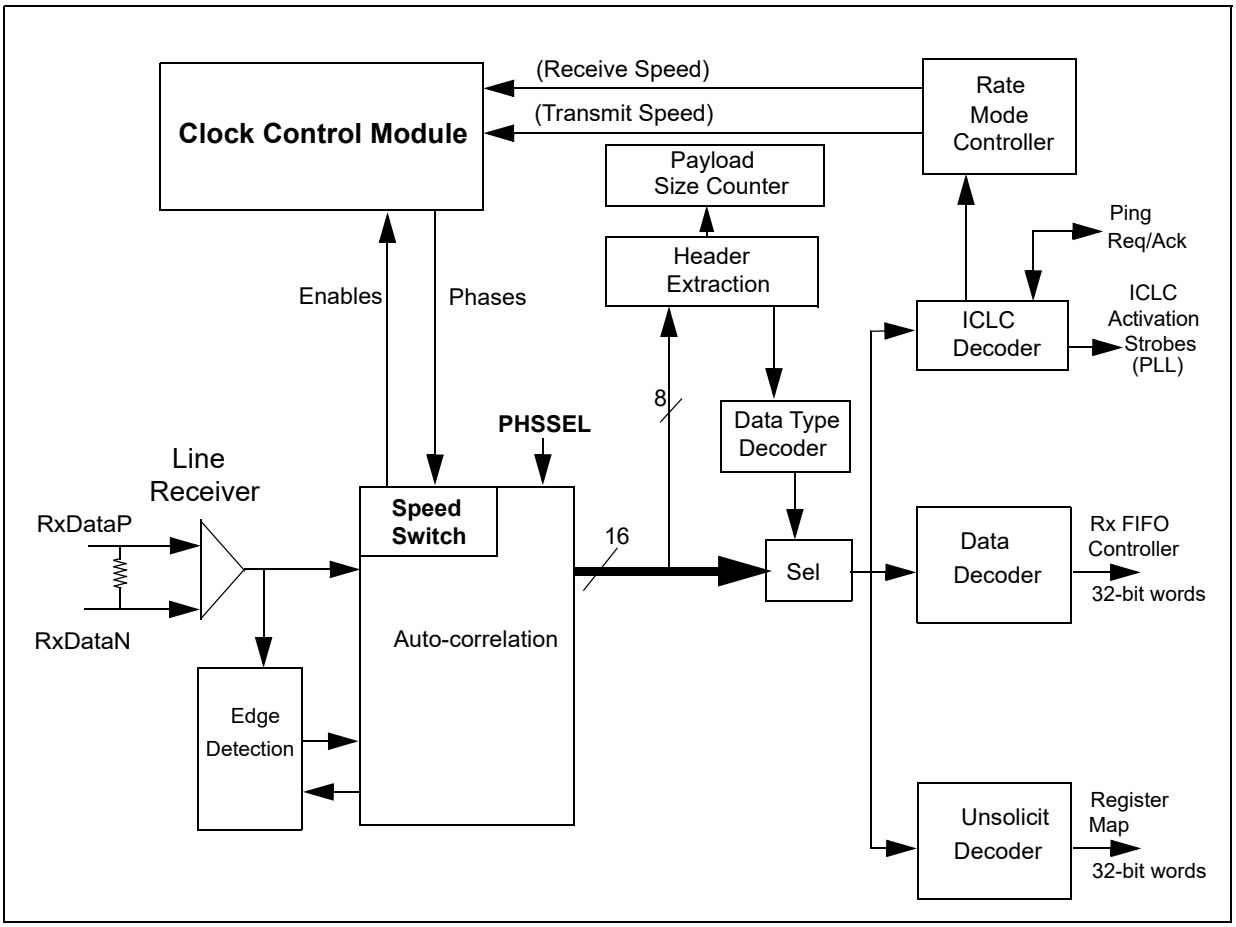
1. After reset the SLCR and RCDCR are programmed according to the LVDS parameters in the device datasheet.
2. The PLLCR is programmed with the configuration parameters for the PLL.
3. The LCR is programmed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signal and LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following is true:
   – When an ICLC frame with payload 0x31 is received the hardware will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
   – MCRMCR[TXEN] = 1
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
   – When PICR[PNGAUTO] = 1 and an ICLC frame with payload 0x00 frame is received.the hardware writes [ICRPF] = 1
   – PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:
   – When an ICLC frame with payload 0x02 is received. The hardware writes RIISR[IPONF] = 1
   – Write PLLCR[SWPON] = 1.
10. The speed of the Tx interface is changed on one of the following conditions:
   – When SCR[DRMD] = 1 and an ICLC frame with payload 0x80 is received. The hardware writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
   – SCR[TDR] = 1 when SCR[DRMD] = 0
11. The speed of the Rx interface is changed on one of the following conditions:
   – When SCR[DRMD] = 1 and an ICLC frame with payload 0x10 is received. The hardware writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
   – SCR[RDR] = 1, when SCR[DRMD] = 0
12. A Ping Frame is sent on one of the following conditions:
   – When PICR[PNGAUTO] = 1 and an ICLC frame with payload 0x00 is received.The hardware writes RIISR[ICRPF] = 1
   – Write PICR[PNGREQ] = 1.

51.7.2 Line Receiver (LR)

51.7.2.1 Introduction



The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto-correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed

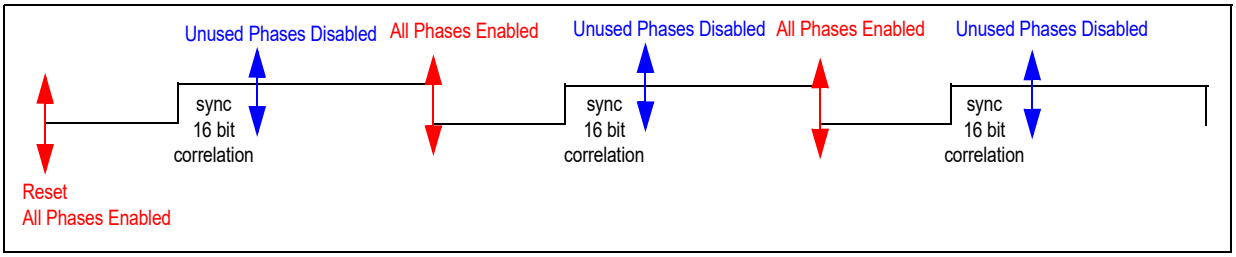
clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 934 shows the block diagram of Uplink controller.

Figure 934. Top level receive controller

51.7.2.2 Edge-detection and auto-correlation



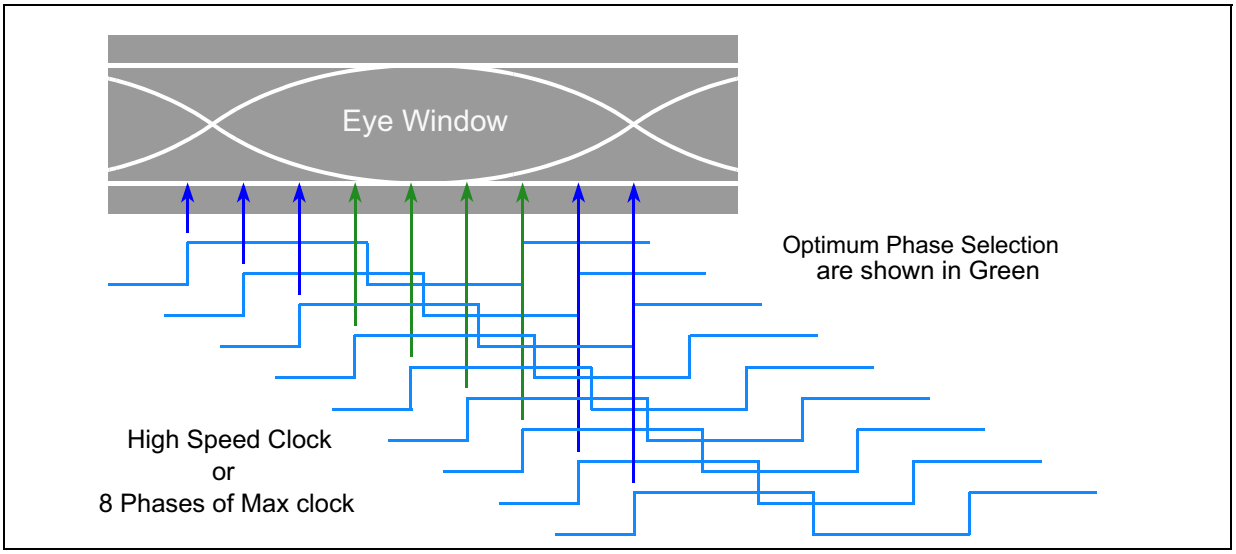
The edge-detection and auto-correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

51.7.2.2.1 Auto-correlation modes

51.7.2.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

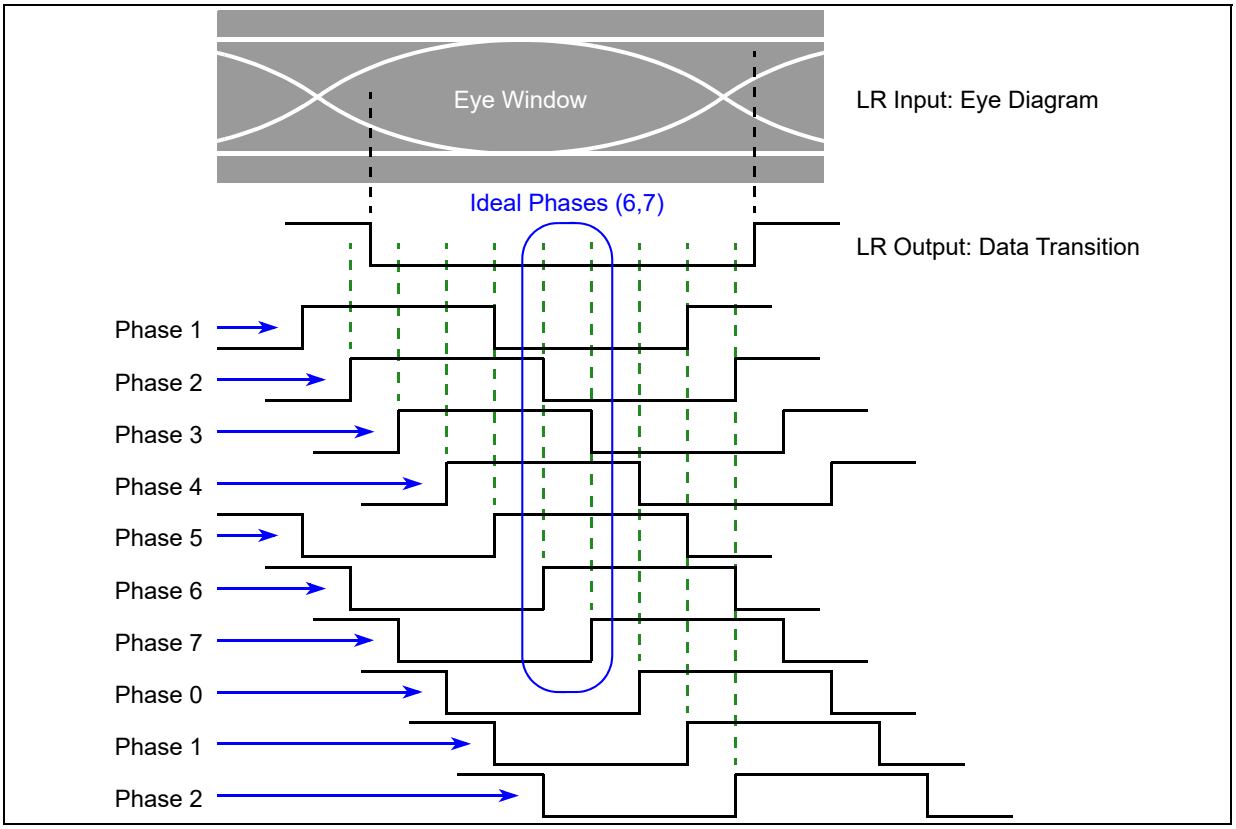
Figure 935. Hunt correlation mode



51.7.2.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

51.7.2.2.3 Auto-correlation



The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto-correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in *Figure 936*.

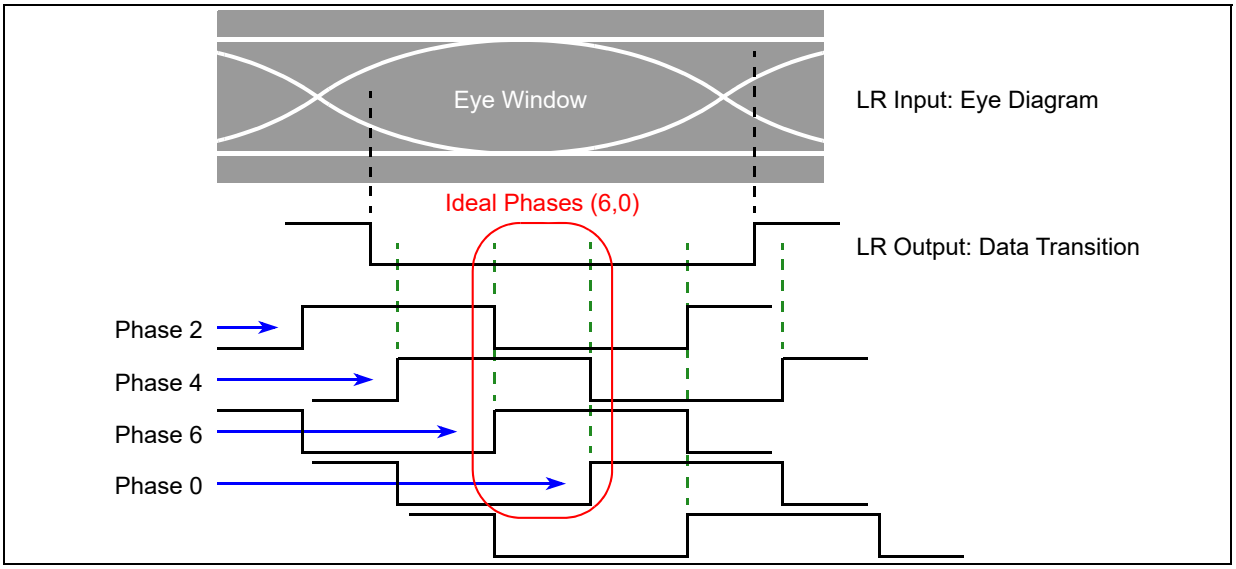
Figure 936. High speed 8 phase selection

The objective of the auto-correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in *Figure 937*.

Figure 937. High speed 8 phase clock alignment example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in *Figure 938* and *Figure 939*.

Figure 938. High speed 4 phase clock alignment example



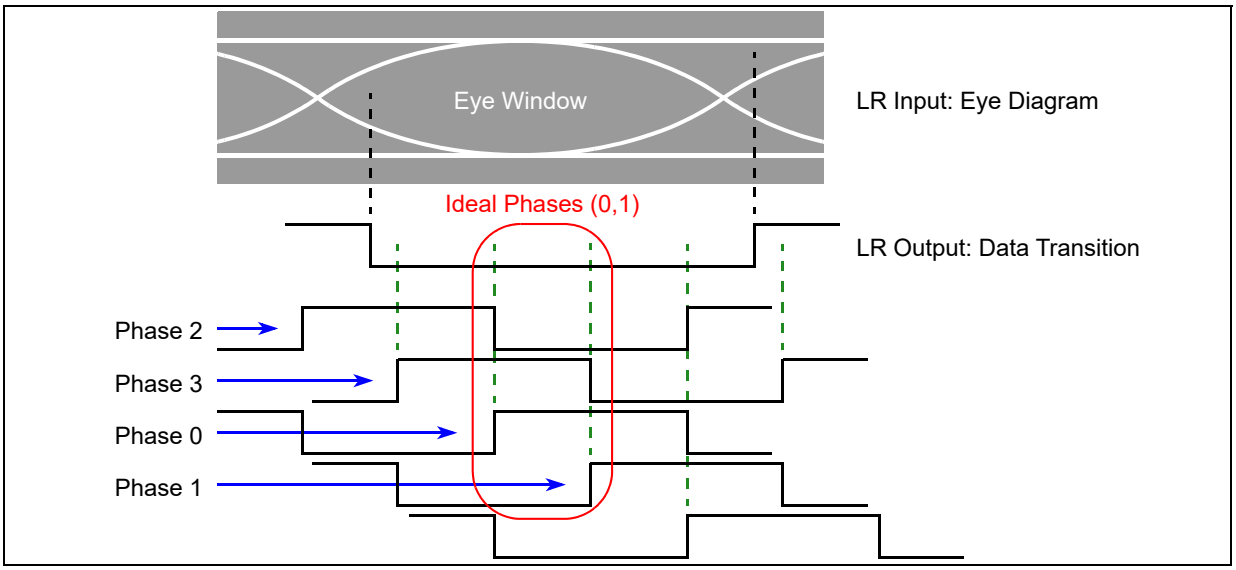


Figure 939. Low speed 4 phase clock alignment example

The auto-correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to an intermediate phase as shown in *Table 999*, *Table 1000*, and

Table 1001 before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 999. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 1000. High speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See *Table 1000*, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

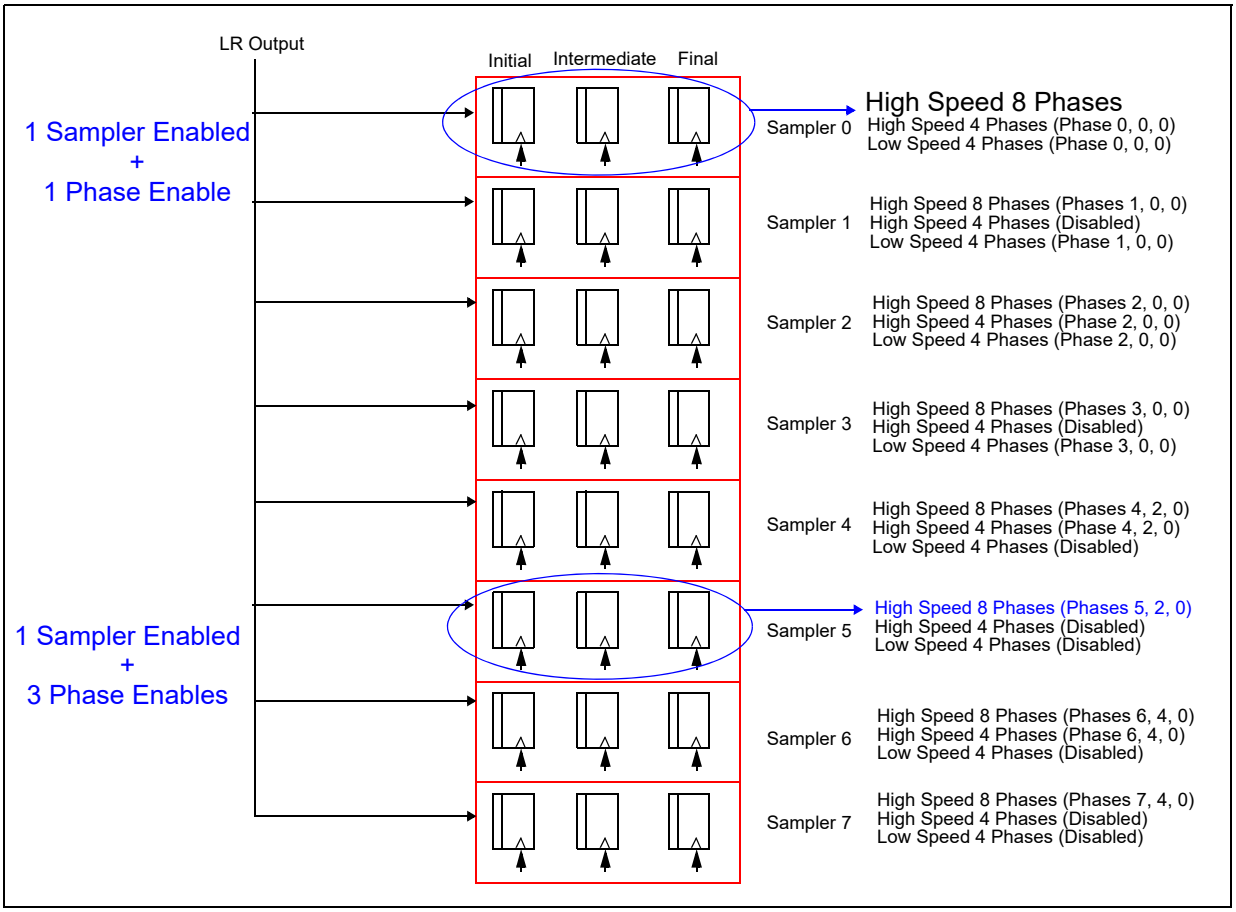
Table 1001. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0

Table 1001. Low speed 4 phase selection - sampling procedure (continued)

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See *Table 1001*, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.



51.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto-correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in *Figure 940*.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for instance Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

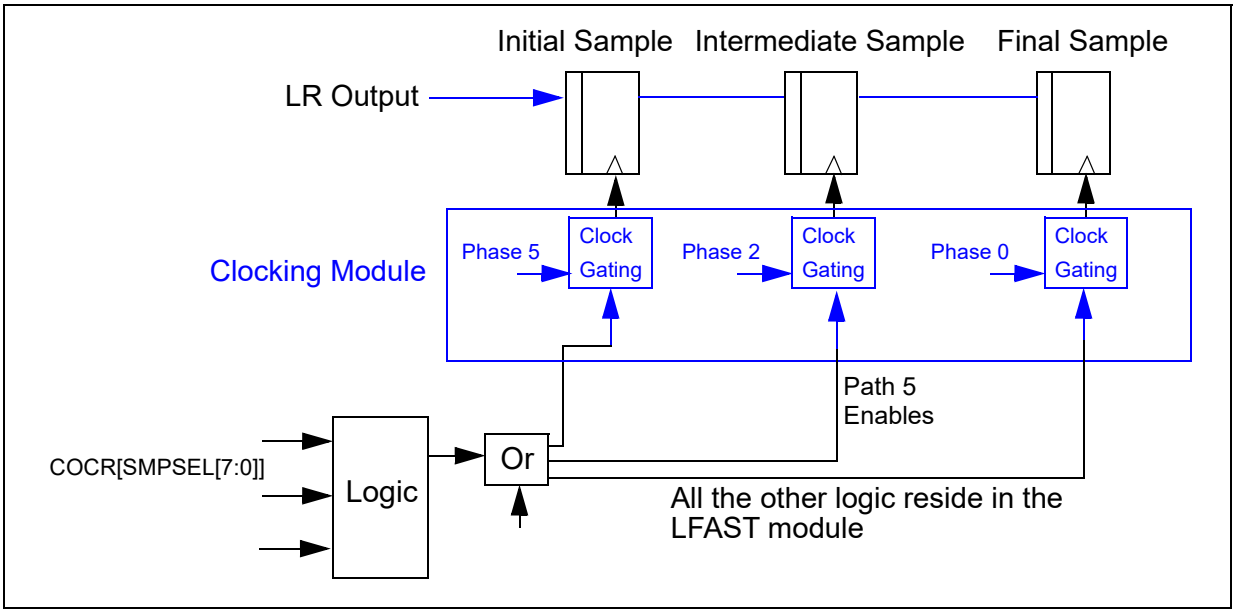


Figure 940. Samplers, each sampler has 3 registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in *Figure 941*.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

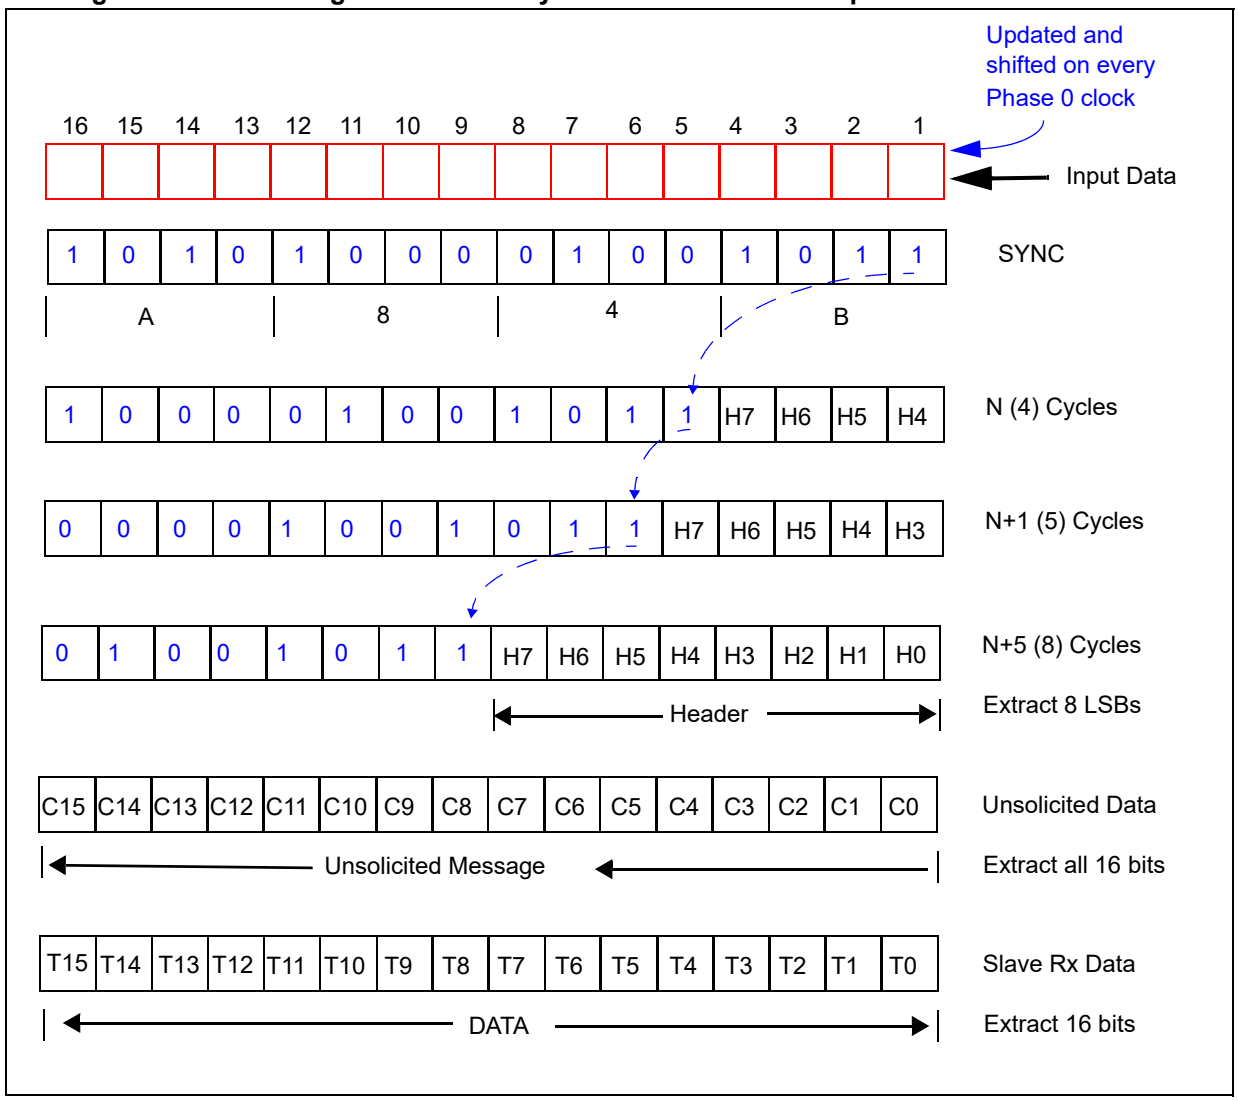

Figure 941. Sampler 5 Logic

51.7.2.3 Header and Payload extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16-bit word, bit shifted every Phase 0 clock as shown in *Figure 942*.

Figure 942. Extracting Header and Payload from the 16-bit output from Auto-correlation

51.7.2.3.1 Line Receiver states

The LD has the following states:

- Shutdown
  The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep
  The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- Normal
  In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 1002. Line Receiver state

LR State	LFAST Master Triggers (at least one of the following)	LFAST Slave Triggers (at least one of the following)
Shutdown	– Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LCR[SWWKLR]	– Programing of LCR[SWSLPLR] or LCR[SWWKLR]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

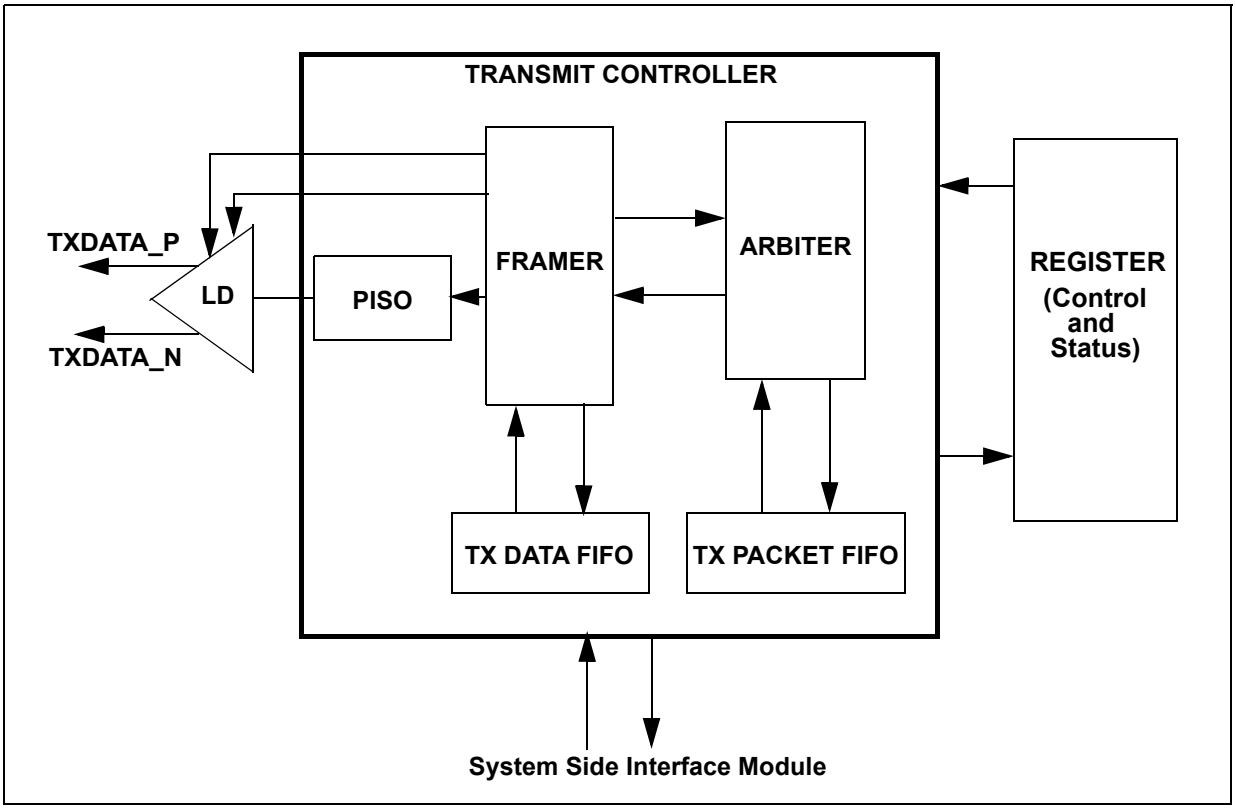
51.7.3 Transmit controller

51.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, such as unsolicited, ICLC, CTS, ping. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:



- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in *Figure 943*.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 943. Transmit controller connections

51.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- Software programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in *Table 1003*.

Table 1003. Priority levels for the Transmit controller

Request	LFAST master priority	LFAST slave priority	Triggering conditions (at least one of the listed)
LFAST interface enable	1	1	– LFAST interface enable is asserted – LFAST interface enable is negated
Tx Interface disabled	2	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received
Tx Interface speed mode change	3	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received

Table 1003. Priority levels for the Transmit controller (continued)

Request	LFAST master priority	LFAST slave priority	Triggering conditions (at least one of the listed)
Loopback frame in Loopback mode	4	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	–	– LFAST Master: ICR[SNDICLC] = 1 – LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	–	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	6	– Last Frame with CTS = 1 received from the peer LFAST device – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	– Tx FIFO contains one or more frames – Last Frame with CTS = 1 received from the peer LFAST device – MCR[DATAEN] = 1
CTS Frame	8	8	– MCR[CTSEN] = 1 – Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

51.7.4 CTS mode support

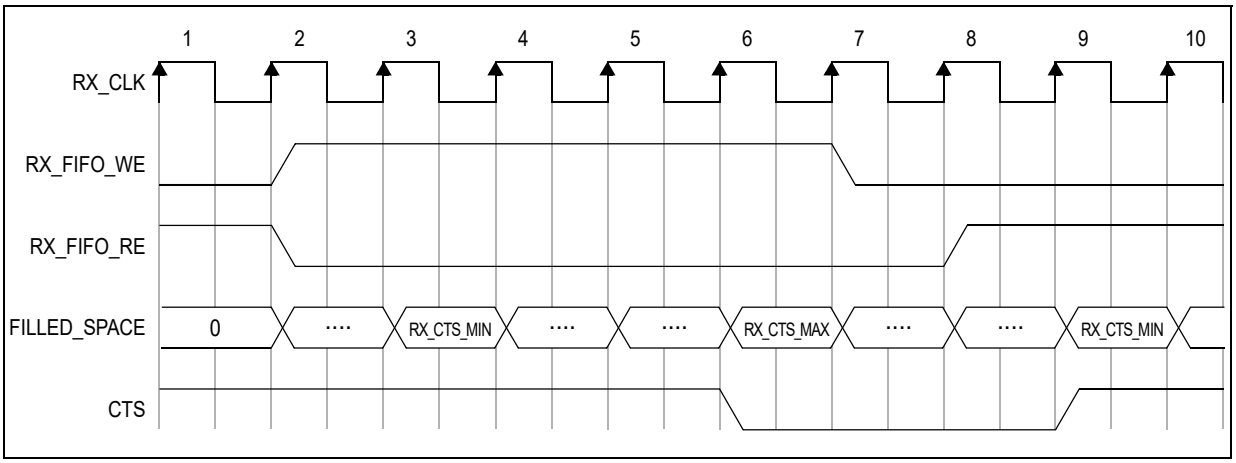
LFAST module supports flow control method defined in the LFAST3G standard. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write MCR[CTSEN] = 1 then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device does not want the peer device to send data. The CTS bit of all frame are sent 0 until the Rx FIFO pointer reaches the lower threshold, as described below.
- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 until the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.



If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frames sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed until a frame with CTS bit 1 is received.

Figure 944. CTS generation

51.7.5 Frames supported

Table 1004 provides the frames supported and their permissible payload sizes

Table 1004. Frames supported by LFAST interfaces

Frame type	LCT code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload size (bits)
Data frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited frame	0001b	YES	YES	8, 32, 64, 96, 128, 256, 288
ICLC frame	0000b	YES	NO(1)	8
CTS frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) codes other than the above mentioned are received then the interrupt flag RISR[RXLCEF] = 1. If the payload size received does not match any value in *Table 1004* then the flag RISR[RXSZF] = 1. In both these error conditions the received frame is ignored. The software may have to take the necessary steps to recover from such an error.

51.7.6 Frame flow

The following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

51.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

51.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

51.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

51.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

51.7.6.2 Unsolicited flow

51.7.6.2.1 Unsolicited frame transmit flow

The software is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

51.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the *Mode Configuration Register (MCR)* to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1.
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.

4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

51.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

51.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

51.7.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see *Table 1005* for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 1005. Supported ICLC payloads

ICLC code (hex)	ICLC function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLL In preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010… continuously using the currently configured clock rate (slow, fast)
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional).
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the *Table 1005*.
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exists.

Note: ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in Table 1005.

51.7.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in *Table 1005* will cause RISR[RXICF] = 1.

51.7.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The software can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame.The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

51.7.6.3.2.2 Start PLL ICLC

The Start PLL ICLC command will write bit RIISR[ICPONF] = 1.

51.7.6.3.2.3 Stop PLL ICLC

The Stop PLL ICLC command will write RIISR[ICPOFF] = 1.

51.7.6.3.2.4 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

51.7.6.3.2.5 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

51.7.6.3.2.6 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or software programs MCR[TXEN] = 1.

51.7.6.3.2.7 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

51.7.6.3.2.8 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

51.7.6.3.2.9 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable .

51.7.6.3.2.10 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

51.7.6.4 CTS flow

51.7.6.4.1 CTS Tx flow

The CTS frame, if enabled by the software, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

51.7.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frames with LCT type CTS are not stored in the LFAST.

51.7.7 Test and debug support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

51.7.7.1 Loopback test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

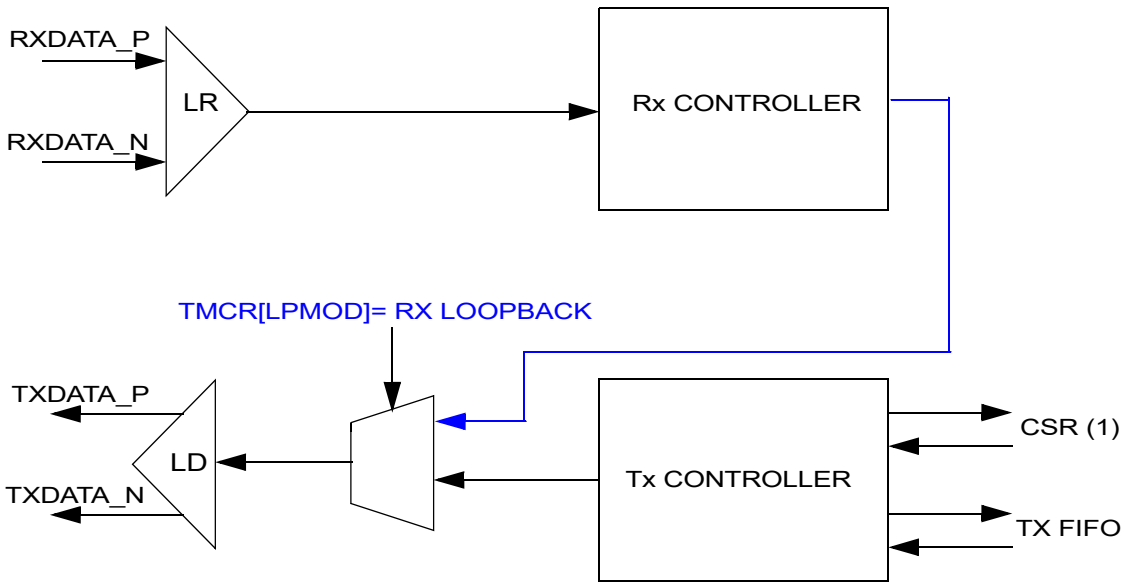
- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for software should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 1006. Loopback modes

LPMOD[2:0]	Mode selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by the software, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.



In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

51.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

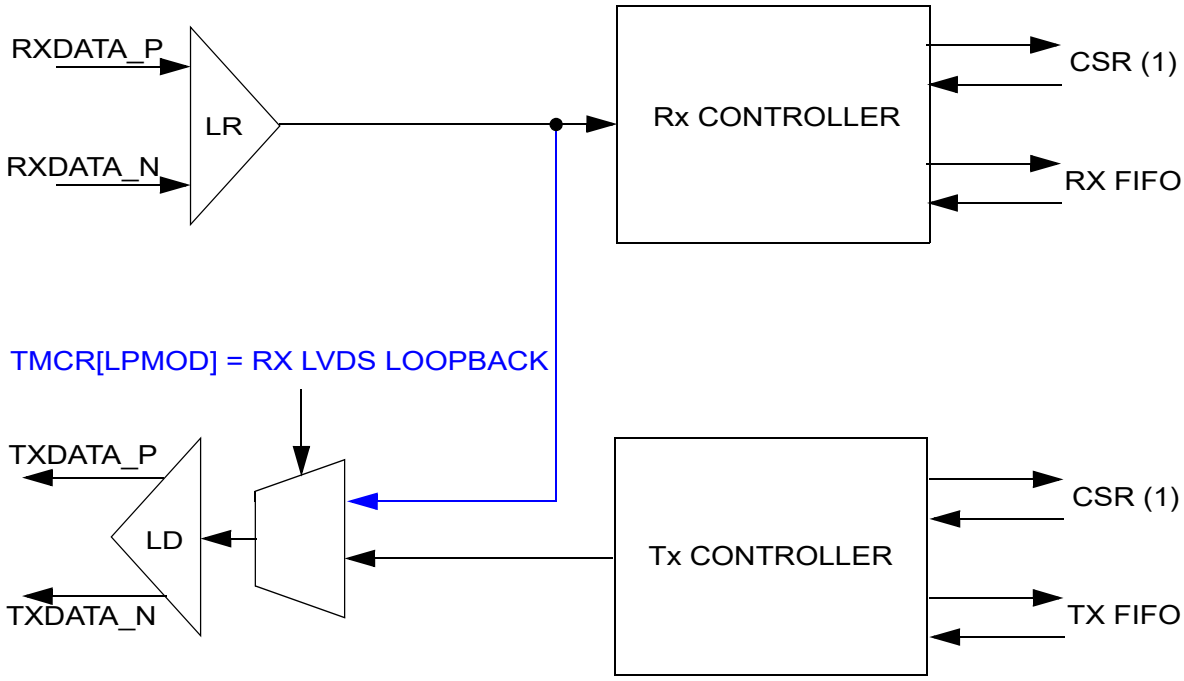
Figure 945. Rx Loopback mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx Loopback mode:

1. Software programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload 0xFF (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:



- Software programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 0x38 (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

51.7.7.1.2 Rx LVDS Loopback mode

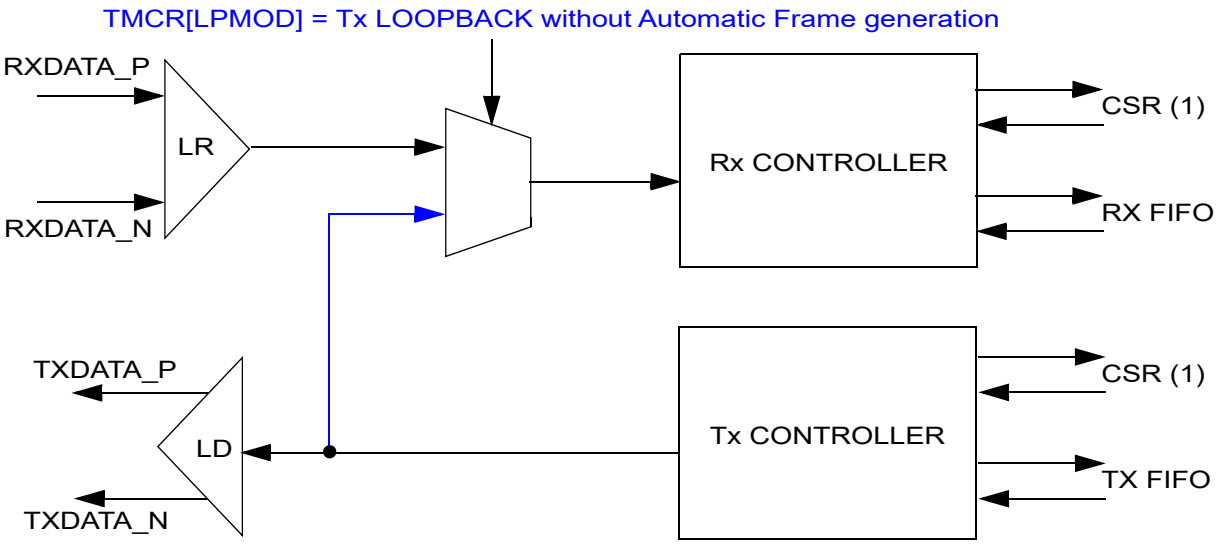
This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 946. Rx LVDS LoopBack mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx LVDS Loopback mode:

1. Software programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   - The software writes TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload = 0xFF (Loopback mode ON), from LFAST Master.



Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 0x38 (Test mode off), from LFAST Master.

51.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 947. Tx LoopBack mode without automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback without Automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from LFAST Master

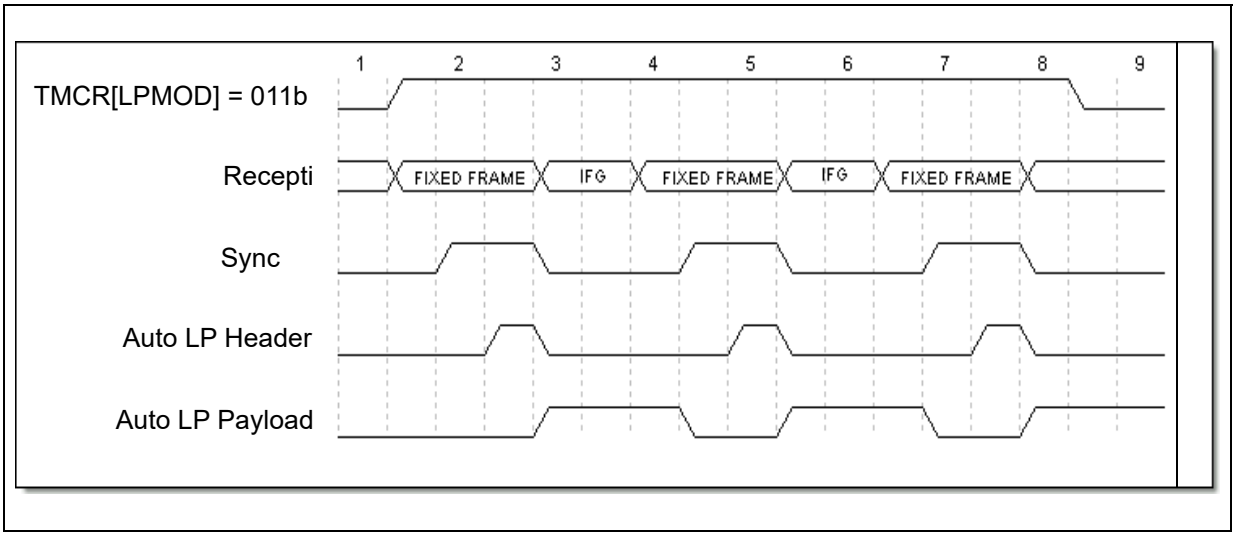
Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

51.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal software intervention.



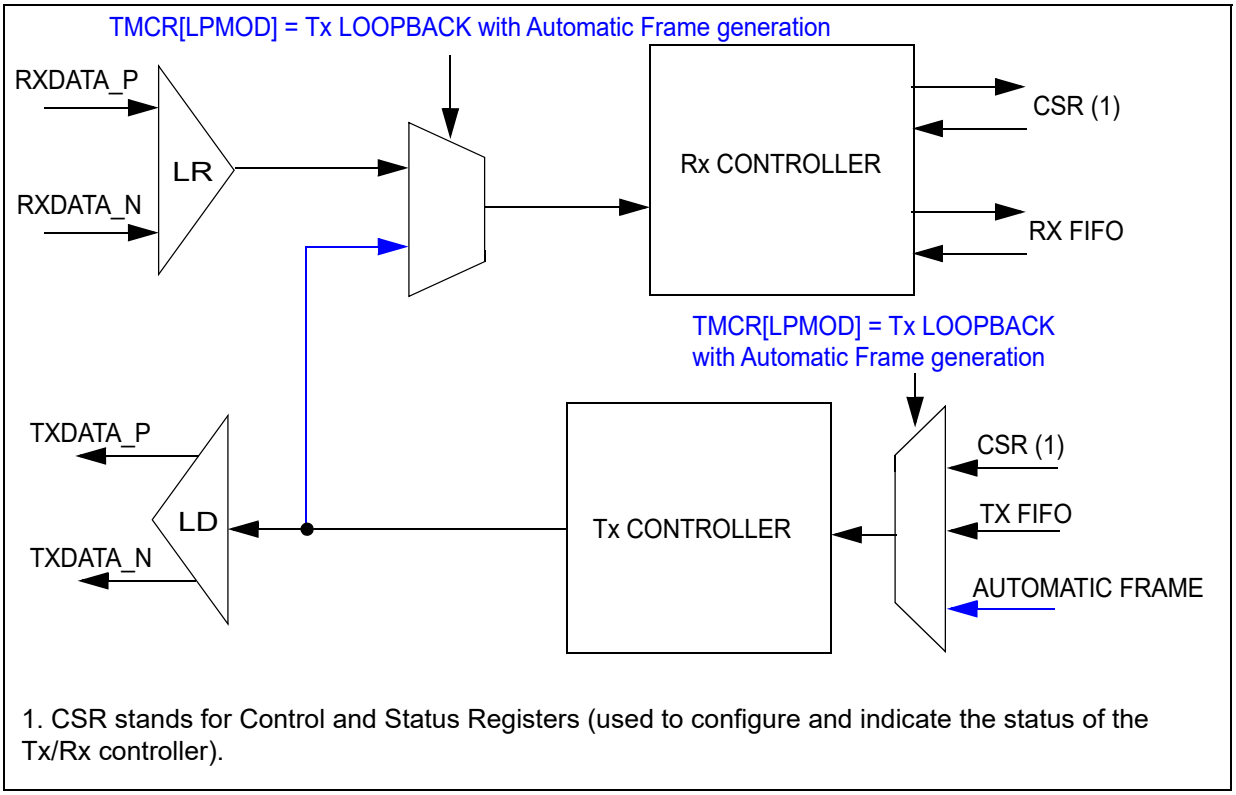
The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 0x13 received.
- GSR[LPCPDV]: Frame with Payload of 0xCB received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 948. Automatic Loopback test status signal timings



The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

51.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

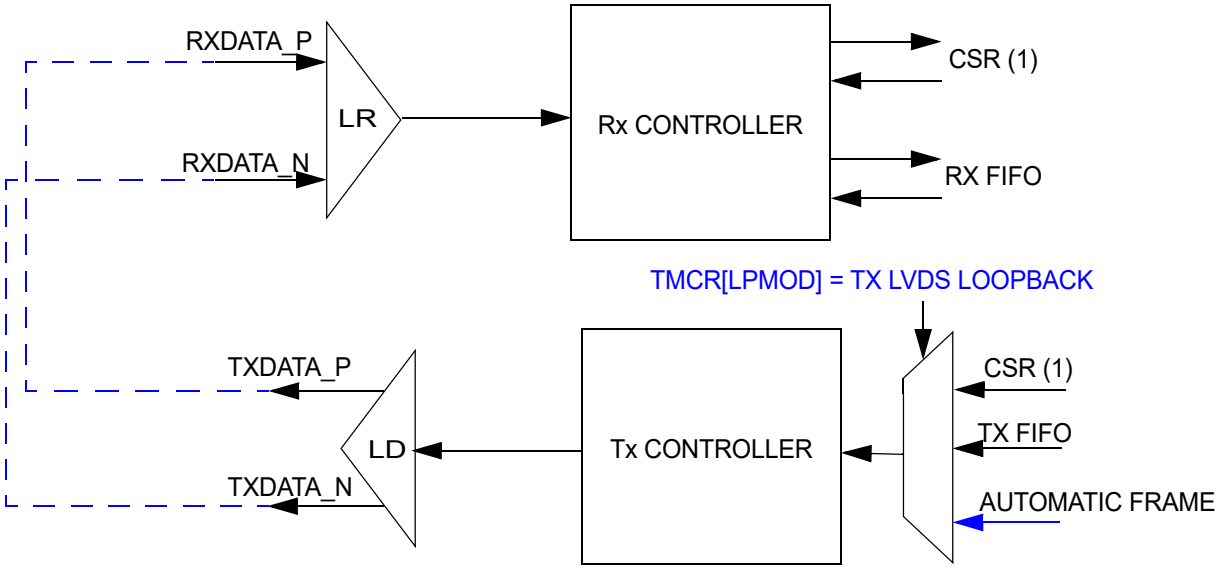
When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the software. The frames generated have fixed header of 0x13 and payload of 0xCB. The successful reception of this frame is indicated by the status signals and registers.

Figure 949. Tx LoopBack mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from the LFAST Master.



Exit from Tx Loopback with Automatic frame generation mode can be done by the following method:

- Software programs TMCR[LPON] = 0.

51.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 950. Tx LVDS Loopback (external) mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx LVDS loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by the following method:

- Software programs TMCR[LPON] = 0.

51.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- Software programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 0x34 (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be canceled by any of the following methods:

- Software programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off) from LFAST Master.

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

51.7.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC receive interrupt

Each interrupt is asserted when any one of their status conditions is met.

51.7.8.1 Transmit complete interrupt

This interrupt indicates a transfer completion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

51.7.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 1007. Recommended transmit exception handling

Exception	Recommendation
TXOVF	– MCR[TXEN] = 0 – The system level interfaces transmit is reseted and enabled again – For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set – For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	– The MCR[TXEN] should be set

51.7.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

51.7.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 1008. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required

Table 1008. Recommended receive exception handling mechanism (continued)

Exception	Recommendation
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	– The MCR[RXEN] may be cleared – The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RXMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

51.7.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

51.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 1009. Frames supported by LFAST interfaces

Frame type	Tx buffer (in bits)	Rx buffer (in bits)	Memory type
Data frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC frame	1 × 8 max 1 packet(1)	1 × 8 max 1 packet(2)	Registers ICR, PISR
CTS frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1.
2. Only for ping response data when MCR[MSEN] = 1.

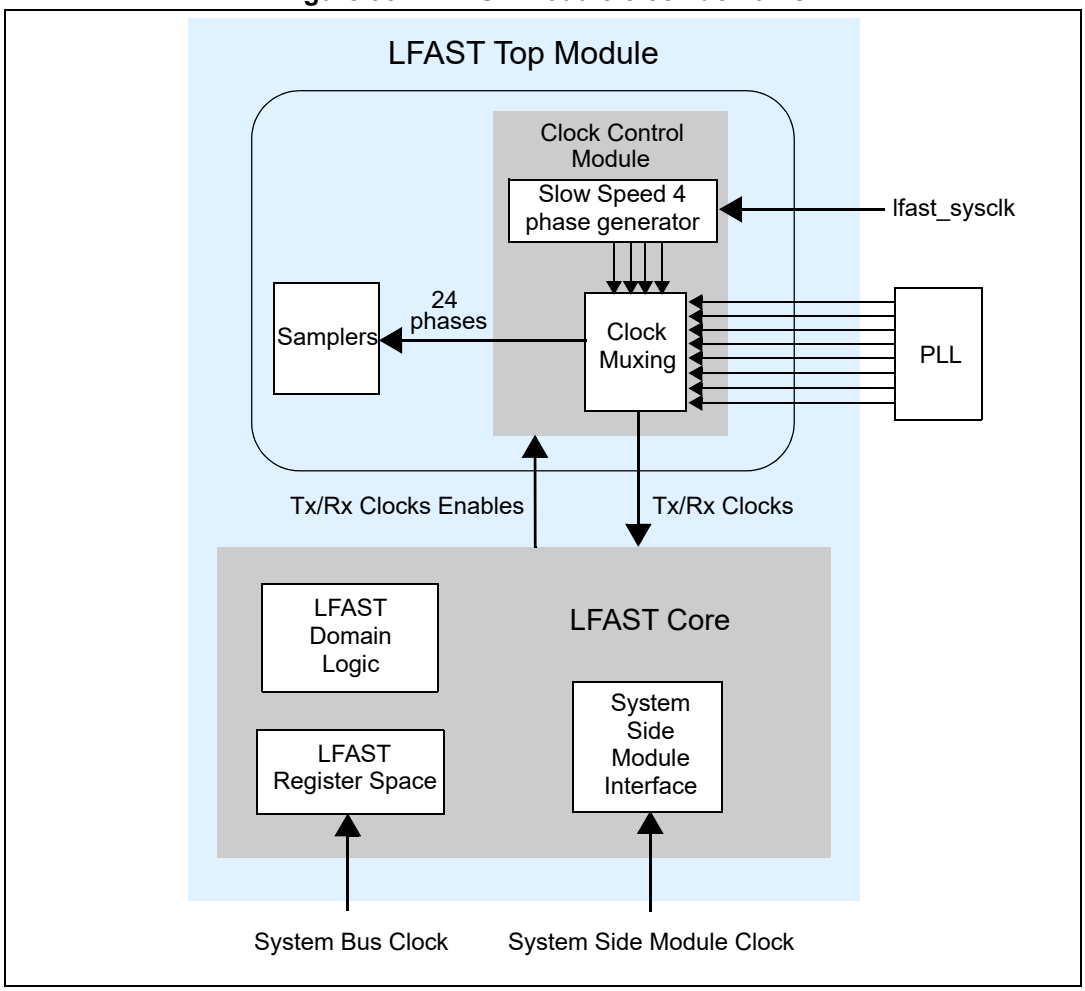
51.9 Resets

The various blocks in LFAST are reset as described in *Table 1010*.

Table 1010. Recommended receive exception handling mechanism

Reset	Blocks reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of *Mode Configuration Register (MCR)*	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFEN bit of *Mode Configuration Register (MCR)*	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]

51.10 Clocks



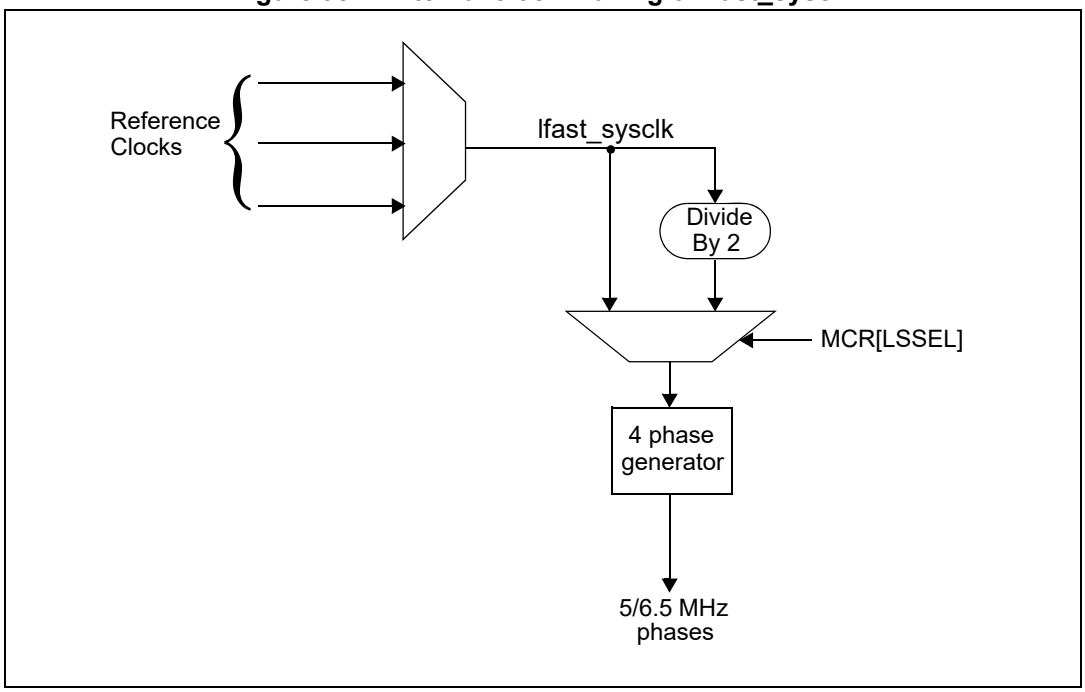
The LFAST mainly works on three clocks:

- System Bus Clock, used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

51.10.1 Clocking strategy

Figure 951 shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 951. LFAST module clock domains



51.10.2 Slow speed clock

51.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in *Figure 952*, *Figure 953* and *Figure 954*.

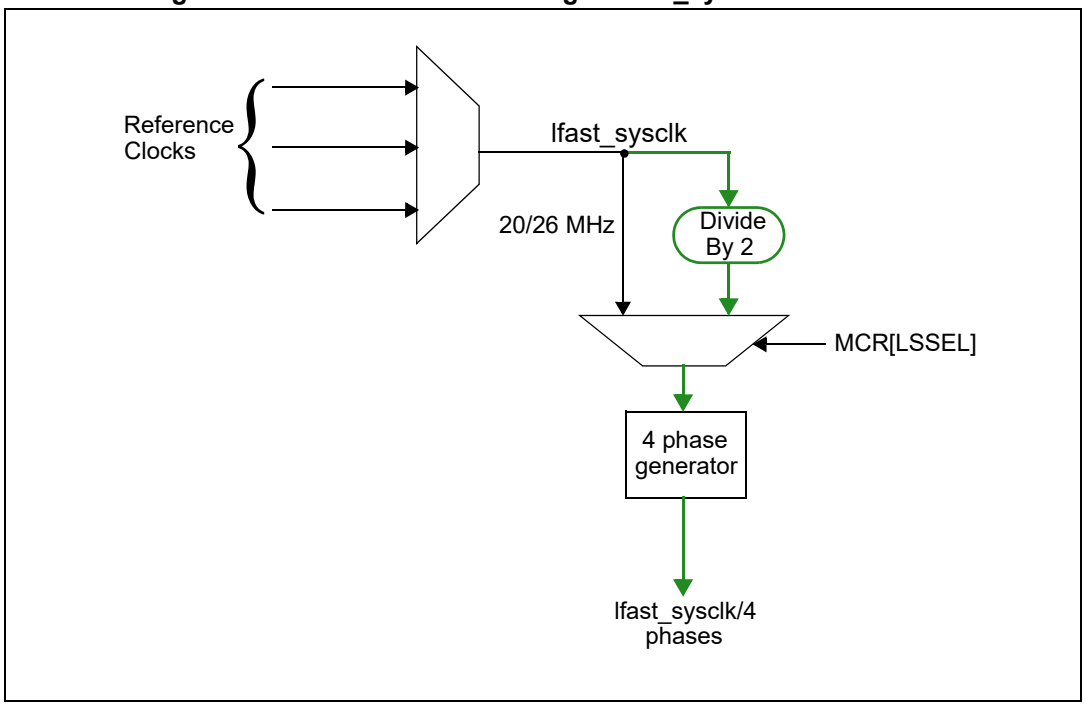


Figure 952. External clock muxing of lfast_sysclk

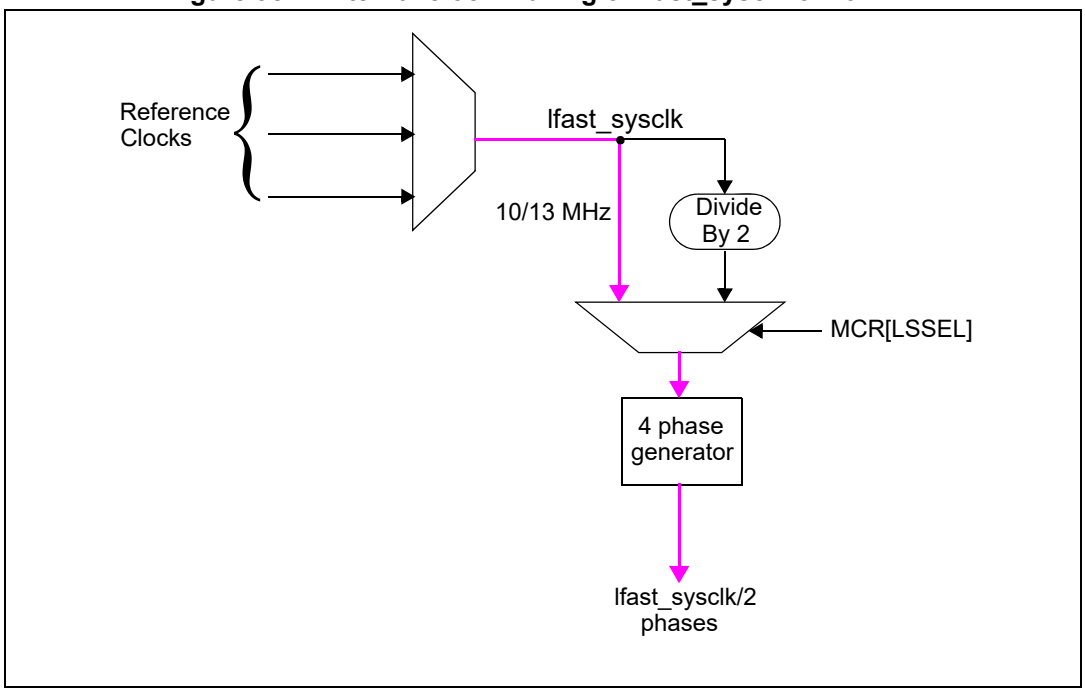
All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in *Figure 952*.



The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 953* (selected clock path shown in green).

Figure 953. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 954* (selected clock path selected shown in magenta).

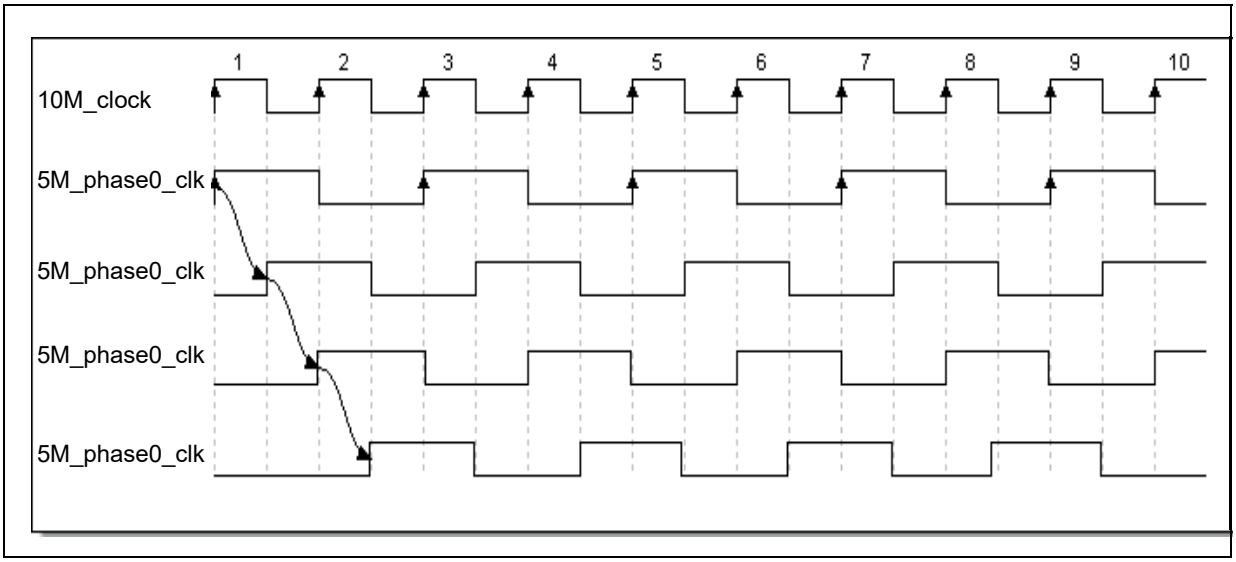


Figure 954. External clock muxing of lfast_sysclk of 10 MHz

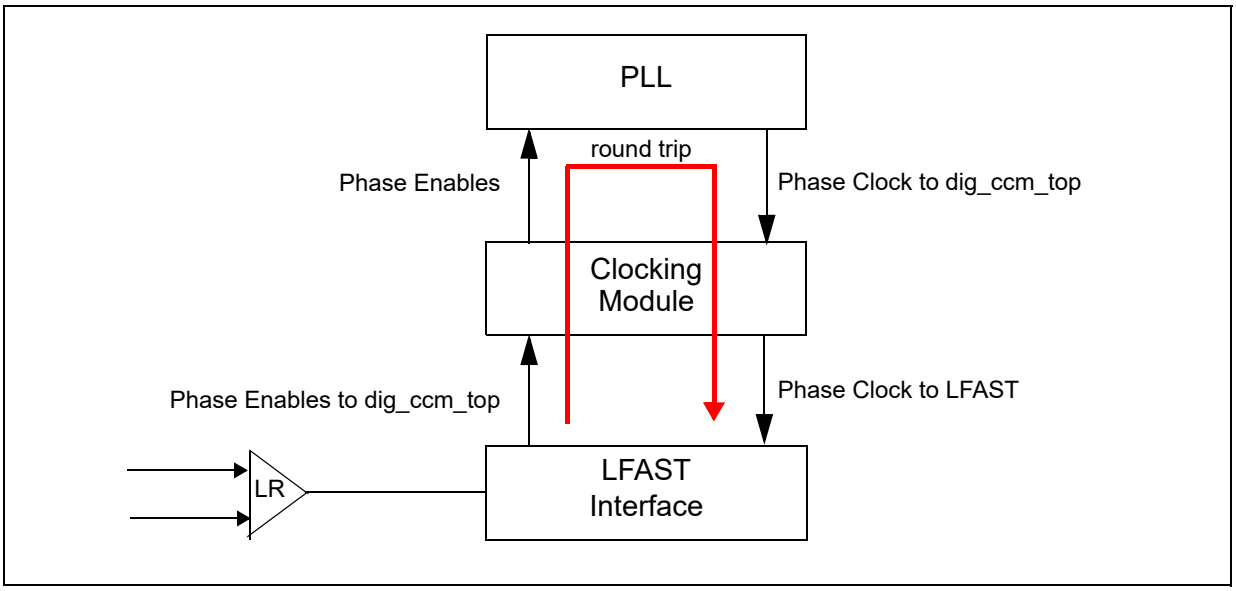
51.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. *Figure 955* Shows 4 phases getting generated using lfast_sysclk.

Figure 955. Slow speed 4 phases generation



51.10.3 Rx controller clocks

51.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in *Figure 956*.

Figure 956. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

51.10.3.2 Clock module requirements for low speed phases

51.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

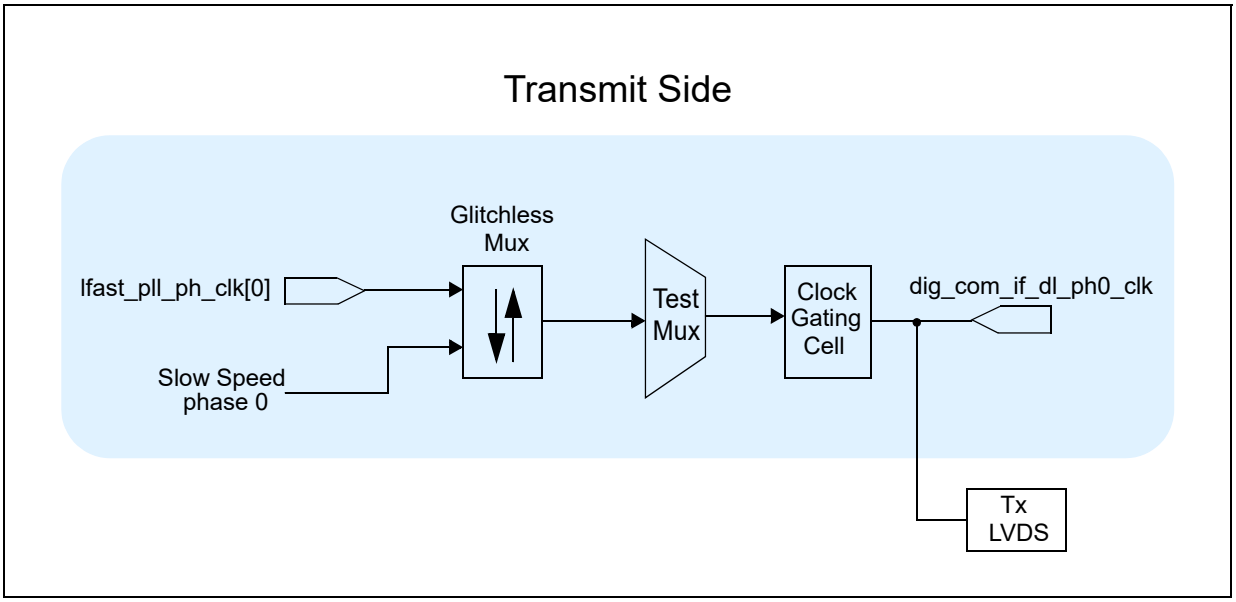
Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 1011. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

51.10.4 Tx controller clocks

51.10.4.1 Clocking module requirements for speed phases



The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See *Table 1012*.

Table 1012. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

51.10.4.2 Transmit clock muxing

Figure 957. Transmit clocks muxing

51.10.4.3 Tx request clock control

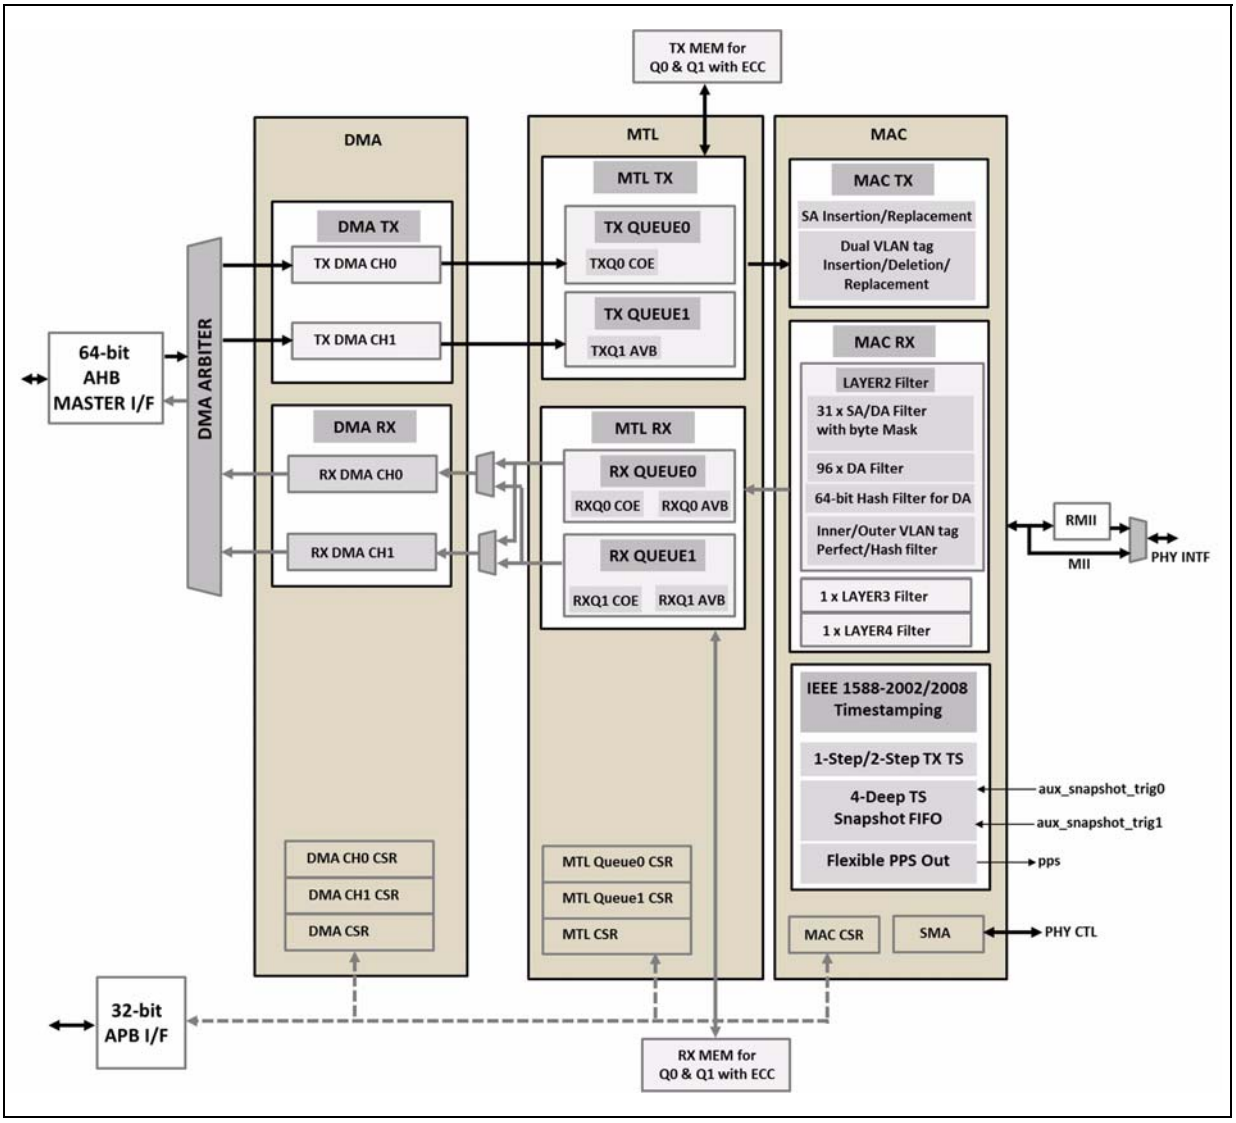
The Tx phase 0 clock is enabled when all the resets are negated.

52 Ethernet

52.1 Overview

The Ethernet module enables a host to transmit and receive data over the Ethernet in compliance with the IEEE 802.3-2008. *Figure 958* shows a system-level block diagram of the Ethernet module.

As shown in *Figure 958*, the Ethernet module uses a 64-bit AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through AHB master interface. One AHB master interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all the paths (Transmit and Receive) in all channels.



As shown in *Figure 958*, the Ethernet module uses a 32-bit APB interface to program the Control and Status registers (CSR). Each channel has a separate set of Control and Status registers (CSR) for managing the Transmit and Receive functions, descriptor handling, and interrupt handling.

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the Ethernet module. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are one-ported RAM of 68-bit width for 64 data bus widths. The extra bits are used for storing the byte-enable information.

For multiple queues, all Tx queue share the Tx FIFO memory and all Rx queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue. The Ethernet module provides a direct read or write access to the FIFO memories in Debug mode.

The Ethernet module can be programed to use either of MII or RMII PHY interfaces.

Figure 958. System Level block diagram

52.1.1 Ethernet module Features

52.1.1.1 Standard Compliance

The Ethernet module is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC, Media Independent Interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization
- IEEE 802.1AS-2011 and 802.1-Qav-2009 for Audio Video (AV) traffic
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and APB slave ports
- RMII specification version 1.2 from RMII consortium

52.1.1.2 MAC

The MAC supports the following features:

- MAC Tx and Rx features
- MAC Tx features
- MAC Rx features

52.1.1.2.1 MAC Tx and Rx features

Following is the list of MAC Tx and Rx features:

- Separate transmission, reception, and control interfaces to the application
- 10 and 100, Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using backpressure support
  - Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs.
- 64-bit data transfer interface on the application side
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- Network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Support for Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in TX direction
- Flexibility to control the Pulse-Per-Second (PPS) output signal
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

52.1.1.2.2 MAC Tx features

Following is the list of MAC Tx features:

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 16 KB of size
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Source Address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement, or deletion of up to two VLAN tags
- Option to transmit packets with reduced preamble size in full-duplex mode

52.1.1.2.3 MAC Rx features

Following is the list of MAC Rx features:

- Automatic Pad and CRC Stripping options
- Option to disable Automatic CRC checking
- Preamble and SFD deletion
- Separate 112-bit or 128-bit status
- Programmable watchdog timeout limit
- Flexible address filtering modes:
  - 128 MAC addresses for unicast 48-bit perfect filtering
    - 31 filters for destination address (DA) or source address (SA) comparison with masks for each byte
    - 97 filters for destination address (DA) that can be selected in blocks of 32 and 64 registers
  - 64 bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multicast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- module to detect remote wake-up packets and AMD magic packets
- forwarding of received Pause packets to the application (in full-duplex mode)
- Receive module for Layer 3/Layer 4 checksum offload for received packets
- Stripping of up to two VLAN Tags and providing the tags in the status

52.1.1.3 MAC Transaction Layer (MTL)

The MTL block consists of the following FIFOs: Tx FIFO and Rx FIFO. The FIFO space is shared by multiple queues. The buffer size is configured for each queue in multiples of 256 bytes.

52.1.1.3.1 MTL Tx and Rx features

Following is the list of MTL Tx and Rx features:

- 64-bit Transaction Layer block (bridges the application and the MAC)
- Data transfers executed using simple FIFO protocol
- Synchronization for all clocks in the design (Transmit, Receive, and Application clocks)
- Optimization for packet-oriented transfers with packets delimiters
- Programmable threshold capability for each queue (default of 64 bytes)
- Debug and slave mode operation on Queue 0 (default queue)

52.1.1.3.2 MTL Tx features

Following is the list of MTL Tx features:

- Two single-port RAM-based (SPRAM) synchronous FIFO controllers
- 4 KB TX FIFO size
- Dual queues on the Transmit path with a common memory for both Tx queues
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable queue size. Each queue size can be programed in terms of 256 bytes
- Automatic retransmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Disabling of Data Memory RAM chip-select when inactive to reduce power consumption
- Checksum offload engine calculates and inserts IPv4 header checksum and TCP, UDP, or ICMP checksum
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Programmable interrupt options for different operational conditions
- Option to support dropping of Tx Status to improve the Transmit throughput
- Packet-level control for:
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer3/Layer4 Checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
- Following scheduling algorithms in configurations with multiple queues:
  - Weighted Round Robin (WRR)
  - Strict Priority (SP)
  - Credit-based Shaper (CBS) for AVB
- Statistics related to bandwidth consumption by each queue of up to 16 blocks over a 125 µs period

52.1.1.3.3 MTL Rx features

Following is the list of MTL Rx features:

- 8 KB Rx FIFO size
- Dual queues on the Receive path with a common memory for all Rx queues
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)

52.1.1.4 DMA block

The DMA block exchanges data between the MTL block and system memory. The well-defined descriptors structure acts as a software and hardware interface. The application can use a set of registers (DMA CSR) to control the DMA operations. The DMA block supports the following features:

- 64-bit data transfers
- 2-channel Transmit and 2-channel Receive engines
- Separate DMA channel in the Transmit path for each queue in MTL
- 2-DMA channels for queues in MTL Receive path
- Fully synchronous design operating on a single application clock except for CSR module
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 KB of data)
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions

- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host CSR access and host data interface
- Routing of received packets to the RX DMA channels based on the DA or VLAN Priority in multi-channel DMA configurations
- Time-sensitive conditional packet transmission by comparing the Slot Time information provided in the descriptor (useful for AV applications)

52.1.1.5 AMBA AHB Master Interface

The AHB master interface supports the following features:

- Interfaces with the application through 64-bit AHB
- Option to select address-aligned bursts from AHB master port
- Split, Retry, and Error AHB responses
- AHB 1 K boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)

The AHB master interface does not generate the following:

- Wrap burst
- Locked or Protected transfers

52.1.1.6 AMBA APB Slave Interface

The Ethernet module supports the 32-bit APB slave interface without any byte-enable to program the CSR registers.

52.1.1.7 Audio Video Support

The Ethernet module supports the following Audio Video (AV) features:

- Separate channels or queues for AV data transfer in 100 Mbps modes
- Up to 2-queues on the Receive paths for AV traffic and 1-queue on the Transmit path for AV traffic
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for Transmit channels
- Single Tx FIFO and Rx FIFO (MTL) for all selected queues (system-side interface [AHB] remains the same)

52.1.1.8 Monitoring, Testing, and Debugging Support

The Ethernet module supports the following features for monitoring, testing, and debugging:

- Internal loopback from Tx to Rx on the MII for debugging
- DMA states (Tx and Rx) as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data paths and FIFO fill-levels
- Application Abort status bits
- MMC (RMON) module
- Current Tx or Rx Buffer pointer as status registers
- Current Tx or Rx Descriptor pointer as status registers
- Statistical counters to calculate the bandwidth served by each Transmit channel when AV support is enabled
- Tx or Rx Queues memory accessible through Slave port for debug

52.2 Memory map and register description

This section provides a detailed description of all registers accessible in this module.

Table 1013. Ethernet memory map

Address offset (hex)	Register	Location
0x0000	MAC Configuration register (MAC_CONFIGURATION)	*Section 52.2.1*
0x0004	MAC Extended Configuration register (MAC_EXT_CONFIGURATION)	*Section 52.2.2*
0x0008	MAC Packet Filter register (MAC_PACKET_FILTER)	*Section 52.2.3*
0x000C	Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)	*Section 52.2.4*
0x0010	Hash Table register 0 (MAC_HASH_TABLE_REG0)	*Section 52.2.5*
0x0014	Hash Table register 1 (MAC_HASH_TABLE_REG1)	*Section 52.2.6*
0x0018–0x004F	Reserved	
0x0050	VLAN Tag register (MAC_VLAN_TAG)	*Section 52.2.7*
0x0054–0x0057	Reserved	
0x0058	VLAN Hash Table register (MAC_VLAN_HASH_TABLE)	*Section 52.2.8*
0x005C–0x005F	Reserved	
0x0060	VLAN Tag Inclusion register (MAC_VLAN_INCL)	*Section 52.2.9*
0x0064	Inner VLAN Tag Inclusion register (MAC_INNER_VLAN_INCL)	*Section 52.2.10*
0x0068–0x006F	Reserved	
0x0070	MAC Q0 Flow Control register (MAC_Q0_TX_FLOW_CTRL)	*Section 52.2.11*
0x0074	MAC Q1 Flow Control register (MAC_Q1_TX_FLOW_CTRL)	*Section 52.2.12*
0x0078–0x008F	Reserved	
0x0090	MAC Receive Flow Control register (MAC_RX_FLOW_CTRL)	*Section 52.2.13*
0x0094–0x0097	Reserved	

Table 1013. Ethernet memory map (continued)

Address offset (hex)	Register	Location
0x0098	Transmit Queue Priority Mapping 0 register (MAC_TXQ_PRTY_MAP0)	*Section 52.2.14*
0x009C–0x009F	Reserved	
0x00A0	Receive Queue Control 0 register (MAC_RXQ_CTRL0)	*Section 52.2.15*

Figure 959. MAC Configuration Register (MAC_CONFIGURATION)

Table 1014. MAC_CONFIGURATION field descriptions

Field	Description
0 ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It will forward the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.
1:3 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 1 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[2:3]: 0x If TDES3[SAIC] = 3'b000 then the application provides the correct SA field else insertion logic will work according to the setting of TDES3[SAIC]. 10 If Bit 1 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 11 If Bit 1 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. **Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. These bits are reserved and RO when the Enable SA and VLAN Insertion on Tx feature is not selected while configuring the core.
4 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.
5:7 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. 000 96 bit times 001 88 bit times 010 80 bit times ... 111 40 bit times This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register.

Table 1014. MAC_CONFIGURATION field descriptions (continued)

Field	Description
8 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programed giant packet limit should be less than the watchdog limit to get the giant packet status.
9 S2KP	IEEE 802.3 as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, refer to Giant Packet Status based on S2KP and JE Bits. **Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.
10 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. This function is valid when Type 2 Checksum Offload Engine is enabled. **Note:** For information about how the settings of the ACS bit and this bit impact the packet length, refer to *Table 1015*.
11 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. For more details, refer to *Table 1015* **Note:** For information about how the settings of CST bit and this bit impact the packet length, refer to *Table 1015*.
12 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Table 1014. MAC_CONFIGURATION field descriptions (continued)

Field	Description
14 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.
15 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
16 PS	Port Select 1 For 10 or 100 Mbps operations
17 FES	Speed This bit selects the speed in the 10/100 Mbps mode: 0 10 Mbps 1 100 Mbps
18 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously.
19 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.
20 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal.
21 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the MII_TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode.
22 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.
23 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode.

Table 1014. MAC_CONFIGURATION field descriptions (continued)

Field	Description
25:26 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. 00 k = min (n, 10) 01 k = min (n, 8) 10 k = min (n, 4) 11 k = min (n, 1) where - = retransmission attempt The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode.
27 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.
28:29 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 7 bytes of preamble 01 5 bytes of preamble 10 3 bytes of preamble 11 Reserved
30 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.
31 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

Table 1015. Packet length based on the CST and ACS bits

Receive checksum offload engine	Receive packet length	CST	ACS	FCS stripping done
IPCKSUM_EN = 0 and IPC_FULL_OFFLOAD = 0 or IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 1	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	0	x	No
		1	x	Yes (for Type packets)
IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 0	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	x	x	No

52.2.2 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Offset 0x0004 Access: User Read/Write

Figure 960. MAC_Ext_Configuration Register (MAC_EXT_CONFIGURATION)

Table 1016. MAC_EXT_CONFIGURATION field descriptions

Field	Description
2:6 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
7 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. **Note:** The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode.
13 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
14 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.
15 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.
18:31 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programed in this field must be greater than or equal to 1,518 bytes. Any other programed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

52.2.3 MAC Packet Filter Register (MAC_PACKET_FILTER)

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Figure 961. MAC Packet Filter Register (MAC_PACKET_FILTER)

Table 1017. MAC_PACKET_FILTER field descriptions

Field	Description
0 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.
10 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
11 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.
15 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.
21 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Table 1017. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
22 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. **Note:** According to the IEEE specification, Bit 47 of the SA is reserved. However, in the Ethernet module, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.
23 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programed in the SA registers, it is marked as failing the SA Address filter.
24:25 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 The MAC filters all control packets from reaching the application. 01 The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 10 The MAC forwards all control packets to the application even if they fail the Address filter. 11 The MAC forwards the control packets that pass the Address filter.
26 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets.
27 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
28 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
29 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programed in DA registers.

Table 1017. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
30 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programed in DA registers.
31 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

52.2.4 Watchdog Timeout Register (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

Offset 0x000C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 962. MAC Watchdog Timeout Register (MAC_WATCHDOG_TIMEOUT)

Table 1018. MAC_WATCHDOG_TIMEOUT field descriptions

Field	Description
23 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register.
28:31 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Encoding is as follows: 0x0 2 KB 0x1 3 KB 0x2 4 KB 0x3 5 KB ... 0xC 14 KB 0xD 15 KB 0xE 16383 Bytes 0xF Reserved **Note:** When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

52.2.5 Hash Table Register 0 (MAC_HASH_TABLE_REG0)

The Hash Table Register 0 contains the first 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bit determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (Refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

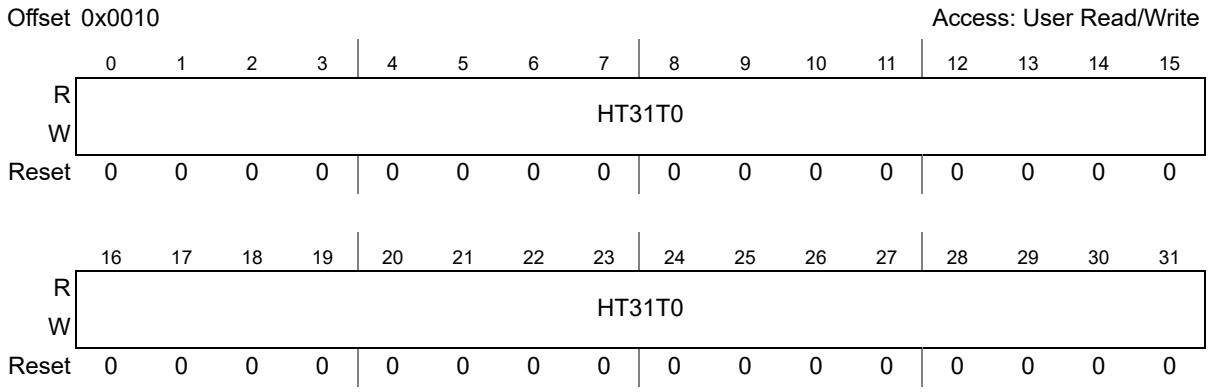

Figure 963. MAC Hash Table Reg0 Register (MAC_HASH_TABLE_REG0)

Table 1019. MAC_HASH_TABLE_REG0 field descriptions

Field	Description
0:31 HT31T0	This field contains the first 32 Bits [0:31] of the Hash table.

52.2.6 Hash Table Register 1 (MAC_HASH_TABLE_REG1)

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determine the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

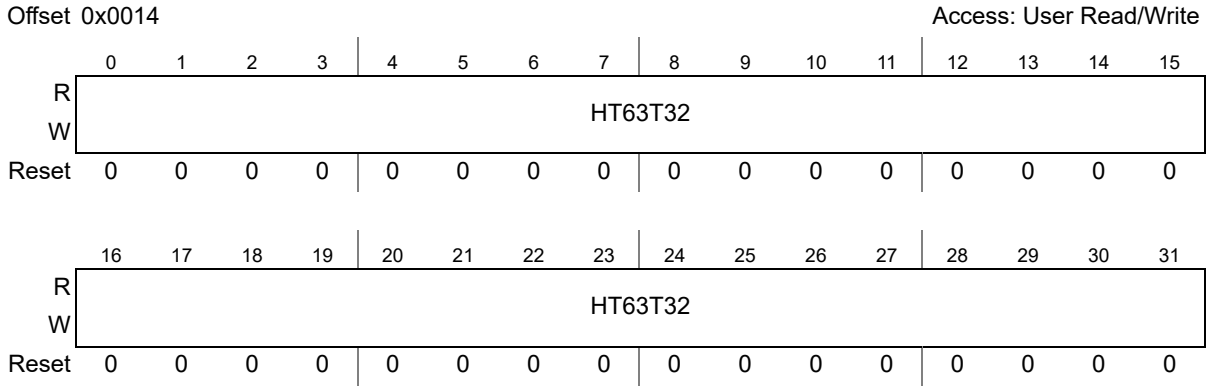

Figure 964. Hash Table Reg1 Register (MAC_HASH_TABLE_REG1)

Table 1020. MAC_HASH_TABLE_REG1 field descriptions

Field	Description
0:31 HT63T32	This field contains the second 32 Bits [31:0] of the Hash table.

52.2.7 VLAN Tag Register (MAC_VLAN_TAG)

The VLAN Tag register identifies the IEEE 802.1Q VLAN type packets.

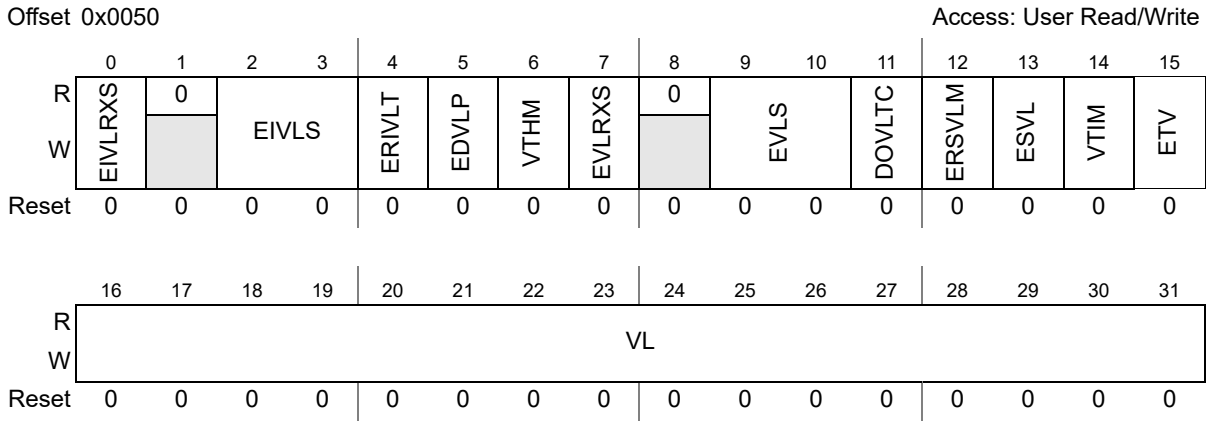

Figure 965. VLAN Tag Register (MAC_VLAN_TAG)

Table 1021. MAC_VLAN_TAG field descriptions

Field	Description
0 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.
2:3 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
4 ERIVLT	Enable Inner VLAN Tag When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
5 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).
6 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed.
7 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.
9:10 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
11 DOVLTC	Disable VLAN Type Check When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Table 1021. MAC_VLAN_TAG field descriptions (continued)

Field	Description
12 ERSVLM	Enable Receive S-VLAN Match When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching.
13 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.
14 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.
15 ETV	Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[20:31] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN hash filtering.
16:31 VL	VLAN Tag Identifier for Receive Packets This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: – Bits[16:18]: User Priority – Bit 19: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31]: VLAN Identifier (VID) field of VLAN tag When the ETV bit is set, only the VID is used for comparison. If this field ([20:31] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.

52.2.8 VLAN Hash Table Register (MAC_VLAN_HASH_TABLE)

When the ERSVLM bit of MAC_Hash_Table_Reg1 register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, refer to Section 3.2.8 of IEEE 802.3 - 2008).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 967. VLAN Tag Inclusion Register (MAC_VLAN_INCL)

Table 1023. MAC_VLAN_INCL field descriptions

Field	Description
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
13 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.
14:15 VLC	VLAN Tag Control in Transmit Packets 00 No VLAN tag deletion, insertion, or replacement 01 VLAN tag deletion, The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. 10 VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11 VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

52.2.10 Inner VLAN Tag Inclusion Register (MAC_INNER_VLAN_INCL)

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
13 VLP	VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.
14:15 VLC	VLAN Tag Control in Transmit Packets 00 No VLAN tag deletion, insertion, or replacement 01 VLAN tag deletion. The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. 10 VLAN tag insertion. The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11 VLAN tag replacement. The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

52.2.11 MAC Q0 Flow Control Register (MAC_Q0_TX_FLOW_CTRL)

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

Figure 969. MAC Q0 Flow Control Register (MAC_Q0_TX_FLOW_CTRL)

Table 1025. MAC_Q0_TX_FLOW_CTRL field descriptions

Name	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.

Table 1025. MAC_Q0_TX_FLOW_CTRL field descriptions (continued)

Name	Description
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.
30 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.
31 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.12 MAC Q1 Flow Control Register (MAC_Q1_TX_FLOW_CTRL)

This register controls the generation of PFC Control packets of priorities mapped as per the PSRQ*i* field in the MAC_RxQ_Ctrl2 registers. This register is present only when the Enable Data Center Bridging feature is selected during configuration.

Offset 0x0074 Access: User Read

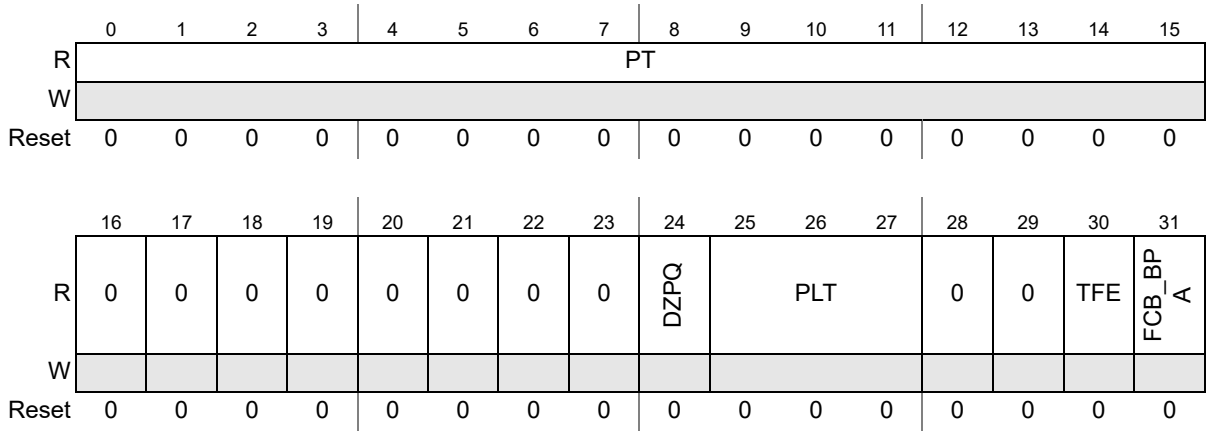

Figure 970. MAC Q1 Flow Control Register (MAC_Q1_TX_FLOW_CTRL)

Table 1026. MAC_Q1_TX_FLOW_CTRL field descriptions

Name	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Table 1026. MAC_Q1_TX_FLOW_CTRL field descriptions (continued)

Name	Description
30 TFE	When this bit is set in full-duplex mode, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.
31 FCB_BPA	This bit initiates a PFC packet if the TFE bit is set. To initiate a PFC packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When PFC packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.13 MAC Receive Flow Control Register (MAC_RX_FLOW_CTRL)

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Offset 0x0090 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 971. MAC Receive Flow Control Register (MAC_RX_FLOW_CTRL)

Table 1027. MAC_RX_FLOW_CTRL field descriptions

Field	Description
30 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. **Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.
31 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

52.2.14 Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)

The Transmit Queue Priority Mapping 0 register contains the priority values assigned to Tx Queue 0 and Tx Queue1.

Offset 0x0098 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 972. Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)

Table 1028. MAC_TXQ_PRTY_MAP0 field descriptions

Field	Description
16:23 PSTQ1	Priorities Selected in Transmit Queue 1 This bit is similar to the PSTQ0 bit.
24:31 PSTQ0	Priorities Selected in Transmit Queue 0 This field holds the priorities assigned to Tx Queue 0 by the software. This field determines if Tx Queue 0 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programed in this field. If the content of this field is not mutually exclusive to corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority for specified time.

52.2.15 Receive Queue Control 0 Register (MAC_RXQ_CTRL0)

The Receive Queue Control 0 register controls the queue management in the MAC Receiver.

Offset 0x00A0 Access: User Read/Write

Figure 974. Receive Queue Control 1 Register (MAC_RXQ_CTRL1)

Table 1030. MAC_RXQ_CTRL1 field descriptions

Field	Description
11 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field.
13:15 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/AV traffic can be used to route the Multicast or Broadcast Packets. 000 Rx Queue 0 001 Rx Queue 1 others Reserved
17:19 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/AV traffic can be used to route the Untagged Packets. 000 Rx Queue 0 001 Rx Queue 1 others Reserved

Table 1030. MAC_RXQ_CTRL1 field descriptions (continued)

Field	Description
25:27 AVPTPQ	AV PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. 000 Rx Queue 0 001 Rx Queue 1 others: Reserved When the AV8021ASMEN bit of MAC_Timestamp_Control register is set, only untagged PTP over Ethernet packets are routed on an Rx queue.
29:31 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV untagged control packets are routed: 000 Receive Queue 0 001 Receive Queue 1 others: Reserved The AV tagged control and data packets are routed based on PSRQ field in the Transmit Flow Control Register of corresponding queue.

52.2.17 Receive Queue Control 2 Register (MAC_RXQ_CTRL2)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 1.

Offset 0x00A8 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1031. MAC_RXQ_CTRL2 field descriptions

Name	Description
16:23 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
24:31 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. Value After Reset: 0x0

52.2.18 Interrupt Status Register (MAC_INTERRUPT_STATUS)

The Interrupt Status register contains the status of interrupts.

Offset 0x00B0 Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 976. Interrupt Status Register (MAC_INTERRUPT_STATUS)

Table 1032. MAC_INTERRUPT_STATUS field descriptions

Field	Description
17 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read in the MAC_Rx_Tx_Status register.
18 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: – Excessive Collision (EXCOL) – Late Collision (LCOL) – Excessive Deferral (EXDEF) – Loss of Carrier (LCARR) – No Carrier (NCARR) – Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read in the MAC_Rx_Tx_Status register.
19 TSIS	Timestamp Interrupt Status This bit is set when any of the following conditions is true: – The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. – There is an overflow in the Seconds register. – The Target Time Error occurred, that is, programed target time already elapsed. – When the auxiliary snapshot trigger is asserted. – When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read in the MAC_Timestamp_Status register.
20 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
21 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
22 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
23 MMCIS	MMC Interrupt Status This bit is set high when Bit 20, Bit 21, or Bit 22 is set high. This bit is cleared only when all these bits are low.

Table 1032. MAC_INTERRUPT_STATUS field descriptions (continued)

Field	Description
26 LPIIS	LPI Interrupt Status This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of MAC_LPI_Control_Status register is read.
27 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when Bits[25:26] are cleared because of a Read operation to the MAC_PMT_Control_Status register.

52.2.19 Interrupt Enable Register (MAC_INTERRUPT_ENABLE)

The Interrupt Enable register contains the masks for generating the interrupts.

Offset 0x00B4 Access: User Read

Figure 978. Receive Transmit Status Register (MAC_RX_TX_STATUS)

Table 1034. MAC_RX_TX_STATUS field descriptions

Field	Description
23 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1034. MAC_RX_TX_STATUS field descriptions (continued)

Field	Description
27 LCOL	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled). Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 LCARR	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 NCARR	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.21 PMT Control and Status Register (MAC_PMT_CONTROL_STATUS)

This register captures the remote wakeup control and status.

Offset 0x00C0 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 979. PMT Control and Status Register (MAC_PMT_CONTROL_STATUS)

Table 1035. MAC_PMT_CONTROL_STATUS field descriptions

Field	Description
0 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
5:7 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
21 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. **Note:** If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
22 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.

Table 1035. MAC_PMT_CONTROL_STATUS field descriptions (continued)

Field	Description
25 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.
30 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet.
31 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. **Note:** You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.22 Wake-up Packet Filter Registers

The wkuppktfilter_reg register at address 0x00C4 loads the Wake-up Packet Filter register.

To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight register values in address (0x00C4) for wkuppktfilter_reg0, wkuppktfilter_reg1, …, wkuppktfilter_reg7, respectively. The wkuppktfilter_reg register is read in a similar way.

The Ethernet module updates the wkuppktfilter_reg register current pointer value in Bits[5:7] of MAC_PMT_Control_Status register.

- Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3) to determine whether or not a packet is a wake-up packet.
  - The MSB (bit 0) must be zero.
  - Bit j[1:31] is the byte mask.
  - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.
- Filter i Command: The 4-bit filter i command controls the filter i operation.
  - Bit 28 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.
  - Bit 29 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.
  - Bit 29, along with Bit 30, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".
  - Bit 30 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.
  - Bit 31 is the enable for filter i. If Bit 31 is not set, filter i is disabled.
- Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.
  - This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
  - The minimum allowed offset is 12, which refers to the 13th byte of the packet.
  - The offset value 0 refers to the first byte of the packet.
- Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programed to the wake-up filter register block.
  - The 16-bit CRC calculation uses the following polynomial:
    $G(x) = x^{16} + x^{15} + x^2 + 1$
    Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  - 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.
  - 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.

The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.

Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).

When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should

be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).

52.2.22.1 Wakeup Filter0 Byte Mask Register (RWK_FILTER0_BYTE_MASK)

Corresponds to registers wkuppktfilter_reg0 described in *Table 1036*.

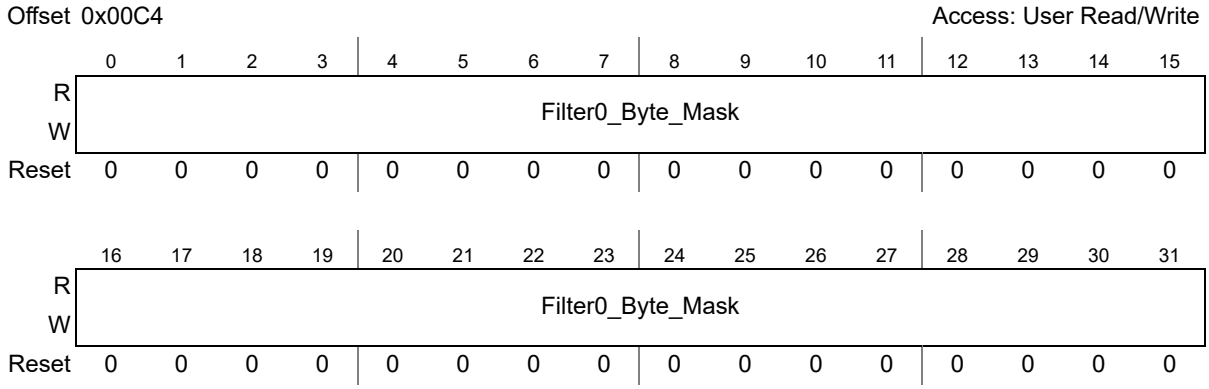

Figure 980. Wakeup Filter0 Byte Mask Register (RWK_FILTER0_BYTE_MASK)

Table 1037. RWK_FILTER0_BYTE_MASK field descriptions

Field	Description
0:31 Filter0_Byte_Mask	The filter 0 byte mask register defines the bytes of the packet that are examined by filter 0 to determine whether or not a packet is a wake-up packet. The MSB (bit 0) must be zero. Bit j[1:31] is the byte mask. If bit j (byte number) of the byte mask is set, the CRC block processes the filter 0 offset + j of the incoming packet; otherwise filter 0 offset + j is ignored.

52.2.22.2 Wakeup Filter 1 Byte Mask Register (RWK_FILTER1_BYTE_MASK)

Corresponds to registers wkuppktfilter_reg1 described in *Table 1036*.

52.2.23 LPI Control and Status Register (MAC_LPI_CONTROL_STATUS)

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Offset 0x00D0 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 988. LPI Control and Status Register (MAC_LPI_CONTROL_STATUS)

Table 1045. MAC_LPI_CONTROL_STATUS field descriptions

Field	Description
10 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode.
11 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions.
12 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of the MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.
14 PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit
15 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.
22 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.
23 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Table 1045. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
28 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
29 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
30 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register.
31 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register.

52.2.24 LPI Timers Control Register (MAC_LPI_TIMERS_CONTROL)

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Figure 989. LPI Timers Control Register (MAC_LPI_TIMERS_CONTROL)

Table 1046. MAC_LPI_TIMERS_CONTROL field descriptions

Field	Description
6:15 LST	LPI LS TIMER This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
16:31 TWT	LPI TW TIMER This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

52.2.25 LPI Entry Timer Register (MAC_LPI_ENTRY_TIMER)

This register controls the Tx LPI entry timer. This counter is enabled only when bit[11](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Offset 0x00D8 Access: User Read/Write

Figure 990. LPI Entry Timer Register (MAC_LPI_ENTRY_TIMER)

Table 1047. MAC_LPI_ENTRY_TIMER field descriptions

Field	Description
12:28 LPIET	LPI Entry Timer This field specifies the time in microseconds the MAC will wait to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [29:31] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

52.2.26 1US Tic Counter Register (MAC_1US_TIC_COUNTER)

This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programed by the software initially.

Offset 0x00DC Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 991. 1US Tic Counter Register (MAC_1US_TIC_COUNTER)

Table 1048. MAC_1US_TIC_COUNTER field descriptions

Field	Description
20:31 TIC_1US_CNTR	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100MHz then this field needs to be programed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

52.2.27 Version Register (MAC_VERSION)

The version register identifies the version of the Ethernet module.

Figure 995. Hardware Feature1 Register (MAC_HW_FEATURE1)

Table 1052. MAC_HW_FEATURE1 field descriptions

Field	Description
1:4 L3L4FNUM	Total number of L3 or L4 Filters This field indicates the total number of L3 or L4 filters: 0001 1 L3 or L4 Filter
6:7 HASHTBLSZ	Hash Table Size This field indicates the size of the hash table: 01 64 bit hash table
8 LPMODEEN	Low Power Mode Enabled This bit is set to 1 when the Enable UPF-Based Low-Power Support is present.
11 AVSEL	AV Feature Enabled This bit is set to 1 when the Enable Audio Video Bridging is present.
12 DBGMEMA	DMA Debug Registers Enabled This bit is set to 1 when the Debug Mode is present
16:17 ADDR64	Address Width. This field indicates the configured address width: 00 32-bit address width
18 ADVTHWORD	IEEE 1588 High Word Register Present
20 OSTEN	One-Step Timestamping Present

Table 1052. MAC_HW_FEATURE1 field descriptions (continued)

Field	Description
21:25 TXFIFOSIZE	MTL Transmit FIFO Size This field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(TXFIFO_SIZE) -7: 00101 4,096 bytes
27:31 RXFIFOSIZE	MTL Receive FIFO Size This field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(RXFIFO_SIZE) -7: 00110 8,192 bytes

52.2.31 Hardware Feature2 Register (MAC_HW_FEATURE2)

This register indicates the presence of the optional features or functions of the Ethernet module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Figure 997. MDIO Address Register (MAC_MDIO_ADDRESS)

Table 1054. MAC_MDIO_ADDRESS field description

Field	Description
4 PSE	Preamble Suppression Enable When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.
5 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0.
6:10 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

Table 1054. MAC_MDIO_ADDRESS field description (continued)

Field	Description
11:15 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
17:19 NTC	Number of Training Clocks This field controls the number of trailing clock cycles generated on sma_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
20:23 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0000 CSR clock = 60-100 MHz; MDC clock = CSR clock/42 0001 CSR clock = 100-150 MHz; MDC clock = CSR clock/62 0010 CSR clock = 20-35 MHz; MDC clock = CSR clock/16 0011 CSR clock = 35-60 MHz; MDC clock = CSR clock/26 0100 CSR clock = 150-250 MHz; MDC clock = CSR clock/102 0101 CSR clock = 250-300 MHz; MDC clock = CSR clock/124 0110 Reserved 0111 Reserved The suggested range of CSR clock frequency applicable for each value (when Bit 20 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 20 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000 CSR clock/4 1001 CSR clock/6 1010 CSR clock/8 1011 CSR clock/10 1100 CSR clock/12 1101 CSR clock/14 1110 CSR clock/16 1111 CSR clock/18
27 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
28:29 GOC	PHY SMA interface Operation Command This field indicates the operation command to the PHY: 00 Reserved 01 Write 10 Post Read Increment Address for Clause 45 PHY 11 Read When Clause 22 PHY is enabled, only Write (01) and Read (11) commands are valid.

Table 1054. MAC_MDIO_ADDRESS field description (continued)

Field	Description
30 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
31 GB	PHY SMA interface Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. **Note:** Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.33 MDIO Data Register (MAC_MDIO_DATA)

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Offset 0x0204 Access: User Read/Write

Figure 998. MDIO Data Register (MAC_MDIO_DATA)

Table 1055. MAC_MDIO_DATA field descriptions

Name	Description
0:15 RA	Register Address This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.
16:31 GD	PHY management Data This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.

52.2.34 ARP Address Register (MAC_ARP_ADDRESS)

The ARP Address register contains the IPv4 Destination Address of the MAC.

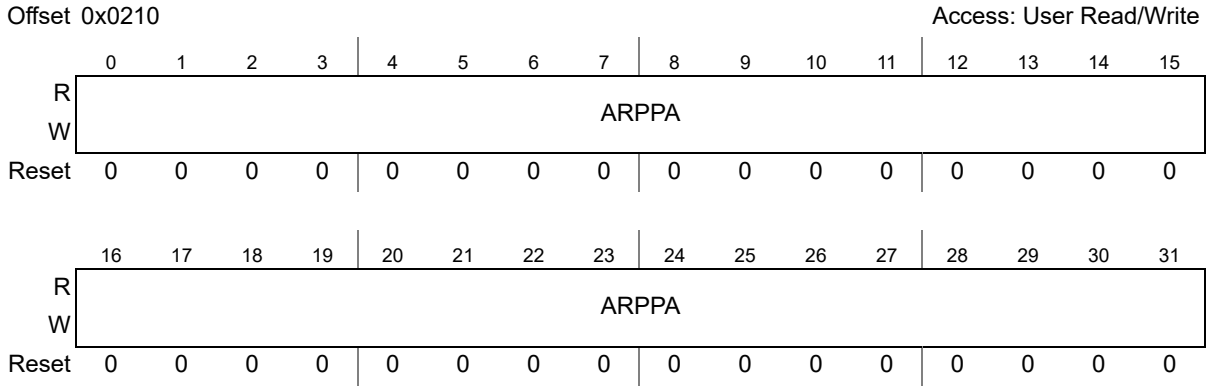

Figure 999. ARP Address Register (MAC_ARP_ADDRESS)

Table 1056. MAC_ARP_ADDRESS field descriptions

Name	Description
0:31 ARPPA	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

52.2.35 Address0 High Register (MAC_ADDRESS0_HIGH)

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [24:31]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [0:47] is compared with 0x665544332211.

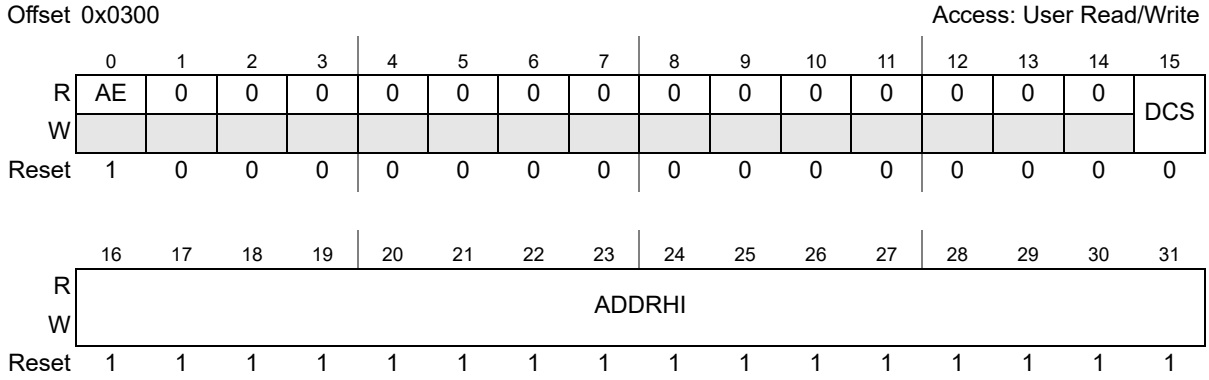

Figure 1000. Address0 High Register (MAC_ADDRESS0_HIGH)

Table 1057. MAC_ADDRESS0_HIGH field descriptions

Field	Description
0 AE	Address Enable This bit is always set to 1.
15 DCS	DMA Channel Select This field contains the DMA Channel number to which the Rx packet whose DA matches the MAC Address0 content is routed. 0 Route RX packet to DMA channel0 1 Route RX packet to DMA channel1
16:31 ADDRHI	MAC Address0[0:15] This field contains the upper 16 bits [0:15] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

52.2.36 Address0 Low Register (MAC_ADDRESS0_LOW)

The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

Figure 1001. Address0 Low Register (MAC_ADDRESS0_LOW)

Table 1058. MAC_ADDRESS0_LOW field descriptions

Name	Description
0:31 ADDRLO	MAC Address0[16:47] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

52.2.37 MAC Address High register 1 to 31 (MAC_ADDRESS*n*_HIGH31_1)

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

Offset 0x0300 + *n**0x8 (n=1 to 31) Access: User Read/Write

Figure 1002. MAC Address High register 1 to 31 (MAC_ADDRESS*n*_HIGH31_1)

Table 1059. MAC_ADDRESS*n*_HIGH31_1 field descriptions

Field	Description
0 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.
1 SA	Source Address When this bit is set, the MAC Address1[0:47] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[0:47] is used to compare with the DA fields of the received packet.
2:7 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: Bit 2: Register 194[16:23] Bit 3: Register 194[24:31] Bit 4: Register 195[0:7] … Bit 7: Register 195[24:31] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
15 DCS	DMA Channel Select This field contains the DMA Channel number to which the Rx packet whose DA matches the MAC Address1 content is routed. 0 Route RX packet to DMA channel0 1 Route RX packet to DMA channel1
16:31 ADDRHI	MAC Address1 [0:15] This field contains the upper 16 bits[0:15] of the second 6-byte MAC address.

52.2.38 MAC Address Low register 1 to 31 (MAC_ADDRESS*n*_LOW31_1)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1008. MMC Control Register (MMC_CONTROL)

Table 1065. MMC_CONTROL field descriptions

Field	Description
23 UCDBC	Update MMC Counters for Dropped Broadcast Packets When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets.
26 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16).

Table 1065. MMC_CONTROL field descriptions (continued)

Field	Description
27 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.
28 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
29 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[0:7]) is read.
30 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value.
31 CNTRST	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

52.2.44 MMC Receive Interrupt Register (MMC_RX_INTERRUPT)

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values, that is 0x8000_0000.
- Receive statistic counters cross their maximum values, that is 0xFFFF_FFFF.
- When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Figure 1009. MMC Receive Interrupt Register (MMC_RX_INTERRUPT)

Table 1066. MMC_RX_INTERRUPT field descriptions

Field	Description
4 RXLPITRCIS	MMC Receive LPI Transition Counter Interrupt Status This bit is set when the RX_LPI_TRAN_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5 RXLPIUSCIS	MMC Receive LPI Microsecond Counter Interrupt Status This bit is set when the RX_LPI_USEC_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
6 RXCTRLPIS	MMC Receive Control Packet Counter Interrupt Status This bit is set when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1066. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
7 RXRCVERRPIS	MMC Receive Error Packet Counter Interrupt Status This bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
8 RXWDOGPIS	MMC Receive Watchdog Error Packet Counter Interrupt Status This bit is set when the rxwatchdog error counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
9 RXVLANGBPIS	MMC Receive VLAN Good Bad Packet Counter Interrupt Status This bit is set when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
10 RXFOVPIS	MMC Receive FIFO Overflow Packet Counter Interrupt Status This bit is set when the rxfifooverflow counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
11 RXPAUSPIS	MMC Receive Pause Packet Counter Interrupt Status This bit is set when the rxpausepackets counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
12 RXORANGEPIS	MMC Receive Out Of Range Error Packet Counter Interrupt Status. This bit is set when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
13 RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
14 RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15 RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1066. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
16 RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
17 RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
18 RX128T255OCTGBPIS	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
19 RX65T127OCTGBPIS	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 RX64OCTGBPIS	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21 RXOSIZEGPIS	MMC Receive Oversize Good Packet Counter Interrupt Status This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
22 RXUSIZEGPIS	MMC Receive Undersize Good Packet Counter Interrupt Status This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
23 RXJABERPIS	MMC Receive Jabber Error Packet Counter Interrupt Status This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1066. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
24 RXRUNTPIS	MMC Receive Runt Packet Counter Interrupt Status This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
25 RXALGNERPIS	MMC Receive Alignment Error Packet Counter Interrupt Status This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 RXCRCERPIS	MMC Receive CRC Error Packet Counter Interrupt Status This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
27 RXMCGPIS	MMC Receive Multicast Good Packet Counter Interrupt Status This bit is set when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 RXBCGPIS	MMC Receive Broadcast Good Packet Counter Interrupt Status This bit is set when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 RXGOCTIS	MMC Receive Good Octet Counter Interrupt Status This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.45 MMC Tx Interrupt Register (MMC_TX_INTERRUPT)

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values, that is 0x8000_0000, and when they cross their maximum values, that is 0xFFFF_FFFF. When Counter Stop Rollover is set, then

interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Figure 1010. MMC Tx Interrupt Register (MMC_TX_INTERRUPT)

Table 1067. MMC_TX_INTERRUPT field descriptions

Field	Description
4 TXLPITRCIS	MMC Transmit LPI Transition Counter Interrupt Status This bit is set when the TX_LPI_TRAN_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5 TXLPIUSCIS	MMC Transmit LPI Microsecond Counter Interrupt Status This bit is set when the TX_LPI_USEC_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
6 TXOSIZEGPIS	MMC Transmit Oversize Good Packet Counter Interrupt Status This bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1067. MMC_TX_INTERRUPT field descriptions (continued)

Field	Description
7 TXVLANGPIS	MMC Transmit VLAN Good Packet Counter Interrupt Status This bit is set when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
8 TXPAUSPIS	MMC Transmit Pause Packet Counter Interrupt Status This bit is set when the txpausepacketserror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
9 TXEXDEFPIS	MMC Transmit Excessive Deferral Packet Counter Interrupt Status This bit is set when the txexcessdef counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
10 TXGPKTIS	MMC Transmit Good Packet Counter Interrupt Status This bit is set when the txpacketcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
11 TXGOCTIS	MMC Transmit Good Octet Counter Interrupt Status This bit is set when the txoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
12 TXCARERPIS	MMC Transmit Carrier Error Packet Counter Interrupt Status This bit is set when the txcarriererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
13 TXEXCOLPIS	MMC Transmit Excessive Collision Packet Counter Interrupt Status This bit is set when the txexesscol counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
14 TXLATCOLPIS	MMC Transmit Late Collision Packet Counter Interrupt Status This bit is set when the txlatecol counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15 TXDEFPIS	MMC Transmit Deferred Packet Counter Interrupt Status This bit is set when the txdeferred counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1067. MMC_TX_INTERRUPT field descriptions (continued)

Field	Description
16 TXMCOLGPIS	MMC Transmit Multiple Collision Good Packet Counter Interrupt Status This bit is set when the txmulticol_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
17 TXSCOLGPIS	MMC Transmit Single Collision Good Packet Counter Interrupt Status This bit is set when the txsinglecol_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
18 TXUFLOWERPIS	MMC Transmit Underflow Error Packet Counter Interrupt Status This bit is set when the txunderflowerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
19 TXBCGBPIS	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status This bit is set when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 TXMCGBPIS	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status The bit is set when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21 TXUCGBPIS	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status This bit is set when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
22 TX1024TMAXOCTGBPIS	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
23 TX512T1023OCTGBPIS	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1067. MMC_TX_INTERRUPT field descriptions (continued)

Field	Description
24 TX256T511OCTGBPIS	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
25 TX128T255OCTGBPIS	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 TX65T127OCTGBPIS	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
27 TX64OCTGBPIS	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 TXMCGPIS	MMC Transmit Multicast Good Packet Counter Interrupt Status This bit is set when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 TXBCGPIS	MMC Transmit Broadcast Good Packet Counter Interrupt Status This bit is set when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 TXGBPKTIS	MMC Transmit Good Bad Packet Counter Interrupt Status This bit is set when the txpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TXGBOCTIS	MMC Transmit Good Bad Octet Counter Interrupt Status This bit is set when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.46 MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Receive statistics counters.

Offset 0x070C

Access: Software read/write

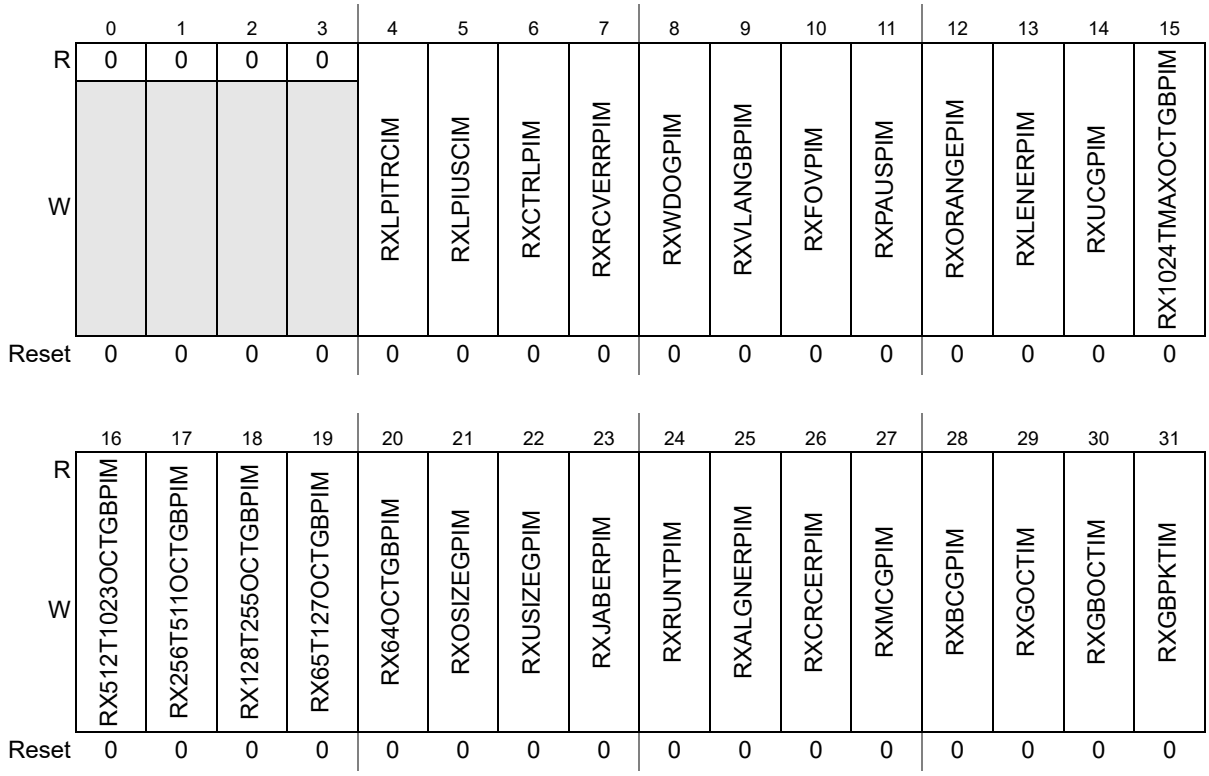

Figure 1011. MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK)

Table 1068. MMC_RX_INTERRUPT_MASK field descriptions

Field	Description
4 RXLPITRCIM	MMC Receive LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 RXLPIUSCIM	MMC Receive LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.
6 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value.
7 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.

Table 1068. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
8 RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value.
9 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value.
10 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxfifooverflow counter reaches half of the maximum value or the maximum value.
11 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpausepackets counter reaches half of the maximum value or the maximum value.
12 RXORANGEPIM	MMC Receive Out Of Range Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value.
13 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value.
14 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.
15 RX1024TMAXOCTGBPIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask. Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
16 RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value.
17 RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value.
18 RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value.
19 RX65T127OCTGBPIM	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value.
20 RX64OCTGBPIM	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value.

Table 1068. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
21 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value.
22 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value.
23 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value.
24 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value.
25 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value.
26 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value.
27 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value.
28 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
29 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value.
30 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value.
31 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value.

52.2.47 MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Transmit statistics counters.

18 TXUFLOWERPIM	MMC Transmit Underflow Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value.
19 TXBCGBPIM	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value.
20 TXMCGBPIM	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value.
21 TXUCGBPIM	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value.
22 TX1024TMAXOCTGBPIM	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
23 TX512T1023OCTGBPIM	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value.

Table 1069. MMC_TX_INTERRUPT_MASK field descriptions (continued)

Field	Description
24 TX256T511OCTGBPIM	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value.
25 TX128T255OCTGBPIM	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value.
26 TX65T127OCTGBPIM	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value.
27 TX64OCTGBPIM	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value.
28 TXMCGPIM	MMC Transmit Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value.
29 TXBCGPIM	MMC Transmit Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
30 TXGBPKTIM	MMC Transmit Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_gb counter reaches half of the maximum value or the maximum value.
31 TXGBOCTIM	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value.

52.2.48 Transmit Octet Count Good Bad Register (TX_OCTET_COUNT_GOOD_BAD)

This register provides the number of bytes transmitted by the Ethernet module, exclusive of preamble and retried bytes, in good and bad packets.

Field	Description
0:31 TXLPIUSC	This field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond.

52.2.101 Transmit LPI Transaction Counter Register (TX_LPI_TRAN_CNTR)

This register provides the number of times the Ethernet module has entered Tx LPI.

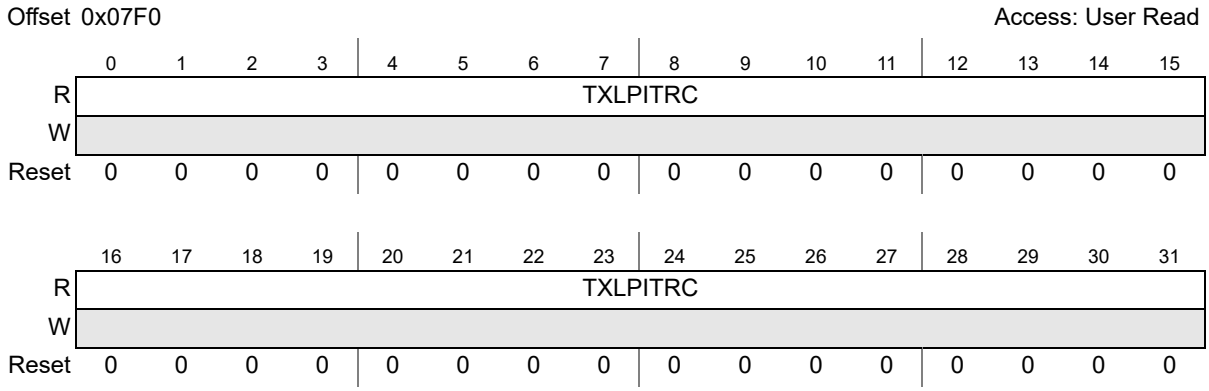

Figure 1066. Transmit LPI Transaction Counter Register (TX_LPI_TRAN_CNTR)

Table 1123. TX_LPI_TRAN_CNTR descriptions

Field	Description
0:31 TXLPITRC	This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate Mode (because of LPITXA bit set in the LPI Control and Status register), the counter will increment.

52.2.102 Receive LPI USEC Counter (RX_LPI_USEC_CNTR)

This register provides the number of microseconds Rx LPI is sampled by the Ethernet module.

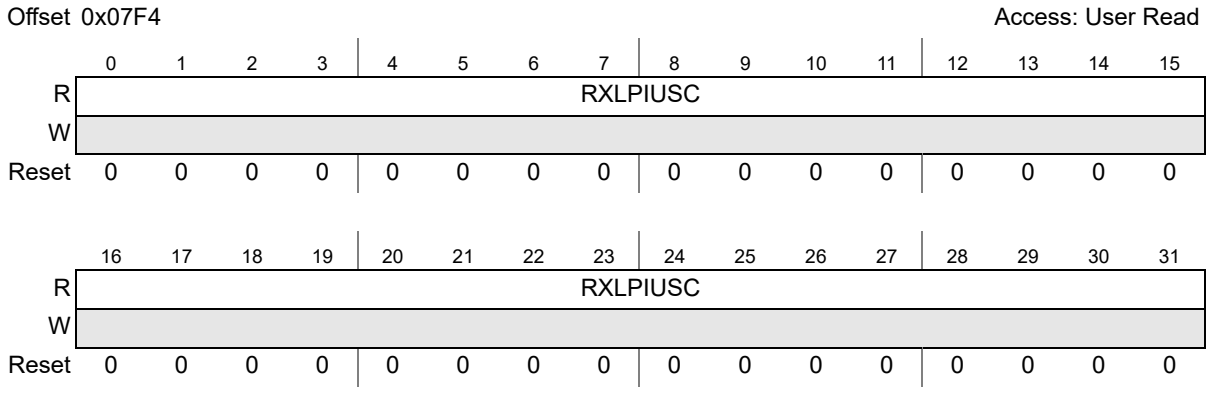

Figure 1067. Receive LPI USEC Counter (RX_LPI_USEC_CNTR)

Table 1124. RX_LPI_USEC_CNTR field descriptions

Field	Description
0:31 RXLPIUSC	This field indicates the number of microseconds Rx LPI is asserted. For every Rx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond.

52.2.103 Receive LPI Transaction Counter Register (RX_LPI_TRAN_CNTR)

This register provides the number of times the Ethernet module has entered Rx LPI.

Figure 1069. MMC IPC Receive Interrupt Mask Register (MMC_IPC_RX_INTERRUPT_MASK)

Table 1126. MMC_IPC_RX_INTERRUPT_MASK field descriptions

Field	Description
2 RXICMPEROIM	MMC Receive ICMP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_octets counter reaches half of the maximum value or the maximum value.
3 RXICMPGOIM	MMC Receive ICMP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_octets counter reaches half of the maximum value or the maximum value.
4 RXTCPEROIM	MMC Receive TCP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_octets counter reaches half of the maximum value or the maximum value.
5 RXTCPGOIM	MMC Receive TCP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_octets counter reaches half of the maximum value or the maximum value.
6 RXUDPEROIM	MMC Receive UDP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_octets counter reaches half of the maximum value or the maximum value.
7 RXUDPGOIM	MMC Receive IPV6 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_octets counter reaches half of the maximum value or the maximum value.
8 RXIPV6NOPAYOIM	MMC Receive IPV6 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_octets counter reaches half of the maximum value or the maximum value.

Table 1126. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
9 RXIPV6HEROIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_octets counter reaches half of the maximum value or the maximum value.
10 RXIPV6GOIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half of the maximum value or the maximum value.
11 RXIPV4UDSBLOIM	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half of the maximum value or the maximum value.
12 RXIPV4FRAGOIM	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half of the maximum value or the maximum value.
13 RXIPV4NOPAYOIM	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value.
14 RXIPV4HEROIM	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value.
15 RXIPV4GOIM	MMC Receive IPV4 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value.
18 RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_pkts counter reaches half of the maximum value or the maximum value.
19 RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_pkts counter reaches half of the maximum value or the maximum value.
20 RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_pkts counter reaches half of the maximum value or the maximum value.
21 RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_pkts counter reaches half of the maximum value or the maximum value.
22 RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_pkts counter reaches half of the maximum value or the maximum value.
23 RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_pkts counter reaches half of the maximum value or the maximum value.
24 RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_pkts counter reaches half of the maximum value or the maximum value.

Table 1126. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
25 RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
26 RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value.
27 RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value.
28 RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value.
29 RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value.
30 RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
31 RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value.

52.2.105 MMC IPC Receive Interrupt Register (MMC_IPC_RX_INTERRUPT)

This register maintains the interrupt that the receive IPC statistic counters generate.

Field	Description
0:31 RXICMPERRPKT	This field indicates the number of good IP datagrams received whose ICMP payload has a checksum error.

52.2.120 Receive IPv4 Good Octets Register (RXIPV4_GOOD_OCTETS)

This register provides the number of bytes received by the Ethernet module in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

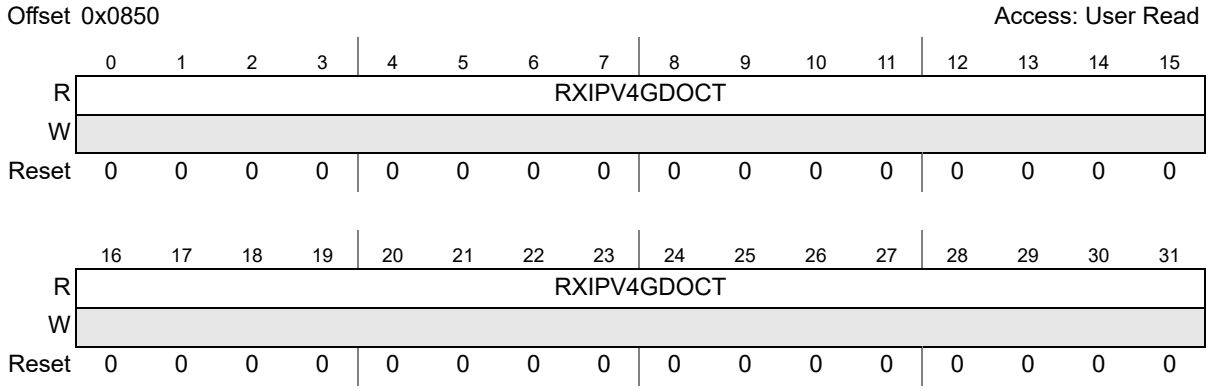

Figure 1085. Receive IPv4 Good Octets Register (RXIPV4_GOOD_OCTETS)

Table 1142. RXIPV4_GOOD_OCTETS field descriptions

Field	Description
0:31 RXIPV4GDOCT	This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

52.2.121 Receive IPv4 Header Error Octets Register (RXIPV4_HEADER_ERROR_OCTETS)

This register provides the number of bytes received by the Ethernet module in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

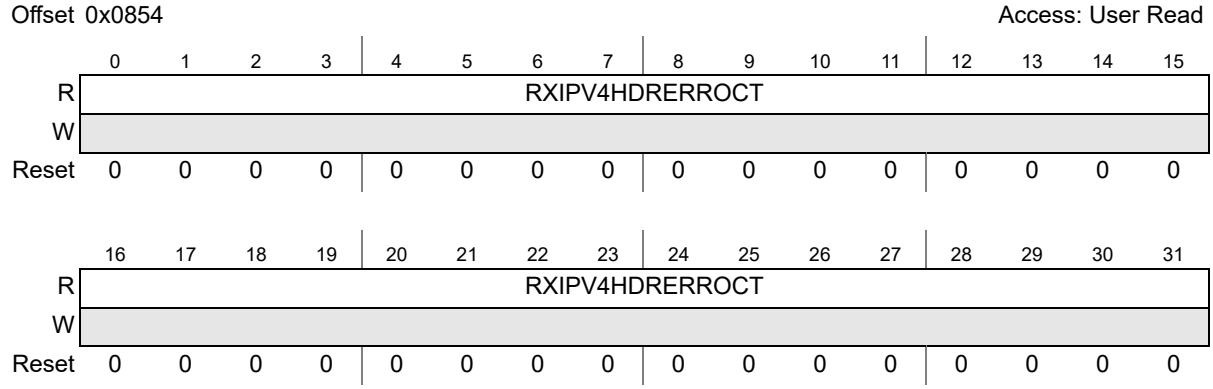

Figure 1086. Receive IPv4 Header Error Octets Register (RXIPV4_HEADER_ERROR_OCTETS)

52.2.134 Layer 3 and Layer 4 Control 0 Register (MAC_L3_L4_CONTROL0)

The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.

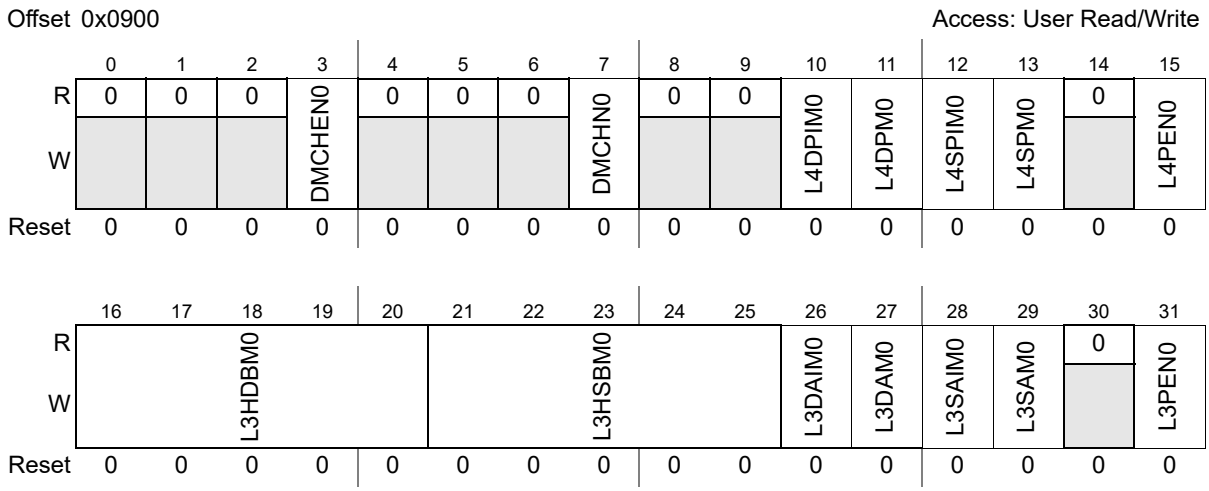

Figure 1099. Layer 3 and Layer 4 Control 0 Register (MAC_L3_L4_CONTROL0)

Table 1156. MAC_L3_L4_CONTROL0 field descriptions

Field	Description
3 DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter.
7 DMCHN0	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. 0 Packet is passed by this filter to DMA CH 0 1 Packet is passed by this filter to DMA CH 1
10 L4DPIM0	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high.
11 L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
12 L4SPIM0	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high.
13 L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
15 L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.

Table 1156. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
16:20 L3HDBM0	Layer 3 IP DA Higher Bits Match **IPv4 Packets:** This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: 0x00 No bits are masked. 0x01 1 LSb is masked 0x02 Two LSbs are masked ... 0x1F All bits except MSb are masked. **IPv6 Packets:** Bits[29:30] of this field correspond to Bits[25:26] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[30:31] and L3HSBM0 bits: - 0x00 No bits are masked. - 0x01 1 LSb is masked. - 0x02 Two LSbs are masked - … - 0x7F All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
21:25 L3HSBM0	Layer 3 IP SA Higher Bits Match **IPv4 Packets:** This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: 0x00 No bits are masked. 0x01 1 LSb is masked 0x02 Two LSbs are masked … 0x1F All bits except MSb are masked. **IPv6 Packets:** This field contains Bits[27:31] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
26 L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.
27 L3DAM0	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Table 1156. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
28 L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
29 L3SAM0	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
31 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. Value After Reset: 0x0

52.2.135 Layer 4 Address 0 Register (MAC_LAYER4_ADDRESS0)

This register holds the TCP source and destination port numbers against which a match is performed.

Offset 0x0904 Access: User Read/Write

Figure 1100. Layer4 Address 0 Register (MAC_LAYER4_ADDRESS0)

Table 1157. MAC_LAYER4_ADDRESS0 field descriptions

Field	Description
0:15 L4DP0	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
16:31 L4SP0	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

52.2.136 Layer 3 Address 0 Register 0 Register (MAC_LAYER3_ADDRESS0_REG0)

For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[96:127] of the 128-bit IP Source Address or Destination Address field.

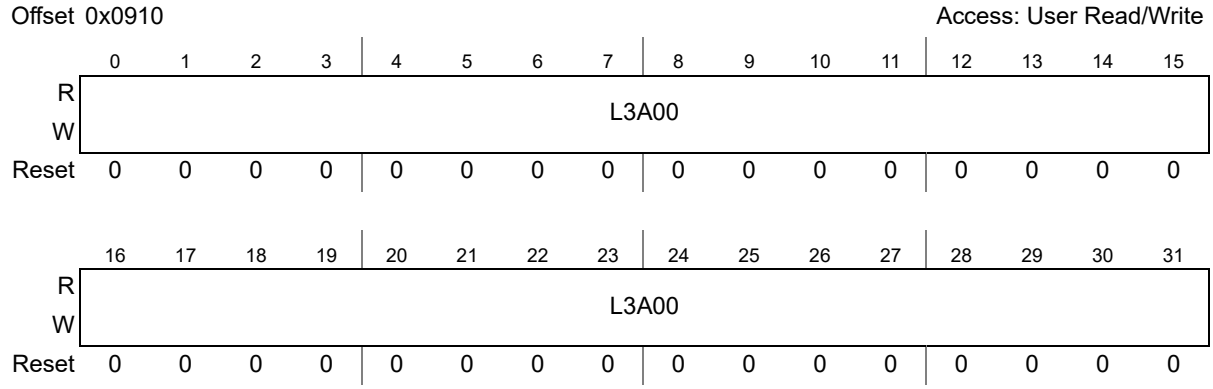

Figure 1101. Layer 3 Address 0 Register 0 Register (MAC_LAYER3_ADDRESS0_REG0)

Table 1158. MAC_LAYER3_ADDRESS0_REG0 field descriptions

Field	Description
0:31 L3A00	Layer 3 Address 0 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

52.2.137 Layer3 Address1 Register 0 Register (MAC_LAYER3_ADDRESS1_REG0)

For IPv4 packets, the Layer 3 Address 1 Register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[64:95] of the 128-bit IP Source Address or Destination Address field.

Table 1160. MAC_LAYER3_ADDRESS2_REG0 field descriptions

Field	Description
0:31 L3A20	Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

52.2.139 Layer3 Address3 Register 0 Register (MAC_LAYER3_ADDRESS3_REG0)

The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[0:31] of 128-bit IP Source Address or Destination Address field.

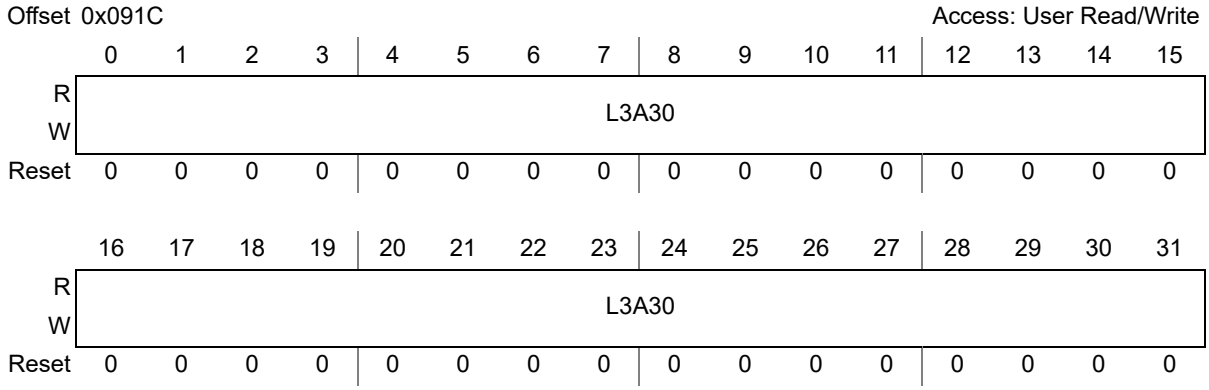

Figure 1104. Layer3 Address3 Register 0 Register (MAC_LAYER3_ADDRESS3_REG0)

Table 1161. MAC_LAYER3_ADDRESS3_REG0 field descriptions

Field	Description
0:31 L3A30	Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

52.2.140 Timestamp Control Register (MAC_TIMESTAMP_CONTROL)

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Offset 0x0B00 Access: User Read/Write

Figure 1105. Timestamp Control Register (MAC_TIMESTAMP_CONTROL)

Table 1162. MAC_TIMESTAMP_CONTROL field descriptions

Field	Description
3 AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation.
7 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the MAC_TxTimestamp_Status_Seconds register.
13 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. MAC address registers 0 to 31 is considered for unicast destination address matching.
14:15 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 16 and 17, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.

Table 1162. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
16 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.
17 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, refer to Timestamp Snapshot Dependency on Register Bits Table.
18 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.
19 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.
20 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
21 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.
22 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programed correctly depending on the PTP reference clock frequency and the value of this bit.
23 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.
26 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
27 TSTRIG	Enable Timestamp Interrupt Trigger When this bit is set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the Timestamp Trigger Interrupt is generated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table 1162. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
28 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
29 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
30 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.
31 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set.

52.2.141 Sub Second Increment Register (MAC_SUB_SECOND_INCREMENT)

In Coarse Update mode [Bit 30 in MAC_Timestamp_Control], the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Offset 0x0B04 Access: User Read/Write

Figure 1106. Sub Second Increment Register (MAC_SUB_SECOND_INCREMENT)

Table 1163. MAC_SUB_SECOND_INCREMENT field descriptions

Name	Description
8:15 SSINC	Sub-second Increment Value The value programed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 22 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
16:23 SNSINC	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2 ^ 8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set, and if the required increment is 5.3 ns, then SSINC should be 0x05 and SNSINC should be 0x4C. This field is reserved and read-only when Enable One-Step Timestamp Feature and Enable IEEE 1588 Sub-Nanoseconds Timestamp Support features are not selected.

52.2.142 System Time Seconds Register (MAC_SYSTEM_TIME_SECONDS)

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

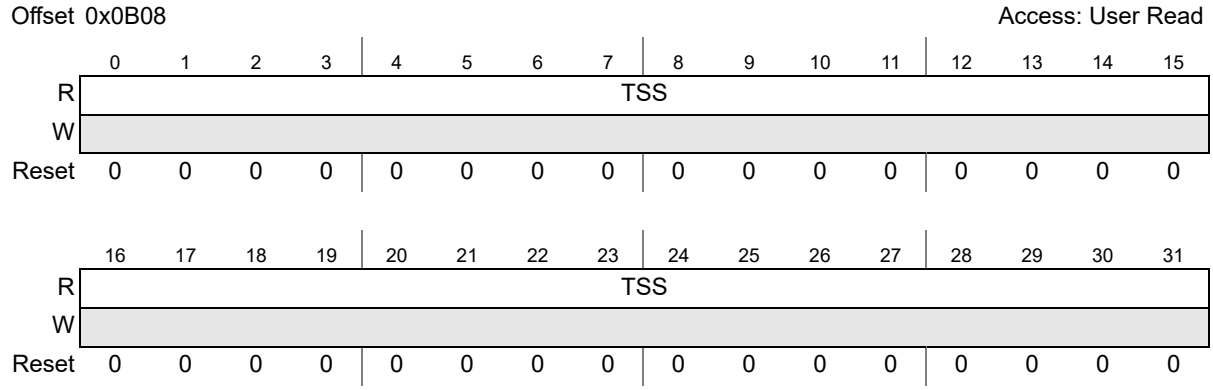

Figure 1107. System Time Seconds Register (MAC_SYSTEM_TIME_SECONDS)

Table 1164. MAC_SYSTEM_TIME_SECONDS field descriptions

Name	Description
0:31 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

52.2.143 System Time Nanoseconds Register (MAC_SYSTEM_TIME_NANOSECONDS)

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

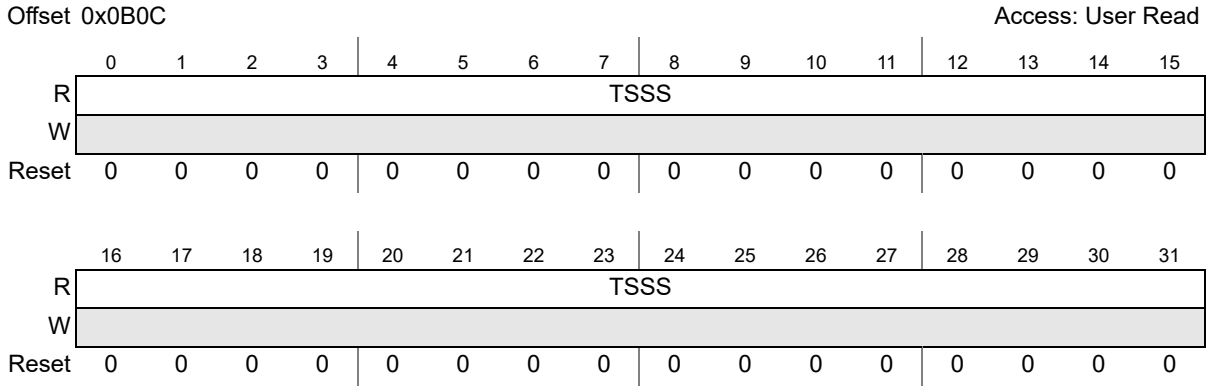

Figure 1108. System Time Nanoseconds Register (MAC_SYSTEM_TIME_NANOSECONDS)

Table 1165. MAC_SYSTEM_TIME_NANOSECONDS field descriptions

Name	Description
0:31 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 22 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

52.2.144 System Time Seconds Update Register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in MAC_Timestamp_Control.

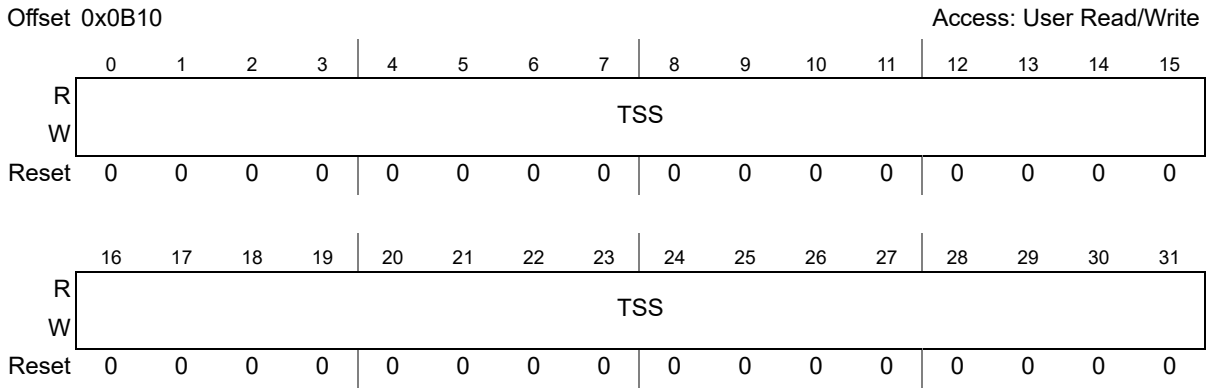

Figure 1109. System Time Seconds Update Register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

Table 1166. MAC_SYSTEM_TIME_SECONDS_UPDATE field descriptions

Field	Description
0:31 TSS	Timestamp Seconds The value in this field is the sub-second part of the update. When ADDSUB is reset, this field must be programed with the subsecond part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, then this field must be programed with the complement of the sub-second part of the update value as described below. When TSCTRLSSR is set, then the programed value must be 10^9 - <sub-second value>. When TSCTRLSSR is reset, then the programed value must be 2^31 - <sub-second_value> For example, when TSCTRLSSR bit is set and if 2.000000001 seconds need to be subtracted from the system time, then the TSS field in the MAC_Timestamp Seconds update register must be 0xFFFF_FFFE (that is, 2^32 - 2), ADDSUB bit in this register should be set, and the TSSS field must be 0x3B9A_C9FF (that is, 10^9 - 1).

Table 1167. MAC_SYSTEM_TIME_NANOSECONDS_UPDATE field descriptions

Field	Description
0 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.
1:31 TSS	Timestamp Sub Seconds The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programed value should not exceed 0x3B9A_C9FF.

52.2.146 Timestamp Addend Register (MAC_TIMESTAMP_ADDEND)

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Figure 1113. Timestamp Status Register (MAC_TIMESTAMP_STATUS)

Table 1170. MAC_TIMESTAMP_STATUS field descriptions

Field	Description
2:6 ATSNS	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. value equal to 4 indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.
7 ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.

Table 1170. MAC_TIMESTAMP_STATUS field descriptions (continued)

Field	Description
14:15 ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. Bit 15: Auxiliary trigger 0 Bit 14: Auxiliary trigger 1 The software can read this register to find the triggers that are set when the timestamp is taken. Access restriction applies. Clears on read. Self-set to 1 on internal event.
16 TXTSSIS	Tx Timestamp Status Interrupt Status When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. This bit is cleared when the MAC_TxTimestamp_Status_Seconds register is read.
28 TSTRGTERR0	Timestamp Target Time Error This bit is set when the latest target time programed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.149 Transmit Timestamp Status Nanoseconds Register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

This register contains the nanosecond part of timestamp captured for Transmit when Tx status is disabled.

The MAC_TxTimestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TxTimestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [16] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

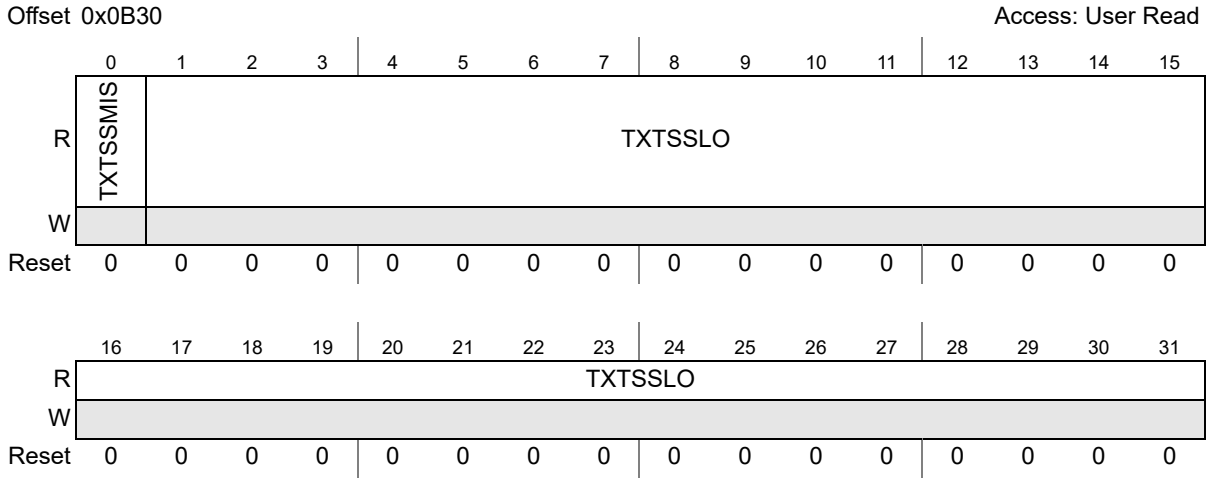

Figure 1114. Transmit Timestamp Status Nanoseconds Register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

Table 1171. MAC_TX_TIMESTAMP_STATUS_NANOSECONDS field descriptions

Field	Description
0 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event.
1:31 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

52.2.150 Transmit Timestamp Status Seconds Register (MAC_TX_TIMESTAMP_STATUS_SECONDS)

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Figure 1116. Auxiliary Control Register (MAC_AUXILIARY_CONTROL)

Table 1173. MAC_AUXILIARY_CONTROL field descriptions

Field	Description
26 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored.
27 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored.
31 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.152 Auxiliary Timestamp Nanoseconds Register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4.

You can store multiple snapshots in this FIFO. Bits[2:6] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

Field	Description
1:31 AUXTSLO	Contains the lower 31 bits (nanoseconds field) of the auxiliary timestamp.

52.2.153 Auxiliary Timestamp Seconds Register (MAC_AUXILIARY_TIMESTAMP_SECONDS)

The Auxiliary Timestamp - Seconds register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register.

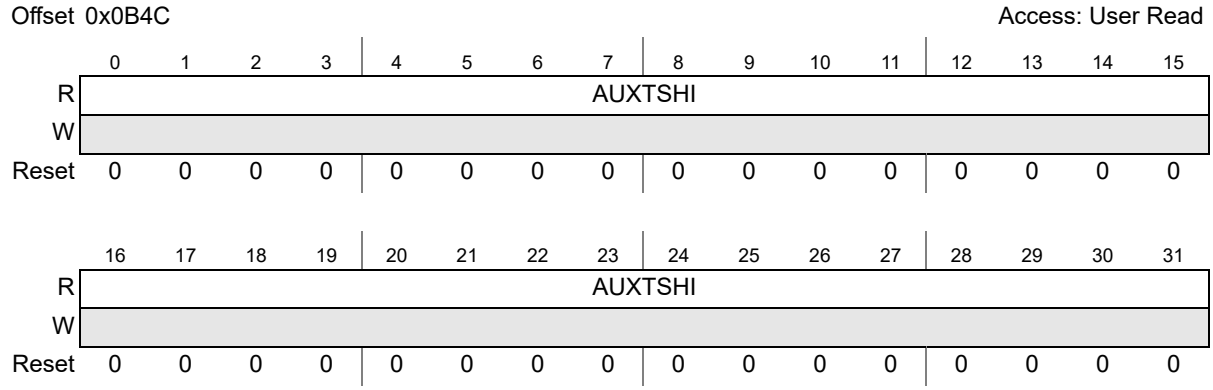

Figure 1118. Auxiliary Timestamp Seconds Register (MAC_AUXILIARY_TIMESTAMP_SECONDS)

Table 1175. MAC_AUXILIARY_TIMESTAMP_SECONDS field descriptions

Field	Description
0:31 AUXTSHI	Contains the lower 32 bits of the Seconds field of the auxiliary timestamp.

52.2.154 Timestamp Ingress Asymmetry Correction Register (MAC_TIMESTAMP_INGRESS_ASYM_CORR)

The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

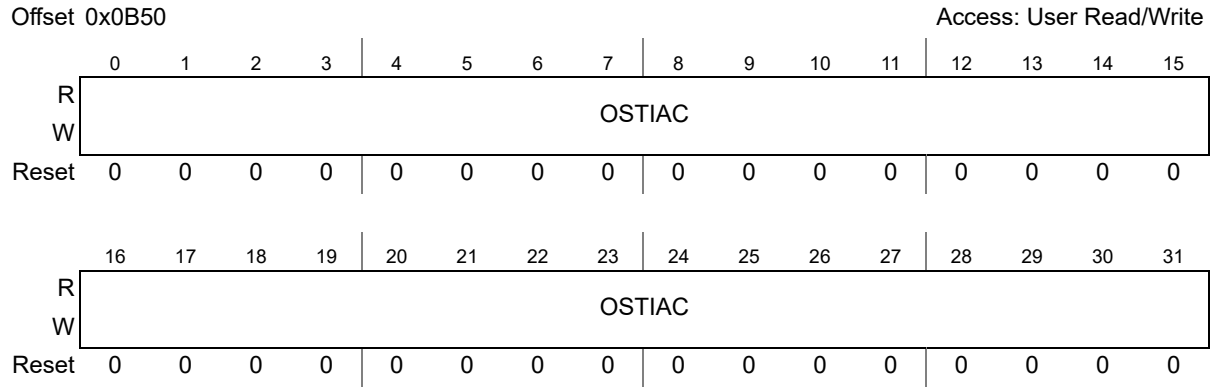

Figure 1119. Timestamp Ingress Asymmetry Correction Register (MAC_TIMESTAMP_INGRESS_ASYM_CORR)

Table 1176. MAC_TIMESTAMP_INGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 0 representing the sign bit.

52.2.155 Timestamp Egress Asymmetry Correction Register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

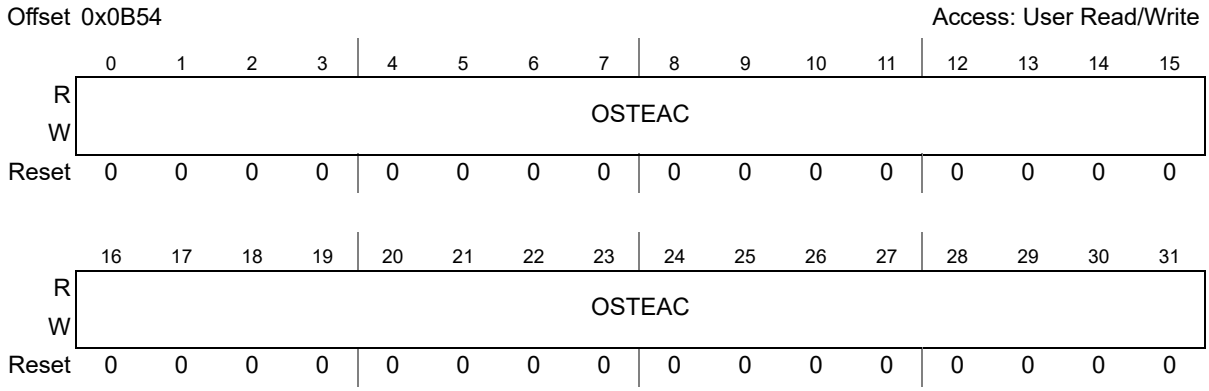

Figure 1120. Timestamp Egress Asymmetry Correction Register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

Table 1177. MAC_TIMESTAMP_EGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000 (2.5 * 216). Similarly, if the required correction is -3.3 ns, the programed value is 0x0003_4CCC (3.3 * 216).

52.2.156 Timestamp Ingress Correction Nanosecond Register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Offset 0x0B58 Access: User Read/Write

Figure 1123. PPS Control Register (MAC_PPS_CONTROL)

Table 1180. MAC_PPS_CONTROL field descriptions

Field	Description
25:26 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS0 output signal: 00 Target Time registers are programed only for generating the interrupt event. 01 Reserved 10 Target Time registers are programed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11 Target Time registers are programed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.

Table 1180. MAC_PPS_CONTROL field descriptions (continued)

Field	Description
27 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[28:31] function as PPSCMD. When this bit is reset, Bits[28:31] function as PPSCTRL (Fixed PPS mode).
28:31 PPSCTRL _PPSCMD	**PPS Output Frequency Control** This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 0001 The binary rollover is 2 Hz, and the digital rollover is 1 Hz 0010 The binary rollover is 4 Hz, and the digital rollover is 2 Hz 0011 The binary rollover is 8 Hz, and the digital rollover is 4 Hz 0100 The binary rollover is 16 Hz, and the digital rollover is 8 Hz ... 1111 The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz **Note:** In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second.(1) or **Flexible PPS Output (ptp_pps_o[0]) Control** Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000 No Command - 0001 START Single Pulse. This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. - 0010 START Pulse Train. This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011 Cancel START. This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programed start time. - 0100 STOP Pulse train at time. This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programed in the Target Time registers elapses. - 0101 STOP Pulse Train immediately. This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 0110 Cancel STOP Pulse train. This command cancels the STOP pulse train at time command if the programed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111 Reserved - 1111 Reserved Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

1. For example:
When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and 537 ms period. Second clock of 463 ms period (268 ms low and 195 ms high)
When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and 268 ms period. Fourth clock of 195 ms period (134 ms low and 61 ms high)
This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

52.2.159 PPS0 Target Time Seconds Register (MAC_PPS0_TARGET_TIME_SECONDS)

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 30 of MAC_Timestamp_Status] when the system time exceeds the value programed in these registers

Offset 0x0B80 Access: User Read/Write

Figure 1124. PPS0 Target Time Seconds Register (MAC_PPS0_TARGET_TIME_SECONDS)

Table 1181. MAC_PPS0_TARGET_TIME_SECONDS field descriptions

Field	Description
0:31 TSTRH0	PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register.

52.2.160 PPS0 Target Time Nanoseconds Register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

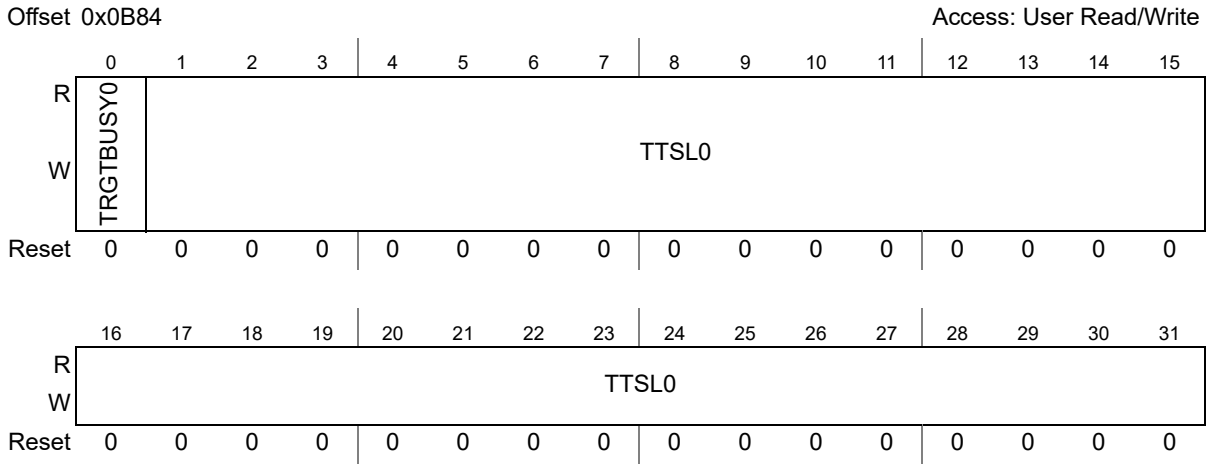

Figure 1125. PPS0 Target Time Nanoseconds Register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

Table 1182. MAC_PPS0_TARGET_TIME_NANOSECONDS field descriptions

Field	Description
0 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programed time gets corrupted.
1:31 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [25:26]) in MAC_PPS_Control. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.161 PPS0_Interval Register (MAC_PPS0_INTERVAL)

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B88 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1126. PPS0_Interval Register (MAC_PPS0_INTERVAL)

Table 1183. MAC_PPS0_INTERVAL field descriptions

Field	Description
0:31 PPSINT0	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

52.2.162 PPS0 Width Register (MAC_PPS0_WIDTH)

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B8C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1127. PPS0 Width Register (MAC_PPS0_WIDTH)

Table 1184. MAC_PPS0_WIDTH field descriptions

Field	Description
0:31 PPSWIDTH0	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. **Note:** The value programed in this register must be lesser than the value programed in MAC_PPS0_Interval.

52.2.163 Operation Mode Register (MTL_OPERATION_MODE)

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

Offset 0x0C00 Access: User Read/Write

Figure 1129. Debug Access Control Register (MTL_DBG_CTL)

Table 1186. MTL_DBG_CTL field descriptions

Field	Description
16 STSIE	Transmit Status Available Interrupt Status Enable When this bit is set, an interrupt is generated when Transmit status is available in slave mode.
17 PKTIE	Receive Packet Available Interrupt Status Enable When this bit is set, an interrupt is generated when EOP of received packet is written to the Rx FIFO.
18:19 FIFOSEL	FIFO Selected for Access This field indicates the FIFO selected for debug access: 00 Tx FIFO 01 Tx Status FIFO (only read access when SLVMOD is set) 10 Reserved 11 Rx FIFO
20 FIFOWREN	FIFO Write Enable When this bit is set, it enables the Write operation on selected FIFO. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
21 FIFORDEN	FIFO Read Enable When this bit is set, it enables the Read operation on selected FIFO. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
22 RSTSEL	Reset Pointers of Selected FIFO When this bit is set, the pointers of the currently-selected FIFO are reset. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
23 RSTALL	Reset All Pointers When this bit is set, the pointers of all FIFOs are reset. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
25:26 PKTSTATE	Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO / Rx FIFO: 00 Packet Data / Packet Data 01 Control Word/ Normal Status 10 SOP Data / Last Status 11 EOP Data / EOP
28:29 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid

Table 1186. MTL_DBG_CTL field descriptions (continued)

Field	Description
30 DBGMOD	Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: Write access to the Tx FIFO Read access to the Rx FIFO and Tx Status FIFO
31 FDBGEN	FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface.

52.2.165 Debug Status Register (MTL_DBG_STS)

The FIFO Debug Status register contains the status of FIFO debug access.

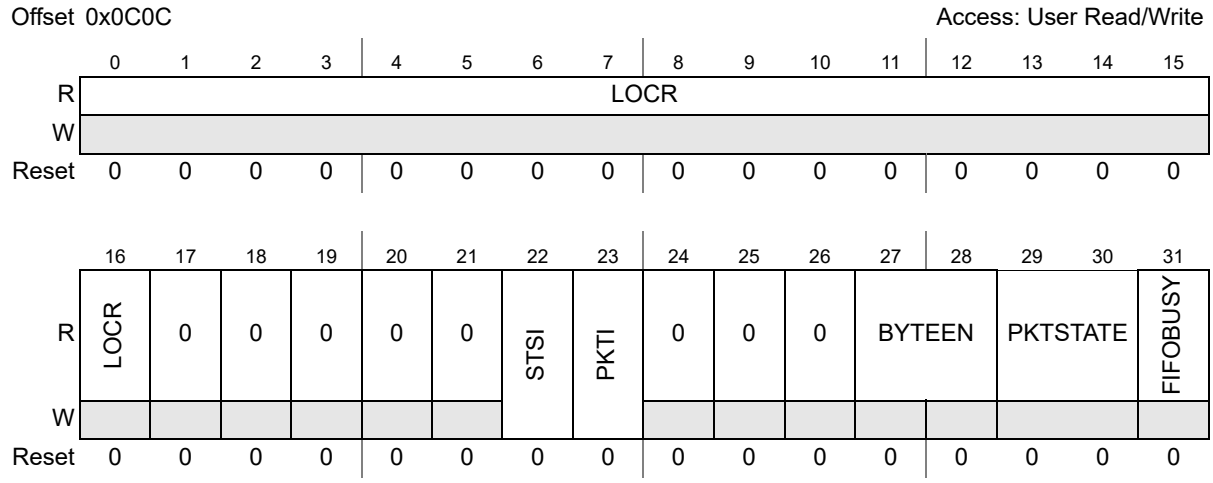

Figure 1130. Debug Status Register (MTL_DBG_STS)

Table 1187. MTL_DBG_STS field descriptions

Field	Description
0:16 LOCR	Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively.
22 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit.
23 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit.
27:28 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid
29:30 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. Tx FIFO: 00 Packet Data 01 Control Word 10 SOP Data 11 EOP Data Rx FIFO: 00 Packet Data 01 Normal Status 10 Last Status 11 EOP This field is applicable only for Tx FIFO and Rx FIFO during Read operation.
31 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: All other fields of this register All fields of the MTL_FIFO_Debug_Data register

52.2.166 FIFO Debug Data register (MTL_FIFO_DEBUG_DATA)

The FIFO Debug Data register contains the data to be written to or read from the FIFOs.

Figure 1134. Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)

Table 1191. MTL_TXQ0_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 4096, the width of this field is 4 bits: LOG2(4096/256) = LOG2(16) = 4 bits A value of 0 indicates 256 bytes
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 00 Not enabled 01 Reserved 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.170 Queue 0 Underflow Counter Register (MTL_TXQ0_UNDERFLOW)

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 Access: User Read

Figure 1135. Queue 0 Underflow Counter Register (MTL_TXQ0_UNDERFLOW)

Table 1192. MTL_TXQ0_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.171 Queue 0 Transmit Debug Register (MTL_TXQ0_DEBUG)

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Figure 1136. Queue 0 Transmit Debug Register (MTL_TXQ0_DEBUG)

Table 1193. MTL_TXQ0_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 1193. MTL_TXQ0_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

52.2.172 Queue 0 ETS Status Register (MTL_TXQ0_ETS_STATUS)

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

Figure 1139. Interrupt Control Status Register (MTL_Q0_INTERRUPT_CONTROL_STATUS)

Table 1196. MTL_Q0_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[10]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

52.2.175 Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command.

Figure 1140. Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)

Table 1197. MTL_RXQ0_OPERATION_MODE field descriptions

Bits	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one and the reset value is 0x0. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size. For example, if the memory size is 8192, the width of this field is 5 bits: LOG2(8192/256) = LOG2(32) = 5 bits
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.

Table 1197. MTL_RXQ0_OPERATION_MODE field descriptions (continued)

Bits	Description
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

52.2.176 Queue 0 Missed Packet and Overflow Counter Register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 Access: User Read

Table 1198. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1198. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.177 Queue 0 Receive Debug Register (MTL_RXQ0_DEBUG)

The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Figure 1143. Queue Receive Control Register (MTL_RXQ0_CONTROL)

Table 1200. MTL_RXQ0_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.

52.2.179 Transmit Q*n* Operation Mode register (MTL_TXQ*n*_OPERATION_MODE)

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Offset 0x0D00 + *n**0x40 (n=1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1144. Transmit Q*n* Operation Mode register (MTL_TXQ*n*_OPERATION_MODE)

Table 1201. MTL_TXQ*n*_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(4096/256) = LOG2(16) = 4 bits
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue n. 00 Not enabled 01 Enable in AV mode 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.180 Transmit Q*n* Underflow register (MTL_TXQ*n*_UNDERFLOW)

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 + *n**0x40 (n=1) Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1145. Transmit Q*n* Underflow register (MTL_TXQ*n*_UNDERFLOW)

Table 1202. MTL_TXQ*n*_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.181 Transmit Q*n* Debug register (MTL_TXQ*n*_DEBUG)

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 + *n**0x40 (*n*=1) Access: User Read

Figure 1146. Transmit Q Debug register (MTL_TXQ*n*_DEBUG)

Table 1203. MTL_TXQ*n*_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 1203. MTL_TXQ*n*_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

52.2.182 Transmit Q*n* ETS Control register (MTL_TXQ*n*_ETS_CONTROL)

The Queue ETS Control register controls the enhanced transmission selection operation.

Offset 0x0D10 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 1147. MTL_Transmit Q*n* ETS Control register (MTL_TXQ*n*_ETS_CONTROL)

Table 1204. MTL_TXQ*n*_ETS_CONTROL field descriptions

Field	Description
25:27 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of 125 µs duration) over which the average transmitted bits per slot, provided in the MTL_TxQ1_ETS_Status register, need to be computed for Queue 1. The encoding is as follows: 000 1 Slot 001 2 Slots 010 4 Slots 011 8 Slots 100 16 Slots 101 Reserved 110 Reserved 111 Reserved
28 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated.
29 AVALG	AV Algorithm When Queue 1 is programed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected.

52.2.183 Transmit Q*n* ETS Status register (MTL_TXQ*n*_ETS_STATUS)

The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

Offset 0x0D14 + *n**0x40 (n=1) Access: User Read

Figure 1148. Transmit Q*n* ETS Status register (MTL_TXQ*n*_ETS_STATUS)

Table 1205. MTL_TXQ*n*_ETS_STATUS field descriptions

Field	Description
8:31 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. For AV operation for Queue 1, this field is computed over number of slots, programed in the SLC field of MTL_TxQ1_ETS_CONTROL register, for Queue 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps. Bits [8:14] are always read as zero.

52.2.184 Transmit Q*n* Quantum Weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Offset 0x0D18 + *n**0x40 (n=1) Access: User Read/Write

Figure 1149. Transmit Q*n* Quantum Weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

Table 1206. MTL_TXQ*n*_QUANTUM_WEIGHT field descriptions

Filed	Description
11:31 ISCQW	idleSlopeCredit, Quantum or Weights **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. **Weights** When enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [11:24] must be written to zero.

52.2.185 Transmit Q*n* Send Slope Credit register (MTL_TXQ*n*_SENDSPLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D1C + *n**0x40 (n=1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1150. Transmit Q*n* Send Slope Credit register (MTL_TXQ*n*_SENDSPLOPECREDIT)

Table 1207. MTL_TXQ*n*_SENDSPLOPECREDIT field descriptions

Field	Description
18:31 SSC	sendSlopeCredit With AV operation enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x1000 in 100 Mbps mode. This field should be programed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.

52.2.186 Transmit Q*n* High Credit register (MTL_TXQ*n*_HICREDIT)

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D20 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 1151. MTL_Transmit Q*n* High Credit register (MTL_TXQ*n*_HICREDIT)

Table 1208. MTL_TXQ*n*_HICREDIT field descriptions

Field	Description
3:31 HC	hiCredit When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

52.2.187 Transmit Q*n* Low Credit register (MTL_TXQ*n*_LOCREDIT)

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D24 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 1152. Transmit Q*n* Low Credit register (MTL_TXQ*n*_LOCREDIT)

Table 1209. MTL_TXQ*n*_LOCREDIT field descriptions

Field	Description
3:31 LC	loCredit When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxFrameSize transmitted from this queue, that is, 16384 * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programed value is 2's complement of the value, that is, 0x1800_0000.

52.2.188 Q*n* Interrupt Control Status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue 1 interrupts.

Offset 0x0D2C + *n**0x40 (n=1) Access: User Read/Write

Figure 1153. Q*n* Interrupt Control Status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

Table 1210. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

52.2.189 Receive Q*n* Operation Mode register (MTL_RXQ*n*_OPERATION_MODE)

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 1154. MTL_Receive Q*n* Operation Mode register (MTL_RXQ*n*_OPERATION_MODE)

Table 1211. MTL_RXQ*n*_OPERATION_MODE field descriptions

Field	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one and the reset value is 0x0. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 8192, the width of this field is 5 bits: LOG2(8192/256) = LOG2(32) = 5 bits
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Table 1211. MTL_RXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_RX_ERR, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

52.2.190 Receive Q*n* Missed Packet and Overflow Counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 + *n**0x40 (*n*=1) Access: User Read

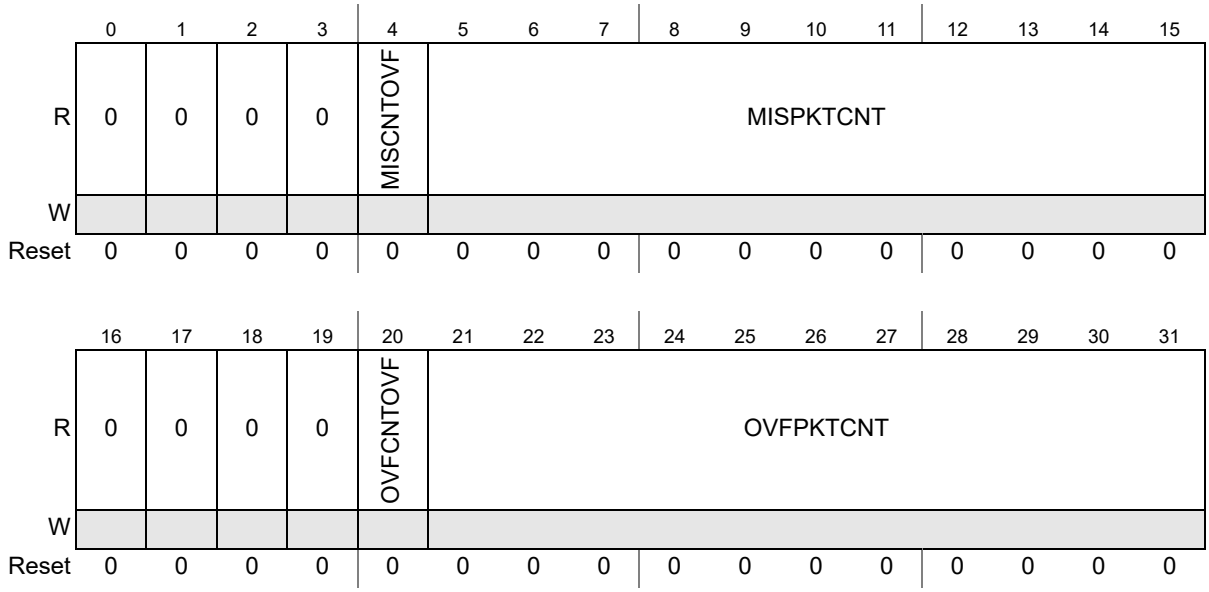

Figure 1155. Receive Q*n* Missed Packet and Overflow Counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

Table 1212. MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.2.191 Receive Q*n* Debug register (MTL_RXQ*n*_DEBUG)

The Queue 1 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 + *n**0x40 (n=1) Access: User Read

Figure 1157. Receive Q*n* Control register (MTL_RXQ*n*_CONTROL)

Table 1214. MTL_RXQ*n*_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.

52.2.193 DMA_Mode Register (DMA_MODE)

The Bus Mode register establishes the bus operating modes for the DMA.

Figure 1158. DMA_Mode Register (DMA_MODE)

Table 1215. DMA_MODE field descriptions

Field	Description
14:15 INTM	Interrupt Mode This field defines the interrupt mode of the Ethernet module. The behavior of the following outputs changes depending on the following settings: sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) interrupt (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status.
17:19 PR	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. 000 The priority ratio is 1:1 001 The priority ratio is 2:1 010 The priority ratio is 3:1 011 The priority ratio is 4:1 100 The priority ratio is 5:1 101 The priority ratio is 6:1 110 The priority ratio is 7:1 111 The priority ratio is 8:1
20 TXPR	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.
27:29 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000 Fixed priority In fixed priority, Channel 0 has the lowest priority and the last channel has the highest priority. 001 Weighted Strict Priority (WSP) 010 Weighted Round-Robin (WRR) 011 Reserved ... 111 Reserved

Table 1215. DMA_MODE field descriptions (continued)

Field	Description
30 DA	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: 0 Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[17:19] and the priority weight is specified in the TXPR bit. 1 Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.
31 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all Ethernet module clock domains. Before reprogramming any Ethernet module register, a value of zero should be read in this bit. **Note:** The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

52.2.194 System Bus Mode Register (DMA_SYSBUS_MODE)

The System Bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

Offset 0x1004 Access: User Read/Write

Figure 1159. System Bus Mode Register (DMA_SYSBUS_MODE)

Table 1216. DMA_SYSBUS_MODE field descriptions

Field	Description
16 RB	Rebuild INCRx Burst When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.
17 MB	Mixed Burst When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).
19 AAL	Address-Aligned Beats When this bit is set to 1, AHB master performs address-aligned burst transfers on Read and Write channels.
31 FB	Fixed Burst Length When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE). When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.

52.2.195 Interrupt Status Register (DMA_INTERRUPT_STATUS)

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Offset 0x1008 Access: User Read

Figure 1162. DMA Channel *n* Control register (DMA_CH*n*_CONTROL)

Table 1219. DMA_CH*n*_CONTROL field descriptions

Field	Description
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programed in Bits[10:15] in DMA_CH0_Tx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

52.2.198 DMA Channel *n* Transmit Control register (DMA_CH*n*_TX_CONTROL)

The DMA Channel Transmit Control register controls the Tx features such as PBL, and Tx Channel weights.

Offset 0x1104 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 1163. DMA Channel *n* Transmit Control register (DMA_CH*n*_TX_CONTROL)

Table 1220. DMA_CH*n*_TX_CONTROL field descriptions

Field	Description
10:15 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in DMA_CH0_Control register. – Set the PBL.
27 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.
28:30 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
31 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: – The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. – The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.

52.2.199 DMA Channel *n* Receive Control register (DMA_CH*n*_RX_CONTROL)

The DMA Channel *n* Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset 0x1108 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 1164. DMA Channel *n* Receive Control register (DMA_CH*n*_RX_CONTROL)

Table 1221. DMA_CH*n*_RX_CONTROL field descriptions

Field	Description
0 RPF	DMA Rx Channel0 Packet Flush When this bit is set to 1, the DMA will automatically flush the packet from the Rx Queues destined to DMA Rx Channel 0 when the DMA Rx Channel 0 is stopped after a system bus error has occurred. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0 the EQOS will not flush the packet in the Rx Queue destined to DMA Rx Channel 0 after the DMA is stopped due to a system bus error.
10:15 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in the DMA_CH0_Control register. – Set the PBL.

Table 1221. DMA_CH*n*_RX_CONTROL field descriptions (continued)

Field	Description
17:30 RBSZ	Receive Buffer size This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. **Note:** The buffer size must be a multiple of 4, 8, or 16 depending on the bus widths (32, 64, or 128 respectively). This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, 8, or 16, it may result into undefined behavior. The 3 LSB bits for 64-bit bus width are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).
31 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

52.2.200 DMA Channel *n* Transmit Descriptor List Address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

The Channel *n* Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset 0x1114 + *n**0x80 (*n*=0 to 1) Access: User Read/Write

Figure 1165. DMA Channel *n* Transmit Descriptor List Address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

Table 1222. DMA_CH*n*_TXDESC_LIST_ADDRESS field descriptions

Field	Description
0:31 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the 3 LSB bits for 64-bit data bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

52.2.201 DMA Channel *n* Receive Descriptor List Address register (DMA_CH*n*_RXDESC_LIST_ADDRESS)

The Channel*n* Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programed descriptor base address.

Figure 1171. DMA Channel *n* Interrupt Enable register (DMA_CH*n*_INTERRUPT_ENABLE)

Table 1228. DMA_CH*n*_INTERRUPT_ENABLE field descriptions

Field	Description
16 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 31: Transmit Interrupt – Bit 29: Transmit Buffer Unavailable – Bit 25: Receive Interrupt – Bit 20: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled.
17 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 30: Transmit Process Stopped – Bit 24: Rx Buffer Unavailable – Bit 23: Receive Process Stopped – Bit 22: Receive Watchdog Timeout – Bit 21: Early Transmit Interrupt – Bit 19: Fatal Bus Error When this bit is reset, the abnormal interrupt summary is disabled.
18 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.
19 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.
20 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.
21 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.
22 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.
23 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.
24 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.
25 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Table 1228. DMA_CH*n*_INTERRUPT_ENABLE field descriptions (continued)

Field	Description
29 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.
30 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.
31 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.

52.2.207 DMA Channel *n* Receive Interrupt Watchdog Timer register (DMA_CH*n*_Rx_INTERRUPT_WATCHDOG_TIMER)

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH*n*_Status register.

Offset 0x1138 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 1172. DMA Channel *n* Receive Interrupt Watchdog Timer register (DMA_CH*n*_Rx_INTERRUPT_WATCHDOG_TIMER)

Table 1229. DMA_CH*n*_Rx_INTERRUPT_WATCHDOG_TIMER field descriptions

Field	Description
14:15 RWTU	Receive Interrupt Watchdog Timer Count Units This field indicates the number of system clock cycles corresponding to one unit in RWT field. 00 256 01 512 10 1024 11 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
24:31 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[1]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[1] of any received packet.

52.2.208 DMA Channel *n* Slot Function Control Status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset 0x113C + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 1173. DMA Channel *n* Slot Function Control Status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

Table 1230. DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS field descriptions

Field	Description
12:15 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
30 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programed in the Tx descriptor is – equal to the reference slot number given in the RSN field or – ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set.
31 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is – equal to the reference slot number or – ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

52.2.209 DMA Channel *n* Current Application Transmit Descriptor register (DMA_CH*n*_CURRENT_APP_TXDESC)

Field	Description
10:12 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 10 1'b1: Error during data transfer by Rx DMA 1'b0: No Error during data transfer by Rx DMA Bit 11 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 12 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
13:15 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 13 1'b1: Error during data transfer by Tx DMA 1'b0: No Error during data transfer by Tx DMA Bit 14 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 15 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Table 1235. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
16 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 31: Transmit Interrupt Bit 29: Transmit Buffer Unavailable Bit 25: Receive Interrupt Bit 20: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
17 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 30: Transmit Process Stopped Bit 24: Receive Buffer Unavailable Bit 23: Receive Process Stopped Bit 21: Early Transmit Interrupt Bit 19: Fatal Bus Error Bit 18: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
18 CDE	Context Descriptor Error This bit indicates that the DMA Tx engine received a context descriptor in the middle of a packet (in an intermediate descriptor), and the DMA Tx engine ignored it. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
19 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
20 ERI	Early Receive Interrupt This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1235. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
21 ETI	Early Transmit Interrupt This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.
23 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
24 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
25 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 0 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
29 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 0 of TDES0. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1235. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
30 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 0 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

52.2.214 DMA Channel *n* Miss Frame Counter register (DMA_CH*n*_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in DMA_CH0_Rx_Control register.

Offset 0x116C + *n**0x80 (n=0 to 1) Access: User Read

Table 1236. DMA_CH*n*_MISS_FRAME_CNT field descriptions

Field	Description
16 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 MFC	This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH0_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

52.3 Functional Description

52.3.1 AHB Master Interface

The DMA controller interfaces with the application through the AMBA AHB interface. The AHB master interface converts the internal DMA request cycles into AHB cycles. The AHB master interface has the following features:

- The AHB master interface is AMBA 2.0-compliant AHB master with no restrictions
- The AHB master interface supports the following burst length modes: fixed, unspecified, and mixed. These modes are explained in *Section 52.3.1.1: AHB Burst Length Modes*
- The AHB master interface can handle the AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response halts all further transactions for that DMA and indicates the error as fatal through CSR and interrupt. The application can choose to give a hard or soft reset to the module to restart the operation
- The AHB master interface can handle the AHB 1 K boundary breaking
- The AHB master interface can handle all 64-bit data transfers except for Descriptor Status Write accesses (which may be 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size
- The AHB master interface can align all AHB burst transfers to an address value. For more information, refer to *Section 52.3.1.2: Aligning AHB Burst Transfers to an Address Value*
- The DMA requests an AHB Burst Read transfer only when it can completely accept the received burst data. The data read from the AHB is always pushed into the DMA without any delay or Busy cycles. However, when multiple channels are selected, there may be some delay and busy cycles may be inserted because of the shared-memory architecture for the channels
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to completely transfer the burst. The AHB interface always assumes that it has the data available to push into the AHB bus. However, the DMA can prematurely indicate end-of-valid data (because of the transfer of EOP of an Ethernet packet) during the burst
- In Fixed Burst Length mode, the AHB master interface continues the burst with dummy data until the specified length is completed. In INCR mode, it ends the burst transfer prematurely

52.3.1.1 AHB Burst Length Modes

The AHB master interface supports the following burst length modes:

- Fixed Burst Length: In fixed burst length mode, the AHB master always initiates a burst with SINGLE, INCR4, INCR8, or INCR16 type. However, when such a burst is responded with SPLIT, RETRY, or Early Burst Termination (EBT), by default, the AHB master again initiates the pending transfers of the burst with INCR or SINGLE burst length type. When only one beat is remaining, the AHB master performs a SINGLE transfer. If more than one beat is remaining, the AHB master performs an INCR transfer. The AHB master terminates such INCR bursts when remaining beats of the original requested fixed burst are transferred.
  To ensure that the AHB master always performs the INCRx and SINGLE transfers even when a part of the burst is initiated again after a SPLIT, RETRY, or EBT response, use the RIB bit of the register. However, when you enable this mode, the pending burst may

further get split into multiple transfers as per the following rules before any new transfer is initiated:

  – If the DMA requests a burst transfer that is not equal to INCR4, INCR8, or INCR16, the AHB application interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4, and three SINGLE transactions
  – If the burst length is more than 16, the AHB master interface splits it into multiple burst transfers. For example, if the burst length is 32 and the DMA starts a 32-beat transfer, the AHB master splits the burst into two INCR16

- Unspecified Burst Length: In unspecified burst mode, the AHB master always initiates a transfer with INCR and completes the DMA requested burst in one transfer
- Mixed Burst Mode: In mixed burst mode, the AHB master always initiates the bursts with fixed-size (INCRx) when the DMA requests transfers of size less than or equal to 16 beats. When the DMA requests bursts of length more than 16, the AHB master initiates such transfers with INCR and completes the request in one transfer

To ensure that the pending burst of a transfer is rebuilt only with INCRx transfers when an INCRx transfer is interrupted by RETRY, SPLIT, or EBT response, use the RB bit of the DMA_SysBus_Mode register. However, if an INCR burst initiated in this mode is interrupted, the AHB master rebuilds the burst only with INCR transfers.

You can choose the burst modes by programming the FB bit in the DMA_SysBus_Mode register.

Note: The AHB master does not generate the WRAP bursts.

The AHB master does not generate the locked or protected transfers. Therefore, the Ethernet IP does not have the HLOCK or HPROT output signals.

52.3.1.2 Aligning AHB Burst Transfers to an Address Value

The AHB master interface can align all AHB burst transfers to an address value. You can enable this by using the AAL bit in the DMA_SysBus_Mode register. If Bit 31 and Bit 19 of DMA_SysBus_Mode register are set to 1, the AHB interface and the DMA ensure that all initiated beats are aligned to the address, completing the packet transfer in the minimum number of required beats.

The AHB interface and the DMA split unaligned address beats for a 64-bit data bus and initiate INCR16 beats only when the seven least-significant bits of the address have a zero value.

52.3.2 DMA Controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The DMA supports up to 2 Tx and 2 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. You can control the offset by the DSL field of DMA_CH*n*_Control register. The number of descriptors in the list is programed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The Ethernet IP supports the ring structure for the DMA descriptor. For more information on the descriptor, refer to *Section 52.3: Functional Description* that describes the descriptor structure and how the DMA accesses the descriptors.

52.3.2.1 Application Bus Burst Access

When configured through Bit 31 of the DMA_SysBus_Mode register, the DMA attempts to execute the fixed-length burst transfers on the AHB master interface. The PBL field of Transmit Control and Receive Control registers of respective DMA channel indicates and limits the maximum burst length. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB Interface is configured for fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the AHB interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise, (Bit 31 of DMA_SysBus_Mode

register is reset), the DMA transfers the data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AHB is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16) for AHB interface because it does not support more than INCR16.

52.3.2.1.1 Application Data Buffer Alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 1237. Application Data Buffer Alignment Examples

Data Buffer	Examples
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

52.3.2.1.2 Buffer Size Calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FS bit of TDES2 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LS bit of TDES2), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FS bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits[17:30] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (FL bits of RDES3[17:31]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

Note: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to have a 0x1002 offset. The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programed as 1024 bytes, because of the start address offset.

52.3.2.1.3 DMA Arbiter

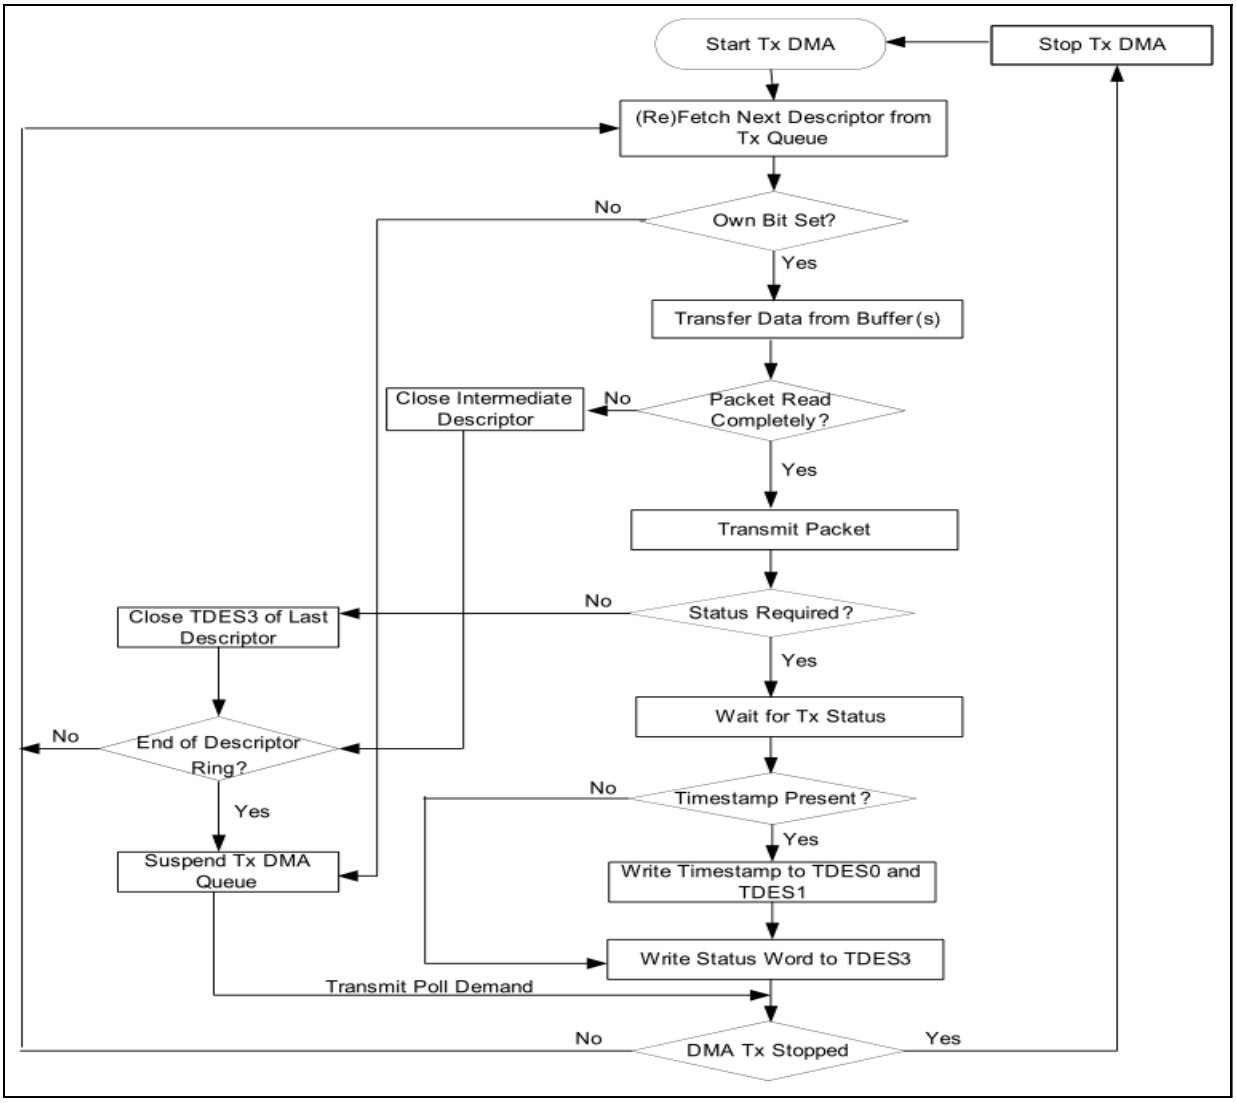
The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface. The following two types of arbitrations are supported:

- Round-Robin Arbitration: When Bit 30 of the DMA_Mode register is reset and both Tx and Rx DMAs are simultaneously requesting for access, the arbiter allocates the data bus in ratio set by Bits[17:19] of DMA_Mode register
- Fixed-Priority Arbitration: When Bit 30 of the DMA_Mode register is set, the Rx DMA always gets priority over the Tx DMA for data access by default. When Bit 20 of DMA_Mode register is also set, the Tx DMA gets priority over the Rx DMA

52.3.2.2 DMA Transmission

52.3.2.2.1 TX DMA Operation: Default (Non-OSP) Mode

The TX DMA engine in default mode proceeds as follows:



1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[0]) after setting up the corresponding data buffer(s) with Ethernet Packet data
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and Bit 29 and Bit 15 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to Step *11*:
   a) The descriptor is flagged as owned by the application (TDES3 [0] = 1'b0)
   b) The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   c) An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[0] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Step *3* through Step *7* are repeated until the end-of-Ethernet-packet data is transferred to the MTL
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The

status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.
If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1

10. Bit 31 of Status Register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[0]) set in its Last Descriptor. The DMA engine returns to Step *3*
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to Step *3*). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state

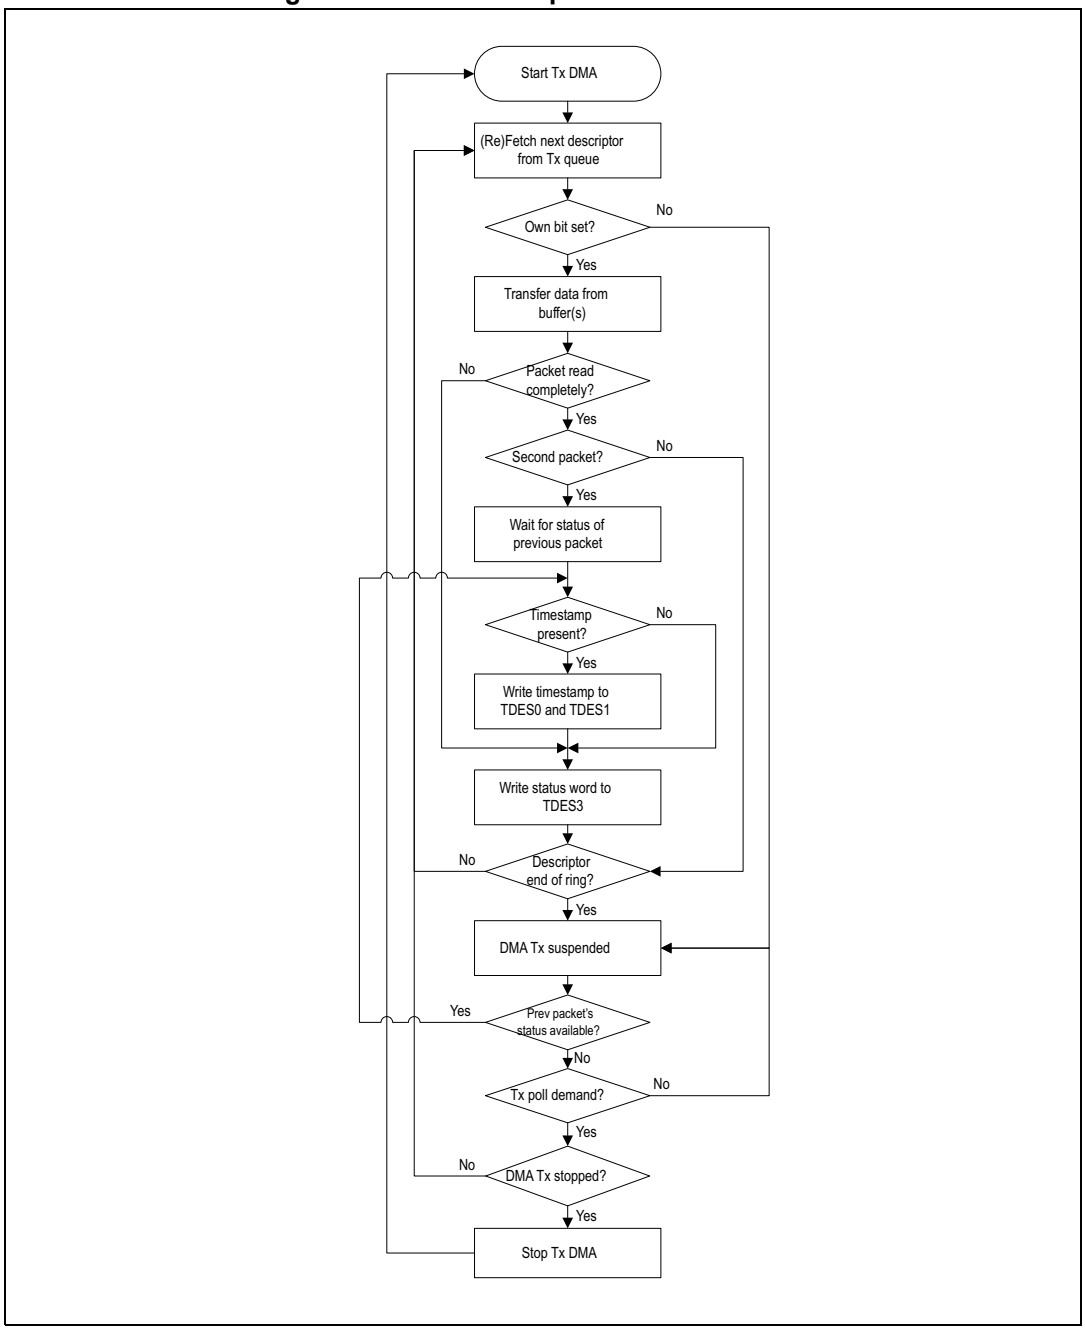
The Tx DMA transmission flow in default mode is shown in *Figure 1180*.

Figure 1180. TX DMA Operation in Default Mode

52.3.2.2.2 TX DMA Operation: OSP Mode

In the Run state, if Bit 27 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:



1. The DMA operates as described in Step *1* – Step *7* of the Tx DMA (default mode)
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step *7*
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES0 and TDES1
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to Step *3* (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step *7*)
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:
   a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1
   b) Writes the status to the corresponding TDES3
   c) Sets relevant interrupts and returns to Suspend mode

   If no status is pending and the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state
8. The DMA can exit Suspend mode and enter the Run state (goes to Step *1* or Step *2* depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel

Note: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. It is recommended to have a minimum descriptor length of four.

The basic flow is described in *Figure 1181*.

Figure 1181. Tx DMA Operation in OSP Mode

52.3.2.2.3 Transmit Packet Processing

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[2]) and the Last Descriptor (TDES3[3]). As transmission starts, the First Descriptor must have TDES3[2] set. When this occurs, the packet data is

transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[3]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[2] clear. If TDES3[3] is clear, it indicates an intermediary buffer. If TDES3[3] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor Bit set in Transmit Descriptor 3 (TDES3[3]). At this time, if Interrupt on Completion (TDES2[0]) is set, Bit 31 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (Bits[25:27] of Transmit Operation Mode register of corresponding MTL Transmit Queue)
- A full packet is contained in the FIFO

You can also use the store-and-forward mode (Bit 30 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[0] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[3]) set.

52.3.2.2.4 Transmit Polling Suspended

Transmit polling can be suspended by any of the following conditions:

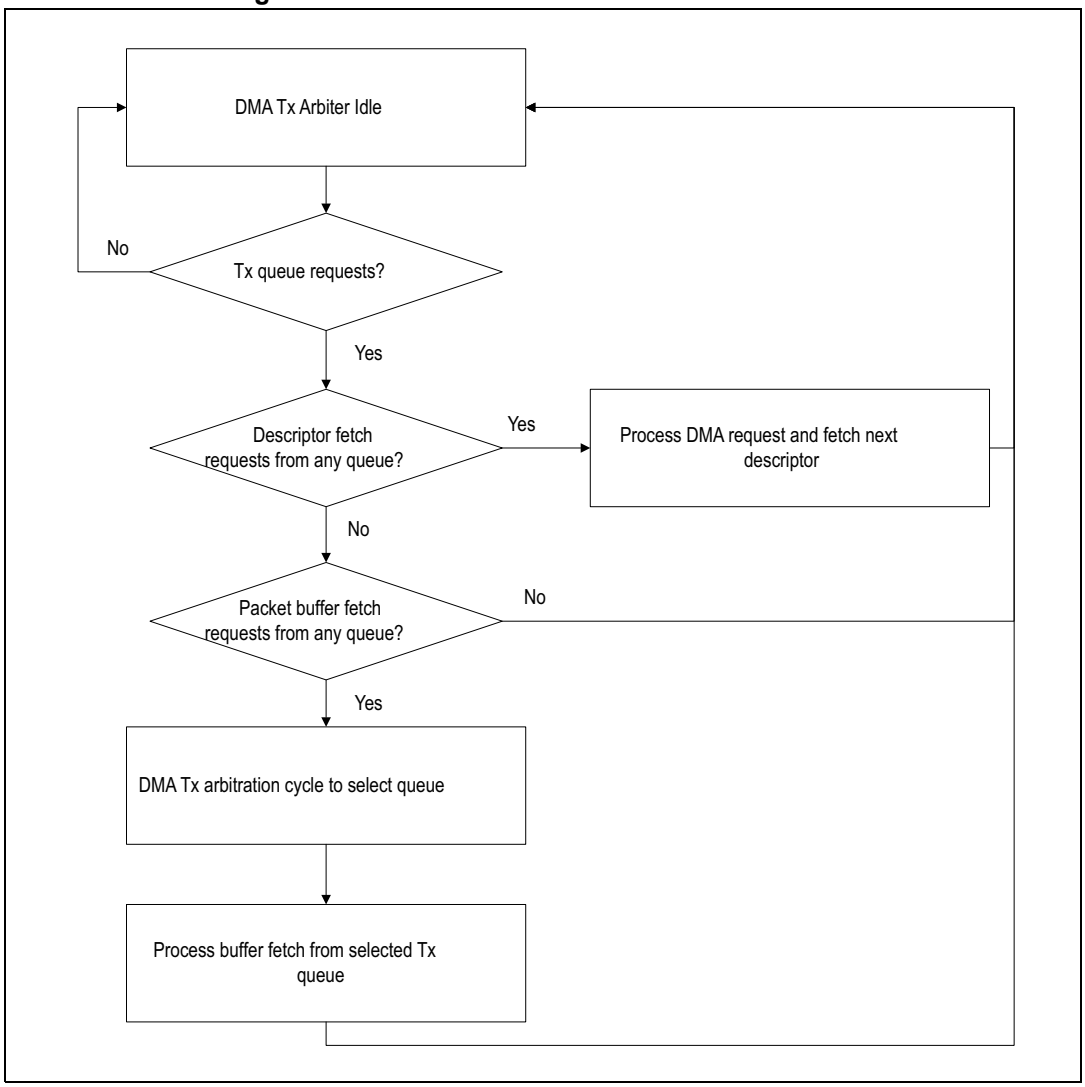
- The DMA detects a descriptor owned by the application (TDES3[0]=0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, Bit 16 and Bit 29 of Status Register of corresponding DMA channel are set
- A packet transmission is aborted when a Transmit error is detected because of underflow.
  The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 17 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_Interrupt_Status
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by it.
  To resume, the software driver must modify the Tail Pointer register

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

52.3.2.2.5 Transmit Channel Arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). *Figure 1182* shows the DMA Tx Channel Arbitration Process.

When there is any request in the Tx queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the



DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0). For packet buffer fetches, the DMA arbiter uses the programed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 1 (or the last enabled channel) and then Channel 0. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to Channel1 (or last enabled channel). If Channel 1 has no frames to transmit, the remaining weight is assigned to Channel 0
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programed in the Transmit Control register of a channel is ignored

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

Figure 1182. DMA Tx Channel Arbitration Process

52.3.2.3 DMA Reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 1183 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[0]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel
2. When Bit 31 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state.
   The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor

Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to Step *11*

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the RDES3[CTXT] field
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to Step *10*
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor)
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step *3*; otherwise, go to the Suspend state (Step *11*)
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel

The engine proceeds to Step *2* and re-fetches the next descriptor.

Figure 1183. RX DMA Operation

52.3.2.3.1 Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 31 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed
- A Receive poll demand is issued (update of the Tail Pointer register)

52.3.2.3.2 Receive Packet Processing

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless Bit 0 of MAC_Packet_Filter register is set)
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue
3. When the DMA application Interface (AHB) becomes ready, it transfers the data and sets the following:
   a) If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[3]) and First Descriptor (RDES3[2])
   b) If the packets fits into more than one descriptor, the DMA sets the First Descriptor (RDES3[2]) to delimit the packet
4. The DMA releases the descriptors by resetting the Own (RDES3[0]) bit to 0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor
5. If Interrupt Enabled on Completion (RDES3[1]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and Bit 25 of Interrupt Enable Register of corresponding DMA channel is set, the DMA sets Bit 25 of Status register of corresponding DMA channel.
   The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if Bit 24 of Interrupt Enable Register of corresponding DMA channel is set, the Receive Process sets Bit 24 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained

52.3.2.4 DMA Error Response

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to Ethernet IP or re-initialize the DMA descriptor list and start again. The rest of the DMA

channels are not affected by such errors. In AHB the DMA receives the error response through hresp_i signal.

52.3.3 MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The data path for both directions is 64-bit wide.

52.3.3.1 MTL Transmit Path

The DMA pushes the Ethernet packets read from the application or system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application. The fill level of the queue is indicated to the internal DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the application or system memory. The following two modes of operation trigger reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue
- Store-and-forward mode: In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the Queue
  - The Tx FIFO becomes almost full
  - The ATI watermark becomes low

The watermark becomes low when the requested Queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx Queue size.

The application can flush complete content of the Tx Queue by setting Bit 31 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

52.3.3.1.1 Initialization Flow

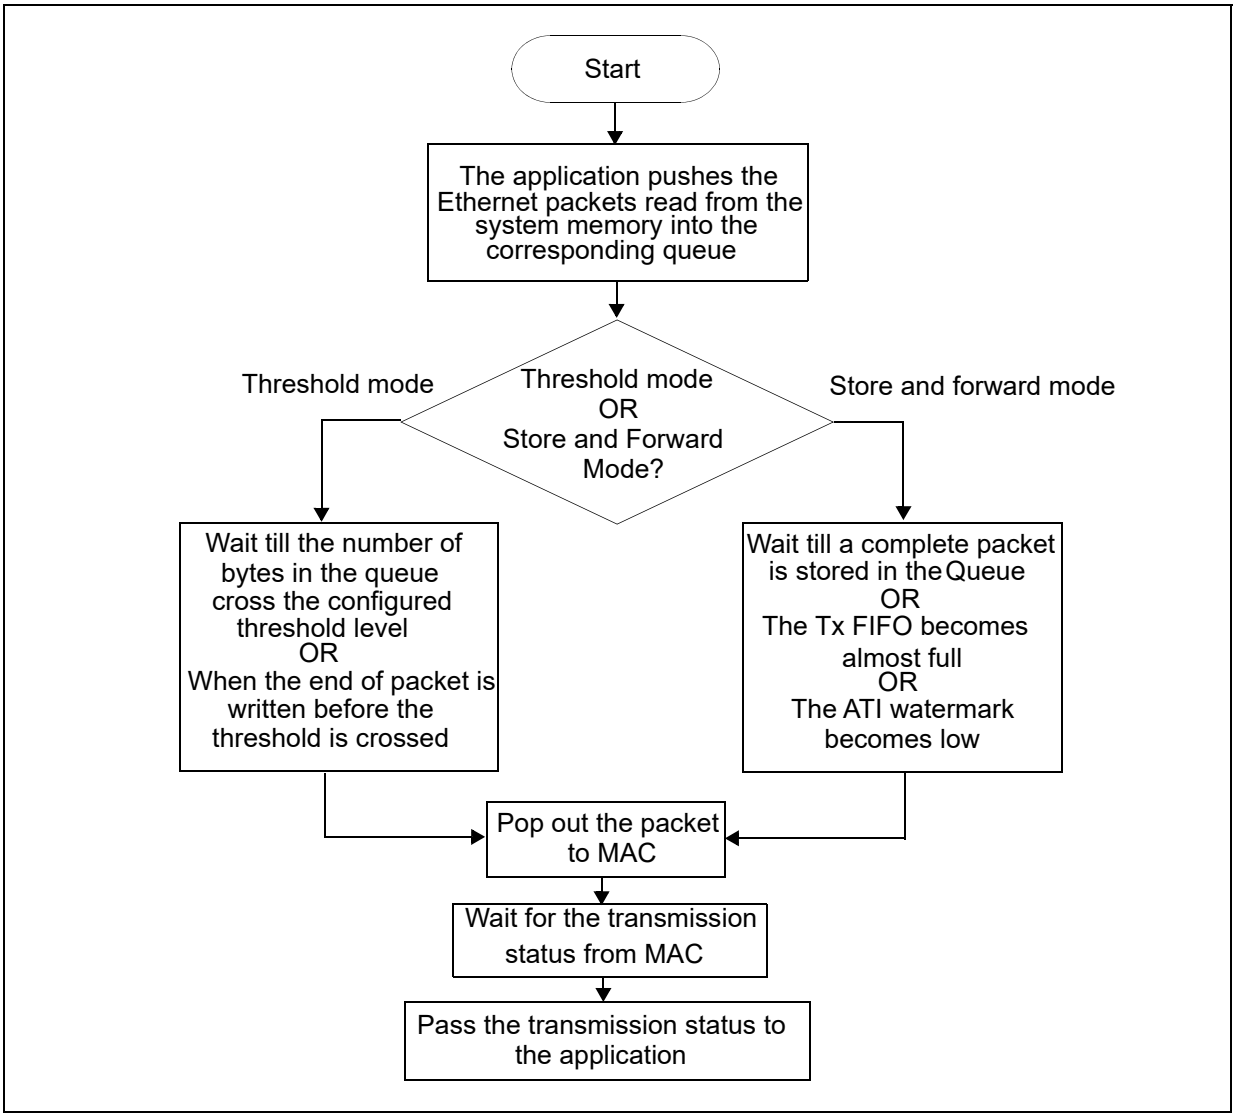
Upon reset, the MTL is ready to manage the flow of data to and from the application or DMA, and MAC.

First you need to initialize the Queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. You also need to initialize the MAC block. The internal DMA controllers must be individually enabled through their respective Cars.

52.3.3.1.2 Data Flow between the DMA and the MTL

This section describes the interaction process between the MTL and the DMA.

52.3.3.1.2.1 Single-Packet Transmit Operation



The following flow is valid when the core is operating in non-OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 0.

During a Transmit operation, the MTL block is a slave for the DMA controller. The general sequence of events for a Transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller (if enabled) fetches the data from the application through the AHB master interface and starts forwarding it to the MTL. The DMA descriptor memory contains the information related to packet control which is used to drive the MTL Control Word. The DMA data buffer memory contains the packet data
2. The MTL pushes the data received from the DMA into the corresponding queue. This process continues until the EOP is transferred
3. When the threshold level is crossed or a full packet of data is received into the queue, the MTL reads the packet data and drives it to the MAC
4. The queue controller continues to transfer data from the queue until a complete packet is transferred to the MAC
5. When the packet transfer is complete, the MTL receives the status from the MAC and notifies the DMA controller

Figure 1184 illustrates the MTL single-packet transmit operation.

Figure 1184. MTL Single Packet Transmit Flow

Note: When Bit 30 (DTXSTS) of Section 52.2.163 register is set, the MTL does not provide any status to the DMA.

52.3.3.1.2.2 Transmit Operation: Two Packets in the Buffer

The following flow is valid when the core is operating in OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 1.

The flow is similar to the flow described in Single-Packet Transmit Operation. However after fetching a packet, the DMA instead of waiting for the status, it continues to fetch another packet if available in the system memory. So, MTL can receive the second packet while it is processing the first packet. This flow improves the performance because the DMA can process two packets back to back before waiting for the status of the first packet.

52.3.3.1.2.3 Relationship between the Number of TX DMA Channels and Tx Queues

The number of Tx DMA channels is always equal to the Tx queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Bursts Lengths). However, the Tx queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and Tx queues to maintain the packet-level coherency.

52.3.3.1.2.4 Retransmission during Collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a Retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes are read out towards the MAC, the Queue Controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

When a packet transmission is aborted because of underflow and a collision event immediately follows (initiating a retry), retry has higher priority than abort.

Note: Before issuing the Transmit Queue Flush command, make sure that the Tx Queue is not empty, that is, Bit 27 (TXQSTS) of Transmit Debug Register of corresponding queue is reset.

52.3.3.1.2.5 Transmit Status Word

At the end of transfer of the Ethernet packet to the MAC and after the MAC completes the transmission of the packet, the MTL provides the Transmit status on respective queues. The detailed description of the Transmit Status is the same as for Bits[17:31] of TDES3 normal descriptor in write-back format. If IEEE 1588 Timestamp feature is enabled, the MTL returns 64-bit timestamp of the packet, along with the Transmit status.

If Bit 30 (DTXSTS) of MTL_Operation_Mode register is set then it disables the dependency of the DMA to read the status words from the Status FIFO thus the DMA can push as many packets as possible into the Tx queues because the application or DMA is not required to read the status words from the Status FIFO.

52.3.3.2 Receive Path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured Receive threshold (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

52.3.3.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data
2. The MAC indicates the SOP and EOP delimiters
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. For the 64-bit bus, one additional location is taken
6. The MTL takes the data out of the queue and sends it to the DMA depending on the below two modes
7. Threshold mode: In the (default) Threshold mode, the MTL reads the data and indicates its availability to DMA when one of the following happens:
   a) data bytes equal to the threshold amount are written to the Rx queue (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue)
   b) a full packet of data is received into the queue
8. Store-and-forward mode: In the store-and-forward mode (when Bit 26 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 27 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application

Note: In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.

52.3.3.2.2 Receive Operation Multi-Packet Handling

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

52.3.3.2.3 Error Handling

If the MTL Rx queue is full before it receives the EOP data from the MAC, the following happens:

1. An overflow is declared
2. The whole packet (including the status word) is dropped
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented

This is true even if Bit 27 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to

operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. The MTL then starts the transfer of next packet (if available).

52.3.3.2.4 Receive Status Word Format

The Rx packet status words are sent to the application after the packet data in Threshold mode and before the packet data in the Store and Forward Mode.

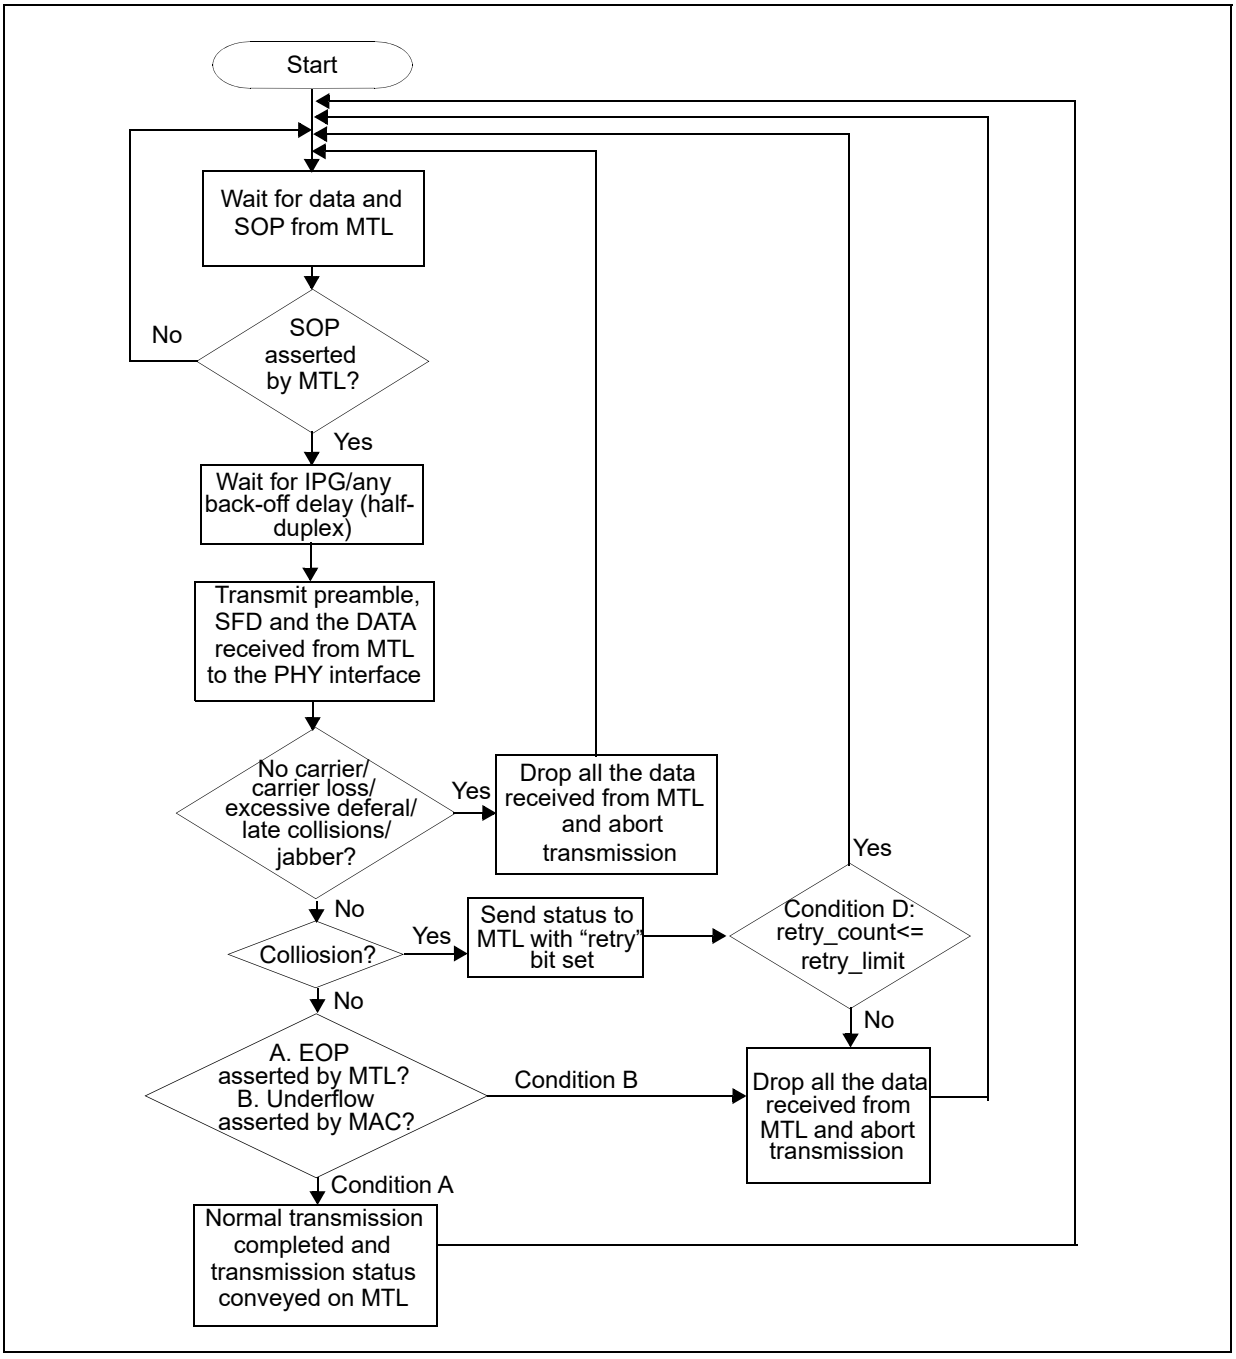
52.3.4 MAC

The MAC supports MII and RMII interfaces towards the PHY chip. The PHY interface can be selected only once after reset.

52.3.4.1 MAC Transmission

The transmission process is as follows:

1. Transmission is initiated when the MTL pushes in data with the SOP
2. When the SOP is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the packet data to the MII after the application initiates the transmission depends on delay factors such as IPG delay, time to transmit preamble or SFD, and any back-off delays for half-duplex mode. While the packets data is being transmitted, the MAC can throttle the MTL
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   a) The MAC completes the normal transmission and gives the transmission status to the MTL
   b) If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till either the packet is successfully transmitted or maximum retry requests expire
4. When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until



the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC

5. The MAC aborts the packet transmission under the following conditions:
   a) No carrier (half-duplex mode)
   b) Loss of carrier (half-duplex mode)
   c) Excessive deferral (half-duplex mode)
   d) Late collisions (half-duplex mode)
   e) Jabber

   The MAC accepts and drops all further data until the next SOP is received
6. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received
7. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet

Figure 1185 illustrates the MAC transmission process flow.

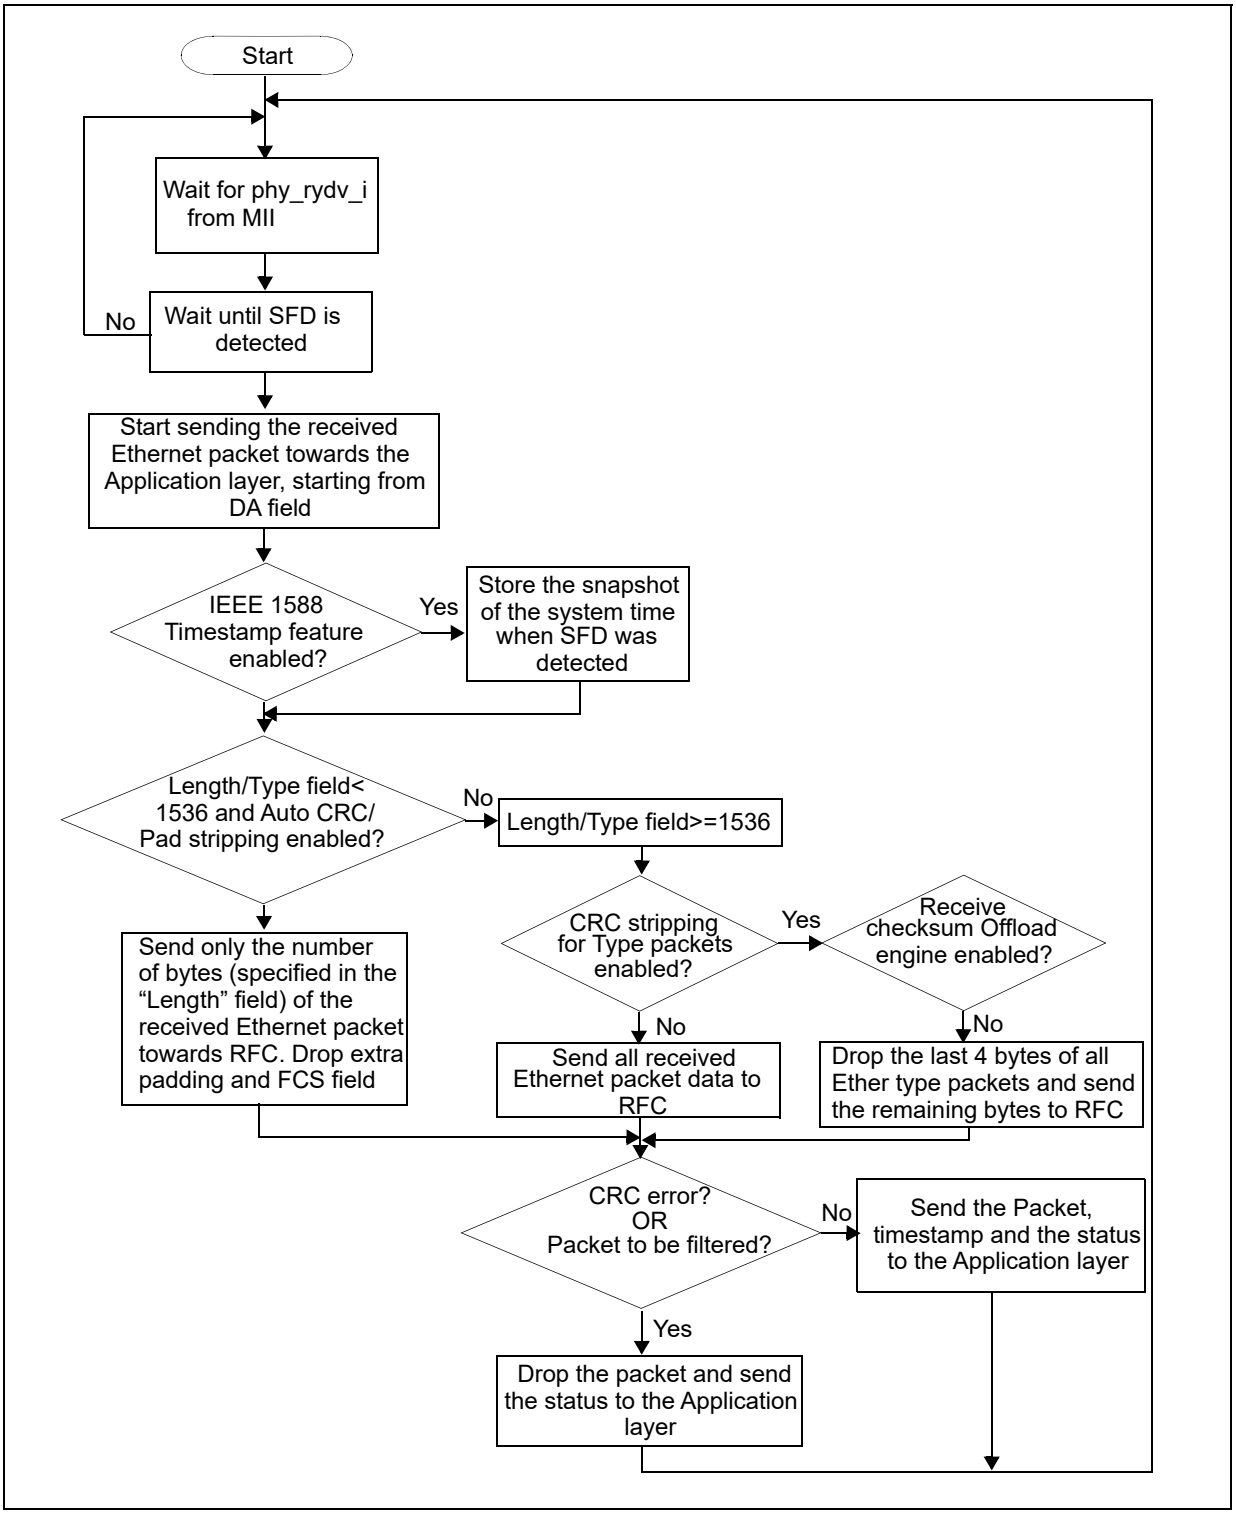


Figure 1185. Overview of MAC Transmission Process Flow

52.3.4.2 MAC Reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

Figure 1186. Overview of MAC RX Operation

52.3.5 Multiple Channels and Queues Support

The Ethernet module supports 2- queues and 2-channels on Tx and Rx paths. *Figure 958* shows the architecture of the Ethernet module with multiple queues and channels. This section describes how the Ethernet module supports multiple queues and channels. It contains the following sub-sections:

- DMA with Multiple Channels
- MTL with Multiple Queues

52.3.5.1 DMA with Multiple Channels

This section describes how multiple queues are supported in the Transmit and Receive DMA paths.

52.3.5.1.1 Multi-Channel DMA Transmit Path

The Ethernet module supports 2- Tx channels with the following priority schemes:

- Fixed Priority Scheme
- Weighted Strict Priority
- Weighted Round Robin

52.3.5.1.1.1 Fixed Priority Scheme

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. Fixed Priority Scheme for DMA Channels provides information about the priority levels of DMA channels.

Table 1238. Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1 (high)	Channel 1

52.3.5.1.1.2 Weighted Strict Priority

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. Channel 1 has the highest priority and Channel 0 has the lowest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

52.3.5.1.1.3 Weighted Round Robin

In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the DMA_CHIn Weighted Round Robin (WRR), all

channels are _Tx_Control register provides the weight for each Transmit channel as shown in Weights for DMA Channels.

Table 1239. Weights for DMA Channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

52.3.5.1.2 Multi-Channel DMA Receive Path

The Ethernet module supports 2- Rx channels. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programed priorities.

52.3.5.1.3 Priority Scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the register. For round-robin arbitration, you can use the PR field of the register to specify the weighted priority between the Tx DMA and Rx DMA. Table 5-1 Priority Scheme for Tx DMA and Rx DMA5-1 provides information about the priority scheme between Tx DMA and Rx DMA.

Table 1240. Priority Scheme for Tx DMA and Rx DMA(1)

Bit 17	Bit 18	Bit 19	Bit 20	Bit 30	Priority Scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

1. Bits 17, 18, 19, 20 and 30 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

52.3.5.1.4 Slot Number Function

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals. You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels.

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated every 125 µs of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the second's field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program Bit 31 of the Slot Function Control and Status register of the corresponding DMA channel.

You can enable the check for slot number by setting Bit 31 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, Bits [12:15] indicate the value of the reference slot number in DMA.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

52.3.5.1.5 Rx Queue to DMA RX Channel Mapping

The packets in the MTL Rx Queues can be routed to any one of the 2-RX DMA channels by programming the MTL_RxQ_DMA_Map0 Register. The following types of Rx Queue to DMA mapping is possible through programming:

- Static Mapping
- Dynamic (Per Packet) Mapping

52.3.5.1.5.1 Static Mapping

In this mode, all the packets of an Rx Queue is connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[28:31]) and Q0DDMACH (bit[24] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

52.3.5.1.5.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from an Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: When the Layer 3 and Layer 4 Packet Filter is enabled, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If the L3-L4 Registers do not give a comparison match, then the Ethernet module proceeds to the next step below
2. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programed DA values in MAC Address Registers. If the address matches any of the programed values, the corresponding DCS field (when enabled) determines the destination DMA channel number

If none of the above operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default

52.3.5.1.6 Selection of Tag Priorities assigned to Tx and Rx Queues

The VLAN Tag priorities can be assigned to Tx Queues by programming the corresponding PSTQIn field in the *Section 52.2.14: Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)* (for Tx Queues 0 and 1).

The bit corresponding to the VLAN Tag priority can be set in the PSTQIn field for assigning that priority to the Tx Queue. For example, if you want to assign VLAN Tag priority of 3 to Tx Queue 0, set bit [3] in PSTQ0 field.

The same VLAN Tag priority can be set for multiple Tx queues. The Tx packet association to particular Tx Queue is governed by the application, so the MAC does not route the packet based on Tx Queue priority mapping; it is only used for Pause Flow Control (PFC). The settings in the PSTQ*n* field determines the Tx Queues blocked for transmission when the PFC packet is received with corresponding VLAN Tag priorities enabled.

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field are used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

52.3.5.1.7 Rx Side Routing from MAC to Queues

The MAC routes the Rx packets to the Rx Queues based on following packet types:

- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged IEEE1588 PTP over Ethernet packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL

bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for generic through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the AVPTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

52.3.5.1.8 Rx Side Arbitration between DMA and MTL

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

52.3.5.2 MTL with Multiple Queues

The Ethernet module supports 2xTx and 2xRx queues. The number of Tx queues is equal to the number of DMA channels. You can control a Tx queue through *Section 52.2.169: Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)*. You can control an Rx queue through *Section 52.2.175: Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)*.

52.3.5.2.1 Queue Memory

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of *Section 52.2.169: Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)* and the Rx queue size in the RQS field of the *Section 52.2.175: Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)*.

52.3.5.2.2 Queue Modes

You can enable a Tx queue for generic, AV, or all types of traffic. Generic Tx queues use WRR or WSP queuing algorithms. AV Tx queue uses CBS or SP queuing algorithms.

You can enable an Rx queue for generic, AV, or all types of traffic. A particular queue enabled for generic or AV based routing is determined by the RXQ*n*EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Generic Rx queues: All queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. Untagged packets are routed through Queue 0. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register
- Multiple Rx queues with AV feature: When you select the *Enable Audio Video Bridging* option, AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register

52.3.5.2.3 Queue Priorities

You can program the priority of a Tx queue in the MAC_TxQ_Prty_Map0 register. You can program the priority of an Rx queue in Bits[16:23] of corresponding Rx Flow Control Register. The priority should be assigned in the following order:

a) AV queue (high priority)

b) Best-effort queue (low priority)

The software should put packets with correct priorities in the respective programed queue on Tx side. The MAC uses the programed priorities for blocking the Tx queues when a PFC packet is received. If a single queue is selected for multiple priorities and PFC is enabled, the entire queue is paused if one or more priorities in the queue are paused.

52.3.5.2.4 AV Feature

The Ethernet module supports the AV data transfer in 100 Mbps mode. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration

52.3.5.2.4.1 Transmit Path Functions

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets
- The credit for the queue is positive as per the algorithm

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue, as shown in *Figure 958*. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit
- If the higher priority queue has no packet waiting in the FIFO

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Fixed Priority Scheme for DMA Channels.

52.3.5.2.4.2 Receive Path Functions

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in *Section 52.4.1.4: Receive Descriptor*. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programed priority value. To specify the channel to which an AV packet with a given priority must be sent, program Bits[16:23] in the Transmit Flow Control Register of the corresponding queue
- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these

packets on any other queue, you can program Bits[29:31] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programed priority value

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[25:27] of the MAC_RxQ_Ctrl1 register.

52.3.5.2.4.3 Credit-Based Shaper Algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

Credit Value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in Credit Value Per Transmit Cycle Example.

Table 1241. Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	– portTransmitRate = 100 Mbps – idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) – sendSlope = 30 Mbps	– credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. – credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The Ethernet module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 30 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programed in Bits[25:27] of the CBS control register of the respective queue. For example, if you have programed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

52.3.5.2.5 Tx Side Arbitration between DMA and MTL

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX Checksum Engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

52.3.6 Double VLAN Processing

The Ethernet module supports the double VLAN tagging feature in which the MAC can process up to two VLAN tags (inner and outer). The Ethernet module supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

52.3.6.1 VLAN Processing in Transmit Path

Table 1242 describes the double VLAN processing features supported by the MAC on the Transmit side.

Table 1242. Double VLAN Processing Features in Tx Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_Incl and MAC_Inner_VLAN_Incl registers. The Ethernet module supports processing of any sequence of outer and inner VLAN tags. **Note:** The Ethernet module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: – The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. – The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. – The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. – The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields. Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in *Table 1243*

Table 1243. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) – VLAN Tag field with the Content of the VT field of Transmit context descriptor of the packet.
VLTI bit is reset	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) – VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets. To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_Incl register
- Enabling VLAN insertion, replacement, or deletion for selective packets. To enable this feature for selective packets, Program the VTIR field of TDES2 Normal Descriptor

52.3.6.2 VLAN Processing in Receive Path

Table 1244 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 1244. Double VLAN Processing in Rx Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.

Table 1244. Double VLAN Processing in Rx Path (continued)

Feature	Description
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

52.3.7 Source Address Insertion, Replacement, or Deletion

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

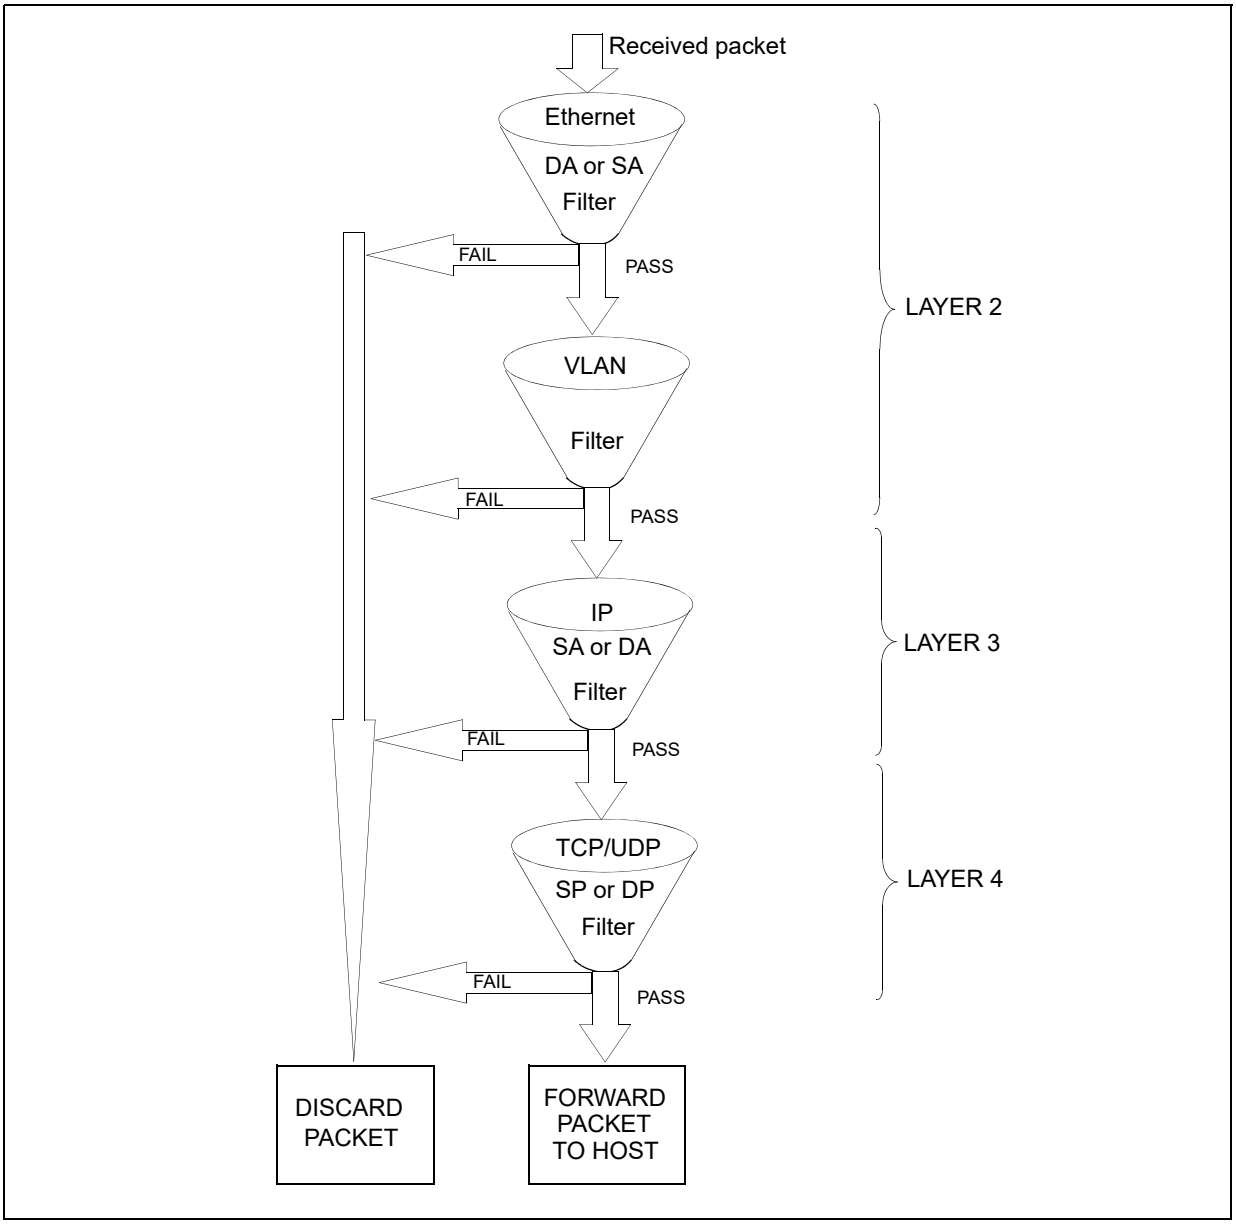
- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- To enable this feature for all packets, program the SARC field of the MAC_Configuration register
- To enable this feature for selective packets, use the following method:
  Program the SA Insertion Control field (Bits[6:8] of TDES3 Normal Descriptor (Read Format)) in the first Transmit descriptor of the packet. When Bit 6 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 6 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers
- If both MAC_Configuration Register and TDES3 are programed for SA insertion, then setting of MAC_Configuration register takes precedence

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.



52.3.8 Packet Filtering

The Ethernet module supports the following types of filtering for Rx packets:

- Source Address or Destination Address Filtering: The Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet
- VLAN Filtering: The Ethernet module supports the VLAN tag-based and VLAN hash filtering
- Layer 3 and Layer 4 Filtering: Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering

Figure 1187 shows the filtering sequence for Rx packets.

Figure 1187. Packet Filtering Sequence

52.3.8.1 Source Address or Destination Address Filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

52.3.8.1.1 Unicast Destination Address Filtering

The MAC supports up to 128 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr127 addresses are selected with an individual enable bit. For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA. The MacAddr32 to MacAddr127 addresses do not have mask control and all 6-bytes of the MAC address are compared with the received 6-bytes of DA.

In hash filtering mode (when HUC of MAC_Packet_Filter register bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects Bit 63 of selected register, and a value of 11111 selects Bit 0 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

52.3.8.1.2 Multicast Destination Address Filtering

To program the MAC to pass all multicast packets, set the PM bit in *Section 52.2.3: MAC Packet Filter Register (MAC_PACKET_FILTER)*. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

In Perfect filtering mode, the multicast address is compared with the programed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 63 of selected register and a value of 111111 selects Bit 0 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

52.3.8.1.3 Hash or Perfect Address Filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in *Section 52.2.3: MAC Packet Filter Register (MAC_PACKET_FILTER)*. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

52.3.8.1.4 Broadcast Address Filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

52.3.8.1.5 Unicast Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 1 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and

DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

52.3.8.1.6 Inverse Filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 1245 and *Table 1246* summarize the DA and SA filtering based on the type of packets received.

Table 1245. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 1246. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

52.3.8.2 VLAN Filtering

The Ethernet module supports the following types of VLAN filtering:

- VLAN Tag Perfect Filtering
- VLAN Tag Hash Filtering

52.3.8.2.1 VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. The VLAN packet status bit (Bit 21 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

52.3.8.2.2 VLAN Tag Hash Filtering

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered

as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 1247 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of the MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in the MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail. In *Table 1247*, value *X* means that this column can have any value.

When VLAN VID is programed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 1247. VLAN Match Status(1)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

1. In this table, X represents any value.

Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_Tag register. When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.

52.3.8.3 Layer 3 and Layer 4 Filtering

The Ethernet module supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the MAC_Configuration register to enable the Rx Checksum Offload Engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled
- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

52.3.8.3.1 Layer 3 and Layer 4 Filters Register Set

The MAC implements a set of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_Control0, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address0
- MAC_Layer3_Address0_Reg0
- MAC_Layer3_Address1_Reg0
- MAC_Layer3_Address2_Reg0
- MAC_Layer3_Address3_Reg0

52.3.8.3.2 Layer 3 Filtering

The Ethernet module supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

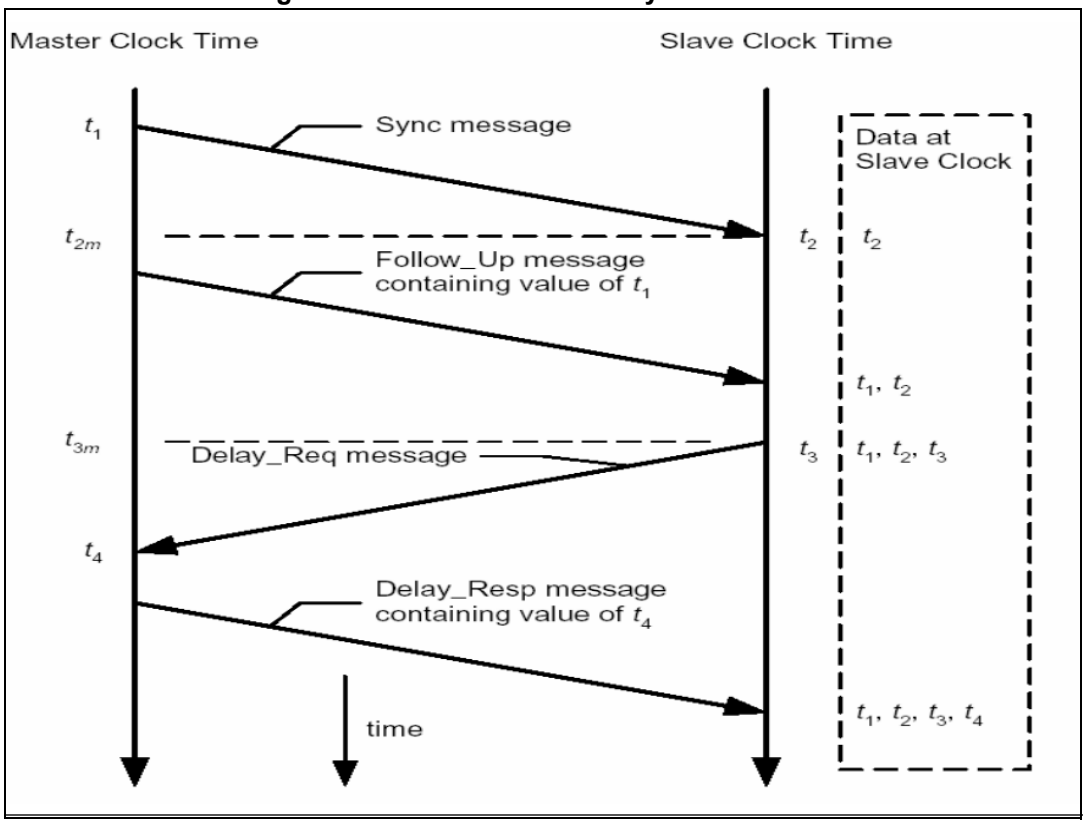
52.3.8.3.3 Layer 4 Filtering

The Ethernet module supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

52.3.9 IEEE 1588 Timestamps

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.



The Ethernet module supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet module provides programmable support for both standards. It supports the following features:

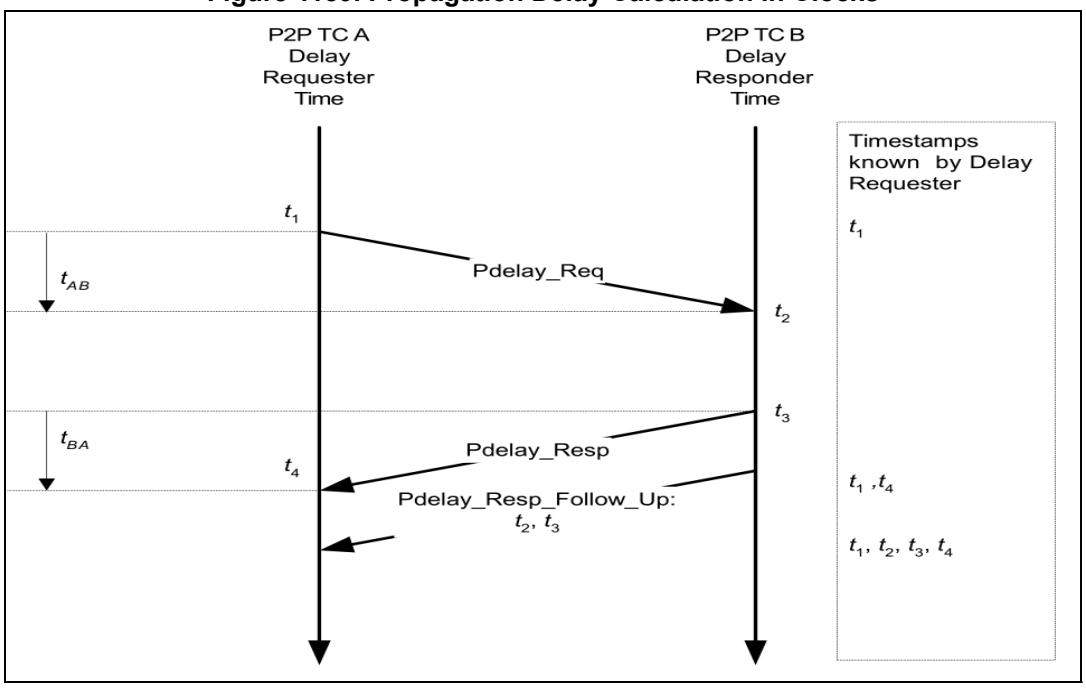
- Supports both timestamp formats
- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

52.3.9.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. *Figure 1188*, shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 1188. Networked Time Synchronization

As shown, the PTP uses the following process:



1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference
3. The master sends a Follow_up message to the slave, which contains t1 information for later use
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface
5. The master receives the message, capturing the exact time t4, at which the message enters its system
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

52.3.9.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. *Figure 1189* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 1189. Propagation Delay Calculation in Clocks

As shown, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message

To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

   a) Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   b) Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   c) Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message
5. Port 1 uses all four timestamps to compute the mean link delay

52.3.9.3 Clock Types

The Ethernet module supports the following clock types defined in the IEEE 1588-2008:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

52.3.9.3.1 Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled
- Maintains the data sets such as timestamp values

Table 1248 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 1248. Ordinary Clock: PTP Messages for Snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control Register.

52.3.9.3.2 Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock
- The local clock is common to all ports of the boundary clock

52.3.9.3.3 End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in the bullet points below. The snapshot is taken by setting the SNAPTYPSEL bits to '10' in the MAC_Timestamp_Control register.
End to End Transparent Clock: PTP Messages for Snapshot:

- SYNC
- Delay_Req

52.3.9.3.4 Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as mentioned in the below bullet points.
Peer-to-Peer Transparent Clock: PTP Messages for Snapshot:

- SYNC
- Pdelay_Req
- Pdelay_Resp

The snapshot is taken by setting the SNAPTYPESEL bit to '11' in MAC_Timestamp_Control register.

52.3.9.4 Reference Timing Source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

The Ethernet module provides an Internal Reference Time (80-bit). It takes the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

- UInteger48 secondsField: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002
- UInteger32 nanosecondsField: The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001

The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit

These modes are set through TSCTRLSSR bit in MAC_Timestamp_Control register.

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. You can read the values of the upper 16-bits of the seconds field from the CSR register.

The Ethernet module supports the following reference timing source features:

- Fixed Pulse-Per-Second OutputPulse-Per-Second Output
- Flexible Pulse-Per-Second OutputPulse-Per-Second Output
- Auxiliary Snapshots with External Events

52.3.9.4.1 Fixed Pulse-Per-Second Output

The Ethernet module supports the pulse-per-second (PPS) output that is given to indicate 1 second interval (default). You can change the frequency of the PPS output by setting the PPSCTRL0 field in the MAC_PPS_Control register.

52.3.9.4.2 Flexible Pulse-Per-Second Output

The Ethernet module also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. The Ethernet module provides the following features with the flexible PPS output:

- Supports programming the start or stop time in terms of system time
- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time
- Supports programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed
- Supports programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programed in the MAC_Sub_Second_Increment register. You can program the width of pulse from 1 to 2^{32}-1 units of sub-second increment value
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^{32}-1 units of sub-second increment value
- Provides the option to cancel the programed PPS start or stop request
- Indicates error if the start or stop time being programed has already elapsed

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of MAC_Timestamp_Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated (using incr_sub_sec_reg shown in Figure 1190).

52.3.9.4.2.1 PPS Start or Stop Time

You can initially program the start time in the Target Time register. If required, you can again program the start or stop time but you can do it only after the earlier programed value is synchronized to the PTP clock domain. Bit 0 of MAC_PPS*n*_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the

MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

52.3.9.4.2.2 PPS Width and Interval

The PPS width and interval are programed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

52.3.9.4.3 Auxiliary Snapshots with External Events

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the ptp_aux_ts_trig_i sideband signal.

The Ethernet module has two auxiliary snapshot inputs and depth 4 of a single common auxiliary snapshot FIFO. The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Timestamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

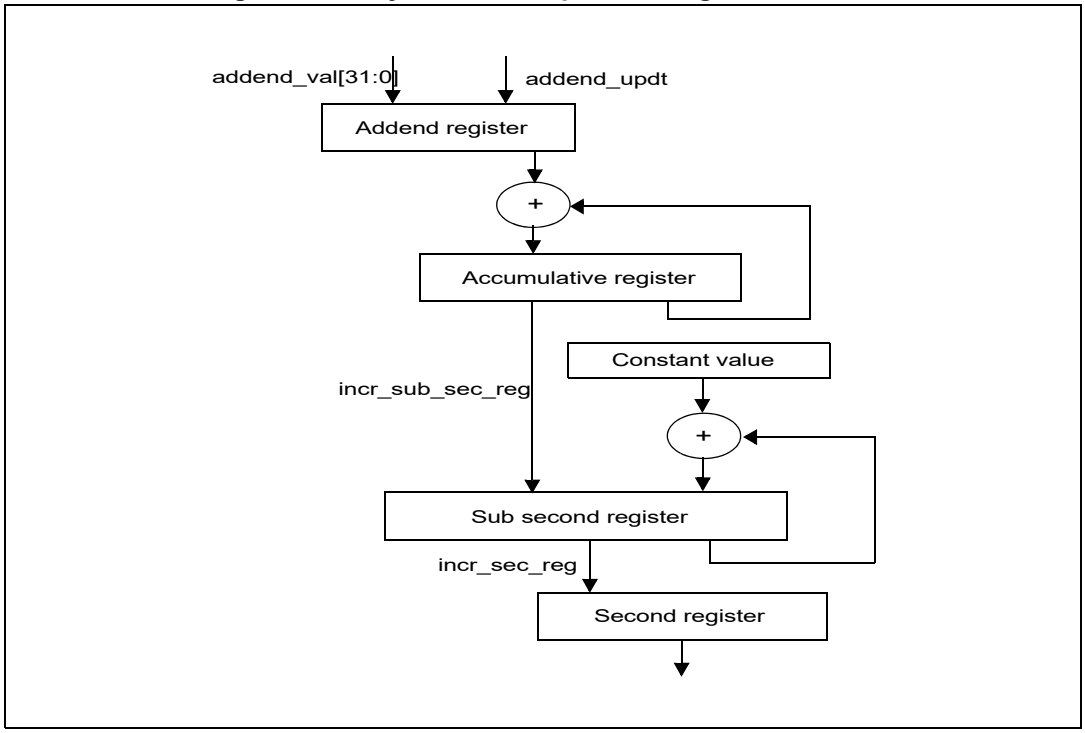
The MAC stores these snapshots in a FIFO. Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from the MAC_System_Time_Higher_Word_Seconds register. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in Bits[4:6] of MAC_Timestamp_Status register.

52.3.9.5 System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the MII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.



In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time

instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in *Figure 1190*. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

This algorithm is shown in *Figure 1190*.

Figure 1190. System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programed.

In 5-12, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32} / FreqDivisionRatio$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

52.3.9.6 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can do this by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

52.3.9.7 Receive Path Functions

The MAC can be programed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the

snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register.

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Note: The Ethernet module also supports the PTP messages over VLAN packets.

52.3.9.8 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock ***clk_ptp_ref_i***) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

52.3.9.8.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programed in the Ingress Correction register. The value that needs to be programed in the ingress correction register is calculated as mentioned below:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value.

```
INGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp.

```
Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY
```

Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

It is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programed value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <ingress_correction_value> represented in binary.

52.3.9.8.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value) programed in the Egress Correction register. The value that needs to be programed in the egress correction register as mentioned below:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value.

When Enable one step timestamp feature is selected,

```
EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)
```

Otherwise,

```
EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp.

```
Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY
```

Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The value must not exceed 0x3B9A_C9FF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <egress_correction_value> represented in binary.

52.3.9.9 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, that is, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

52.3.9.9.1 Maximum PTP Clock Frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

52.3.9.9.2 Minimum PTP Clock Frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the MII clock domain. This relationship is given in the following equation:

Equation 36

3 * PTP clock period + 4 * MII clock period <= Minimum gap between two SFDs

The MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in *Table 1249*.

Note: It is recommended that you use a clock that has constant frequency, preferably a divided application clock.
When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Increment register limits the minimum PTP frequency that can be used to ~4 MHz.

Table 1249. Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with Internal Timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
10 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
100 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz

52.3.9.10 PTP Processing and Control

Table 1250 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 1250. Message Format Defined in IEEE 1588-2008

Bits								Octets	Offset
0	1	2	3	4	5	6	7		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField(1)								1	32
logMessageInterval								1	33

1. ControlField is used in version 1. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets over IPv4Packets over IPv4
- PTP Frames over IPv6Frames over IPv6
- PTP Packets over EthernetPackets over Ethernet

52.3.9.10.1 PTP Packets over IPv4

Table 1251 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1251*.

Table 1251. IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP Primary multicast address: 224.0.1.129 PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	0x013F: PTP event message(1) 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only)

52.3.9.10.2 PTP Frames over IPv6

Table 1252 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1252*.

52.3.9.10.3 PTP Packets over Ethernet

Table 1252. IPv6-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [0:3])	0x6	IP version is IPv6
Layer 4 Protocol	20(1)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57(1)	0x013F, 0x140	0x013F: PTP event message 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94(1)	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management (version1)
PTP Message Type Field (IEEE 1588 version 2)	62(1) (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The Extension Header is not defined for PTP packets.

Table 1253 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in Table 5-12 Message Format Defined in IEEE 1588-2008n 5-12.

52.3.9.11 One-Step Timestamp

Table 1253. Ethernet PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address(1)	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses(2): 01-1B-19-00-00-00 01-80-C2-00-00-0E(3)
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, *Annex F*
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

The Ethernet module supports the one-step timestamp feature. When this feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application at that offset.

You can enable the one-step timestamp feature for a packet by setting Bit 11 (OSTC) in ATI Control Word. The inserted timestamp consists of 80-bits, the 64-bit TSSL and TSSH received from the application and the content of higher 16 bits of Higher Timestamp Word Register.

Note: The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets because the timestamp insertion happens in the MAC and the IP payload checksum needs to be updated. However, the checksum computation happens in the MTL.

52.3.9.11.1 MAC Transmit PTP Mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- Correction Field in the PTP header of messages
- OriginTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 1254 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the *Section 52.2.140: Timestamp Control Register (MAC_TIMESTAMP_CONTROL)* and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Table 1254. MAC Transmit PTP Mode and One-Step Timestamping Operation

Programming			Mode	Per Packet Control(1)			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE(2)	OSTC(3)	TTS(4)	
X	X	X	N/A	1	X	X	Timestamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
2'b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)

Table 1254. MAC Transmit PTP Mode and One-Step Timestamping Operation (continued)

Programming			Mode	Per Packet Control[1]			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE[2]	OSTC[3]	TTS[4]	
2'b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b01	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

1. The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programed mode.
2. TTSE represents TTSE bit of transmit descriptor in EQOS-AXI configuration, TTSE bit in TX control word in EQOS-MTL configuration, mti_ena_timestamp_i signal in EQOS-CORE configuration. The TTSE function is independent of the OST function and the programed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.
3. OSTC represents OSTC bit of transmit descriptor in EQOS-AXI configuration, OSTC bit in TX control word in EQOS-MTL configuration, mti_ost_en_i signal in EQOS-CORE configuration.

4. TTS represents the timestamp value provided in the TTSH, TTSL fields of transmit descriptor in EQOS-AXI configuration, timestamp provided in the TTSH, TTSL fields in the TX control word in EQOS-MTL configuration, mti_ost_i signal in EQOS-CORE configuration.
Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp.
When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy.
Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

52.3.10 IPv4 ARP Offload

The Ethernet module supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. The Ethernet module generates the ARP reply packets for appropriate ARP request packets**.** The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programed in the L3 register of the MAC
2. The MAC generates an ARP reply packet
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   – DA field of the Ethernet packet header
   – Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet
5. The MAC places its MAC address in the following fields:
   – SA field of the Ethernet packet header
   – Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet
9. The MAC transmitter sends the ARP reply

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 21) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of an ARP request Packet. The ARP request Packet must always have a valid CRC. It can generate an ARP response packet if the other conditions are valid.

52.3.11 Memory Access in Debug Mode

The Ethernet module supports the debug access to the FIFO memory. When you enable this feature, you must program the entire selected Tx memory to Tx Queue 0 and Rx memory to Rx Queue 0. In addition, the offload features such as Checksum Offload Engine and IEEE timestamp should not be enabled with this feature.

When this feature is enabled, the MAC insert the pad (if required) and computed CRC in the Transmit packet. The FIFOs operate in the store-and-forward mode.

52.3.11.1 Slave Mode Access

You can use this mode to send or receive a packet through a slave interface. The following sections describe how to transmit or receive a packet through a slave interface.

52.3.11.1.1 Transmitting Packets through a Slave Interface

To write a packet to the Tx memory through a slave interface, complete the steps given in *Table 1255*.

Table 1255. Steps to Write a Packet to Tx memory through a Slave Interface

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the Packet control word.
MTL_DBG_CTL	Complete the following: a. Set the PKTSTATE field to Control field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Reset the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write the SOP, the first word of the packet data.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to SOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write subsequent data words.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to Packet Data. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL and MTL_DBG_STS	Repeat Write subsequent data words. and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). till the penultimate word of the packet data.

Table 1255. Steps to Write a Packet to Tx memory through a Slave Interface (continued)

Register Name	Step Number and Description
MTL_FIFO_DEBUG_DATA	Write the last data word in the FDBGDATA field.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to EOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Set the number of valid bytes in the field.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.

After Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations. in *Table 1255*, the core automatically initiates the packet transmission. The status of the packet transmission can be obtained as explained in *Table 1255*. To get the status of a Tx packet, complete the steps given in *Table 1256*.

Table 1256. Steps to Get the Status of a Tx Packet

Register Name	Step Number and Description
MTL_DBG_STS	Wait for the STSI interrupt bit to set.
MTL_DBG_CTL	Complete the following steps: a. Set the FIFOSEL field to Tx Status FIFO. b. Reset the FIFWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_CTL	Read the FIFOBUSY bit and wait till this bit is low.
MTL_FIFO_DEBUG_DATA	Read the FDBGDATA field.

52.3.11.1.2 Receiving Packets through a Slave Interface

To read a packet from the Rx memory through a slave interface, complete the steps given in *Table 1257*.

Table 1257. Steps to Read a Packet from Rx memory through a Slave Interface

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_DBG_STS	Wait for the PKTI interrupt.

Table 1257. Steps to Read a Packet from Rx memory through a Slave Interface (continued)

Register Name	Step Number and Description
MTL_DBG_CTL	Complete the following: a. Set the FIFOSEL field to Rx FIFO. b. Reset the FIFOWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low.
MTL_DBG_CTL	Read the PKTSTATE and fields.
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field to know the number of available locations.
MTL_DBG_STS, MTL_DBG_CTL, MTL_FIFO_DEBUG_DATA	Repeat Read the FIFOBUSY bit and wait till this bit is low. through Read the LOCR field to know the number of available locations. till the complete packet, along with the Rx status, is received. **Note:** The format of the received packet is as follows First (One or multiple words) Last Status Word (One Word. Acts as delimiter between the status and data) Frame Data Word (multiple) Last Frame Data Word (One Word. Acts as a delimited among subsequent packets on the received Queue)

52.3.11.2 Debug Mode Access

Debug Mode enables you to do both the following operations:

- Write and Read back the Tx Queue
- Read and Write to the Tx Queue

This mode is useful for Memory BIST applications.

52.3.11.2.1 Writing to FIFO Memory in Debug Mode

To write to FIFO memory in the debug mode, complete the steps given in *Table 1258*.

Table 1258. Steps to Write to FIFO memory in Debug Mode

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the data in the FDBGDATA field.
MTL_DBG_CTL	Complete the following: – Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. – Reset the FIFORDEN bit. – Set the FIFOWREN bit.

Table 1258. Steps to Write to FIFO memory in Debug Mode (continued)

Register Name	Step Number and Description
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL - MTL_DBG_STS	Repeat Complete the following: and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). twice to write one complete data word in 64-bit mode.

52.3.11.2.2 Reading from FIFO Memory in Debug Mode

To read from FIFO memory in the debug mode, complete the steps given in *Table 1259*.

Table 1259. Steps to Read from FIFO Memory in Debug Mode

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. b. Reset the FIFOWEN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field (if required).
MTL_DBG_CTL, MTL_DBG_STS, MTL_FIFO_DEBUG_DATA	Repeat Complete the following: and Read the LOCR field (if required). twice to read one complete data word in 64-bit mode.

52.3.12 Loopback

The MAC supports Loopback of transmitted packets to its receiver. By default, the MAC Loopback function is disabled. You can enable this feature by programming the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block. The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping
- If the loopback mode is enabled without connecting a PHY chip, you should externally generate the Tx and Rx clocks and provide these clocks to the MAC
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO
- The MAC does not process ARP or PMT packets that are looped back

52.3.13 MAC Flow Control

This section describes the flow control for Transmit and Receive paths.

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

In the Receive path, the Flow Control is functional only in the full-duplex mode. The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

52.3.13.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

The Transmit Flow Control is enabled independently for each Rx queue when TFE bit is set in MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

SW can request the MAC to send a Pause packet or initiate backpressure by setting the FCB_BPA bit in the corresponding MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

HW can automatically trigger TX flow control based on the Rx Queue Threshold**.** The HW flow control operation of the MAC is enabled when the EHFC bit of the corresponding MTL_RxQ*n*_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in the RFA field of the MTL_RxQ*n*_Operation_Mode register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field.

Table 1260, describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE bit of the MAC_Q0_Tx_Flow_Ctrl register
- DM bit of the MAC_Configuration register
- RFA field of the MTL_RxQ0_Operation_Mode register
- RFD field of the MTL_RxQ0_Operation_Mode register
- FCB_BPA bit of the MAC_Q0_Tx_Flow_Ctrl

Flow control is similar for Queue1.

Table 1260. TX MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX performs backpressure when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.

Table 1260. TX MAC Flow Control (continued)

EHFC	TFE	DM	Description
0	1	1	The MAC transmitter sends the pause packet when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	1	The MAC transmitter sends the pause packet when FCB_BPA of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX sends a pause packet when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.

52.3.13.1.1 Flow Control in Full-Duplex Mode

In full-duplex mode, the Ethernet module uses IEEE 802.3x Pause packets for flow control. *Table 1261*, describes the fields of a Pause packet. When the FCB_BPA bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Table 1261. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets
PT	Contains Pause time specified in the PT field of the MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register

52.3.13.1.2 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

52.3.13.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet. You can enable the Pause flow control by setting the RFE bit in the MAC_Rx_Flow_Ctrl register. *Table 1262*, describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 1262. RX MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

When the RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   – Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001)
   – Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set.
   If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address
2. The MAC decodes the following fields of the received packet:
   – Type field: This field is checked for 16'h8808
   – Opcode field: This field is checked for 16'h0001 (Pause packet)
   – Pause Time: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times)
3. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register
4. If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value

52.3.14 Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path. On the transmit path the Checksum Offload Engine is present in Queue0 only.

52.3.14.1 Transmit Checksum Offload Engine

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[14:15]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the Ethernet module is configured for Threshold (cut-through) mode.
You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. When reading starts, the COE fails and consequently all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the following number of bytes in size: TXFIFO_SIZE – ((PBL + N)(DATAWIDTH/8)), Where N= 5*

52.3.14.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 31). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
  - The total packet length is less than the value given in the IPv4 Header Length field
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received

52.3.14.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 19). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 1263 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 1263. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2 K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	No
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Authentication	Not applicable	Yes

Table 1263. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Any other next header field in main or extension headers	Not applicable	No
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

52.3.14.2 Receive Checksum Offload Engine

You can enable the Receive Checksum Offload Engine (Rx COE) by setting the IPC bit of MAC_Configuration register. When enabled, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is sent in the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 1264, describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status*Table 1265*.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 1264. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	Yes
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes

Table 1264. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

52.3.15 MAC Management Counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the CSR. Each register is 32-bits wide. The width of each MMC counter is 32-bit.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, you should set Bit 31 in the MAC_Packet_Filter register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

The following definitions define the terminology.

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - MII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN Frame maxsize = 1,522
  - Jumbo Frame maxsize = 9,018
  - JumboVLAN Frame maxsize = 9,022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in *Table 1265*.

Table 1265. Size of the Maximum Receive Packet Size

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maxsize in bytes	Single VLAN Frame maxsize in bytes	Double VLAN Frame maxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

52.3.16 Low Power Modes

This chapter describes the low power modes supported by the Ethernet module. It contains the following sections:

- Energy Efficient Ethernet
- Power Management

52.3.16.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities, negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Note: The EEE feature is not supported when the MAC is configured to use the RMII PHY interface. Even if the MAC supports multiple PHY interfaces, you should activate the EEE mode only when the MAC is operating with the MII interface.
According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

52.3.16.1.1 Transmit Path Functions

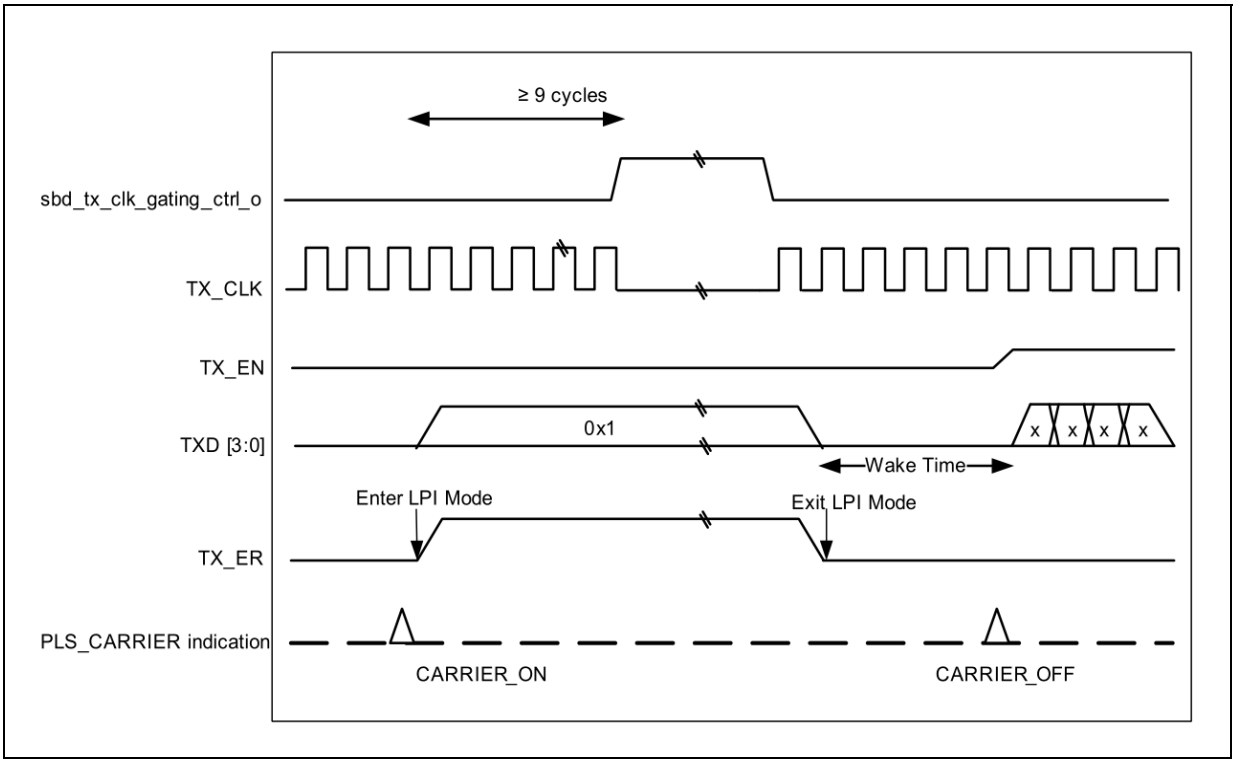
In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Timers_Control register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

Note: According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN
2. Asserts TX_ER
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:



1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMER
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programed in the TWT field of the MAC_LPI_Timers_Control register
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt

Figure 1191 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

The MAC does not stop the TX_CLK clock. You can stop this clock (as shown in Figure 1191) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after 9 Tx Clock Cycles, one Pulse Synchronizer delay (BCM22), and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status Register.
If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

Figure 1191. LPI Transitions (Transmit)

52.3.16.1.1.1 Automated Entry/Exit of LPI mode in TX Path

The MAC transmitter can be programed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[12]) and LPITXEN (Bit[15]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[11] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

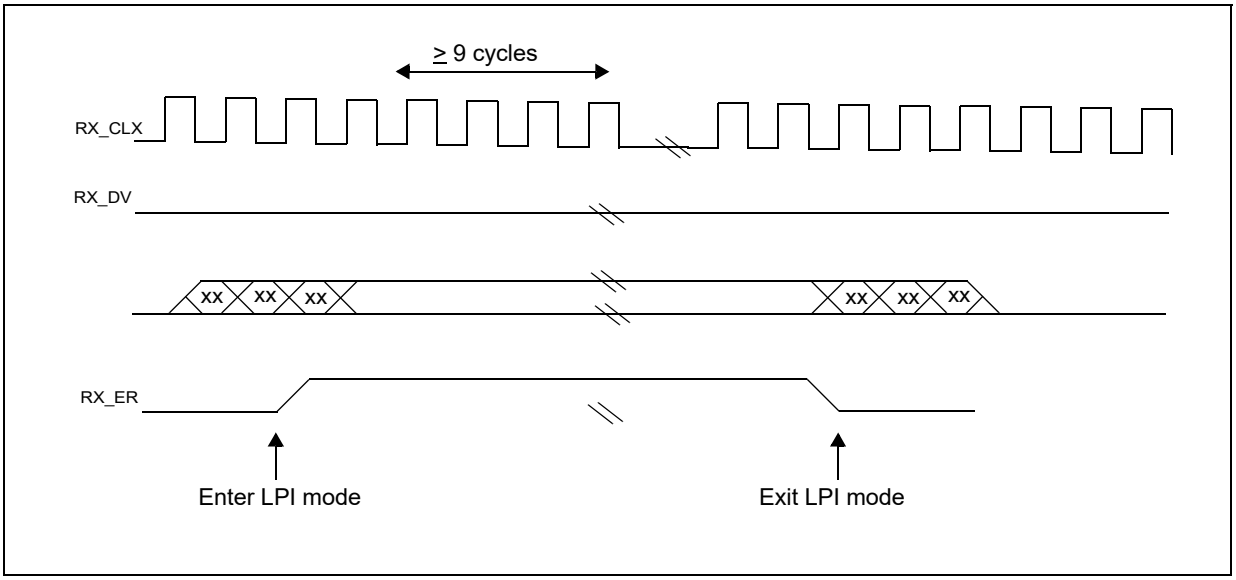
When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

52.3.16.1.2 Receive Path Functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER
2. The PHY sets RXD[7:0] to 0x01
3. The PHY de-asserts RX_DV
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt

Note: If the LPI pattern is detected for a very short duration (that is, less than 2 cycles of Rx clock), the MAC does not enter the Rx LPI mode.
If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than 2 cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.



The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 1192 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 1192. LPI Transitions (Receive)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in Figure 1192.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.
When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

52.3.16.1.3 LPI Timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER: The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.
  This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programed in Bits[6:15] of the MAC_LPI_Timers_Control register. The MII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.
- LPI TW TIMER: The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programed in Bit[16:31] of MAC_LPI_Timers_Control register. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal

operation after the TW timer reaches the terminal count.
The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µs.

- LPI AUTO ENTRY TIMER: This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

52.3.16.2 Power Management

The power management (PMT) block supports the reception of network (remote) wake-up packets and magic packets. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up packets and magic packets that the MAC receives.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up packet is received and the corresponding detection is enabled.

The PMT block is available in the receive path of MAC. You can select both types of power management packet (remote wake-up packet and magic packet). You can use the RWKPKTEN and MGKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

Note: The magic packet feature is implemented based on the Magic Packet Technology white paper. The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

52.3.16.2.1 PMT Block Registers

The following are the PMT block registers:

- MAC_PMT_Control_Status
- MAC_RWK_Packet_Filter

52.3.16.2.2 Remote Wake-Up Packet Detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status, the normal operation is resumed after a remote wake-up packet is received. The application writes all eight wake-up filter registers, by performing a sequential Write to address (00C4H). The application enables remote wake-up by writing 1 to the RWKPKTEN bit of the MAC_PMT_Control_Status register.

The PMT block supports 4 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wake-up packet.

The Filter Offset determines the offset from which the packet is to be examined. The Filter Byte Mask determines which bytes of the packet must be examined. The bit 0 of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up packet is checked only for length error, FCS error, dribble bit

error, MII error, and collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wake-up packet detection is updated in the PMT Control and Status register for every remote wake-up packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wake-up packet.

Note: The watchdog timeout limit for a remote wake-up frame is 2,048 bytes irrespective of the value programed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programed in DCRCC bit of MAC_Ext_Configuration register is applicable to a remote wake-up frame only when Enable IPv4 ARP Offload is selected in the configuration.

52.3.16.2.3 Magic Packet Detection

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wake-up packet data format of 6 bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wake-up by writing 1 to the MGKPKTEN bit of the MAC_PMT_Control_Status register. The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48’hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48’hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48’hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

Destination Address Source Address …….. FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

The Ethernet module checks the remote wake-up packet only for length error, FCS error, dribble bit error, MII error, collision. In addition, the remote wake-up packet is checked to

ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, the Ethernet module considers it a valid packet.

The magic packet detection is updated in the MAC_PMT_Control_Status register for the received magic packet. A PMT interrupt to the Application triggers a read to the MAC_PMT_Control_Status register to determine whether a magic packet has been received.

Note: The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet only when Enable IPv4 ARP Offload is selected in the configuration.

52.3.16.2.4 System Considerations during Power Down

The Ethernet module neither gates nor stops clocks when the power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during the power-down mode, because it is involved in the magic packet or remote wake-up packet detection. However, the application path clock can be gated during the power-down mode. The transmit Path clock must be gated during the power-down mode only if ARP Offload is not enabled.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt [Bit 31 of the register] is received
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the_ MAC_Configuration register
3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. You can do this by reading the appropriate bits of Debug registers in the DMA and MTL CSR space
4. Enable Power-Down mode by appropriately configuring the PMT registers
5. Enable the MAC Receiver and enter the Power-Down mode
6. Gate the application and transmit clock (transmit clock must be gated only if ARP Offload is not enabled) inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode
7. On receiving a valid remote wake-up packet, the Ethernet module asserts the pmt_intr_o signal and exits the Power-Down mode
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation

52.3.17 Interrupts

Interrupt can be generated as a result of various events in the Ethernet IP core. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (interrupt) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the DMA_Interrupt_Status register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH*n*_Status register
- MTL_Interrupt_Status register
- MAC_Interrupt_Status register

The interrupt is a level signal and will get de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

52.3.17.1 DMA Interrupts

The DMA_CH*n*_Status register captures all the interrupt events of that TxDMA and RxDMA channel pair. The DMA_CH*n*_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[16:17] of DMA_CH*n*_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[25] of DMA_CH*n*_Status register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the register for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of the DMA_Interrupt_Status register are cleared.

52.3.17.1.1 Periodic scheduling of DMA Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet IP gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[0]) once for every “required” number of packets to be transmitted
2. Similarly, set the IOC (RDES3[1]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated

In addition to above, an interrupt timer (DMA_CH*n*_Rx_Interrupt_Watchdog_Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programed with a non-zero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt

because the corresponding interrupt of completion IOC bit (RDES3[1]) is not set. When this timer runs out as per the programed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH*n*_Interrupt_Enable register. The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

52.3.17.1.2 Per DMA channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CH*n*_Status register. The TI bit is set whenever the Tx DMA channel closes the a descriptor in which the IOC (Interrupt On Completion - TDES2[0]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[1]) bit is set.

The common interrupt output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH*n*_Interrupt_Enable register.

52.3.17.2 MTL Interrupts

In MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the Transmit and Receive paths respectively. The interrupt status are captured and organized in a hierarchical manner in order to identify the root cause quickly.

The MTL_Interrupt_Status register identifies the top level modules that can cause the interrupt to be asserted.

- Bits[30:31] identify 2 Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Q*n*_Interrupt_Status register to identify the exact cause and set the corresponding bits to 1 to clear the interrupt event. The assertion of interrupt due to these events is enabled by the corresponding enable bits in MTL_Q*n*_Interrupt_Enable register
- Bit[15] is made high in case the event is present in the MAC core. The application should in turn read the MTL_Interrupt_Status register to identify the cause
- Bit[14] is related to indirect access completion events to the TxFIFO and RxFIFO memory in Debug Mode

52.3.17.3 MAC Interrupts

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_Interrupt_Status register describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the MAC_Interrupt_Enable register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, Bit 26 of the MAC_Interrupt_Status register indicates that the LPI interrupt status has changed. You must read the TLPIEN bit of MAC_LPI_Control_Status register to clear this interrupt event.

The interrupts from the MAC are combined (OR'ed) and given as the MACIS bit in the DMA_Interrupt_Status register.

52.3.17.4 LPI Interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt mci_intr_o (interrupt in EQOS-DMA configurations) is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the mci_intr_o (interrupt in EQOS-DMA configurations), the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. You can use the lpi_intr_o signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state. If you do not want to gate-off the application clock during the Rx LPI state, you can leave the lpi_intr_o signal unconnected and use the mci_intr_o (interrupt in EQOS-DMA configurations) signal to detect Rx LPI exit.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

52.3.17.5 PMT Interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. In addition to the interrupt, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode.

You can use the pmt_intr_o interrupt to trigger the external clock-gating circuitry to restore the application clock and Tx clock to the MAC. If you do not want to gate-off these clocks during the power-down mode, you can leave the pmt_intr_o signal unconnected and use the interrupt to detect the MAC wake-up operation.

The pmt_intr_o signal is generated in the Rx clock domain. It is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

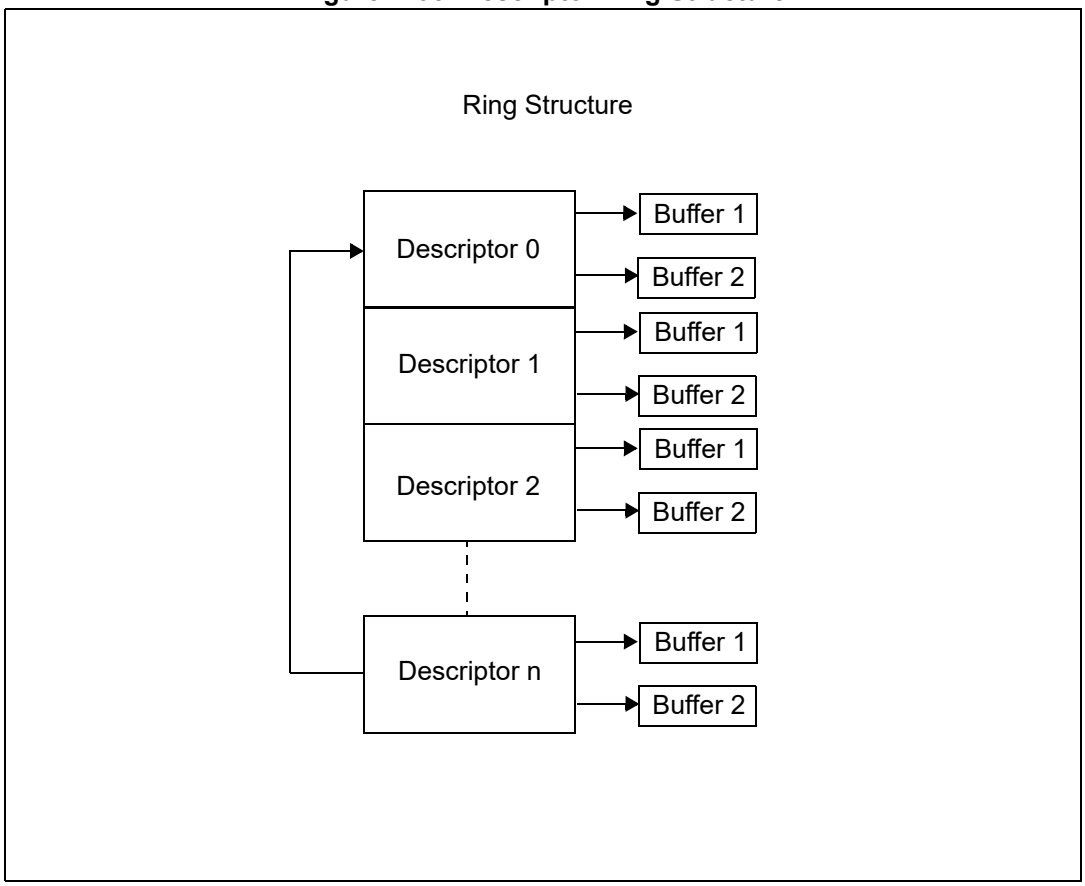
When software resets the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

52.4 Descriptors

52.4.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The Ethernet module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted



Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for number of descriptors that can be used for a single packet.

52.4.1.1 Descriptor Structure

The Ethernet module supports the ring structure for DMA descriptor.

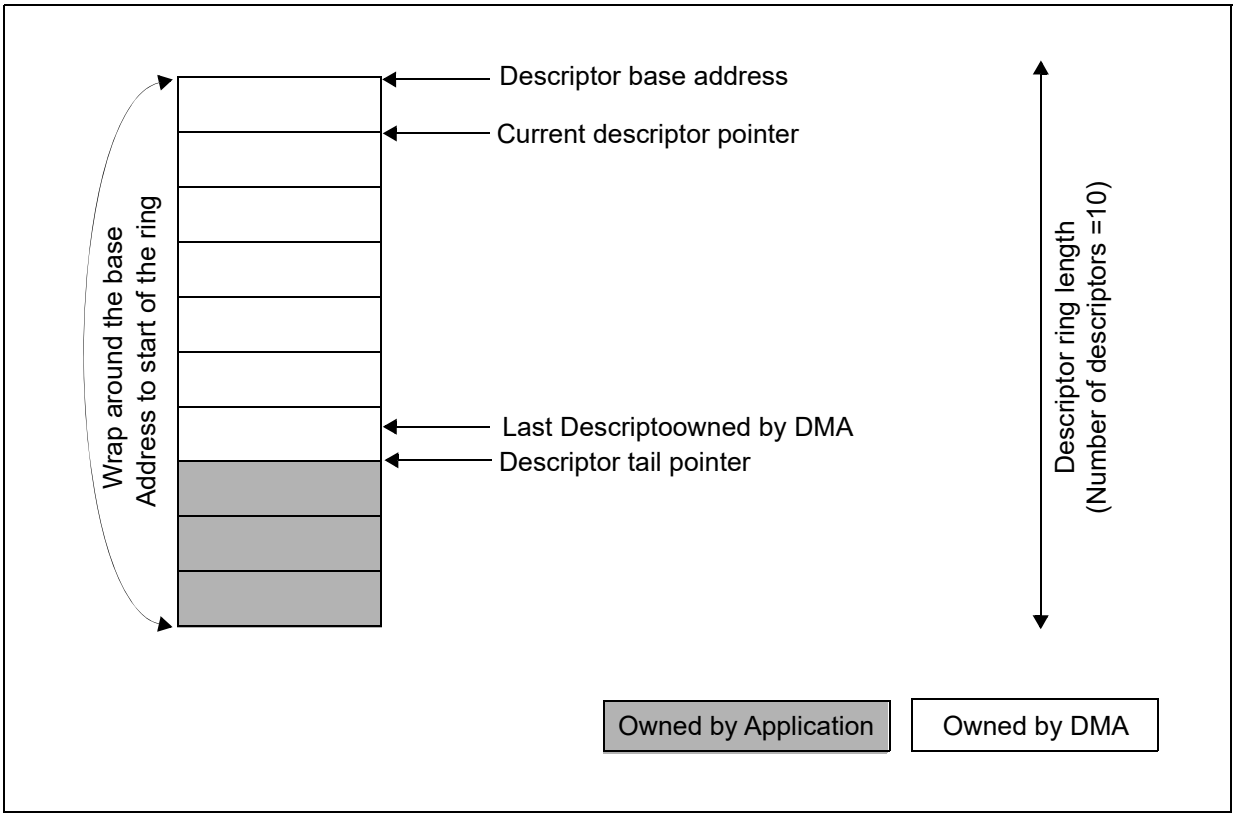
Figure 1193. Descriptor Ring Structure

In Ring structure, descriptors are separated by the DWord number programed in the DSL field of the DMA_CH*n*_Control register. The application needs to program the total ring

length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH*n*_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH*n*_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (*N*). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (*N* – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:



```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in *Figure 1194*.

Figure 1194. DMA Descriptor Ring

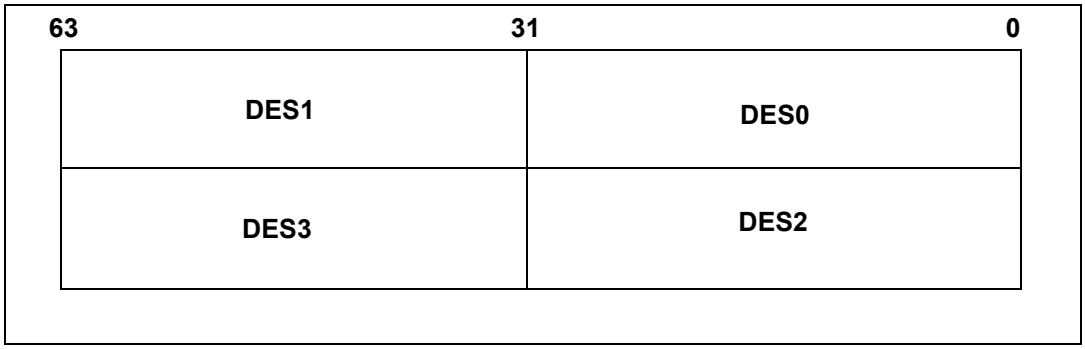
For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

52.4.1.2 Descriptor Endianness

The descriptor addresses must be aligned to configured bus width (DWord for 64-bit bus). The data bus can be configured for either little-endian or big-endian format.

Figure 1195 shows the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is little-endian or big-endian and the endian mode of descriptors is reverse-endian.

Figure 1195. Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus



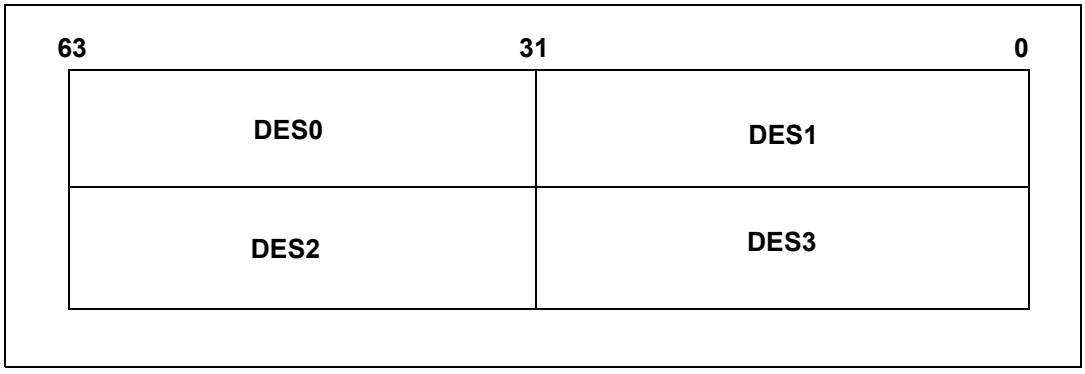


Figure 1195 and *Figure 1196* show the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is big-endian and the endian mode of descriptors is reverse-endian. In 64-bit big-endian data bus systems, when the descriptors are configured for reverse endianness, the order of the descriptor subset is reversed from the default (7-3 Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus). For example, Bits[63:32] are DES0 while Bits[31:0] are DES1.

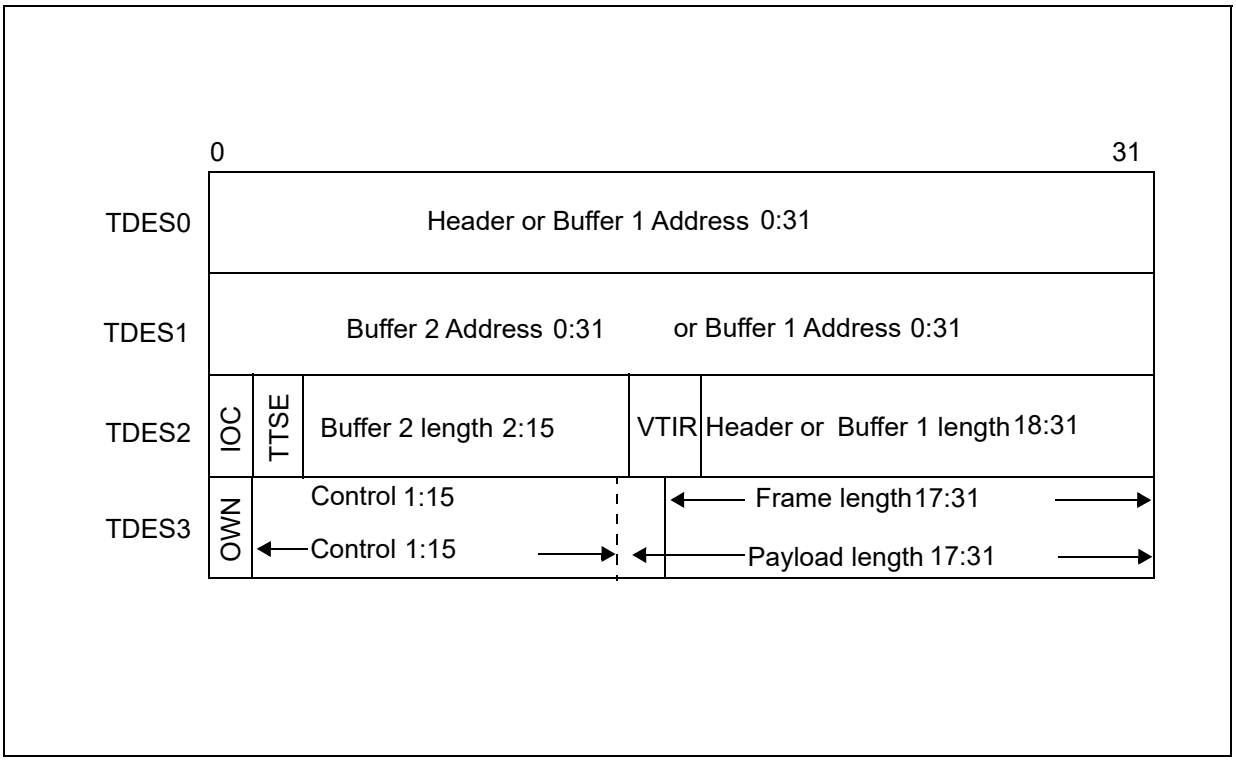
Figure 1196. Rx/Tx Descriptors in Reverse-Endian Mode for 64-Bit, Big-Endian Data Bus



52.4.1.3 Transmit Descriptor

The DMA in the Ethernet module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has the following two formats: Read format and Write-Back format

52.4.1.3.1 Transmit Normal Descriptor (Read Format)

Figure 1197 shows the Read Format for a Transmit normal descriptor.

Figure 1197. Transmit Descriptor Read Format

52.4.1.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 1266. TDES0 Normal Descriptor (Read Format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1.

52.4.1.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 1267. TDES1 Normal Descriptor (Read Format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

52.4.1.3.1.3 TDES2 Normal Descriptor (Read Format)

Figure 1198. TDES2 Normal Descriptor (Read Format)

0	1	2:15	16:17	18:31
IOC	TTSE	B2L	VTIR	B1L

Table 1268. TDES2 Normal Descriptor (Read Format)

Field	Description
0 IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CH*n*_Status register after the present packet has been transmitted.
1 TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor.
2:15 B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
16:17 VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: 00 Do not add a VLAN tag. 01 Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. 10 Insert a VLAN tag with the tag value programed in the MAC_VLAN_Incl register or context descriptor. 11 Replace the VLAN tag in packets with the tag value programed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets.
18:31 B1L	Buffer 1 Length

52.4.1.3.1.4 TDES3 Normal Descriptor (Read Format)

Figure 1199. TDES3 Normal Descriptor (Read Format)

0	1	2	3	4:5	6:8	9:12	13	14:15	16	17:31
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM	Rsvd	CIC	Reserved	FL

Table 1269. TDES3 Normal Descriptor (Read Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
1 CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
2 FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
4:5 CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[2]) is set. The following list describes the values of Bits[4:5]: 00 CRC and Pad Insertion - The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. 01 CRC Insertion (Disable Pad Insertion) - The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. 10 Disable CRC Insertion - The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. 11 CRC Replacement - The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.
6:8 SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 6 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[7:8]: 00 Do not include the source address 01 Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 Reserved

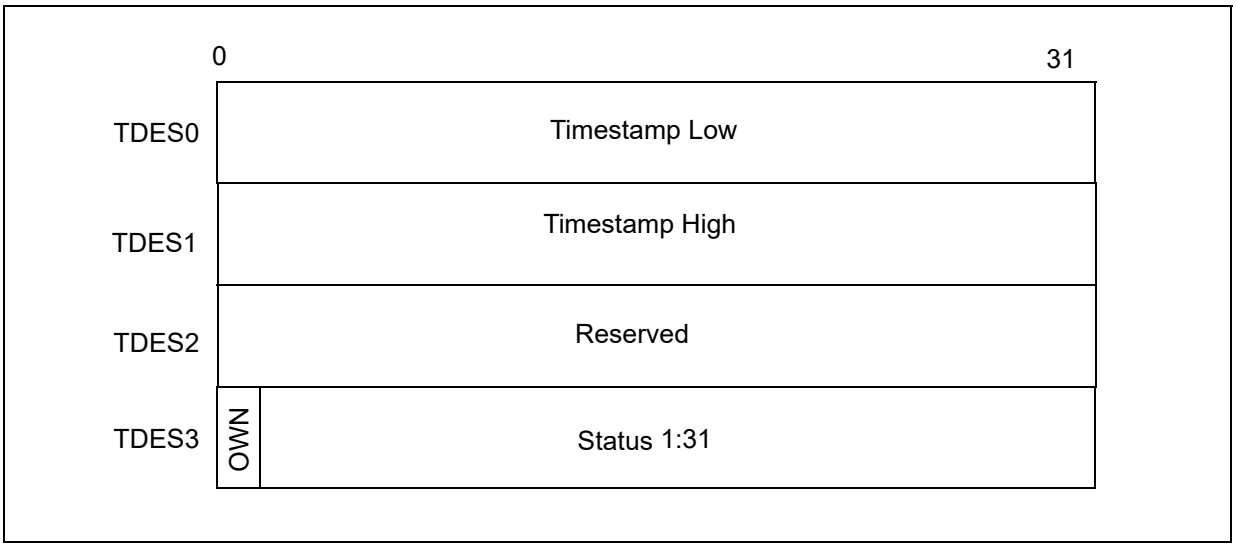


Table 1269. TDES3 Normal Descriptor (Read Format) (continued)

Field	Description
9:12 SLOTNUM	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH*n*_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.
13	Reserved
14:15 CIC	Checksum Insertion Control These bits control the checksum calculation and insertion. The following list describes the bit encoding: 00 Checksum Insertion Disabled. 01 Only IP header checksum calculation and insertion are enabled. 10 IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.
16	Reserved
17:31 FL	Packet Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length

52.4.1.3.1.5 Transmit Normal Descriptor (Write-Back Format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[3]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 1200. Transmit Descriptor Write-Back Format

52.4.1.3.1.6 TDES0 Normal Descriptor (Write-Back Format)

This format is only applicable to the last descriptor of a packet.

Table 1270. TDES0 Normal Descriptor (Write-Back Format)

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

52.4.1.3.1.7 TDES1 Normal Descriptor (Write-Back Format)

This format is only applicable to the last descriptor of a packet.

Table 1271. TDES1 Normal Descriptor (Write-Back Format)

Field	Description
0:31 TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding Receive packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

52.4.1.3.1.8 TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 1272. TDES2 Normal Descriptor (Write-Back Format)

Field	Description
0:31	Reserved

52.4.1.3.1.9 TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Figure 1201. TDES3 Normal Descriptor (Write-Back Format)

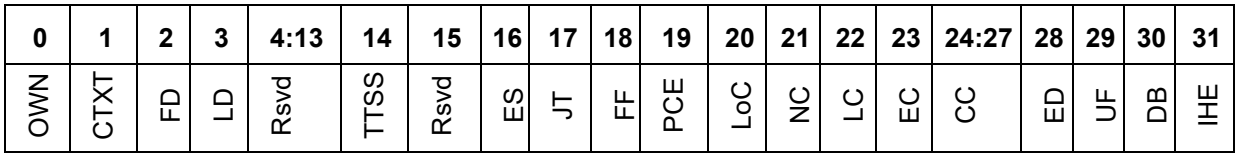

Table 1273. TDES3 Normal Descriptor (Write-Back Format)

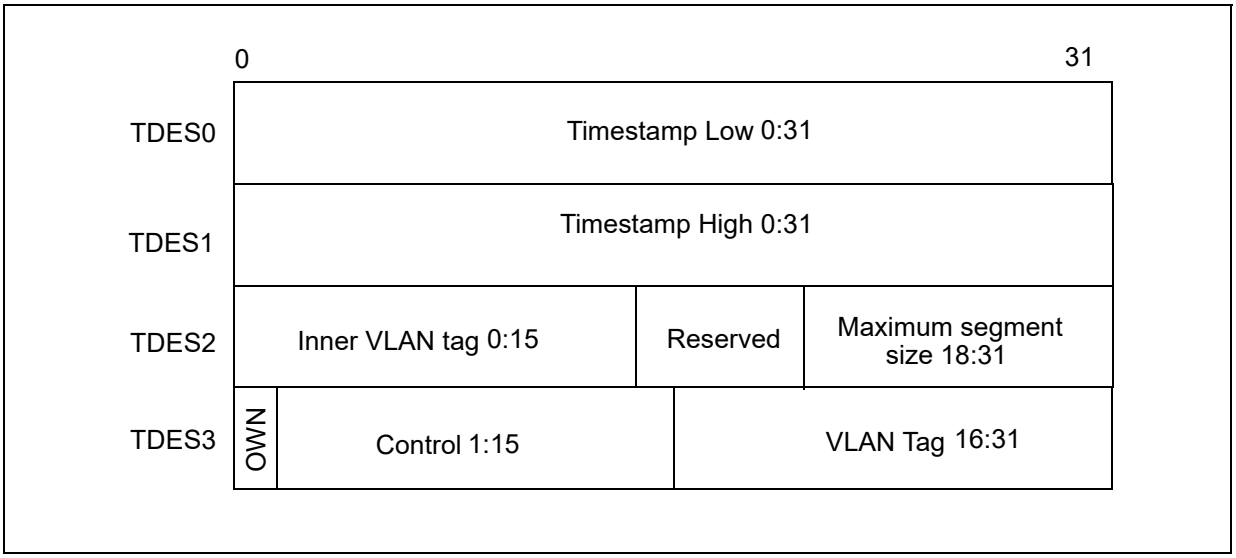
Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
1 CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
2 FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
4:13	Reserved
14 TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [3]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
15	Reserved
16 ES	Error Summary This bit indicates the logical OR of the following bits: TDES3[31]: IP Header Error TDES3[17]: Jabber Timeout TDES3[18]: Packet Flush TDES3[19]: Payload Checksum Error TDES3[20]: Loss of Carrier TDES3[21]: No Carrier TDES3[22]: Late Collision TDES3[23]: Excessive Collision TDES3[28]: Excessive Deferral TDES3[29]: Underflow Error
17 JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
18 FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

Table 1273. TDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
19 PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode.
20 LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the MII_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
21 NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
22 LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
23 EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
24:27 CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
28 ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register.
29 UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: The DMA encountered an empty Transmit Buffer while transmitting the packet The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.

Table 1273. TDES3 Normal Descriptor (Write-Back Format) (continued)



Field	Description
30 DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
31 IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

52.4.1.3.2 Transmit Context Descriptor

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.
When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.
The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 1202. Transmit Context Descriptor Format

52.4.1.3.2.1 TDES0 Context Descriptor

Table 1274. TDES0 Context Descriptor

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

52.4.1.3.2.2 TDES1 Context Descriptor

Table 1275. TDES1 Context Descriptor

Field	Description
0:31 TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

52.4.1.3.2.3 TDES2 Context Descriptor

Table 1276. TDES2 Context Descriptor

Field	Description
0:15 IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[0:15] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
16:31	Reserved

52.4.1.3.2.4 TDES3 Context Descriptor

Figure 1203. TDES3 Context Descriptor

0	1	2:3	4	5	6:7	8	9:13	14	15	16:31
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

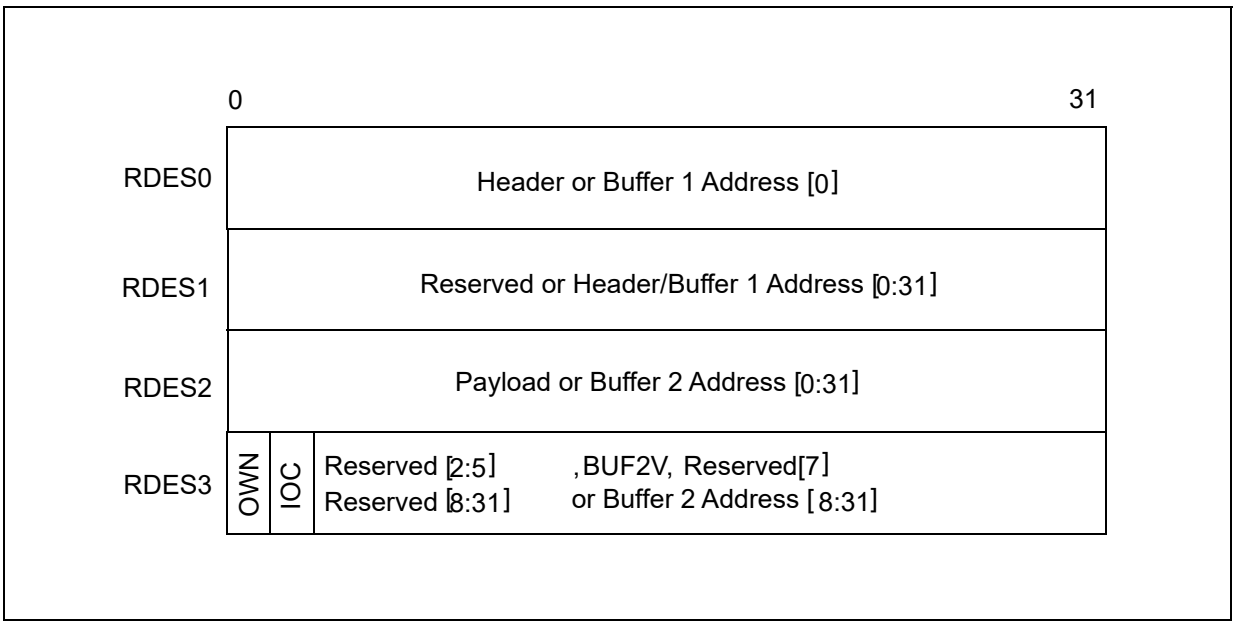
Table 1277. TDES3 Context Descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
2:3	Reserved
4 OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
5 TCMSSV	One-Step Timestamp Correction Input When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.
6:7	Reserved
8 CDE	Context Descriptor Error When this bit is set, it indicates that the context descriptor was provided in the incorrect sequence and the DMA ignored it. The DMA sets this bit during write-back while closing the context descriptor.
9:11	Reserved
12:13 IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: 00 Do not add the inner VLAN tag. 01 Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. 10 Insert an inner VLAN tag with the tag value programed in the MAC_VLAN_Incl register or context descriptor. 11 Replace the inner VLAN tag in packets with the tag value programed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames.
14 IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
15 VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
16:13 VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

52.4.1.4 Receive Descriptor

The DMA in the Ethernet module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:



- Normal and
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in *Section 52.4.1.4.1: Receive Normal Descriptor (Read Format)*. The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the *Section 52.4.1.4.2: Receive Normal Descriptor (Write-Back Format)*.

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA will write the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in *Section 52.4.1.4.3: Receive Context Descriptor*.

52.4.1.4.1 Receive Normal Descriptor (Read Format)

Figure 1204. Receive Normal Descriptor (Read Format)

Note: In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the Ethernet module does not transfer data to that buffer and skips to the next buffer or next descriptor.

52.4.1.4.1.1 RDES0 Normal Descriptor (Read Format)

Table 1278. RDES0 Normal Descriptor (Read Format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[29:31] as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

52.4.1.4.1.2 RDES1 Normal Descriptor (Read Format)

Table 1279. RDES1 Normal Descriptor (Read Format)

Field	Description
0:31	This field is reserved.

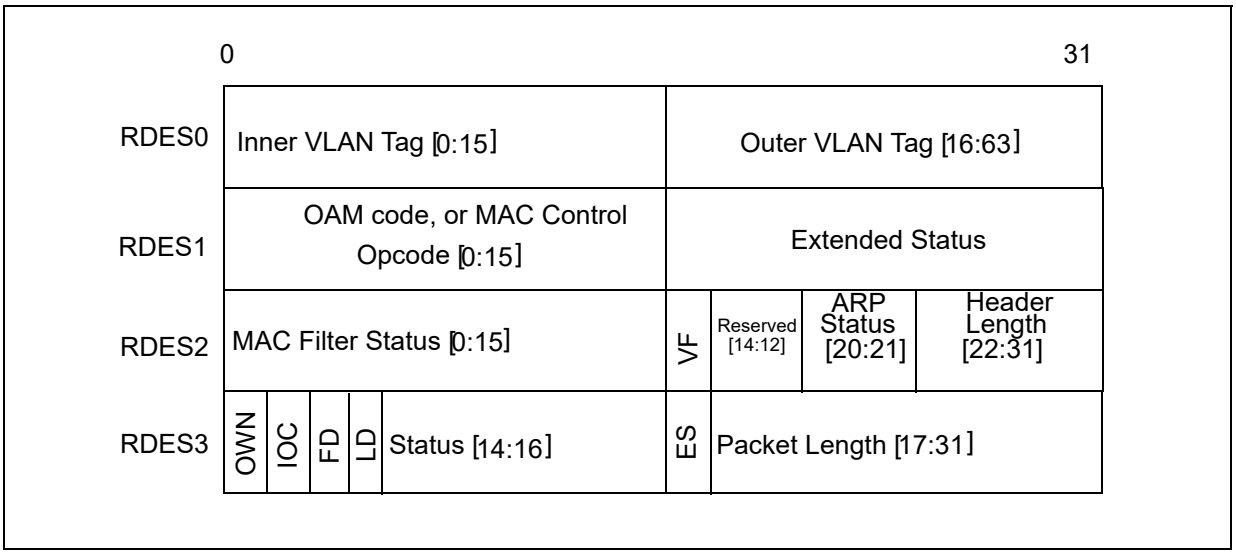
52.4.1.4.1.3 RDES2 Normal Descriptor (Read Format)

Table 1280. RDES2 Normal Descriptor (Read Format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[29:31] and writes to the complete location.

52.4.1.4.1.4 RDES3 Normal Descriptor (Read Format)

Figure 1205. RDES3 Normal Descriptor (Read Format)



0	1	2:5	6	7	8:31
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 1281. RDES3 Normal Descriptor (Read Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
2:5	Reserved
6 BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is Valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
7 BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
8:31	Reserved

52.4.1.4.2 Receive Normal Descriptor (Write-Back Format)

Figure 1206. Receive Normal Descriptor (Write-Back Format)

OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 1283. RDES1 Normal Descriptor (Write-Back Format)

Field	Description
0:15 OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If bits[13:15] of RDES3 are set to 111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If bits[13:15] of RDES3 are set to 110, this field contains the MAC Control packet opcode field.
16 TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table 1283. RDES1 Normal Descriptor (Write-Back Format) (continued)

Field	Description
17 TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [3]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
18 PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
19 PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
20:23 PMT	PTP Message Type These bits are encoded to give the type of the message received: 0000 No PTP message received 0001 SYNC (all clock types) 0010 Follow_Up (all clock types) 0011 Delay_Req (all clock types) 0100 Delay_Resp (all clock types) 0101 Pdelay_Req (in peer-to-peer transparent clock) 0110 Pdelay_Resp (in peer-to-peer transparent clock) 0111 Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) 1000 Announce 1001 Management 1010 Signaling 1011–1110 Reserved 1111 PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
24 IPCE	IP Payload Error When this bit is set, it indicates either of the following: The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 16 (ES) of RDES3 is not set when this bit is set.
25 IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed.
26 IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected.
27 IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected.

Table 1283. RDES1 Normal Descriptor (Write-Back Format) (continued)

Field	Description
28 IPHE	IP Header Error When this bit is set, it indicates either of the following: The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. The IP datagram version is not consistent with the Ethernet Type value. Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 26 or bit 27 is set.
29:31 PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): 000 Unknown type or IP/AV payload not processed 001 UDP 010 TCP 011 ICMP 110 AV Tagged Data Packet 111 AV Tagged Control Packet 101 AV Untagged Control Packet 100 IGMP if IPV4 Header Present bit is set else data center bridging (DCB) link layer discovery protocol (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000.

52.4.1.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

Figure 1209. RDES2 Normal Descriptor (Write-Back Format)

Table 1284. RDES2 Normal Descriptor (Write-Back Format)

Field	Description
0:2 L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: 000 Filter 0 001 Filter 1 010 Filter 2 011 Filter 3 100 Filter 4 101 Filter 5 110 Filter 6 111 Filter 7 This field is valid only when Bit 3 or Bit 4 is set high. When more than one filter matches, these bits give the number of lowest filter.
3 L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: Layer 3 fields are not enabled and all enabled Layer 4 fields match All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[0:2].
4 L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[0:2].
5:12 MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register.
13 HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[5:12] indicate the hash value.
14 DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC.
15 SAF	SA Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC.
16 VF	VLAN Filter Status When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter.

Table 1284. RDES2 Normal Descriptor (Write-Back Format) (continued)

Field	Description
17:20	Reserved
21 ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).
22:31	Reserved

52.4.1.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Figure 1210. RDES3 Normal Descriptor (Write-Back Format)

OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 1285. RDES3 Normal Descriptor (Write-Back Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor.
2 FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
4 RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
5 RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
6 RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.

Table 1285. RDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
7 CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
8 GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). **Note:** Giant packet indicates only the packet length. It does not cause any packet truncation.
9 RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
10 OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. **Note:** This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
11 RE	Receive Error When this bit is set, it indicates that the MII_RXER signal is asserted while the MII_RX_DV signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
12 DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
13:15 LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: 000 The packet is a length packet 001 The packet is a type packet. 011 The packet is a ARP Request packet type 100 The packet is a type packet with VLAN Tag 101 The packet is a type packet with Double VLAN Tag 110 The packet is a MAC Control packet type 111 The packet is a OAM packet type 010 Reserved

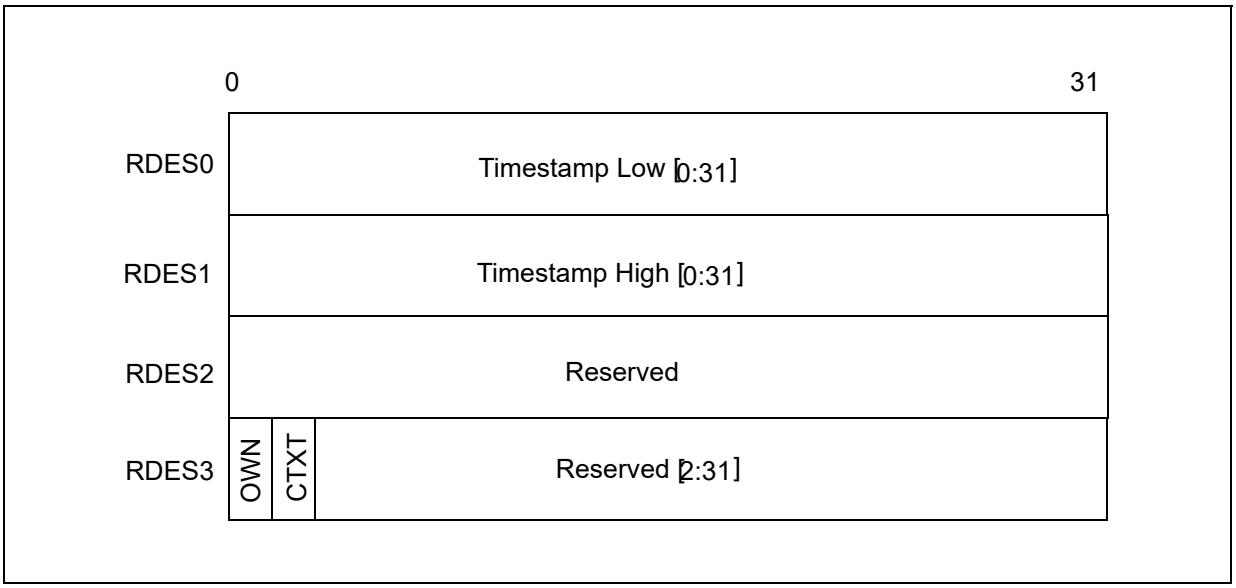

Table 1285. RDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
16 ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: RDES3[7]: CRC Error RDES3[12]: Dribble Error RDES3[11]: Receive Error RDES3[9]: Watchdog Timeout RDES3[10]: Overflow Error RDES3[8]: Giant Packet This field is valid only when the LD bit of RDES3 is set.
17:31 PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and either the Descriptor Error (RDES3[18]) or Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

52.4.1.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 1 of RDES3 indicates the context type descriptor.

Figure 1211. Receive Context Descriptor

52.4.1.4.3.1 RDES0 Context Descriptor

Table 1286. RDES0 Context Descriptor

Field	Description
0:31 RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

52.4.1.4.3.2 RDES1 Context Descriptor

Table 1287. RDES1 Context Descriptor

Field	Description
0:31 RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

Table 1289. RDES3 Context Descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor.
2:31	Reserved

52.5 Programming Guidelines

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

52.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit 31 of *DMA_Mode Register (DMA_MODE)*)
2. Wait for the completion of the reset process (poll bit 31 of the *DMA_Mode Register (DMA_MODE)*, which is only cleared after the reset operation is completed)
3. Program the following fields to initialize the *System Bus Mode Register (DMA_SYSBUS_MODE)*:
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values for AHB bus interface
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 0 of descriptor TDES3/RDES3)

Note: Descriptor address from start to end of the ring should not cross the 4 GB boundary.

5. Program the Transmit and Receive Ring length registers_ (DMA_CH*n*_TxDesc_Ring_Length and DMA_CH*n*_RxDesc_Ring_Length). The ring length programed must be at least 4
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH*n*_TxDesc_List_Address, DMA_CH*n*_RxDesc_List_Address). Also, program transmit and receive tail pointer

registers indicating to the DMA about the available descriptors (DMA_CH*n*_TxDesc_Tail_Pointer and DMA_CH*n*_RxDesc_Tail_Pointer)

7. Program the settings of the following registers for the parameters such as maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   a) DMA_CH*n*_TX_Control
   b) DMA_CH*n*_TX_Control
   c) DMA_CH*n*_TX_Control
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register
9. Start the Receive and Transmit DMAs by setting SR (bit 31) of the DMA_CH*n*_RX_Control and ST (bit 31) of the DMA_CH*n*_TX_Control register
10. Repeat steps *4* to *9* for all the Tx DMA and Rx DMA channels selected in the hardware

52.5.2 Initializing MTL Registers

Complete the following steps to initialize the MTL Registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation for multiple Tx and Rx queues
2. Program the Receive Queue to DMA mapping in the MTL_RxQ_DMA_Map0 register
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   c) Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a) Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d) Receive Queue Size (RQS)
5. Repeat previous two steps for the second MTL Tx and Rx queue

52.5.3 Initializing MAC

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. For more than one MAC address program the MAC addresses appropriately
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   a) Receive All
   b) Promiscuous mode
   c) Hash or Perfect Filter
   d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a) Pause time and other Pause frame control bits
   b) Transmit Flow control bits
   c) Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 31 and 30 in MAC_Configuration registers to start the MAC transmitter and receiver

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive)
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register
   a) DMA_CH*n*_TxDesc_Tail_Pointer
   b) DMA_CH*n*_RxDesc_Tail_Pointer
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process
   a) DMA_CH*n*_Current_App_TxDesc
   b) DMA_CH*n*_Current_App_RxDesc
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process
   a) DMA_CH*n*_Current_App_TxBuffer
   b) DMA_CH*n*_Current_App_RxBuffer

52.5.3.1 For Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time.

Note: The steps are provided for Channel 0.

1. Disable the transmit DMA (if applicable) by clearing Bit 31 (ST) of the DMA_CH*n*_TX_Control register
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of the MTL_TxQ0_Debug register (TRCSTS is not 01 and TXQSTS=0)
3. Disable the MAC transmitter and MAC receiver by clearing Bit 31 (RE) and Bit 30(TE) of the MAC_Configuration register
4. Disable the receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of the MTL_RxQ0_Debug register, PRXQ=0 and RXQSTS=00)
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register)
6. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver

Note: Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. The Software should change these parameters only when the MAC transmitter and receiver are not active.
Similarly the DMA related configuration should not be changed when Transmit and Receive DMA are in active.

52.5.4 Programming Guidelines for Multi-Channel Multi-Queuing

Following are the steps for Transmit:

1. Program the Transmit queue size in the TQS field of MTL_TxQ*n*_Operation_Mode register. Based on the value programed in TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel to Queue mapping is fixed
2. Enable ST bit of DMA_CH*n*_TX_Control register and corresponding TXQEN in MTL_TxQ*n*_Operation_Mode register
3. The scheduling method need to be programed in SCHALG of the MTL_Operation_Mode register
4. In case of CBS algorithm in AVB queues, the following registers also needs to be programed as required:
   a) MTL_TxQ*n*_ETS_Control
   b) MTL_TxQ*n*_SendSlopeCredit
   c) MTL_TxQ*n*_HiCredit
   d) MTL_TxQ*n*_LoCredit

Following are the steps for Receive:

1. Program the Receive queue size in the RQS field of MTL_RxQ*n*_Operation_Mode Register. Based on the value programed in RQS field, the size of the queue is determined
2. Enable the Receive Queues 0 to 1 in the fields RXQ0EN to RXQ1EN in MAC_RxQ_Ctrl0 Register for AV. In DMA configurations, SR bit of statically or

dynamically mapped DMA_CH*n*_RX_Control Register and corresponding RXQ*n*_EN in MAC_RxQ_Ctrl0 Register needs to be enabled

3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a) AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register
   b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 register
   c) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ1-0 of the MAC_RxQ_Ctrl2 register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 1
   d) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 register
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory
   b) Program the MTL_RxQ*n*_Control to decide the weights and the packet arbitration for each RxQ
   c) If static mapping is programed in MTL_RxQ_DMA_Map0 register (RXQ*n*DADMACH is reset to 0), bits RXQx2DMA and others need to be programed to select the channel for which each queue is mapped
   d) Set RXQ*n*DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue
   e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register

Note: The priorities set in PSRQ1-0 should be unique.

52.5.5 Programming Guidelines for MII Link State Transitions

The following steps are to be performed when the link is down but the Transmit and Receive clocks are running:

Note: The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 31 (ST) of DMA_CH*n*_TX_Control Register
2. Disable the MAC receiver by clearing Bit 29 (RE) of the MAC_Configuration register
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01).
   -or-
   Flush the Tx FIFO for faster empty operation
4. Disable the MAC transmitter by clearing Bit 30 (TE) of the MAC_Configuration register
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register)
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver

You do not need to disable the Rx DMA. As the Receiver is disabled, the FIFO does not get any data in the Rx FIFO.

Do the following steps when the link is down and the Transmit and Receive clocks are stopped:

Note: The steps are provided for Channel 0.

1. Disable the MAC Transmitter and Receiver by clearing bits RE & TE of MAC_Configuration register. This will not take effect immediately as the clocks are absent
2. Wait till the link is up and the clocks are restored
3. Wait for the completion of the transfer of any partial frame if any at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug Register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers
5. Restart the MAC Transmitter and Receiver by setting RE & TE bits

52.5.6 Programming Guidelines for IEEE 1588 Timestamping

52.5.6.1 Initialization Guideline for System Time Generation

The timestamp feature is enabled by setting Bit 31 of the MAC_Timestamp_Control register. However, it is essential that the timestamp counter should be initialized after this bit is set. Complete the following steps during for initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 15 of MAC_Interrupt_Enable Register
2. Set Bit 31 of MAC_Timestamp_Control register to enable timestamping
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 26 of MAC_Timestamp_Control register
5. Poll the MAC_Timestamp_Control register until Bit 26 is cleared
6. Program Bit 30 of MAC_Timestamp_Control register to select the Fine Update method (if required)
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value
8. Set Bit 29 in MAC_Timestamp_Control register.
   The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers.
   If one-step timestamping is enabled:
   a) To enable one-step timestamping, program Bit 4 of the TDES Context Descriptor
   b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages
9. Enable the MAC receiver and transmitter for proper timestamping

Note: If timestamp operation is disabled by clearing Bit 31 of MAC_Timestamp_Control Register, you need to repeat all these steps to restart the timestamp operation.

52.5.6.2 System Time Correction

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update)
2. Set Bit 28 (TSUPDT) of the MAC_Timestamp_Control Register.
   The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in System Time Register Module, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_Timestamp_Addend with the new value and set Bit 26 of the MAC_Timestamp_Control Register
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value
4. Program the required target time in the MAC_PPS0_Target_Time_Seconds register and the MAC_PPS0_Target_Time_Nanoseconds register
5. Enable the Timestamp interrupt in bit 19 of MAC_Interrupt_Enable register
6. Set bit 27 in Register MAC_Timestamp_Control
7. When this trigger causes an interrupt, read MAC_Interrupt_Status Register
8. Reprogram MAC_Timestamp_Addend Register with the old value and set bit 26 again

52.5.7 Programming Guidelines for AV Feature

Complete the following steps to initialize the DMA for AV Feature:

1. Provide a software reset to reset all QOS internal registers and logic (bit 31 in DMA_Mode register)
2. Wait for the completion of the reset process. Poll bit 31 of the DMA_Mode register, which is cleared only after the reset operation is completed
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required
5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors
6. Program the Transmit and Receive Ring length registers. The ring length programed must be at least 4. Then initialize receive and transmit descriptor list address with the

base address of transmit and receive descriptor. Finally program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors:

a) DMA_CH*n*_TxDesc_Ring_Length
b) DMA_CH*n*_RxDesc_Ring_Length
c) DMA_CH*n*_TxDesc_List_Address
d) DMA_CH*n*_RxDesc_List_Address
e) DMA_CH*n*_TxDesc_Tail_Pointer
f) DMA_CHn_RxDesc_Tail_Pointer

7. Program the following fields to initialize the mode of operation in the MTL_TxQ1_Operation_Mode register:
   a) Transmit Store And Forward (TSF)
   b) Transmit Threshold Control (TTC)
   c) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
   d) Transmit Queue Size (TQS)
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register
9. Repeat steps *4* through *9* for all additional channels of AV feature.
10. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues
11. Start the Receive and Transmit DMA by setting bit 31 of the DMA_CH*n*_TX_Control register and bit 31 of the DMA_CH*n*_RX_Control register

52.5.7.1 Enabling Slot Number Checking

The slot number check feature is used to specify the intervals at which the DMA Channels mapped to AV Queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable time-stamping and program the MAC_Sub_Second_Increment register. Complete the following steps to enable the slot number checking:

Note: These steps should be completed after Step 10 and before Step 11 of Section 52.5.7: Programming Guidelines for AV Feature.

1. Enable time-stamping by following the steps described in *Section 52.5.6.1: Initialization Guideline for System Time Generation*
2. Make sure that the SLOTNUM field (bits 9:12) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH*n*_Slot_Function_Control_Status
3. Set Bit 31 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking

52.5.7.2 Enabling Average Bits Per Slot Reporting

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. Enable time-stamping by following the steps described in *Section 52.5.6.1: Initialization Guideline for System Time Generation*
2. Program Bits [25:27], SLC, of the MTL_TxQ*n*_ETS_Control register of a channel with number of slots over which the average transmitted bits per slot need to be computed
3. Enable Bit 22 (ABPSSIE) of the MTL_Q*n*_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt
4. Read Bits [15:31], ABS, from the MTL_TxQ*n*_ETS_Status register of a channel on each interrupt

Note: The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 30 (ABPSIS) of the MTL_TxQn_ETS_Status register indicates that a new value is updated in the ABS field.

The frequency of this interrupt depends on the value programed in the Step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
When not required, you can disable this interrupt to stop the interrupt flooding.

52.5.8 Programming Guidelines for Energy Efficient Ethernet

52.5.8.1 Entering and Exiting the Tx LPI Mode

For entering and exiting the Tx LPI Mode, complete the following steps:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode)
3. Program Bits[6:15] and Bits[16:31] in MAC_LPI_Timers_Control register
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 14 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own
7. Set LPIET and LPITXA (bit[11:12]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state
8. Set Bit 15 of MAC_LPI_Control_Status register to make the MAC Transmitter enter the LPI state.
   The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[31]) after entry to LPI state
9. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission
10. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues
11. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set Bit 12 in MAC_LPI_Control_Status register.
To switch off the MII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.
To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

52.5.8.2 Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

52.5.8.3 Gating Off the CSR Clock in the Rx LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY.

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN interrupt of MAC_LPI_Control_Status register is set
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register

After the interrupt is asserted and the MAC Tx is also in the LPI mode, you can gate-off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status register is read.

52.5.8.4 Gating Off the CSR Clock in the Tx LPI Mode

The following operations are performed when Bit 15 (LPIEN) of MAC_LPI_Control_Status register is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of MAC_LPI_Control_Status register) is set
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register

After the interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR.

For restoring the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. After the CSR clock is resumed, reset Bit 15 (LPIEN) of MAC_LPI_Control_Status register to bring the MAC out of the LPI mode.

52.5.9 Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

52.5.9.1 Generating single Pulse on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control register. This instructs the MAC to use the Target Time registers

(MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output

2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds)
3. Program the width of the PPS signal output in MAC_PPS0_Width Register
4. Program Bits [28:31], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programed in the Target Time registers

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse
2. Program the width of the next PPS signal output in MAC_PPS0_Width
3. Program Bits [28:3], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programed in Target Time registers

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

52.5.9.2 Generating a pulse train on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of the PPS signal output
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds)
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS0_Interval Register
4. Program the width of the PPS signal output in MAC_PPS0_Width Register
5. Program Bits[28:3], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programed in Target Time registers.
   By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.
6. Program the stop value in the Target Time registers. Ensure that Bit 0 (TSTRBUSY) of MAC_PPS0_Target_Time_Nanoseconds Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 28:31) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programed stop time specified in Step *6* elapses.

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programed start time (in Step 2) elapses.

52.5.9.3 Generating an Interrupt without Affecting the PPS

The Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) to do any one of the following:

- Generate only interrupts
- Generate interrupts and the PPS start and stop time
- Generate only PPS start and stop time

To program the Target Time registers to generate only interrupt event:

1. Program 00 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers for target time interrupt
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.
   If Bits [25:26], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programed Target Time register value

52.5.10 Programming Guidelines for VLAN filtering on Receive

1. Program MAC_VLAN_Tag Register for the following bit to select the filtering method:
   a) ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison. VTHM: VLAN Tag Hash Table Match Enable
   b) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   c) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   d) DOVLTC: Ignores VLAN Type for Tag Match
   e) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching
2. Program VL of MAC_VLAN_Tag register for the 12 bit or 16 bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table Register. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table

53 FlexRay communication controller (FlexRay)

53.1 Introduction

53.1.1 Reference

The following documents are referenced in this chapter. They may be consulted for further information on the FlexRay communication controller's operation.

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A[q]
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0

53.1.2 Color coding

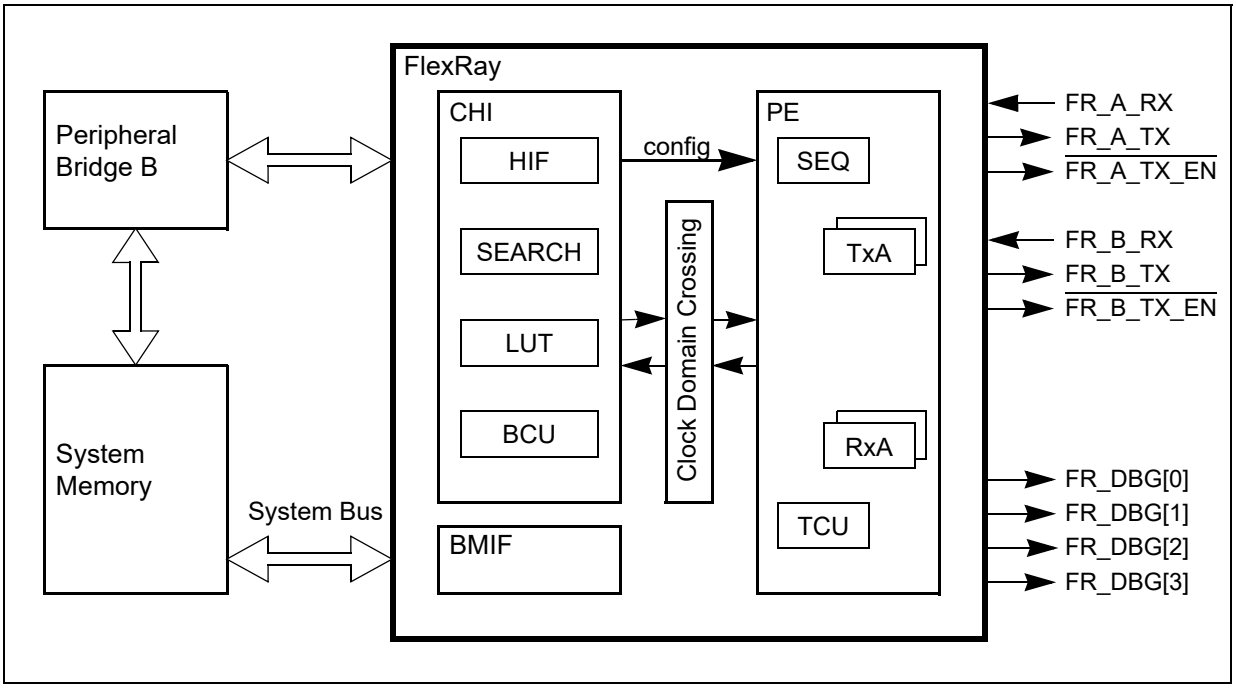
Throughout this chapter, some items are displayed in an italicized, colored font.

FlexRay protocol parameters, constants, and variables are highlighted with *blue italics*. An example is the parameter *gdActionPointOffset*.

FlexRay protocol states are highlighted in *green italics*. An example is the state *POC:normal active*.

53.1.3 Overview

The Communication Controller (CC) is a FlexRay communication controller that implements the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*



The CC has three main components:

- Controller Host Interface (CHI)
- Protocol Engine (PE)
- Clock Domain Crossing unit (CDC)

A block diagram of the CC with its surrounding modules is given in *Figure 1213*.

q. The FlexRay specifications have been developed for automotive applications. The FlexRay specifications have been neither developed nor tested for non-automotive applications.

Figure 1213. FlexRay block diagram

The protocol engine has two transmitter units, TxA and TxB, and two receiver units, RxA and RxB, for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the protocol engine (PE) is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, as well as the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the controller host interface (CHI) clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the *Section 53.5.2.5: System Memory Base Address Register (FR_SYMBADR)*. All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note: The CC does not provide a memory protection scheme for the FlexRay memory area.

53.1.4 Features

The CC provides the following features:

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A-compliant protocol implementation
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0-compliant bus driver interface
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 128 configurable message buffers with
  - Individual frame ID filtering
  - Individual channel ID filtering
  - Individual cycle counter filtering
- Message buffer header, status, and payload data stored in dedicated FlexRay memory area
  - Allows for flexible and efficient message buffer implementation
  - Ensures consistent data access by means of a buffer-locking scheme
  - Application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0–254 bytes
- Two independent message buffer segments with configurable size of payload data section
  - Each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
  - Applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
  - Receive message buffer
  - Transmit message buffer
- Individual message buffers can be reconfigured
  - Individual message buffers can be disabled safely
  - Disabled message buffers can be reconfigured
- Two independent receive FIFOs
  - One receive FIFO per channel
  - Up to 255 entries for each FIFO
  - Global frame ID filtering, based on both value/mask filters and range filters
  - Global channel ID filtering
  - Global message ID filtering for the dynamic segment
- Four configurable slot error counters
- Four dedicated slot status indicators
  - Used to observe slots without using receive message buffers

- Measured value indicators for clock synchronization
  - Internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- One absolute timer
- One timer that can be configured as absolute or relative
- SECDED for protocol engine data RAM
- SEDDED for CHI lookup table RAM

53.1.5 Modes of operation

This section describes the basic operational power modes of the CC.

53.1.5.1 Disabled mode

The CC enters Disabled mode during hard reset or when the host clears the 'MEN' field in the Module Configuration Register (FR_MCR). The host can clear this field by writing '0' and only when the module is in *POC:default config* mode. The Disabled mode can be checked by reading the module enable field, MEN, in the *Module Configuration Register (FR_MCR)* .

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled mode* can be accessed for writing as stated in *Section 53.5: Memory map and register description*.

The application configures the CC by accessing the configuration fields in the *Module Configuration Register (FR_MCR)* as described in *Section 53.7.2.1: Module initialization*.

53.1.5.1.1 Leave Disabled mode

The CC leaves Disabled mode and enters Normal mode, when the application writes 1 to FR_MCR[MEN].

Note: Once the CC is enabled, it cannot be disabled later.

53.1.5.2 Normal mode

In this mode, the CC is fully functional. The CC indicates that it is in Normal mode by asserting FR_MCR[EN].

53.1.5.2.1 Enter Normal mode

This mode is entered when the application requests that the CC leave Disabled mode. If Normal mode is entered after leaving Disabled mode, the application has to perform the protocol initialization described in *Section 53.7.2.2: Protocol initialization* to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB fields in the *Module Configuration Register (FR_MCR)*, the corresponding FlexRay bus driver ports are enabled and driven.

53.2 External signal description

This section lists and describes the CC signals connected to external pins. These signals are summarized in *Table 1290* and described in detail in *Section 53.2.1: Detailed signal description*.

Note: The off-chip FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ signals are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 1290. External signal properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR_A_TX_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR_B_TX_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

53.2.1 Detailed signal description

This section provides a detailed description of the CC signals connected to external pins.

53.2.1.1 FR_A_RX – Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

53.2.1.2 FR_A_TX – Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

53.2.1.3 $\overline{\text{FR_A_TX_EN}}$ – Transmit Enable Channel A

The $\overline{\text{FR_A_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

53.2.1.4 FR_B_RX – Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

53.2.1.5 FR_B_TX – Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

53.2.1.6 $\overline{\text{FR_B_TX_EN}}$ – Transmit Enable Channel B

The $\overline{\text{FR_B_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

53.2.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] – Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection, refer to *Section 53.6.16: Strobe signal support*.

53.3 Controller host interface clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

- The first constraint corresponds to the number of utilized message buffers and is specified in *Section 53.7.5: Number of usable message buffers*.
- The second constraint corresponds to the value of the TIMEOUT field in the *Section 53.5.2.33: System Memory Access Timeout Register (FR_SYMATOR)* and is specified in *Section 53.7.1.1: Configure System Memory Access Timeout Register (FR_SYMATOR)*.

53.4 Protocol engine clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select field, CLKSEL, in the *Section 53.5.2.4: Module Configuration Register (FR_MCR)*.

Note: Refer to the device clocking details for the exact clock sources used.

53.4.1 Oscillator clocking

If the protocol engine is clocked by the internal crystal oscillator, a 40 MHz crystal or CMOS-compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*

53.4.2 PLL clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately to generate the 40 MHz and 180 degree phase-shifted 40 MHz clocks and provide them to the PE. For more details, refer to the clocking chapter of the device reference manual.

53.5 Memory map and register description

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU.

Note: The following registers are 16-bit write accessible only:

- *Strobe Signal Control Register (FR_STBSCR)*
- *PE DRAM Access Register (FR_PEDRAR)*
- *PE DRAM Data Register (FR_PEDRDR)*
- *Sync Frame ID Rejection Filter Register (FR_SFIDRFR)*
- *Slot Status Selection Register (FR_SSSR)*
- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Index Register (FR_RSBIR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*
- *Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)*
- *Message Buffer Frame ID Register (FR_MBFIDRn)*
- *Message Buffer Index Register (FR_MBIDXRn)*
- *Message Buffer Data Field Offset Register (FR_MBDORn)*
- *LRAM ECC Error Test Register (FR_LEETRn)*

53.5.1 Memory map

The complete memory map of the CC is shown in *Table 1291*. The addresses presented here are the offsets relative to the CC base address, which is defined by the MCU address map.

Table 1291. FlexRay memory map

Address offset	Register name	Location
Module configuration and control		
0x0000	Module Version Register (FR_MVR)	*Section 53.5.2.3*
0x0002	Module Configuration Register (FR_MCR)	*Section 53.5.2.4*
0x0004	System Memory Base Address High Register (FR_SYMBADHR)	*Section 53.5.2.5*
0x0006	System Memory Base Address Low Register (FR_SYMBADLR)	*Section 53.5.2.5*
0x0008	Strobe Signal Control Register (FR_STBSCR)	*Section 53.5.2.6*
0x000A	Strobe Port Control Register (FR_STBPCR)	*Section 53.5.2.7*
0x000C	Message Buffer Data Size Register (FR_MBDSR)	*Section 53.5.2.8*
0x000E	Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)	*Section 53.5.2.9*
PE access registers		
0x0010	PE DRAM Access Register (FR_PEDRAR)	*Section 53.5.2.10*
0x0012	PE DRAM Data Register (FR_PEDRDR)	*Section 53.5.2.11*

Table 1291. FlexRay memory map (continued)

Address offset	Register name	Location
Interrupt and error handling		
0x0014	Protocol Operation Control Register (FR_POCR)	*Section 53.5.2.12*
0x0016	Global Interrupt Flag and Enable Register (FR_GIFER)	*Section 53.5.2.13*
0x0018	Protocol Interrupt Flag Register 0 (FR_PIFR0)	*Section 53.5.2.14*
0x001A	Protocol Interrupt Flag Register 1 (FR_PIFR1)	*Section 53.5.2.15*
0x001C	Protocol Interrupt Enable Register 0 (FR_PIER0)	*Section 53.5.2.16*
0x001E	Protocol Interrupt Enable Register 1 (FR_PIER1)	*Section 53.5.2.17*

53.5.2 Register descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

53.5.2.1 Register reset

All registers except the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), and Message Buffer Index Registers (FR_MBIDXRn) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are described in the detailed description of the register. The additional reset conditions are explained in *Table 1292*.

Table 1292. Additional register reset conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes RUN command “0101” to the POCCMD field in the *Section 53.5.2.12: Protocol Operation Control Register (FR_POCR)*.
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants a disable to the application by clearing the FR_MBCCSRn[EDS] bit.

53.5.2.2 Register write access

This section describes the write access restriction terms that apply to all registers.

53.5.2.2.1 Register write access restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in

Table 1293. If, for a specific register field, none of the given write access conditions is fulfilled, any write attempt to this register field is ignored without any notification. The values of the fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 1293. Register write access restrictions

Condition	Indication	Description
Anytime	—	No write access restriction.
Disabled mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled mode.
Normal mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal mode.
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSRn[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.

53.5.2.2.2 Register write access requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

53.5.2.2.3 Internal register access

The following memory-mapped registers are used to access multiple internal registers.

- Strobe Signal Control Register (FR_STBSCR)
- Slot Status Selection Register (FR_SSSR)
- Slot Status Counter Condition Register (FR_SSCCR)
- Receive Shadow Buffer Configuration Data

Each of these memory-mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If WMD is set to 0 during the write access, all fields of the internal register are updated. If WMD is set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

53.5.2.3 Module Version Register (FR_MVR)

Offset: 0x0000 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CHIVER								PEVER							
W																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

Figure 1214. Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Table 1294. FR_MVR field descriptions

Field	Description
0:7 CHIVER	**CHI Version Number** This field provides the version number of the controller host interface.
8:15 PEVER	**PE Version Number** This field provides the version number of the protocol engine.

53.5.2.4 Module Configuration Register (FR_MCR)

Access: Read/Write
Write: SBFF, SCM, CHB, CHA, ECCE, FUM, FAM, CLKSEL, BITRATE: Disabled mode
Offset: 0x0002
Write: MEN: Disabled or *POC:default config*
SFFE: Disabled Mode or *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MEN	SBFF	SCM	CHB	CHA	SFFE	ECCE	Reserved(1)	FUM	FAM	0	CLKSEL	BITRATE			0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. It is read as 0. Application must not write 1 to this bit.

Figure 1215. Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Table 1295. FR_MCR field descriptions

Field	Description
0 MEN	**Module Enable** This bit indicates whether or not the CC is in Disabled mode. The application requests that the CC leave Disabled mode by writing 1 to this bit Before leaving Disabled mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, and BITRATE values. For details, refer to *Section 53.1.5: Modes of operation*. 0 Write: only during *POC:default config*, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled **Note:** If the CC is enabled, it can only be disabled during mode: POC:default config
1 SBFF	**System Bus Failure Freeze** This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to Freeze mode
2 SCM	**Single Channel Device Mode** This control bit defines the channel device mode of the CC as described in *Section 53.6.10: Channel device modes*. 0 CC works in Dual-Channel Device mode 1 CC works in Single-Channel Device mode
3 CHB	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 1296*.
4 CHA	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 1296*.
5 SFFE	**Synchronization Frame Filter Enable** This bit controls the filtering for received synchronization frames. For details, refer to *Section 53.6.15: Sync frame filtering*. 0 Synchronization frame filtering disabled 1 Synchronization frame filtering enabled
6 ECCE	**ECC Functionality Enable** This bit controls the ECC memory error detection functionality. For details, refer to *Section 53.6.24: Memory content error detection*. 0 ECC functionality (injection, detection, reporting, response) disabled 1 ECC functionality enabled
8 FUM	**FIFO Update Mode** This bit controls the FIFO update behavior when the interrupt flags FR_GIFER[FAFAIF] and FR_GIFER[FAFBIF] are written by the application (refer to *Section 53.6.9.8: FIFO update*) 0 FIFOA/FIFOB is updated on writing 1 to FR_GIFER[FAFAIF] /FR_GIFER[FAFBIF] 1 FIFOA/FIFOB) is *not* updated on writing 1 to FR_GIFER[FAFAIF]/FR_GIFER[FAFBIF]

Table 1295. FR_MCR field descriptions (continued)

Field	Description
9 FAM	**FIFO Address Mode** This bit controls the location of the system memory base address for the FIFOs (refer to *Section 53.6.9.2: FIFO configuration*). 0 FIFO Base Address located in *Section 53.5.2.5: System Memory Base Address Register (FR_SYMBADR)* 1 FIFO Base Address located in *Section 53.5.2.71: Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)*
11 CLKSEL	**Protocol Engine Clock Source Select** This bit is used to select the clock source for the protocol engine. 0 PE clock source is generated by on-chip crystal oscillator. 1 PE clock source is generated by on-chip PLL.
12:14 BITRATE	**FlexRay Bus Bit Rate** This field defines the FlexRay bus bit rate. 000 10.0 Mbit/s 001 5.0 Mbit/s 010 2.5 Mbit/s 011 8.0 Mbit/s 100 Reserved 101 Reserved 110 Reserved 111 Reserved

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1217. System Memory Base Address Low Register (FR_SYMBADLR)

Note: The system memory base address must be set before the CC is enabled.

The system memory base address registers define the base address of the FlexRay memory area within the system memory. The base address is used by the bus master interface (BMIF) to calculate the physical memory address for system memory accesses.

Table 1297. FR_SYMBADR field descriptions

Field	Description
SMBA	**System Memory Base Address** This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if FR_MCR[FAM] is set to 1. It is defined as a byte address.

53.5.2.6 Strobe Signal Control Register (FR_STBSCR)

Offset: 0x0008

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	SEL				0	0	0	ENB	0	0	STBPSEL	
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1218. Strobe Signal Control Register (FR_STBSCR)

This register is used to assign the individual protocol timing-related strobe signals given in *Table 1299* to the external strobe ports. Each strobe signal can be assigned to at most one strobe port. Each write access to registers overwrites the previously-written ENB and STBPSEL values for the signal indicated by SEL. If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port. If no strobe signal is assigned to a strobe port, the strobe port carries logic 0. For more detailed and timing information refer to *Section 53.6.16: Strobe signal support*.

Note: In Single-channel device mode, channel B-related strobe signals are undefined and should not be assigned to the strobe ports.

Table 1298. FR_STBSCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
4:7 SEL	**Strobe Signal Select** This control field selects one of the strobe signals given in *Table 1299* to be enabled or disabled and assigned to one of the four strobe ports.
11 ENB	**Strobe Signal Enable** The control bit is used to enable and disable the strobe signal selected by STBSSEL. 0 Strobe signal is disabled and not assigned to any strobe port. 1 Strobe signal is enabled and assigned to the strobe port selected by STBPSEL.
14:15 STBPSEL	**Strobe Port Select** This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 Assign selected signal to FR_DBG[0]. 01 Assign selected signal to FR_DBG[1]. 10 Assign selected signal to FR_DBG[2]. 11 Assign selected signal to FR_DBG[3].

Table 1299. Strobe signal mapping

SEL		Description	Channel	Type	Offset(1)	Reference

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1220. Message Buffer Data Size Register (FR_MBDSR)

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Table 1301. FR_MBDSR field descriptions

Field	Description
1:7 MBSEG2DS	**Message Buffer Segment 2 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *second* message buffer segment.
9:15 MBSEG1DS	**Message Buffer Segment 1 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *first* message buffer segment.

53.5.2.9 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Offset: 0x000E

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	LAST_MB_SEG1							0	LAST_MB_UTIL						
W																
Reset	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

Figure 1221. Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

This register defines the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Table 1302. FR_MBSSUTR field descriptions

Field	Description
1:7 LAST_MB_SEG1	**Last Message Buffer In Segment 1** This field defines the message buffer number of the last individual message buffer that is assigned to the *first* message buffer segment. The individual message buffers in the *first* segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn with n ≤ LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1 + 1 individual message buffers. **Note:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the *second* message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 128. **Note:** If LAST_MB_SEG1 = 127, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
9:15 LAST_MB_UTIL	**Last Message Buffer Utilized** This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n ≤ LAST_MB_UTIL. **Note:** If LAST_MB_UTIL=LAST_MB_SEG1, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

53.5.2.10 PE DRAM Access Register (FR_PEDRAR)

Offset: 0x0010

Access: Read/Write(1)
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	INST				ADDR											DAD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1222. PE DRAM Access Register (FR_PEDRAR)

The FR_PEDRAR is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this register initiates a read or write operation on the PE DRAM. The access done status bit, DAD, is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR is written into the PE DRAM, read back from the PE DRAM, and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data is read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description, refer to *Section 53.6.24: Memory content error detection*.

Table 1303. FR_PEDRAR field descriptions

Field	Description
0:3 INST	**PE DRAM Access Instruction** This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16-bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16-bit) into FR_PEDRDR[DATA] other reserved
4:14 ADDR	**PE DRAM Access Address** This field defines the address in the PE DRAM to be written to or read from.
15 DAD	**PE DRAM Access Done** This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done

53.5.2.11 PE DRAM Data Register (FR_PEDRDR)

Offset: 0x0012

Access: Read/Write(1)
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA

R	0	0	0	0	EOC_AP		ERC_AP		BSY_WMC	0	0	0	POCCMD			
W	WME															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1224. Protocol Operation Control Register (FR_POCR)

The application uses this register to issue:

- Protocol control commands
- External clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, refer to *Section 53.7.6: Protocol control command execution*.

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to *Section 53.6.11: External clock synchronization*.

Table 1305. FR_POCR field descriptions

Field	Description
0 WME	**Write Mode External Correction** This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write 1 No write to EOC_AP and ERC_AP fields on register write
4:5 EOC_AP	**External Offset Correction Application** This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 Do not apply external offset correction value 01 Reserved 10 Subtract external offset correction value 11 Add external offset correction value
6:7 ERC_AP	**External Rate Correction Application** This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21). 00 Do not apply external rate correction value 01 Reserved 10 Subtract external rate correction value 11 Add external rate correction value

Table 1305. FR_POCR field descriptions (continued)

Field	Description
8 BSY_WMC	**Protocol Control Command Write Busy (BSY)** This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE.When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR), and will not change the value of the POCCMD field. (0) Command write idle, command accepted and ready to receive new protocol command (1) Command write busy, command not yet accepted, not ready to receive new protocol command **Write Mode Command (WMC)** This bit controls the write mode of the POCCMD field. (0) Write to POCCMD field on register write (1) Do not write to POCCMD field on register write
12:15 POCCMD	**Protocol Control Command** The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTAR: Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS: Delayed(1) transition to the All Slots Transmission mode. 0010 CONFIG: Immediately transition to the *POC:config* state. 0011 FREEZE: Immediately transition to the *POC:halt* state. 0100 READY, CONFIG_COMPLETE: Immediately transition to the *POC:ready* state. 0101 RUN: Immediately transition to the *POC:startup start* state. 0110 DEFAULT_CONFIG: Immediately transition to the *POC:default config* state. 0111 HALT: Delayed transition to the *POC:halt* state 1000 WAKEUP: Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

1. Delayed means on completion of current communication cycle.

53.5.2.13 Global Interrupt Flag and Enable Register (FR_GIFER)

Offset: 0x0016

Access: Read/Write
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF	MIE	PRIE	CHIE	WUPIE	FAFBIE	FAFAIE	RBIE	TBIE
W				w1c	w1c	w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1225. Global Interrupt Flag and Enable Register (FR_GIFER)

This register controls some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation scheme for these flags is depicted in *Figure 1373*. For more details on interrupt generation, refer to *Section 53.6.20: Interrupt support*. These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Table 1306. FR_GIFER field descriptions

Field	Description
0 MIF	**Module Interrupt Flag** This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set
1 PRIF	**Protocol Interrupt Flag** This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set
2 CHIF	**CHI Interrupt Flag** This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the CHI error interrupt enable bit FR_GIFER[CHIE] are set. 0 All CHI error flags are equal to 0 or the CHI error interrupt is disabled 1 At least one CHI error flag and the CHI error interrupt enable are is set
3 WUPIF	**Wakeup Interrupt Flag** This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus

Table 1306. FR_GIFER field descriptions (continued)

Field	Description
4 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or b) The current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO B almost full event has occurred **Note:** If the bit MCR[FUM] is set to 0, to clear FAFAIF or FAFBIF will also remove one element from the FIFO.
5 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) The current number of FIFO A entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO A almost full event has occurred
6 RBIF	**Receive Message Buffer Interrupt Flag** This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application cannot clear this interrupt flag directly; instead, it is cleared by the CC when all of the MBIF interrupt flags of the individual receive message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual receive message buffers has the MBIF and MBIE flag set 1 At least one individual receive message buffer has the MBIF and MBIE flag set
7 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application cannot clear this interrupt flag directly; instead, this interrupt flag is cleared by the CC when all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set 1 At least one individual transmit message buffer has the MBIF and MBIE flag set
8 MIE	**Module Interrupt Enable** This bit controls whether the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	**Protocol Interrupt Enable** This bit controls whether the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table 1306. FR_GIFER field descriptions (continued)

Field	Description
10 CHIE	**CHI Interrupt Enable** This bit controls whether the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	**Wakeup Interrupt Enable** This bit controls whether the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
12 FAFBIE	**Receive FIFO Channel B Almost Full Interrupt Enable** This bit controls whether the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	**Receive FIFO Channel A Almost Full Interrupt Enable** This bit controls whether the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	**Receive Message Buffer Interrupt Enable** This bit controls whether the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 TBIE	**Transmit Message Buffer Interrupt Enable** This bit controls whether the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

53.5.2.14 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Offset: 0x0018

Access: Read/Write
Write: Normal mode

Figure 1226. Protocol Interrupt Flag Register 0 (FR_PIFR0)

This register holds one set of the protocol-related individual interrupt flags.

Table 1307. FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	**Fatal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. The fatal protocol errors are: – *pLatestTx* violation, as described in the MAC process of the FlexRay protocol – Transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event 1 Fatal protocol error detected
1 INTL_IF	**Internal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event 1 Internal protocol error detected
2 ILCF_IF	**Illegal Protocol Configuration Interrupt Flag** This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the *POC:halt* state immediately. The protocol engine checks the *listen_timeout* value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of *listen_timeout* is equal to 0, the protocol configuration setting is considered as illegal. 0 No such event 1 Illegal protocol configuration detected
3 CSA_IF	**Cold Start Abort Interrupt Flag** This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event 1 Cold start aborted and no more coldstart attempts allowed
4 MRC_IF	**Missing Rate Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	**Missing Offset Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event 1 Insufficient number of measurements for offset correction detected

Table 1307. FR_PIFR0 field descriptions (continued)

Field	Description
6 CCL_IF	**Clock Correction Limit Reached Interrupt Flag** This flag is set when the internal calculated offset or rate calculation values have reached or exceeded their configured thresholds as given by the *offset_correction_out* field in the Protocol Configuration Register 9 (FR_PCR9) and the *rate_correction_out* field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event 1 Offset or rate correction limit reached
7 MXS_IF	**Max Sync Frames Detected Interrupt Flag** This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the *node_sync_max* field in the Protocol Configuration Register 30 (FR_PCR30). 0 No such event 1 More than *node_sync_max* sync frames detected **Note:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account
